**DISCREPANCIES BETWEEN IMPLICIT AND EXPLICIT MATH ATTITUDES PREDICT IMPAIRED PERFORMANCE AND LOWER CONFIDENCE** Colin Smith<sup>1</sup>, Kate Ranganath<sup>2</sup>, Brian Nosek<sup>3</sup>; <sup>1</sup>Ghent University, <sup>2</sup>Tilburg University, <sup>3</sup>University of Virginia – As research on implicit evaluations evolves, work is beginning to accrue on the consequences of intra-personal discrepancies between implicit and explicit evaluations (see Petty & Brinol, 2009 for a review). The current work adds to the understanding of these consequences by examining effects of discrepant implicit and explicit evaluations on performance and confidence with regard to Mathematics. As such, participants completed explicit measures of attitudes toward math and an Implicit Association Test (Greenwald, McGhee, & Schwartz, 1998) measuring implicit preferences for math relative to liberal arts. Participants indicated a moderate implicit preference for liberal arts relative to math ( $d=0.43$ ); this was correlated with self-reported liking for math at  $r(126)=.46$ . Following the attitude measures, participants attempted 20 SAT math problems of moderate difficulty. Finally, participants reported the confidence they felt in their performance on the math test. Discrepancy scores were then calculated for each participant by standardizing implicit and explicit attitudes and taking an absolute difference. Greater discrepancy between implicit and explicit attitudes predicted lower scores on the math test;  $B=-0.92$ ,  $t(120)=-4.20$ ,  $p<.0001$ . In addition, implicit/explicit discrepancy predicted a reduction in the confidence participants reported feeling about their performance on the math test even when statistically controlling for actual scores;  $B=-0.44$ ,  $t(119)=-3.62$ ,  $p=.0004$ . This suggests that having discrepant implicit and explicit math evaluations has substantive consequences for academic functioning. Interestingly, it may be the case then that rather than encouraging teachers to espouse a "math is fun" message, students should be pushed to "keep trying even if you don't like it."

## Close Relationships/Belonging/Rejection

### C56

**WHY DOESN'T ACCEPTANCE ALWAYS FEEL GOOD?** Anna Luerssen<sup>1</sup>, Ozlem Ayduk<sup>1</sup>; <sup>1</sup>University of California, Berkeley – Previous research has found that there are individual differences in the experience of social acceptance. For example, depressed individuals not only seek out unfavorable feedback, but ironically, when faced with acceptance they experience anxiety and dampen positive affect. It is believed that these reactions contribute to the self-perpetuating cycle of symptoms. Could it be that the accessibility and organization of acceptance information in semantic knowledge structures is one mechanism by which biased processing occurs? The current study investigated this possibility using a semantic priming task. Participants were supraliminally primed with acceptance, rejection, or neutral words and then categorized acceptance or rejection-related targets. We hypothesized, and found, that as depressive symptoms increased, the chronic accessibility of acceptance decreased. High-depressed participants responded slower than their low-depressed counterparts during trials in which neutral primes preceded acceptance targets. Additionally, we predicted that as depressive symptoms increased, activating thoughts of acceptance would heighten the accessibility of rejection. We hypothesized that this process could be one reason why individuals high in depressive symptoms fail to fully appreciate the experience of acceptance. Interestingly, results were exactly the opposite of our predictions. As depressive symptoms increased, participants were slower to respond to rejection targets when they were preceded by acceptance primes. Two explanations for the latter findings are currently being evaluated.

### C57

**APPROACH AND AVOIDANCE MOTIVATION AS PREDICTORS OF SELF-EXPANSION** Brent Mattingly<sup>1</sup>, Kevin McIntyre<sup>2</sup>, Gary Lewandowski Jr.<sup>3</sup>; <sup>1</sup>Ashland University, <sup>2</sup>Trinity University, <sup>3</sup>Monmouth University – Using an approach/avoidance and self-expansion framework, we conducted three studies examining the motivational underpinnings of self-expansion. Because individuals seek close relationships as a way to enhance their own resources and identities, we predicted that current self-expansion would be related to approach (i.e., attaining positive outcomes) but not avoidance (i.e., avoiding negative outcomes) motivations. In Study 1, 49 romantically involved individuals completed measures of self-expansion (Lewandowski & Aron, 2002) and relationship-specific approach and avoidance motivations (adapted from Impett, Gable, & Peplau, 2005). Self-expansion was associated with approach ( $r = .48, p < .01$ ) but not avoidance motivations ( $r = .14, ns$ ). In Study 2, 107 romantically involved individuals completed measures of self-expansion and global approach and avoidance tendencies (Higgins et al., 2001). Again, self-expansion was associated with global approach ( $r = .20, p < .05$ ) but not avoidance ( $r = -.02, ns$ ) motivations. In Study 3, 88 individuals completed measures of approach/avoidance motivation (Carver & White, 1994), imagined meeting someone who provided either many or few self-expansion opportunities, and then indicated their interest in self-expanding with the target. When the target provided many self-expansion opportunities, desired self-expansion was associated with approach ( $r = .39, p < .01$ ) but not avoidance ( $r = .15, ns$ ) motivations. When the target provided few self-expansion opportunities, desired self-expansion was not associated with either approach ( $r = -.01, ns$ ) or avoidance ( $r = -.04, ns$ ) motivations. These results suggest that approach motives lead to desire for self-expansion, but only if the target provides sufficient self-expansion opportunities.

### C58

**HOW CAN YOU RESIST? EXECUTIVE CONTROL AND FLIRTING BEHAVIOR OF MEN IN A ROMANTIC RELATIONSHIP** Tila Pronk<sup>1</sup>, Johan Karremans<sup>1</sup>, Daniël Wigboldus<sup>1</sup>; <sup>1</sup>Radboud University Nijmegen – The present research examined whether executive control helps romantically involved people to deal with the lure of attractive alternatives. Specifically, we examined

whether executive control is related to flirting with a desirable attractive alternative. Our reasoning is based on the general assumption that executive control can help people in suppressing initial impulsive responses, and instead to respond in line with broader relationship-protective motives (see also Pronk, Karremans, Overbeek, Vermulst, & Wigboldus, in press, JPSP). In two studies, we measured (hetero-sexual) romantically involved and non-involved males' executive control, as well as their responses to attractive females. In Study 1, executive control was measured with a 2-back task. Subsequently, participants were placed in a waiting room for 10 minutes, together with an attractive female confederate. After the interaction, the confederate rated the extent to which she felt the participant was flirting with her. Results showed that only for men in a romantic relationship, higher levels of executive control were related to lower levels of perceived flirting. In Study 2 we examined what happens when flirting turns into an actual invitation to go on a date together. First, executive control was measured with a Stroop task. After this task, participants played an 'acquaintance-game', in which they were virtually introduced to an attractive female. During the game, the female asked whether the participant wanted to go out on a date with her. Preliminary results show that for participants with higher levels of executive control, this offer was turned down more often.

### C59

**A MULTI-MODAL APPROACH TO THE STUDY OF ATTACHMENT-RELATED DISTRESS** Marieke Dewitte<sup>1</sup>, Jan De Houwer<sup>1</sup>, Ann Buysse<sup>1</sup>, Liesbet Goubert<sup>1</sup>; <sup>1</sup>Ghent University, Belgium – The present study aimed at providing a comprehensive analysis of individual differences in the regulation of attachment distress as measured through different components of the emotional response, including neuroendocrine reactions, subjectively experienced affect and proximity-seeking behaviour. Emotional responses were measured before, during and after the induction of attachment distress in a sample of 68 couples. Analyses using multilevel modelling revealed that, in both men and women, attachment anxiety was related to physiological (i.e., cortisol) and subjective emotional distress responses, whereas attachment avoidance most consistently predicted subjective and behavioural responses to distress. In addition to one's own attachment style, partner's attachment style was also found to modulate emotional and behavioural responses to relational stress, in both couple members. Results are discussed in relation to an emotion regulation perspective on individual differences in attachment style.

### C60

**WHEN COUPLES FIGHT, WHO SUFFERS MOST? GENDER DIFFERENCES IN NEUROENDOCRINE RESPONDING TO CONFLICT WITH A ROMANTIC PARTNER** Kathryn P. Brooks<sup>1</sup>, Theodore F. Robles<sup>1</sup>; <sup>1</sup>University of California, Los Angeles – Men reap more consistent physical health benefits from romantic relationships, but the mechanisms responsible for these effects are largely unknown. One pathway by which relationships influence health involves hypothalamic-pituitary-adrenal (HPA) responses to stress. While men exhibit greater HPA responses to achievement-oriented stressors, women may be more responsive to relational stressors. The aim of this study was to test whether men and women differ in the extent to which a relational stressor - conflict with a romantic partner - elicits release of the hormone cortisol, and to examine whether the association between qualitative aspects of the relationship and cortisol varies by gender. Thirty dating couples were recruited for a laboratory session, during which they spent 10 minutes discussing areas of disagreement. Saliva samples were obtained at five time points before and after the discussion to assess baseline, peak, and recovery levels of salivary cortisol. In addition, each participant rated the quality of his or her relationship along numerous dimensions prior to the discussion. Results revealed no main effect of gender on cortisol production, but gender moderated the effects of relationship quality on cortisol. Men who were less satisfied with their relationships and who rated their partners as less supportive had larger cortisol responses, while women who were less committed to the relationship had larger responses (all  $ps < .05$ ). These findings sug-

gest that one pathway by which romantic relationships influence physical health involves gender differences in neuroendocrine responses to relational stressors.

### C61

**CONTENT OF COMMUNICATION MATTERS IN ROMANTIC RELATIONSHIPS** Erin Logue<sup>1</sup>, Tammy Zacchilli<sup>1</sup>, Clyde Hendrick<sup>1</sup>, Susan Hendrick<sup>1</sup>; <sup>1</sup>Texas Tech University, <sup>2</sup>Saint Leo University – Many pre-marriage programs focus only on improving the process of communication to manage conflict but emphasize less the content of communication. A few years ago, the New York Times published a list of practical items people should discuss before marriage, as well as communication and intimacy-fostering behaviors that should be occurring in the relationship. The current study examined whether endorsing participation in these items related to satisfaction and five conflict styles. Participants, 589 undergraduates, responded to items adapted from the New York Times article, the Relationship Assessment Scale (S. Hendrick, 1988), and the Romantic Partner Conflict Scale (Zacchilli, Hendrick, and Hendrick, 2009). Data were analyzed using principal axis factoring with promax rotation. As hypothesized, two viable factors with high reliability were extracted: Practicality and Intimacy. The poster will display item loadings, variance accounted for by each factor, and factor intercorrelations. A one-way ANOVA determined that females were more intimacy-fostering than males, but there was no difference in practicality. As predicted, intimacy was positively correlated with compromise during conflict and with relationship satisfaction, but negatively correlated with most other conflict styles. Also as predicted, practicality was correlated with compromise and with relationship satisfaction. Unexpectedly, practicality was unrelated to the remaining conflict styles. It appears that focusing on the process of communication in premarital programs is warranted if the goal is to improve conflict strategies. However, communication regarding practical matters (e.g., having children) is also related to relationship satisfaction, and communicating about these issues could prove important for couples planning to marry.

### C62

**PERCEIVED ALTERNATIVES, SATISFACTION, AND COMMITMENT IN MARRIAGE: A LONGITUDINAL STUDY OF AFRICAN AMERICAN NEWLYWED COUPLES** Christine Stanik<sup>1</sup>, Barlynda Bryant<sup>1</sup>, Chalandra Bryant<sup>1</sup>; <sup>1</sup>The Pennsylvania State University – In comparison to other racial/ethnic groups, African Americans have the lowest rates of marriage and the highest rates of divorce (McKinnon & Bennett, 2005). Partially driving this may be the greater number of marriageable African American women relative to African American men (Guttentag & Secord, 1983). Thus for African Americans who choose to date within their race, men relative to women have a larger pool of alternate partners from which to select. Both theoretical and empirical research in psychology has highlighted the importance of one's perceived alternatives on commitment (Rusbult, 1980; Thibaut & Kelley, 1959; Holland, 2009). Here, we explore several research questions regarding between and within gender variation in perceived quality of alternatives, satisfaction with current partner, and two aspects of commitment: desire to stay in the marriage and willingness to make the marriage work in a longitudinal study of newlywed African American couples. Counter to our expectations, women in our sample reported higher perceived quality of alternatives than did men. Path analyses revealed a significant negative relationship between quality of perceived alternatives and both aspects of commitment, which for women were completely mediated by satisfaction with their partner. However, for men the relationship between alternatives and commitment was only partially mediated by satisfaction with current partner. Along with the implications of our findings, we also present work on the effect of quality of perceived alternatives, satisfaction, and the desire and willingness to work on one's marriage on rates of divorce and separation among participants.

### C63

**THE ELECTORAL LOSS OF A PREFERRED CANDIDATE INCLUDED IN THE SELF IS EXPERIENCED AS PERSONAL REJECTION** Steven G. Young<sup>1</sup>, Michael J. Bernstein<sup>1</sup>, Heather M. Claypool<sup>1</sup>; <sup>1</sup>Miami University – The current research was designed to test whether participants who favored the losing candidate in the latest US Presidential election would feel as if they had been personally rejected. Additionally, we were interested in whether these feelings of rejection would be contingent on the extent to which participants included their candidate in their own self-representation, as measured with the Inclusion-of-Other-in-Self (IOS) scale (Aron, Aron, & Smollan, 1992). To test these hypotheses, we collected data from 51 voters on the day after the election. Participants first indicated for whom they voted (e.g., McCain, Obama, other) and then indicated to what extent they included their preferred candidate in their self-representation. Next, participants completed the Basic Needs Inventory, commonly used in interpersonal rejection research (Williams, 2007), to assess their current feelings of self-esteem, belonging, control, and belief in meaningful existence. Participants were divided into those who voted for McCain (N=25) or Obama (N=26) and into low and high-IOS groups using a median split (median=4). We then created a composite basic needs score (alpha=.70), which was submitted to a 2 (McCain, Obama) x 2 (low-IOS, high-IOS) ANOVA, which revealed an interaction,  $p=.04$ . To test the prediction that only participants who include a losing candidate in the self would feel rejected, we also performed a contrast to compare high-McCain-IOS participants to all other participants. This contrast was significant,  $p=.04$ , and confirmed that high-McCain-IOS participant's basic needs were lower than all others. These results indicate that including others in-the-self can result in experiences of vicarious rejection.

### C64

**WHEN DOES IT HURT THE MOST? THE EFFECTS OF TIME AND EXPLANATION ON REACTIONS TO REJECTION** Susan Markunas<sup>1</sup>, Cheryl Franzen<sup>1</sup>, Beth Polek<sup>1</sup>, Mallory House<sup>1</sup>, Dana Goodwin<sup>2</sup>, Ralph Erber<sup>1</sup>; <sup>1</sup>DePaul University, <sup>2</sup>University of South Carolina – The purpose of the current study was to determine when social rejection was the most detrimental. Is it more distressing when rejection is immediate or delayed? In addition, does the presence of an explanation for the rejection buffer the negative effects? By manipulating time (immediate vs. delayed rejection) and justification (explanation vs. no explanation) of interpersonal rejection, we were able to determine when rejection hurt the most. It was expected that the negative reactions in response to rejection would be highest for individuals who experienced delayed rejection in addition to not receiving an explanation. In order to test the hypothesis, participants wrote an essay that was ostensibly read and rated by two other 'participants' for desirability. The participants were then randomly assigned to one of four rejection conditions (all participants received a not desirable rating on their essay): immediate with explanation, immediate without explanation, delayed with explanation, and delayed without explanation. The post-experimental questionnaire included items assessing mood and Need to Belong. Results indicated a significant interaction between time and explanation for Need to Belong (NTB) and a moderately significant interaction for mood. Participants in the immediate / explanation condition reported the highest NTB score (indicating they felt more rejected) and the lowest mood, while those in the delayed / explanation condition reported the lowest NTB score and highest mood. These results demonstrate that overall, immediate rejection with an explanation was the most detrimental.

### C65

**BALANCE IN DYADIC SUPPORT PERCEPTIONS AND RELATIONSHIP SATISFACTION AMONG PATIENTS WITH CHRONIC ILLNESS AND THEIR PARTNERS** Grace Jackson<sup>1</sup>, Molly Tannenbaum<sup>2</sup>, Christine Wai<sup>3</sup>, Christine Rini<sup>3</sup>; <sup>1</sup>New York University, <sup>2</sup>The New School, <sup>3</sup>Mount Sinai School of Medicine – Equity theorists state that reciprocity is vital for relationship maintenance (Clark and Mills, 1979). Relationships involving chronic illness are in danger of inequity because of the constant focus on patient's

health, particularly among patients coping with an unpredictable relapsing and remitting disease, such as Inflammatory Bowel Disease (IBD). This study investigated perceptions of dyadic supportive coping as predictors of relationship satisfaction in a sample of 36 IBD patients and their partners. We hypothesized that chronic illness would disrupt the equity process in the patients but not their partners. Specifically, we hypothesized that patients' relationship satisfaction would be predicted primarily based on their own perceptions of support received by their partner, whereas partners' relationship satisfaction would be predicted equally by perceived balance in support between the patient and themselves. Relationship satisfaction was measured using the 7-item Dyadic Adjustment Scale, and each reported on their own and their partner's supportive dyadic coping (Bodenmann's Dyadic Coping Inventory, 2007). From an accuracy bias perspective (Kenny and Acitelli, 2004) we found a systematic presence of biased perceptions of others' dyadic support, but a trend of accuracy when patients reported on their partner. Relationship satisfaction was related to all four reports of dyadic support (patient on partner, patient on patient, partner on partner, and partner on patient), but patient's satisfaction was more related to the perceptions of their partner's support than to their own behavior. For partners, the effects on satisfaction were of comparable magnitude. Further research is needed to investigate the implications of this inequity.

### C66

**RELATIONSHIP GOALS AND FEELINGS: HOW RELATIONSHIP GOALS IMPACT UPWARD AND DOWNWARD SPIRALING IN RELATIONSHIPS VIA COOPERATION AND COMPETITION** Mary Liu<sup>1</sup>, Jennifer Crocker<sup>1</sup>, Amy Canevello<sup>1</sup>, <sup>1</sup>University of Michigan – We hypothesized that compassionate and self-image goals make people feel cooperative or competitive, respectively, which predicts feeling either peaceful, clear, and loving, or conflicted, confused, and fearful when interacting with others. Feeling cooperative or competitive, in turn, increases people's compassionate and self-image goals, respectively, creating the potential for upward or downward spirals. 65 freshmen roommate dyads completed 21 daily reports of compassionate and self-image goals for their roommate relationship, and cooperative, competitive, peaceful, conflicted, clear, confused, loving, and fearful feelings when interacting with roommates. Lagged-day analyses showed that increases in feeling cooperative from day 1 to day 2 fully or partially accounted for the association between day 1 compassionate goals and day 2 to 3 increases in feeling peaceful, clear, and loving during roommate interaction. Increases in feeling competitive from day 1 to day 2 fully or partially accounted for the association between day 1 self-image goals and day 2 to 3 increases in feeling conflicted, confused, and fearful during roommate interaction. Furthermore, lagged analyses showed that feeling cooperative predicted increased compassionate goals, and feeling competitive predicted increased self-image goals, creating upward spirals: residual change in relational feelings from day 1 to 2 fully or partially accounted for the association between day 1 cooperative and competitive feelings and day 1 to 2 residual changes in compassionate and self-image goals. Lastly, cooperative feelings one day predicted increased closeness to and perceived responsiveness to and from roommate, suggesting that compassionate goals contribute to upward spiraling of relationship interaction through cooperative feelings.

### C67

**APPRECIATION IN ROMANTIC RELATIONSHIPS: THE UNIQUE CONTRIBUTIONS OF FEELING APPRECIATIVE AND FEELING APPRECIATED** Amie M. Gordon<sup>1</sup>, Emily A. Impett<sup>1</sup>, Aleksandr Kogan<sup>2</sup>, Christopher Oveis<sup>3</sup>, Dacher Keltner<sup>1</sup>, <sup>1</sup>University of California, Berkeley, <sup>2</sup>University of Hong Kong, <sup>3</sup>Harvard University – Appreciation, defined as acknowledging the value and meaning of something—an event, a person, a behavior, an object (Adler & Fagley, 2005), is an important component of relationship quality that has received little empirical attention. We conducted three studies with multiple methods (i.e., cross-sectional, dyadic, short-term longitudinal) to examine how appreciation shapes

relationship quality and pro-relationship behavior. Across all studies, we examined the unique contributions of feeling appreciative and feeling appreciated, as well as the effect of discrepancies between the two. Converging results from all three studies suggest that while feeling appreciative and feeling appreciated are both important for relationship quality, they are associated with different pro-relationship behaviors. Feeling appreciative is associated with pro-relationship behaviors that signify an active desire to maintain the relationship, such as more constructive responses to conflict. In contrast, feeling appreciated is associated with pro-relationship behaviors that signify feeling secure in the relationship, such as giving one's partner the benefit of the doubt. Equal levels of feeling appreciative and appreciated are the most beneficial for relationship outcomes. Implications for the maintenance of satisfying partnerships over time are discussed.

### C68

**COUNTING THE DAYS WHEN YOU'RE AWAY – A STUDY OF LONG-DISTANCE RELATIONSHIPS** Yu-Yang<sup>1</sup>, Kenneth Tan<sup>1</sup>, <sup>1</sup>National University of Singapore – Research on intimate relationships often focuses on relationships whose partners live in close proximity. However it is becoming pervasive for people to find themselves in long-distance romantic relationships (LDRs) as opposed to proximal relationships (nonLDRs). The present research focused on examining the relationship between attachment and attitudes about LDRs as well as investigating the effects of physical separation on intimacy processes, relationship quality and interaction patterns. Attitude towards LDRs was defined as the extent to which participants agreed with "out of sight, out of mind" or "absence makes the heart grow fonder". It was found that attachment anxiety was associated with pessimistic attitudes about LDRs. Moreover, this was moderated by implicit theories of relationship beliefs in that the aforementioned association was more salient among those who held destiny beliefs than those who held growth beliefs. It was also found that anxiously attached individuals were less supportive and more reluctant to let their partners leave to embark on LDRs. On the effect of physical separation on intimacy processes, results showed that individuals in LDRs reported feeling more loved, had more intimate self-disclosure but experienced less companionship than those in nonLDRs. Moreover, in spite of restricted communication where lower frequencies of phone conversations and instant messaging were reported, individuals in LDRs rated levels of relationship satisfaction, idealization and quality of communication similar to nonLDRs. Taken together, this research suggests that in spite of physical separation, success is possible if couples are cognizant of the ways that their unique situation constrains the relationship.

### C69

**PRIVACY CONCERNS AND REVELATION: SELF-DISCLOSURE USING NEW COMMUNICATION TOOLS** Nancy Frye<sup>1</sup>, Michele Domisch<sup>1</sup>, <sup>1</sup>Long Island University – Self-disclosure is an integral part of relationship formation. Since people now have a variety of communication tools to use when they disclose (e.g., text messaging), the question arises of how people disclose information. A key component of this question involves perceptions of the privacy afforded by these mediums of communication. When might privacy concerns predict the degree to which people are likely to communicate via these new communication tools? To address this question, we collected data from 214 participants. Participants were asked to report how comfortable they would feel disclosing on 16 topics (e.g., "times when I felt that I was in love") using 10 communication tools (e.g., chat rooms, email). Thus, participants made 160 ratings concerning their comfort discussing a specific topic using a specific communication tool. To examine when participants felt the most comfortable disclosing information, we used hierarchical linear modeling (HLM) to investigate the roles of topic intimacy, perception of medium, and the interaction between these in predicting disclosure. We found an interaction between topic intimacy and perception of medium, such that levels of disclosure about more intimate topics were most strongly related to perceived privacy of the medium, while levels of disclosure about less intimate topics were unrelated to perceived privacy of the medium. Additionally, we

found that the relationship between topic intimacy and level of disclosure was more pronounced among participants with higher levels of overall trust, and that the association between perceptions of medium and disclosure is less pronounced among frequent users of technology.

### C70

#### **PARTNER EFFECTS OF IDEAL DISCREPANCIES ON RELATIONSHIP SATISFACTION: ACCURACY AND PROJECTION IN INFERRING PARTNER DISCREPANCIES AND THE COMMUNICATIVE ROLE OF INTERPERSONAL BEHAVIOR**

Harris Rubin<sup>1</sup>, Lorne Campbell<sup>1</sup>, Sandra D. Lackenbauer<sup>1</sup>, Nickola C. Overall<sup>2</sup>; <sup>1</sup>The University of Western Ontario, <sup>2</sup>The University of Auckland – Three studies guided by the Ideal Standards Model (ISM; Simpson, Fletcher, & Campbell, 2001) and the perceived partner responsiveness framework (Reis, Clark, & Holmes, 2004) found support for three main hypotheses related to the effects of people's ideal discrepancies on their romantic partner's relationship satisfaction. Study 1 used a dyadic sample of 64 dating couples and found that people's inferences into how closely they are meeting their partner's ideals were based on a blend of accuracy and projection processes (hypothesis 1). As predicted, these inferences mediated the partner effect of one partner's larger ideal discrepancies on the other's lower relationship satisfaction (hypothesis 2). Study 2 collected daily diaries from both members of 67 dating couples and found that the cross-sectional results from Study 1 replicated when measured longitudinally. Study 3 used 116 married couples to examine whether taking part in a conflict resolution discussion increases how accurate individuals are at inferring their spouse's ideal discrepancies. As expected, people's accuracy increased after the discussion, and their spouse's positive and negative behaviors during the discussion mediated this boost in accuracy (hypothesis 3). Results from these dyadic data analyses extend the ISM by leveraging a perceived partner responsiveness framework to identify processes that lead to the partner effect of ideal discrepancies on relationship satisfaction.

### C71

#### **JUST THE FACTS: MORTALITY SALIENCE INDUCTION IN RELATIONSHIP RESEARCH**

Elizabeth Keneski<sup>1</sup>, Jennifer J. Harman<sup>1</sup>; <sup>1</sup>Colorado State University – Mortality salience (MS; Greenberg, Pyszczynski, & Solomon, 1986) involves making death accessible in one's mind. Traditional and direct MS manipulations have sometimes elicited approach behaviors among individuals in intimate relationships (e.g., Florian, Mikulincer, & Hirschberger, 2002), but it is unclear whether an indirect form of MS using death statistics (Jessop, Albery, Rutter, & Garrod, 2008) would effectively induce MS if the statistics were related to death in the context of intimate relationships. Participants (N=181) read facts about death, about death in the context of romantic relationships, or neutral facts. Our hypothesis was supported; both experimental conditions effectively resulted in MS as measured with a word completion task targeting death-related words. No significant differences were found between the two manipulations. Thus, simply reading statistics related to death, within or outside the context of close relationships, effectively results in MS.

### C72

#### **COREGULATION 'FOR BETTER OR WORSE': THE EMOTIONAL TRANSMISSION OF POSITIVE AND NEGATIVE EMOTIONS IN CLOSE RELATIONSHIPS**

Ashley K. Randall<sup>1</sup>, Jessica H. Post<sup>1</sup>, Shannon A. Corkery<sup>1</sup>, Leslie Bosch<sup>1</sup>, Basil Chiu<sup>1</sup>, Emily A. Butler<sup>1</sup>; <sup>1</sup>University of Arizona – Coregulation refers to the complex linkage of emotions between individuals within a close relationship, whereby partners reciprocally influence each other's emotional states. Coregulation has been argued to help maintain an individual's emotional homeostasis by allowing one partner to down-regulate the other's negative states. It is possible however, that coregulation could also lead to the escalation of both positive and negative emotions through the action of positive feedback loops. Research on the transmission of emotions arising outside the relationship (work stress) has demonstrated that this sort of feedback loop for negative

emotions is quite common. It is unknown, however, whether coregulation also manifests as escalation of emotions arising within the relationship (e.g. love or anger). This is an important gap because such emotions are critical for relationship functioning. To investigate this, we conducted a one-week daily-diary study of committed heterosexual couples (N = 62 dyads) assessing positive and negative emotions within the relationship ("How much have you felt positive or negative emotions due to your partner today?"). Using a prospective change dyadic model, we found lagged effects for both positive and negative relationship relevant emotions, such that increases in partner A's emotional experience predicted increases in partner B's emotional experience from one day to the next. This suggests that coregulation can take various forms including the escalation of both positive and negative emotions relevant to the relationship. As such, coregulation may be extremely important for understanding the complex nature of emotional processes contributing to relationship functioning.

### C73

#### **EMPATHY AS A MODERATOR OF EMOTIONAL STABILITY WITHIN COUPLES**

Jessica H. Post<sup>1</sup>, Ashley K. Randall<sup>1</sup>, Shannon A. Corkery<sup>1</sup>, Basil Chiu<sup>1</sup>, Leslie Bosch<sup>1</sup>, Emily A. Butler<sup>1</sup>; <sup>1</sup>University of Arizona – Empathy allows partners to share one another's emotions. When one partner feels an emotion and their partner emphasizes a positive feedback loop may cause both partners to increasingly feel that emotion. This may perpetuate the feeling, resulting in a stable emotional state. Empathy for positive emotions about each other (knowing and sharing that your partner feels affection for you) and negative emotions due to external factors (knowing and sharing that your partner had a bad day at work) are common in well-functioning relationships and increase the closeness between partners. As such we expected high levels of empathizing to be associated with higher stability of these emotions. To test these hypotheses, we conducted a one-week daily-diary study of committed heterosexual couples (N = 62 dyads) assessing empathy ("I tried to empathize with my partner") and daily positive and negative emotions both due to the relationship and due to external factors. Using a dyadic longitudinal model, we found that mutual empathy (the sum of both partners' empathy during the week) led to a stabilization of emotions for both partners. In highly empathetic couples, positive emotions due to the relationship and negative emotions due to external events showed increased stability from day to day. This suggests that couples who engage in empathy may perpetuate not only positive emotions due to the relationship, but also negative emotions originating outside the relationship. Although this may entail additional distress in the short run, it may ultimately allow those negative emotions to be processed more effectively.

### C74

#### **INFIDELITY, CONFESSIONS, AND RELATIONSHIP DISSOLUTION**

Jamal H. Essayli<sup>1</sup>, Ryan S. Darby<sup>1</sup>, Christine R. Harris<sup>1</sup>, Britta Larsen<sup>1</sup>; <sup>1</sup>University of California, San Diego – The present study examined the associations between relationship dissolution, forgiveness, and an individual's decision to conceal or confess to committing an infidelity. 282 undergraduates that committed an infidelity and 389 undergraduates that were victims of an infidelity completed a computer-based survey that assessed relationship outcomes, discovery method, and emotional responses to a previous infidelity. Of unfaithful partners whose relationship did not end due to the infidelity, 61% reported that their partner never found out about the infidelity, 28% reported confessing to the infidelity, and 11% reported their partner discovering from another source. On the other hand, only 30% of unfaithful partners whose relationship ended over the infidelity reported that their partner never found out, while 38% reported confessing and 32% reported their partner discovering from another source. Victims who discovered the infidelity directly from their partner, however, reported more forgiveness, less blame, less retaliation, that their partners sought forgiveness more and apologized more, and were more likely to preserve the relationship than victims who found out through a different source. Regression analyses indicated that forgiveness, degree of apology, and amount of blame attributed to

the unfaithful partner were key predictors of relationship dissolution as a result of the infidelity. In terms of relationship outcome, these findings suggest both costs and benefits to confessing to an infidelity: while concealing an infidelity is associated with relationship preservation, victims are more likely to end their relationship over a partner's infidelity if they discover the infidelity from a source other than their partner.

### C75

#### **A SITUATIONAL MANIPULATION OF RELATIONSHIP AUTHENTICITY**

**Kristen N. Petty<sup>1</sup>, Adam Pazda<sup>1</sup>, C. Raymond Knee<sup>1</sup>**; <sup>1</sup>University of Houston – Authenticity is a combination of awareness, unbiased processing, behavior, and relational orientation, of which higher levels constitute genuineness in a relationship (Kernis, 2003). Individuals who develop authentic relationships should be more willing to acknowledge the benefits of honest self-disclosure, regardless of potential risks or outcomes. The goal of the present study was to investigate how authenticity in relationships might influence the extent to which individuals adjust their reported thoughts and feelings in the presence of their romantic partner. We proposed that romantically involved individuals would be more likely to positively exaggerate their responses to questions about their relationship when in the presence of their partner, versus in private. Furthermore, we predicted that trait authenticity would moderate this effect. An experiment involving 40 romantically involved couples (80 individuals) tested these predictions. Couples were separated and rated their partner's appearance, commitment to their partner, and likelihood of ending their relationship. They were later asked the same questions during an interview, either believing their partner was listening behind a two-way mirror, or believing their partner could not hear them. As predicted, couples generally had a tendency to favorably exaggerate their responses during the interview when they thought their partner was listening. However, those who reported feeling more authentic in their relationship were less likely to exaggerate their answers when they believed their partner was listening. Thus, both person and situation-level authenticity affected how people responded about their romantic relationship.

### C76

#### **THE IMPACT OF RELATIONSHIP COMMITMENT AND ROMANTIC RIVALS ON PARTNER OSTRACISM**

**Nicole M. Cazeppa<sup>1</sup>, JulieAnn Miller<sup>2</sup>, Eric D. Wesselmann<sup>2</sup>, Ximena B. Arriaga<sup>2</sup>, Kipling D. Williams<sup>2</sup>**; <sup>1</sup>Brown University, <sup>2</sup>Purdue University – Research has shown that being ostracized by strangers causes many deleterious effects on a person's sense of well-being. Interestingly, recent research demonstrated that the robust negative impact of ostracism was buffered when a romantic partner was a source of ostracism (Cazeppa, Reed, Arriaga, & Williams, 2009). In this study, we examined two conditions that might shift one's perceptions of being ostracized by a partner: relationship commitment and if the other player is a potential romantic rival (i.e., same sex as participant). High relationship commitment often reduces the negative impact of partner imperfections or hurtful partner acts (e.g., Murray, Holmes, & Griffin, 1996). Thus, we hypothesized that highly committed couple members would be less reactive to being ostracized by a potential rival compared to less committed individuals. Forty-seven dating couples played Cyberball, a virtual ball tossing game, in which each couple member was randomly assigned to one of six conditions that varied in inclusionary status (included or ostracized) and sex of the other player (rival, nonrival, unknown). All participants were led to believe they were playing with their romantic partner. Highly committed individuals were not impacted by the manipulation of the other player. However, less committed individuals reported significantly lower need fulfillment (e.g., self-esteem) when being ostracized by a rival or when the sex of the other player was unknown compared to a nonrival. This study suggests that relationship commitment and whether the source of ostracism is a potential rival are both important variables when assessing the harm of partner ostracism.

### C77

#### **AVOIDANT ATTACHMENT AND THE COGNITIVE REPRESENTATION OF SELF WITH CLOSE OTHERS**

**Jessica L. Williamson<sup>1</sup>, Christopher R. Agnew<sup>1</sup>**; <sup>1</sup>Purdue University – Interpersonal closeness has been operationally defined by Aron, Aron, and Smollan (1992) as greater inclusion of other in the self (IOS). IOS theory argues that individuals include close others into the cognitive representation of their self. Using IOS theory and a connectionist approach, Mashek, Aron, & Boncimino (2003) found that individuals confuse the self with close others (i.e., a romantic partner) in a trait assignment task. The present research examined whether similar trait confusion processes occur in individuals who possess an avoidant attachment style. Procedures were adapted from the Mashek et al. (2003) experimental paradigm. All participants (N=133) were currently involved in an ongoing, romantic relationship of at least two months. Participants completed measures of avoidance (ECR-R: Fraley, Waller, & Brennan, 2000) and interpersonal closeness (IOS: Aron et al., 1992). Participants then completed a rating task requiring a rating of personality traits for four different targets: self, romantic partner, best friend, and familiar stranger (Tiger Woods). Traits were randomly presented one at a time for each target. Afterwards, participants completed a recognition task. The original traits plus distracters were randomly presented. Participants were instructed to recall whether each trait was shown earlier and then identify the original target. Persons scoring high and low in avoidance reported more confusions between the self and romantic partner compared to non-close others. These outcomes suggest the inclusion-of-other-in-the-self effect is robust. Avoidant individuals may cognitively include close others in the self despite engaging in behavioral distancing. Results and implications will be discussed.

### C78

#### **SEEING RACE: TOP-DOWN INFLUENCES ON EARLY VISUAL PROCESSING OF FACES**

**Renana H. Ofan<sup>1</sup>, Nava Rubin<sup>1</sup>, David M. Amodio<sup>1</sup>**; <sup>1</sup>New York University – Is the early visual perception of race driven primarily by bottom-up structural features, or is it influenced by top-down effects, such as motivations or prior knowledge? Similar questions about top-down vs. bottom-up effects have been debated for decades by perception researchers. We tested this question by measuring event-related potentials (ERPs) related to face perception while White participants view White and Black faces (as well as non-face objects). We focused on the N170 ERP component, which is believed to represent a face-specific neural marker that reflects early perceptual processing, both temporally and in terms of brain hierarchy. Face stimuli were normalized for contrast and luminance so that any differences in the N170 to White vs. Black faces could be interpreted as top-down influences rather than bottom-up, stimulus-driven effects. Results indicated that the peak latency of the N170 was significantly longer for Black and White faces. In addition, larger N170 amplitudes to Black vs. White faces were associated with more positive implicit evaluations of White faces. These results suggest that prior knowledge of racial groups affects early perception of group members' faces, suggesting a top-down effect on low-level face perception processes occurring at just 170 ms. In other words, these results suggest that people see members of different racial group differently at the most basic stages of face perception.

### C79

#### **PREDICTORS OF RELATIONSHIP STABILITY: FACTORS UNDERLYING NON-MARITAL ROMANTIC RELATIONSHIP FATE IN CHILE VS. THE UNITED STATES**

**Laura VanderDrift<sup>1</sup>, Christopher Agnew<sup>1</sup>, Juan Wilson<sup>2</sup>**; <sup>1</sup>Purdue University, <sup>2</sup>Universidad de Chile – The current study was designed to examine potential cross-cultural differences in relationship stability-promoting factors. Comparing relationship partners in Chile and the United States, we tested whether certain relationship qualities exert a larger influence on relationship fate in one country than the other. We hypothesized that in cultures that highly value individualism (i.e., the US), predictors that tap an individual's own feelings about the relationship (i.e., commitment, satisfaction) would better predict relationship fate than

they would in a culture that places less value on individualism (i.e., Chile). Conversely, we hypothesized that factors that tap others' feelings toward the relationship (i.e., subjective norms, network disapproval) would be better predictors of relationship fate in Chile than in the US, again due to the differing emphasis on individualism between countries. To test these notions, we collected data from individuals in non-marital romantic relationships in Chile (n=309) and the US (n=268). Initially, participants completed measures of the predictors noted previously. Approximately 4 months later, the same participants reported whether their relationship was intact or dissolved. Results from multiple regression analyses, controlling for the demographic characteristics in which the two samples differed, supported our hypotheses. Commitment and satisfaction were significantly stronger predictors of relationship fate in the US than in Chile, whereas subjective norms and network disapproval of the relationship were stronger predictors in Chile. These results highlight the importance of considering the culture in which a relationship is embedded when predicting outcomes as different cultures may exert unique pressures on relationships.

### C80

#### EFFECTS OF RECENT SEXUAL ACTIVITY ON MATE DESIRABILITY Lisa

Savre<sup>1</sup>; <sup>1</sup>New Mexico State University – Previous research offers a consensus that individuals with promiscuous sexual histories are viewed negatively in terms of acceptability of sexual behavior, evaluation of personality characteristics, and desirability as a potential mate. This finding is often attributed to an increased risk of cuckoldry for men and of diversion of resources for women. However, despite these risks most individuals do have more than one sexual partner over the course of their lifetime. Recentness of a previous sexual relationship could be an important variable that influences willingness to enter a relationship with someone who has a sexual past. In particular, sexual relations occurring within the past four months are of greatest risk to men because a woman may be pregnant but not showing any physical signs that would indicate the pregnancy to others. In this study, participants were asked about their willingness to engage in a casual, long-term, or purely sexual relationship. Time since the most recent sexual relationship of this potential partner was varied between subjects. We found that men's willingness to enter a new casual dating relationship was significantly influenced by the time passed since his potential mate's last sexual relationship had ended. As the amount of time since a woman's last sexual relationship increased, so did men's willingness to begin a relationship with her.

### C81

#### ATTRIBUTIONS OF BEHAVIORAL STABILITY AND THE FUNCTION OF REMORSE: AN EXAMINATION OF THE APOLOGY-FORGIVENESS LINK

James R. Davis<sup>1</sup>, Gregg J. Gold<sup>2</sup>; <sup>1</sup>DePaul University, <sup>2</sup>Humboldt State University – Sincere apologies promote forgiveness by increasing empathetic concern, and by changing the victims' perceptions and attributions of the transgressor's behavior. The effectiveness of an apology is largely determined by remorse. The more remorseful a transgressor appears, the more sincere the apology seems, and thus the more effective it is in promoting forgiveness. In close relationships, the role of empathy in the link between apologies and forgiveness is well established; however in such relationships, less is known about the influence of attributions in promoting forgiveness following an apology—particularly attributions regarding the stability of future behavior. The purpose of this study is to examine the relationship between perceived remorse, empathy and attributions of behavioral stability to further expand our understanding of the apology forgiveness link. We suggest that remorse influences forgiveness through perceptions of behavioral stability, and that these effects are independent of emotional empathy. Participants completed a survey in which they wrote about a time when a romantic partner harmed them, and apologized for their behavior. Following this, participants responded to several questions assessing remorse, empathy, forgiveness and behavioral stability. Results indicate that the relationship between remorse and forgiveness is significantly mediated by percep-

tions of behavioral stability, but not by emotional empathy. This suggests remorse may function to reduce judgments of future harm and may facilitate forgiveness independent of the empathetic concern.

### C82

#### THE EFFECTS OF SELF-ENHANCING PRESENTATIONS ON THE EVALUATIONS FROM FRIENDS AND RELATIONSHIP SATISFACTIONS

Junichi Taniguchi<sup>1</sup>, Hiroshi Shimizu<sup>2</sup>; <sup>1</sup>Tezukayama University, <sup>2</sup>Kwansei Gakuin University – The present study examined the effects of the freshmen's self-enhancing presentations toward their friends on later evaluations from friends, relationship satisfactions, and their self-esteem. 322 freshmen (161 pairs, 93 male pairs and 68 female pairs) participated in the longitudinal study in which they answered the questionnaire four times (April, May, June, and July). Participants were required to pair up with their same-sex friends and answer the questionnaire about them and their friends. Main findings were as follows: 1) As participants presented themselves as more "likeable" and "competent" toward their friends in May, the relationship satisfactions with their friends and their self-esteem were higher in July. 2) The effect of self-presentations of "likeability" (in May) on the relationship satisfactions (in July) was mediated by the actual evaluations from the friends (in June). 3) As participants got more "likeable" evaluations from their friends (in June), the relationship satisfactions of their friends (in July) were higher. That is, as participants presented themselves as more "likeable", relationship satisfactions of both them and their friends were higher. 4) Participant's self-presentations of "competence" (in May) didn't affect the actual evaluations from their friends later (in June). Also, even if participants got much competent evaluations from their friends (in June), their self-esteem (in July) wasn't high. The results were discussed in terms of the beneficial consequences that the freshmen's self-enhancing presentations toward their friends have.

### C83

#### BOOSTING MARITAL IMMUNITY: STRESS INOCULATION EFFECTS IN EARLY MARRIAGE Elizabeth F. Broady<sup>1</sup>, Lisa A. Neff<sup>1</sup>; <sup>1</sup>University of Texas

at Austin – As all couples experience stressful life events, understanding how couples adapt to stress is imperative for understanding marital development. Drawing from theories of stress inoculation, which suggest that the successful adaptation to mildly stressful events may help individuals develop a resilience to future stress, the current study examined whether couples who had more experience effectively coping with minor stressors early in the marriage would be most resilient to the declines in marital satisfaction that can follow the transition to parenthood. The study relied on data collected from 50 newlywed couples who became parents during the first four years of marriage. When couples were first married, two relationship coping skills were assessed: spouses' attributions for a partner's transgressions and spouses' conflict resolution skills observed during videotaped marital discussions. Couples also completed a checklist of stressful life events and a measure of initial marital satisfaction. Then, marital satisfaction was assessed again six months after the birth of their first child. Hierarchical regressions revealed that both attributions and conflict resolution skills interacted with early stress to predict post-child marital satisfaction for wives, but not for husbands. Simple slope tests revealed that among wives who had good relationship skills, those who experienced more stress early in the marriage reported greater marital satisfaction after the transition to parenthood than those with fewer early stress experiences. Thus, simply possessing good relationship skills may not be sufficient to shield marital satisfaction from stress. Rather, couples also may need practice applying those skills to minor stressful events.

### C84

#### CLOSE-OTHER HANDICAPPING: PROVIDING ANOTHER WITH AN EXCUSE FOR FAILURE Brian Richards<sup>1</sup>, Keith Markman<sup>1</sup>; <sup>1</sup>Ohio University

– Self-handicapping is an esteem-protecting strategy whereby individuals prospectively generate impediments to successful performance so that their abilities will not be called into question in the event of failure. Demon-

strations of this phenomenon are replete in the social psychological literature, and thus to extend this work beyond the domain of the self, the current study investigated whether individuals would also be willing to handicap the performance of a close other. Male participants brought a close male friend to the lab and observed him take two intelligence tests. In the contingent feedback condition, participants were led to believe that their friend had performed well on the first test because of his ability, whereas in the non-contingent feedback condition participants were led to believe that their friend's initial success was due to luck. Because lack of preparation could be used, retrospectively, to excuse poor performance, it was expected that participants would allocate less practice time to their friend before taking the second test when they expected him to perform poorly (non-contingent condition) than when they expected him to perform well (contingent condition). Consistent with predictions, participants did in fact allocate less practice time to their friends in the non-contingent condition than in the contingent condition. Additionally, the more participants reported doubting their friends' ability to perform well, the less practice time they allocated to him, thereby supporting the interpretation that participants were motivated to protect their friends' self-esteem by prospectively erecting an external attribution for his potential failure.

### C85

**ATTACHMENT ORIENTATIONS AND REASONS FOR PROMISING IN ROMANTIC RELATIONSHIPS** Fanny Vivian Jimenez<sup>1,2</sup>, Johanna Peetz<sup>3</sup>, Lara Kammrath<sup>3</sup>; <sup>1</sup>Humboldt University Berlin, Germany, <sup>2</sup>International Max Planck Research School LIFE, Berlin, Germany, <sup>3</sup>Wilfrid Laurier University, Waterloo, Canada – We examined the reasons why people may make promises in romantic relationships. A person might make a promise because of how their partner will feel as a result of the promise: It might make their partner happy (external approach), or prevent the partner from getting angry or sad (external avoidance). A person might also make a romantic promise because of internal reasons: She/he might make a promise to feel like a better person (internal approach) or to prevent feeling like a bad person (internal avoidance). We expected that one factor associated with why a person promises would be the individuals' attachment orientation. In this study, 86 participants read several relationship scenarios and indicated whether they would promise a certain behavior in the scenario. Then, they rated the extent to which each of the four reasons described their thoughts leading up to the promise. Avoidant participants made promises for different reasons than anxious, ambivalent or secure people: they promised primarily to avoid negative feelings in their partner, and less because they wanted to make their partner happy. Overall, relationship attachment variables (specifically the avoidant dimension) were more related to the external partner-oriented dimension of promise reasons, whereas participants' personality traits (e.g., agreeableness) were more predictive of the internal self-oriented dimension. This study demonstrated that characteristics of relationship partners can influence underlying reasons for making a promise to their partner, and contributed to the understanding of attachment in romantic relationships.

### C86

**THE IMPACT OF PRIMING IMPLICIT THEORIES OF RELATIONSHIPS ON INDIVIDUALS' RESPONSES TO AMBIGUOUS RELATIONSHIP VIGNETTES** Robert Wickham<sup>1</sup>, Stephanie Tobin<sup>1</sup>, Matylda Osika<sup>1</sup>; <sup>1</sup>University of Houston – The cognitive accessibility of Implicit Theories of Relationships (ITRs) was manipulated in order to assess their role in providing individuals with an attributional framework for determining the causes of events in romantic relationships. Growth beliefs refer to the malleability and adaptability of relationships, while Destiny beliefs concern the degree to which relationships are perceived as fixed and destined to succeed or fail from the beginning (Knee, 1998). We predicted that individuals primed with 'simple' ITR configurations (High Growth or High Destiny beliefs, but not both) would utilize these belief structures when making attributions for relationship events, particularly

when they placed a high degree of importance on understanding the situation. Following random assignment to Growth (High | Low) and Destiny (High | Low) prime conditions, participants completed a scrambled sentences priming task and evaluated a series of 10 vignettes describing ambiguous relationship situations. After generating potential causes for the event described in each vignette, participants reported their level of confidence in their explanation (Causal Certainty), as well as the importance they placed on identifying the cause of the event (Causal Importance). Regression analyses revealed that participants in the High Growth/Low Destiny and Low Growth/High Destiny prime conditions exhibited a strong, positive relationship between Causal Certainty and Causal Importance, while participants in the remaining conditions exhibited no such relationship. These findings suggest that 'simple' ITR configurations provide individuals with an attributional framework that may be utilized to resolve uncertainty in situations where causal understanding is deemed important.

### C87

**RELATIONSHIP IDENTIFICATION AND ITS INSTANT EFFECT: PREDICTING RELATIONSHIP MAINTENANCE RESPONSES IN AN INSTANT MESSAGING TASK** Lisa Linardatos<sup>1</sup>, John E. Lydon<sup>1</sup>; <sup>1</sup>McGill University – Relationship maintenance responses (RMRs) promote healthy romantic relationship functioning and longevity. RMRs are typically examined as the products of relationship commitment and satisfaction, and are measured using self-report scales. Alternatively, relationship identification, the degree to which individuals define themselves in terms of their partner, has been found to contribute to relatively spontaneous, behavioral RMRs. Linardatos and Lydon (2007) demonstrated that individuals higher on relationship identification mention their relationship more when interacting with an attractive alternative over instant messenger (IM), a situation that precludes extensive deliberation of one's responses. The present study expands on this research: we tested whether this effect was specific to an interaction with an attractive alternative, thereby implicating a RMR. Heterosexual participants in dating relationships (N = 125) completed a modified version of Cross et al.'s (2000) RISC scale, assessing relationship identification. Then, they were randomly assigned to interact with an attractive member of the same or opposite sex over IM. Regression analyses revealed a significant relationship identification x condition (same vs. opposite sex) interaction,  $p = .046$ . In the opposite sex condition, low identifiers mentioned their partner less than high identifiers, whereas high identifiers did not differ in their number of partner mentions between conditions. Thus, low identifiers talked less about their partner when chatting with an attractive alternative, whereas high identifiers were generally more vocal about their relationship. This effect remained significant controlling relationship commitment,  $p = .049$ . The present findings demonstrate that relational identity is associated with relatively spontaneous relationship maintenance behavior.

### C88

**FACEBOOK NORMS: HOW PEOPLE USE FACEBOOK TO SHARE AND CONNECT WITH OTHERS** Jeff LaFlam<sup>1</sup>, Melanie Green<sup>1</sup>; <sup>1</sup>University of North Carolina at Chapel Hill – Social networking technologies have become an increasingly common means of maintaining relationships. However, on Facebook, most information is shared through public postings (status updates, wall posts), rather than through private messages to a single individual. This shift to broadcast-style messages may affect relationship development, but these effects may depend on individuals' expectations for social network communication. Our study examined these Facebook norms: the type of information individuals typically share on Facebook, whether they expect responses to their postings, and their perceptions of how Facebook influences their friendships. We surveyed undergraduates (N = 194) and adult Facebook users (N = 322) on their uses of and expectations about Facebook. About half of the participants said they used status updates mainly for important information; the remainder used updates for everyday information or a mix of everyday and important information. The majority of people reported that they post mostly positive (rather than negative) information in their sta-

tus updates. Although many participants did not expect a response to status updates, a substantial minority (33% of undergraduates and 44% of adults) did expect responses. Furthermore, participants reported being upset at finding out some kinds of important information over Facebook rather than privately. Private messages were also rated as more effective at increasing feelings of closeness with friends. Sharing information widely on Facebook may thus have unintended negative consequences. Our findings suggest that although Facebook can strengthen relationships by increasing communication, it may weaken relationships by reducing responsiveness and feelings of intimacy.

### C89

#### WHEN FRIENDS TALK TO EACH OTHER ABOUT ROMANTIC RELATIONSHIPS Marilyn D. Ishler<sup>1</sup>, Linda K. Acitelli<sup>1</sup>; <sup>1</sup>University of Houston

It has been established that women place a high value on sharing personal information with same-sex friendships (e.g., Fehr, 1996), and they talk with friends about their romantic relationships (e.g., Crouter, & McHall, 2003). If experiencing dissatisfaction with her romantic relationship a woman is likely to seek out and engage in social interactions (Buunk, VanYperen, Taylor, & Collins, 1991). In spite of scholarly attention to relationship talk, relationship talk is often portrayed as a monolithic concept. The purpose of this study was to develop and validate a measure of relationship talk and demonstrate that such talk can vary according to level of seriousness. 100 college students were asked to write what they talk about when they talk about their romantic relationships with friends. A 9-item measure of relationship talk was developed based on participants' open-ended responses and administered to another sample of 174 college students. A principal component factor analysis with varimax rotation revealed 2 distinct factors corresponding to lighthearted chat and serious relationship talk. Alpha coefficients for each subscale were .79. As expected, regression analyses showed that lighthearted chat was positively associated with relationship satisfaction, and serious talk was negatively associated with relationship satisfaction (entered separately and simultaneously). Lighthearted chat was positively related to positive affect and extraversion, while serious talk was positively related to depression and neuroticism. Thus, talking about one's romantic relationship with friends not only indicates the state of one's relationship, it could also be indicative of the individual's personality and emotional well-being.

### C90

#### SHARED MEANING EVOKED IN TRANSFERENCE Elizabeth Przybylinski<sup>1</sup>, Susan Andersen<sup>1</sup>; <sup>1</sup>New York University

The social-cognitive process of transference, which arises based on implicit activation of a significant-other representation in relation to a new person, is assumed to serve meaning-making functions (Glassman & Andersen, 1999), and may indirectly activate the worldview that is shared with the significant-other. Three studies were conducted to test this hypothesis. Each used a transference paradigm in which participants in an initial session provided descriptions of a significant-other, some of which were used two weeks later in an ostensibly unrelated experiment. In the experiment, participants learned about three individuals, one of whom was described to subtly resemble their significant other. Tests of participants' memory for and evaluation of these individuals verified that transference occurred in each study. Further, Study 1 demonstrated that, when in the transference condition, participants were quickest to respond to words in a lexical decision task that were related to values that were idiographically identified beforehand as shared with the significant other, indicating shared worldview activation, and participants also expected a particularly meaningful encounter. Study 2 replicated these results using a nomothetic value-identification procedure in which participants named significant others who shared their beliefs on spirituality or politics. Study 3 blocked participants from using their shared values (identified either idiographically or nomothetically) in response to each individual. In the transference condition this led to compensatory activation of the goal to

restore shared meaning as measured by lexical decision. Together these studies suggest that transference entails the maintenance and utilization of a shared worldview within each significant-other relationship.

### C91

#### HOW HOPE FOR AFFILIATION AND FEAR OF REJECTION SHAPE MEMORY AND IMPORTANCE OF SOCIAL EVENTS Courtney Gosnell<sup>1</sup>, Shelly Gable<sup>1</sup>;

<sup>1</sup>University of California-Santa Barbara – The present study examined how differences in motives to seek affiliation and avoid rejection shape memory for daily social events. Eighty-four participants completed hope for affiliation and fear of rejection measures in an initial laboratory session. Over the next week, participants completed nightly diary questionnaires asking them about the positive and negative events of their week. These events were later coded as social vs. non-social events. At the end of the week, participants returned to the lab and completed a surprise recall task in which they were asked to name as many of the events that they had previously recorded in addition to rating the importance of these events. The results of a bivariate linear regression revealed a significant negative association between hope for affiliation and the percentage of recalled negative social events. Fear of rejection, on the other hand, was significantly positively associated with greater recall of negative social events. When examining importance of remembered events, hope for affiliation was significantly associated with greater importance placed on positive social events. A marginally significant association was found between fear of rejection and decreased importance being placed on positive social events. Overall, it seems that motives for seeking affiliation and avoiding rejection shape recall of positive and negative social events differentially. For negative (but not positive) events, these motives differentially affected memory for the event. For positive (but not negative) events, these motives influenced the recalled importance of the event.

### C92

#### THE MAKING OF ROMANTIC ATTACHMENT BONDS: LONGITUDINAL TRAJECTORIES AND CONSEQUENCES FOR RELATIONSHIP STABILITY Christopher P. Fagundes<sup>1</sup>, Ines Schindler<sup>2</sup>; <sup>1</sup>University of Utah, <sup>2</sup>Freie Universität Berlin

The current study assessed the normative time course and implications of adult attachment formation. We used longitudinal data from 107 individuals at different time points during the formation of their relationship to (a) outline the timing of normative attachment formation both before and after one commits to a romantic partner, (b) investigate how individual differences in attachment style are associated with normative attachment formation, and (c) determine whether normative attachment formation is associated with the likelihood of subsequent relationship dissolution. People reported that their romantic partners peaked on their proximity seeking and safe haven hierarchies four months after commitment, while they kept ascending up their secure base hierarchies two years after commitment. Highly anxious individuals reported that their romantic partners ascended up their proximity seeking hierarchies more quickly before commitment, and were more likely to nominate their romantic partners for proximity at time of commitment. Highly avoidant individuals were less likely to report utilizing their romantic partners for proximity seeking, as a safe haven, and as a secure base when they initially committed; however, highly avoidant individuals did not report that their romantic partners ascended up their attachment hierarchies at differential rates. Normatively, people who reported that their romantic partners were higher on their secure base hierarchies at time of commitment and ascended up their secure base hierarchies at greater rates, were less likely to subsequently breakup within the next 18 months. The findings suggest that attachment plays an important role when examining early relationship processes.

**C93**

**SLEEP LOSS, CONFLICT, AND LOVE IN ROMANTIC RELATIONSHIPS: A DAILY DIARY STUDY** Suzanne Riehl<sup>1</sup>, Dylan Selterman<sup>1</sup>, Arthur Aron<sup>1</sup>,<sup>1</sup>State University of New York at Stony Brook – The effect of sleep loss on individual functioning has been extensively studied and shown to be detrimental in several domains (Moorcroft, 2003), but its effects on interpersonal functioning has been understudied (Troxel et al., 2007). We investigated whether sleep predicted relationship feelings and behaviors. Participants were 46 undergraduates currently in romantic relationships. They completed daily diaries for 2 weeks in the morning (about their sleep the previous night) and the evening (about their feelings and behaviors during the day). Questions included total sleep time, conflict with the partner and love felt for the partner. Statistical analyses were conducted using HLM 6.06 (Raudenbush et al., 2000). Preliminary analyses showed that fewer hours of sleep predicted significantly more conflict during the day ( $p = .007$ ). There was also a marginally significant effect in which fewer hours of sleep predicted less love felt towards the partner during the day ( $p = .088$ ). These findings suggest that sleep loss negatively affects interpersonal relationships. Underlying processes, theoretical implications, and potential applications are discussed.

**C94**

**WHO AM I IN IT FOR?: RELATIONSHIP GOALS AND POSITIVE EXPERIENCES IN DATING COUPLES** Benjamin W. Hadden<sup>1</sup>, C. Veronica Smith<sup>1</sup>, Amy Canevello<sup>2</sup>,<sup>1</sup>University of Delaware, <sup>2</sup>University of Michigan – Research by Crocker and Canevello (2008) has investigated two types of relationship goals – compassionate goals to support others and self-image goals to construct and maintain desired images of the self. In their examination of roommate pairs, actors' high self-image goals were associated with partners' perceiving less support in the relationship, while actors' compassionate goals predicted partners' increased perceptions of support. The current study examines how these goals function in romantic relationships. Participants were 45 heterosexual romantic couples. At Time 1, participants completed measures of romantic compassionate and self-image goals as well as measures of relationship satisfaction, commitment, relationship need satisfaction. At Time 2 (4 weeks later), participants completed measures of satisfaction and commitment. Given the interdependence of the data (Kenny, 1995), a series of multilevel random coefficient modeling analyses revealed that both self and partner compassionate goals were predictive of Time 1 satisfaction and commitment. Relationship need satisfaction was predicted by actors' compassionate goals and, to a lesser extent, partner's compassionate goals. Relationship goals were also found to be predictive over time, as Time 2 satisfaction was related to partner compassionate goals even when Time 1 satisfaction was controlled. A similar pattern was found for commitment. Self-image goals predicted lower relationship autonomy. These results suggest that people's compassionate and self-image goals for their relationships have implications not only for their own relationship quality but for their partner's relationship quality as well. In addition, people's goals may continue to affect relationship functioning over time.

**C95**

**I JUST WANT TO BE FRIENDS: CHARACTERISTICS OF FEMALES WHO PARTICIPATE IN FRIENDS-WITH-BENEFITS RELATIONSHIPS** Joseph Gonzales<sup>1</sup>, Heather Adams<sup>1</sup>, Victor X. Luevano<sup>1</sup>,<sup>1</sup>California State University, Stanislaus – Recently there has been a surge of research examining short-term mating strategies in women. Surprisingly, few studies have examined friends-with-benefits (FWB) relationships, which are sexual relationships between friends with no romantic expectation and no defined duration. The present study's goal was to determine what characterizes females who have participated in FWB relationships compared to those who have not. Fifty-eight female participants were asked about their participation in long-term, casual sex and FWB relationships and given a self-report questionnaire, which measured short-term mating orientation, long-term mating orientation, previous sexual behaviors, self-perceived mating success, mate value, mating effort, sexual desire,

psychological masculinity/femininity, depressive symptoms, and attachment style. Due to the exploratory nature of this study, stepwise (forward likelihood ratio) logistic regression was used to create a model that best predicted whether a participant had engaged in a FWB relationship. The resulting model indicated that participant short-term mating orientation ( $B = 1.01$ ,  $SE = .32$ ,  $EXP(B) = 2.75$ ,  $p < .01$ ) and mate value ( $B = 1.69$ ,  $SE = .76$ ,  $EXP(B) = 5.39$ ,  $p < .05$ ) were the best predictors of participation in FWB relationships. This suggests that the women most likely to engage in a FWB relationship have an unrestricted sociosexual orientation and higher mate value.

**C96**

**DEVELOPMENT OF AN EXPANDED MEASURE OF INCLUSION OF OTHER IN THE SELF FOR ROMANTIC RELATIONSHIPS** Daniel J. Weidler<sup>1</sup>, Eddie M. Clark<sup>1</sup>,<sup>1</sup>Saint Louis University – The Inclusion of Other in the Self (IOS) Scale (Aron, Aron, & Smollan 1992) has been well established as a useful and conceptually unique tool for assessing closeness. However, by nature of it being a single-item pictorial measure, it does not allow for more precise measurement and examination of separate domains of the other that are included in the self. Specifically, Aron and colleagues (Aron & Aron, 1986; Aron, Aron, & Norman, 2001) propose that closeness develops as the resources, perspectives, and identities of the other are included in the self. Using these proposed domains, we developed the Inclusion of Partner in the Self (IPS) Scale, an expanded IOS Scale-related measure that independently assesses inclusion of each of these separate aspects of a romantic partner in the self. In study 1, the IPS Scale was developed using data obtained through one-on-one interviews. Eleven total scale items were generated: 4 assessing inclusion of a partner's resources in the self, 3 assessing inclusion of a partner's perspectives in the self, and 4 assessing inclusion of a partner's identities in the self. In study 2, the reliability and validity of the measure were examined. Results indicated that the IPS Scale demonstrated adequate internal consistency reliability, parallel forms reliability, test-retest reliability, concurrent and convergent validity with other closeness measures, discriminant validity, and predictive validity. Theoretical and methodological implications of the IPS Scale for investigation of closeness as inclusion of other in the self are discussed.

**C97**

**ATTACHMENT AND THE MANAGEMENT OF EMPATHIC ACCURACY IN RELATIONSHIP THREATENING SITUATIONS** Jennifer Fillo<sup>1</sup>, John S. Kim<sup>1</sup>, Jeffry A. Simpson<sup>1</sup>, William Ickes<sup>2</sup>, W. Steven Rholes<sup>3</sup>, M. Minda Oriña<sup>4</sup>, Heike A. Winterheld<sup>5</sup>,<sup>1</sup>University of Minnesota, Twin Cities, <sup>2</sup>University of Texas at Arlington, <sup>3</sup>Texas A&M University, <sup>4</sup>Saint Olaf College, <sup>5</sup>California State University at Eastbay – In two studies, we tested how attachment orientations are related to empathic accuracy (i.e., the accuracy with which one infers a partner's private thoughts and feelings) during attachment-relevant discussions. In Study 1, we examined married couples who were videotaped while discussing a relationship issue involving either jealousy or intimacy. In Study 2, we examined dating couples who were videotaped while resolving a point of conflict in their relationship. Consistent with the Empathic Accuracy Model (Ickes & Simpson, 2001), more avoidantly attached individuals in both Study 1 and Study 2 were relatively less empathically accurate. However, more anxiously attached individuals were more empathically accurate in Study 1 when they discussed jealousy issues that posed a clearer threat to their relationship, and in Study 2 if they were rated by observers as more distressed while discussing a relationship conflict. These studies suggest that those higher in attachment anxiety and avoidance are differentially motivated to manage their empathic accuracy in relationship-threatening situations in the service of affect regulation and the facilitation of their interpersonal goals. Whereas more anxiously attached individuals are hypervigilant in their attempts to understand their partners' thoughts and feelings, even in more threatening situations, more avoidant individuals are motivated to avoid, ignore, or misinterpret such information.

**C98****OF LOVE AND SEX: GENDER AND RELATIONSHIP CLOSENESS SHAPE COGNITIVE REPRESENTATIONS OF SELF, PARTNER, AND RELATIONSHIP**

Diana Odom Gunn<sup>1</sup>; <sup>1</sup>University of California, Merced – Klein and Loftus (1993) argue for a mixed model of self-referent memory. Specifically, trait knowledge develops from an accumulation of trait-relevant behavioral episodes. When relevant experience is low, information about a trait is stored as behavioral exemplars. However, when enough relevant experience accumulates, trait concepts evolve. Interdependence theory (Kelley et al., 1983) suggests that people develop close relationships through sharing frequent, diverse, and strong interconnections over time. Behavioral interdependence, or closeness, reflects accumulated relationship relevant experience which may affect the development of trait and autobiographical memory. We extended the mixed model of memory to the relationship domain by examining mental representations of self, close relationship partner, and their relationship. To examine the role of gender in forming relationship representations, gender role was included as a target for comparison. Participants were 40 currently dating undergraduate students. Participants decided whether the trait describes the target: self, partner, relationship, or gender group (fully counterbalanced within subjects). Preliminary analyses suggested support for the hypotheses. We expected greater closeness to be associated with trait accessibility for partner and relationship and lesser closeness to be associated with autobiographical accessibility for partner and relationship representations. Moreover, we expected that the independence of trait and autobiographical memory would depend on relationship closeness. Implications for social judgment and relationship maintenance are discussed.

**C99****I BRUISE EASILY: SENSITIVITY AND REACTIVITY TO REJECTION FROM ROMANTIC PARTNERS**

Fen-Fang Tsai<sup>1</sup>, Nur Syahirah Bte Ahmad<sup>1</sup>; <sup>1</sup>National University of Singapore – Employing a dyadic diary design, this research examined the role of rejection sensitivity (RS) in romantic relationships. Of interest of this research included the macro-level relationship qualities, e.g., couples' overall relationship satisfaction, trust, and perceptions, as well as the micro-level processes e.g., their daily interactions. Both members of 42 heterosexual couples provided a diary entry every 3 days over 1 month. For the macro-level processes, with the aid of actor-partner interaction model (APIM), analyses revealed that high-RS individuals were less satisfied with and committed in their relationships. They also had lower trust in their partners. Furthermore, high-RS individuals' relationship satisfaction and commitment declined more than low-RS individuals' over one month period of time. Results also indicated asymmetrical patterns of perceptions in the following aspects. High-RS individuals, compared to low-RS individuals, perceived they were more involved in their relationships than their partners were, and that they had higher negativity in their perceptions of their partners' behaviors. For the micro-level patterns, using multilevel analyses on diary data, disagreements reported by participants was used to predict their emotional and behavioral responses to disagreements. Results showed some evidence of RS on heightened feelings of rejection in response to disagreements with one's partner among males: high-RS males felt more rejected and were less inclined to accommodate. In conclusion, this study showed that RS presents an important relationship schema that could cause repercussions on both daily relationship processes and general relationship well-being.

**C100****YOU KNOW WHAT I MEAN?: THE EXPECTATION FOR MIND READING FROM OTHERS**

Ildo Kim<sup>1</sup>, Esther Seo<sup>1</sup>, Taekyun Hur<sup>1</sup>, Seongyu Han<sup>1</sup>; <sup>1</sup>Korea University – Previous researches on mind reading have focused on how well and accurately people figure out the others' hidden intention or meaning during interaction. However, one's expectation for others' mind reading of what the person means and its impacts on the person's behaviors have been left unexplored. The present research conceptual-

ized the expectation of mind reading and investigated its relationship with relevant individual differences and contextual factors. Study 1 examined the contents of mind reading expectation, on which Study 2 developed a scale of mind reading expectation. In Study 1, 132 college students answered to an open-ended questionnaire of when and what kinds of mind reading would be expected and the answers were categorized through a content analysis. The result revealed 11 types of mind reading expectation (ex. Expectation for knowing my negative emotion, even what I did not express, what I expressed indirectly, etc.). In Study 2, a Mind Reading Expectation Scale (MRES) was developed to produce a preliminary reliability and validity. Specifically, people's MRES score was significantly correlated with the Production dimension of CIS (Conventional Indirectness Scale), which means that the higher expectation of mind reading a person has, the more he/she uses conversational indirectness. Also, participants showed higher MRES scores when they imagined to interact with a very close friend than when with a not-close classmate. In conclusion, the results proposed the psychological concept of mind reading expectation and its importance in interpersonal interaction. The functional and cultural implications of mind reading expectation were discussed.

**C101****ACTOR-PARTNER AND BIDIRECTIONAL EFFECTS OF ATTACHMENT DIMENSIONS IN PREDICTING RELATIONSHIP FUNCTIONING**

Mehmet Harma<sup>1</sup>, Nebi Sumer; <sup>1</sup>Middle East Technical University, Turkey – Considering potential cultural differences in the nature of attachment insecurity, we expected that attachment avoidance, rather than attachment anxiety, would strongly predict relationship functions in Turkish cultural context. Therefore, we investigated the actor and partner effects of attachment related anxiety and avoidance on marital satisfaction and conflict using a large sample of married couples in Turkey. We also examined the interaction effects between partners' attachment orientations on the relationship functioning. Participants were 1228 married couples (mean duration of marriage = 11.24 years) selected from four main cities in Turkey. Couples completed the measures of attachment anxiety, avoidance, marital conflict and satisfaction. Two separate actor-partner interdependence models were conducted in predicting marital conflict and satisfaction using SEM. Results revealed that regardless of their gender, spouses were less satisfied in their relationships when their partners had high levels of attachment avoidance. This effect was strong especially for the avoidant women who married with anxious husbands. Consistently, actor-partner interaction analyses demonstrated that wives having culturally incompatible attachment pairings (i.e., avoidant wife and anxious husband) reported the highest levels of marital conflict. Furthermore, husbands with high attachment anxiety reported high levels of marital conflict regardless of the levels of their wives' attachment anxiety. Findings suggested that attachment avoidance is a risk factor for both wives and husbands' relationship functioning and additionally, husbands' attachment anxiety seems to increase marital conflict in Turkish cultural context.

**C102****PREDICTORS OF CAREGIVING IN ADULT CLOSE RELATIONSHIPS**

Judi Walsh<sup>1</sup>, Abigail Millings<sup>2</sup>; <sup>1</sup>University of East Anglia, UK, <sup>2</sup>University of Bath, UK – Not all studies investigating the relationship between attachment and caregiving demonstrate the same pattern of association. Some studies have found attachment anxiety to be associated with less effective caregiving (Carnelley et al., 1996; Feeney & Collins, 2001), whereas other studies have found certain dimensions of caregiving to be associated with attachment avoidance and not anxiety (Millings & Walsh, 2009). Recent research has also suggested that relationship satisfaction and provision of care might be influenced by an individual's perception of their partner's caregiving provision as well as their own attachment style (Kane et al., 2008; Millings & Walsh, 2009). This study aimed to assess the contribution of attachment style, perceptions of partner caregiving, and psychological well-being to the prediction of individual caregiving styles. 134 young adults in established close relationships completed an

online questionnaire comprising measures of caregiving (the Caregiving Questionnaire, Kuncie & Shaver, 1994), attachment (the Experiences in Close Relationships Scale, Brennan, Clark & Shaver, 1998), psychological wellbeing, and perceptions of partner's psychological well-being and caregiving style. Attachment avoidance was the only significant predictor of caregiving responsiveness (proximity, sensitivity and cooperation). Attachment anxiety and perceived compulsive caregiving from partner predicted caregiving compulsion. These findings lend weight to the suggestion that there are two components of caregiving: responsiveness and over-involvement, and provide support for the interpretation that avoidance influences effective responsiveness because of a lack of concern for others' needs, but anxiety manifests through over-involvement because of an individual's own attachment-related needs (Collins et al., 2006; Mikulincer & Shaver, 2007).

### C103

#### WHAT'S THE DESIRABLE BEHAVIOR FOR JAPANESE ADOLESCENTS AT THE PROBLEMATIC SITUATIONS IN ROMANTIC RELATIONSHIPS?

Miyuki Aiba<sup>1</sup>; <sup>1</sup>University of Tsukuba – When we are worried about problematic situations in romantic relationships, what kind of behavior should we take toward girl or boy friends? Previous studies of heterosexual skills pointed the most desirable behaviors were active approach and straight talk (e.g., Groer, Nangle, & Zeff, 2005). However, these behaviors may not apply to Japan due to cultural differences. Thus, it is important to reveal what is the best behavior for Japanese adolescents. The purpose of the current study was to identify the most desirable behavior at the problematic situations in romantic relationships of Japanese adolescents. 333 undergraduates in Japan (51% male; mean age=19.1) completed the measure about evaluations of desirability toward behaviors of opposite sex at the problematic situations in romantic relationships (range=1-5). One-way ANOVA showed that talking to each other sincerely ( $M=4.05-4.46$ ) was more desirable behavior than talking their mind straight ( $M=3.50-4.37$ ) in the problematic situations at maintenance and breakup stage such as "anxiety for future relationship". Active approach ( $M=4.12$ ) was desirable at "approach from oneself" situation alone. Thus, the results indicated that "talking to each other sincerely" was the most desirable behavior for Japanese adolescents at the various problematic situations in romantic relationships.

### C104

#### GHOSTS OF STRESSORS PAST: CHILDHOOD STRESS AS A PREDICTOR OF ADULTS' PHYSIOLOGICAL REACTIVITY DURING MARITAL CONFLICT

Dana P. Roth<sup>1</sup>, Paula R. Pietromonaco<sup>1</sup>, Sally I. Powers<sup>1</sup>; <sup>1</sup>University of Massachusetts, Amherst – Children who grow up in a more adverse family environment characterized by conflict, lack of support, or neglect are more likely to have emotional and physical health problems for the rest of their lives. A harsh early environment may disrupt physiological stress response systems (e.g., the hypothalamic-pituitary-adrenal axis and its associated hormone, cortisol), leading over time to increased health risks (Repetti, Taylor, & Seeman, 2002). Separate work has shown a clear link between marital functioning and health (Kiecolt-Glaser & Newton, 2001). The present study brings together these two lines of work by examining whether physiological stress patterns (i.e., cortisol reactivity) during a marital conflict vary as a function of risky family background. Both members of 48 newlywed couples completed the Risky Families Questionnaire to assess their family environment while growing up (e.g., frequency of quarreling with a parent), and spouses discussed a major, unresolved area of conflict for 15 minutes. Each spouse provided saliva samples (to index cortisol) at intervals before and after the discussion. As hypothesized, husbands from riskier environments showed higher cortisol during the conflict interaction,  $r = .36$ ,  $p = .02$ ; this association was not significant for wives. Thus, adverse early experiences, at least for men, may increase physiological reactivity during marital conflict; if this pattern persists over time, these men may be more likely to develop emotional and physical health problems.

Whether support from a spouse ameliorates the greater stress reactivity associated with a risky family background will be important to investigate in future work.

### C105

#### THE IMPACT OF SOCIAL EXCLUSION ON RELIGIOUSNESS

Niluefer Aydin<sup>1</sup>, Peter Fischer, Dieter Frey, Andreas Kastenmueller; <sup>1</sup>Postdoc – Research has revealed several coping reactions to acts of social exclusion, but the role of religion in dealing with social exclusion has been neglected thus far. We postulated that socially excluded individuals turn to religion in order to cope with the stressful experience of rejection. 6 studies were conducted. It was revealed that socially excluded individuals reported higher levels of religious affiliation regarding intrinsic (Studies 1, 3 and 5), extrinsic (Studies 1 and 5) and extrinsic-personal religious orientation (Study 3) than participants in the control conditions. Furthermore, religious behaviors (like practicing religious rituals) seemed significantly more attractive for socially excluded participants than socially included (Study 2). Excluded participants who had received a religious prime also showed lower levels of aggressive and self-defeating behaviour compared to participants in the control conditions (Studies 4a and 4b). Our samples consisted of participants of Christian (Studies 1 – 4) and Muslim (Study 5) religious affiliation.

### C106

#### PASSIONATE LOVE AND RELATIONSHIP THINKERS: EXPERIMENTAL EVIDENCE FOR ACUTE CORTISOL ELEVATIONS IN WOMEN

Timothy Loving<sup>1</sup>, Erin Crockett<sup>1</sup>, Aubri Paxson<sup>1</sup>; <sup>1</sup>The University of Texas at Austin – We assessed the impact of an individual difference variable, relationship-focused thinking (Cate, Koval, Lloyd, & Wilson, 1995), on women's acute salivary cortisol responses during and after a guided imagery task. Specifically, 29 healthy women, all of whom were in the first year of a new romance and experiencing high levels of passionate love, but varied on levels of relationship-focused thinking, were randomly assigned to one of two experimental conditions: a partner reflection condition or a cross-sex friend reflection condition. Results indicated that women experiencing intense passionate love evidenced increased cortisol levels when asked to reflect on their romantic partner and relationship relative to women asked to reflect on a cross-sex friendship, but this difference was particularly pronounced and relatively long-lasting for those women characterized by a high amount of relationship-focused thinking. Low levels of relationship-focused thinking were associated with a brief acute increase in cortisol for women in the partner reflection condition, but cortisol levels of these participants quickly diminished following the conclusion of the experimental manipulation. Our study significantly expands extant work on the passionate love–cortisol link by isolating the impact of a specific psychological variable, relationship-focused thinking, on the physiological experience of falling in love. We believe our work highlights the advances that can be made when established work in the close relationships and neuroendocrine fields are integrated.

### C107

#### ATTACHMENT STYLE AND NEGATIVE HEALTH APPRAISALS A FUNCTIONAL APPROACH

Courtney Worley<sup>1</sup>, James Hamilton<sup>1</sup>, Leslie Swanson<sup>2</sup>; <sup>1</sup>The University of Alabama, <sup>2</sup>The University of Michigan – Insecure attachment styles are positively correlated with physical symptom reporting in general and medically unexplained symptoms (MUS) specifically. Noyes (2003) has advocated an interpersonal explanation of this relation, whereby the illness behavior of persons with insecure attachment is reinforced because it decreases the likelihood of interpersonal rejection or criticism. In this study we tested whether relations between insecure attachment and general health appraisals are mediated by participants' self-reported tendency to use illness as an excuse for not meeting important life goals. College students completed several measures, including a self-report measure of adult attachment style, the SF-36 measure of general health appraisals, and the medical excuse making subscale of the Multi-Factor Health Survey. We replicated the basic relation between insecure attachment and poor health appraisals. More impor-

tantly, this relationship was partially and significantly mediated by medical excuse making. Additional analyses suggested that these relations were independent of the relation between negative affect and poor health appraisals. Thus, the results point to a motivational/functional relationship (rather than an information processing one) between insecure attachment and self-reported health.

### C108

#### THE GHOSTS OF RELATIONSHIPS PAST: HOW COMPARING PAST AND CURRENT ROMANTIC PARTNERS CAN AFFECT RELATIONSHIP EVALUATIONS

Justin V. Cavallo<sup>1</sup>, Grainne M. Fitzsimons<sup>1</sup>, John G. Holmes<sup>1</sup>,  
<sup>1</sup>University of Waterloo – Dissolving a romantic relationship is a traumatic emotional event (Sbarra & Emery, 2005) and accordingly, considerable research has been devoted to examining the intrapersonal consequences of romantic breakup (e.g., Davis, Shaver, & Vernon, 2003). Less is known, however, about how past relationship experiences affect interpersonal functioning with subsequent relationship partners. The present research examined how comparing past and current romantic partners may influence relationship evaluations and optimism about one's romantic future. We hypothesized that perceiving past and present romantic partners as dissimilar to one another minimizes concerns that a painful breakup experience might recur, and thus positively influences evaluations of one's current relationship. In two studies, we manipulated the extent to which participants perceived their current romantic partners to be similar to their most significant past romantic partner. For people high in self-esteem (HSEs), our hypothesis was supported. HSEs reported more positive relationship evaluations and greater romantic optimism when they thought their partners were different from one another. In contrast, low self-esteem people were more positive and more optimistic when they believed their past and current partners to be similar. These results indicate not only that social comparison between past and current romantic partners may impact relationship outcomes, but also that relationally secure and insecure people may differ in their preference for romantic partners who resemble partners from their past. These results are discussed within the context of Murray, Holmes, and Collins' (2006) risk regulation model.

### C109

#### REJECTION SENSITIVITY AND INTERPERSONAL ENGAGEMENT WITH MEDIA FIGURES

Julia R. Lippman<sup>1</sup>, Dara N. Greenwood<sup>1</sup>,<sup>1</sup>University of Michigan – The goals of the present study were to examine the factor structure of the Rejection Sensitivity Questionnaire (RSQ; Downey & Feldman, 1996) and to see if rejection sensitivity (RS) was related viewers' imagined relationships with media figures (i.e., parasocial interaction, PSI) and/or distress felt in response to favored media figures being taken off the air (i.e., parasocial break up, PSB). We expected that those higher in RS would experience higher PSI with favorite media figures because of the low rejection threat that imagined intimacies afford. We also expected those higher in RS would report increased distress in response to PSB. An online survey administered to 152 college undergraduates revealed a 3-factor solution for the RSQ. Specifically, factors appeared to correspond to three distinct types of interpersonal relationship settings: Non-Romantic (i.e., friends, parents), Desired Romantic (i.e., first date), and Established Romantic (i.e., boyfriend/girlfriend). Step-wise regression analyses using the three RS factor scores to predict PSB and PSI respectively revealed a significant association between the Established Romantic Factor and PSB only. That is, individuals who were more likely to experience rejection anxiety in the context of a hypothetical established romantic relationship were also more likely to experience distress at a hypothetical loss of a favorite media figure. These findings contribute to an existing body of literature which finds that individuals utilize media figures in ways that reflect existing relational anxieties and demonstrate the value in continuing to examine the role that media may play in reflecting, perpetuating, or soothing relational anxieties.

### C110

#### PACIFICATION MOTIVES FOR ROMANCE AS A PREDICTOR OF RELATIONSHIP OUTCOMES

Marie-Joelle Estrada<sup>1</sup>, Mark R. Leary<sup>1</sup>,<sup>1</sup>Duke University – People in close relationships engage in romantic behaviors for a variety of reasons, including to fulfill social roles (on Valentine's Day, for example), ingratiate their partner for favors, and pacify their partners. Both members of 80 couples (M relationship duration = 3.5 yrs.) completed a questionnaire that assessed the degree to which they engaged in romance to pacify their partners (i.e., "so my partner won't be angry with me") and relationship quality. The degree to which women behaved romantically to pacify their partners was negatively associated with their male partners' relationship satisfaction and reports of being in love, as well as the length of the relationship. Men's pacification motives were negatively associated with their female partners' reports of wanting to have sex. Furthermore, two interactions revealed an asymmetrical gender effect. Specifically, women who were romantic to pacify their partners indicated that their relationships were more important the degree to which their male partner was also high in pacification motivation. Conversely, men who were lower on pacification motivation felt less "in love" with female partners who were higher in pacification motivation. The implications of pacification motives for the quality of romantic relationships are discussed.

### C111

#### DECIDING WHEN TO SPEAK YOUR MIND: THE EFFECTS OF EXPECTANCIES ON THE DECISION TO VOICE RELATIONAL DISSATISFACTION

Megan McCarthy<sup>1</sup>, Lara Kammrath<sup>1</sup>,<sup>1</sup>Wilfrid Laurier University – When we become dissatisfied with the actions of a close partner, we face a decision: to disclose our concerns to the other person (voice), or to instead remain silent. Past research has shown that degree of dissatisfaction and issue importance do not differentiate concerns that are voiced from those that are not. What, then, influences the decision to voice? Two studies investigated the hypothesis that, because of the outcome uncertainty associated with raising an issue in a relationship, expectancies would be particularly important for this decision. In Studies 1 and 2, participants were asked to think of a relational dissatisfaction that they were considering disclosing to the other person. Participants rated their degree of dissatisfaction, the importance of the issue, and their expectancies for self and relationship outcomes. Participants then rated their intentions to voice sometime during the following week. In Study 2, we followed up with participants 1 week later and asked how much they actually did voice. Expectancies for self outcomes emerged as the strongest predictor of intentions to voice. Study 2 revealed that actual behavior by the week's end was predicted by these intentions and also by expectancies for relationship outcomes. The participants who told their close friends and partners what was bothering them, therefore, were not the ones who were most upset or who attached the most significance to the issue, but rather the ones who thought raising the issue would solve the problem without harming the relationship.

### C112

#### HIGH TRUST COUPLES REPORT GREATER INCREASES IN CLOSENESS, PERCEIVED RESPONSIVENESS, AND FELT SECURITY AFTER STRAIN-TEST DISCUSSIONS

Sandra Shallcross<sup>1</sup>, Jeffrey A Simpson<sup>1</sup>,<sup>1</sup>University of Minnesota – Trust in one's romantic partner is considered critical to individual and dyadic well-being. It fosters greater satisfaction, commitment, and felt security for romantic partners (Mikulincer, 1998). Despite its importance, trust processes and the characteristic behaviors of high- and low-trust partners have rarely been observed within a laboratory setting. In this study, based on the framework of Thibault and Kelley's (1959) interdependence theory, we examined the experience of romantic couples engaged in strain-test situations (situations that benefit one partner while requiring a sacrifice from the other partner). In strain-test situations, individuals who forego self-interested outcomes for the benefit of either their partner or the relationship should engender greater trust (Simpson, 2007). Married and cohabitating couples (N = 92) participated

in two videotaped discussions about goals each partner had that would require a sacrifice from the other partner. Perceptions of closeness, perceived partner responsiveness, and felt security were collected before and after each interaction. Self-reported attributions about the motivation behind partners' behavior were also collected after each interaction. As predicted, high-trust romantic partners reported greater increases in closeness, perceived partner responsiveness, and felt security than low-trust partners. In addition high-trust partners were less likely to make negative or despairing attributions about their partners' motives.

### C113

#### THE MECHANISM OF SOCIAL PAIN: A SOCIAL MOTIVE PERSPECTIVE

Zhansheng Chen<sup>1</sup>; <sup>1</sup>University of Hong Kong – My previous research has shown that people can re-experience pain associated with past socially hurtful experiences (Chen, Williams, Fitness, & Newton, 2008). This study further investigated the mechanism for such an effect from a social motive perspective. Theorists argued that social pain is a signal of deficits in need of belonging (MacDonald & Leary, 2005; Eisenberger & Lieberman, 2004; Williams, 2007); however, no published studies have tested whether the need of belonging mediates the effect of ostracism/social exclusion on social pain. In addition, Williams and colleagues (see William, 2007) have repeatedly demonstrated that ostracism episodes also threaten other social need, such as the need for control. Therefore, it is reasonable to expect that control should mediate the link between ostracism and social pain as well. To test these hypotheses, I asked participants to recall a past experience during which they were hurt physically or socially (i.e., betrayed by someone close to them). To help the participants re-live past experiences, I asked participants to type, on a computer, what had happened to them and how they had felt step-by-step. Immediately following pain reliving, participants were asked to fill questionnaires measuring their need for belonging and their need for control. Participants were then asked to indicate their feelings of pain on a visual analog scale and the McGill Pain Questionnaire (Melzack, 1978). The results showed that both belonging and control accounted for unique variance in social pain.

### C114

#### PERCEIVED, ACTUAL, AND FRIEND-RATED SIMILARITY IN ATTITUDE AND THEIR EFFECTS ON ATTRACTION BETWEEN SAME-SEX FRIENDS

Makiko Nishiura<sup>1</sup>, Ikuo Daibo<sup>1</sup>; <sup>1</sup>Osaka University – The present study examined the effects of perceived, actual, and friend-rated similarity in attitude on interpersonal attraction in same-sex friends. Previous research has revealed the relationships between similarity and interpersonal attraction. To set forth, we predicted that different kinds of similarity would have different effects. Participants (60 males, 77 females, mean age = 18.82) were paired with their friends and rated their attraction (i.e., security, stimulus, faith, and distance; Nishiura & Daibo, 2009). Then, they answered a questionnaire about their own social attitude and predicted how their friends would answer the questionnaire's items. The results showed that perceived similarity had little relation to both actual and friend-rated similarity. The main effect of perceived similarity on friends' attraction was stronger than actual and friend-rated similarity. Moreover, the two-way interaction between perceived and friend-rated similarity was significant for security, which was one of the factors in attraction and measured how comfortable people could feel by being with friends. When perceived similarity was low, participants felt more secure with those friends who scored high on similarity than with those who scored low; on the other hand, when perceived similarity was high, friends' attractiveness did not vary with friend-rated similarity. The present study suggests that, even if people do not perceive similarity with their friends, they can see their friends as attractive when their friends perceived similarity with them. Also, perceiving similarity with friends may have strong effect on attraction; by contrast, the effect of actual similarity may not.

### C115

#### ATTACHMENT STYLE AND DEPRESSION DURING THE TRANSITION TO PARENTHOOD

Jamie L. Rentfro<sup>1</sup>, W. Steven Rholes<sup>1</sup>, Jeffry A. Simpson<sup>2</sup>, A. McLeish Martin, III<sup>1</sup>, Carol Wilson<sup>3</sup>, Sisi Tran<sup>4</sup>; <sup>1</sup>Texas A&M University, <sup>2</sup>University of Minnesota, <sup>3</sup>Pennsylvania State University at Erie, <sup>4</sup>University of Connecticut – The goal of the present study was to examine the association between attachment styles and depressive symptoms among couples having their first child. Couples began the study approximately 6 weeks before the birth of their child and were tested periodically for the next 2 years. Spouses responded to measures that assessed their attachment styles and modes of interacting with one another. Growth curve models examined change in depression over time. For attachment anxiety, depression started and remained high throughout the study for highly anxious spouses who perceived low availability of support from their partners. Less anxious spouses, along with highly anxious spouses who perceived more available support, reported fewer depression symptoms at birth and gradually declined over time. For attachment avoidance, highly avoidant spouses reported more depression when they perceived more work-family conflict. Depression symptoms worsened over time for these spouses. Less avoidant spouses, along with more avoidant spouses who perceived less work-family conflict, reported less depression at birth and declined over time. These findings help identify couples who may be at risk for depression during the transition to parenthood. They also demonstrate that attachment insecurity predicts higher depression primarily when anxious and avoidant people must contend with situations that aggravate their particular forms of insecurity.

### C116

#### TO BE KNOWN BY HIM IS TO LOVE HIM? RELATIONAL AND GLOBAL SELF-VERIFICATION AND POSITIVE ILLUSIONS IN MARRIAGE

Sara Gorchoff<sup>1</sup>, Tammy English<sup>2</sup>, Oliver John<sup>3</sup>; <sup>1</sup>Carleton College, <sup>2</sup>Stanford University, <sup>3</sup>University of California, Berkeley – Is it better for relationship satisfaction to be seen as one sees oneself (self-verification) or more positively than one sees oneself (positive illusions)? We applied a relational self perspective (i.e., individuals have attributes that characterize them in general and attributes that characterize them in the context of specific close relationships) to the study of marital satisfaction in a sample of middle-aged women. We argue that relational selves more closely reflect the pattern of behaviors and experiences within a given relationship and so should more strongly impact relationship satisfaction than global selves. Because of this, self-verification and positive illusions at the relational level may also benefit relationship satisfaction. However, a key function of self-verification, to facilitate harmonious interactions because partners have reasonable expectations of one another based on understanding each other's strengths and weakness, is better served by relational than global self-verification. On the other hand, the function of positive illusions, to idealize partners so that their behavior is interpreted in the best possible light, is better served by positive illusions at the global level. We found support for our two main hypotheses. Women's relational attributes (rated by themselves and their partners) predicted their marital satisfaction better than their global attributes. Also, both relational self-verification and global positive illusions predicted marital satisfaction. This may allow individuals to feel understood and adored (Neff & Karney, 2002). These findings highlight the utility of applying a relational self perspective to the study of marital satisfaction.

### C117

#### TO STALK OR NOT TO STALK: THE EFFECTS OF SELF REGULATION AND REJECTION ON OBSESSIVE RELATIONAL INTRUSION

Roshni Trehan Ladny<sup>1</sup>, H. Colleen Sinclair<sup>1</sup>, Katherine E. Collier<sup>1</sup>; <sup>1</sup>Mississippi State University – Stalking behavior within the context of intimate relationships is classified as obsessive relational intrusion behavior (ORI). Stalking can begin with acts such as hyperintimacy tactics and then lead to more aggressive acts such as coercion and physical violence. According to the I-3 Model of Intimate Partner Violence Perpetration (Finkel, 2008),

aggressive acts such as stalking and physical violence occur when an individual has strong violence impelling forces, strong violence instigating forces, and weak violence inhibiting forces. This 2x3 factorial study focuses on the roles of different types of rejection (an instigating force) and lack of self regulation (weak inhibiting force) on the commission of ORI behaviors, particularly more aggressive behaviors. Rejection was manipulated through vignettes depicting no rejection (control) or one of two types of romantic rejection: an explicit rejection (one that makes an internal attribution) or a passive rejection that "let's the pursuer down easy" (makes an external attribution for relationship demise). Self regulation was manipulated through use of a thought suppression writing exercise (2 conditions: free writing/no suppression vs. restricted writing/thought suppression, e.g. Wegner, et al., 1987). After scenario and writing exercise, participants (n = 222) rated how likely they would be to think about or actually commit ORI behaviors. A main effect of rejection and an interaction of rejection and self regulation were observed. Participants explicitly rejected reported higher scores of thinking and performing aggressive acts as opposed to participants rejected passively. This difference was exacerbated when self-regulation was depleted.

### C118

#### **IN THE EYE OF THE BEHOLDER: PERCEPTIONS OF COMPENSATION MEDIATE THE EFFECTS OF ATTACHMENT STYLE AND TRANSGRESSION SEVERITY ON RELATIONSHIP SATISFACTION** Kevin A. Leary<sup>1</sup>, Catherine E. Seta<sup>2</sup>, <sup>1</sup>North Carolina State University, <sup>2</sup>Wake Forest University –

While interpersonal relationships provide many positive benefits, including social support and a buffer against negative or stressful events, maintaining our relationships requires consistent navigation of the pitfalls that are bound to arise between partners. But what factors determine the ways in which we respond to arguments, disputes, or misdeeds between partners in close relationships? The current research was conducted in order to examine the role of romantic partners' compensatory behaviors in influencing relationship satisfaction as well as investigate the role of attachment style in moderating these effects. Compensatory behaviors were conceptualized as acts that are intended to make-up for transgressions or negative events that occur between relationship partners. 152 undergraduate participants responded to measures including Rusbult's Investment Model, The Experiences in Close Relationships-Revised Scale, and items assessing their partners' compensatory behaviors. The primary hypothesis investigated in this study contended that attachment style would predict ratings of transgression severity which would, in turn, determine the perceptions of how well a compensatory behavior made up for that transgression. The perception of compensation adequacy, then, would ultimately mediate the effects of a transgression on relationship satisfaction. A series of hierarchical multiple regressions were conducted in order to investigate the relationships among the attachment styles and ratings of transgression severity, perceptions of compensation, and satisfaction. The results indicated that perceptions of how adequately a partner's behavior compensated for a transgression ultimately mediated the relationship between attachment style and transgression severity and satisfaction.

### C119

#### **RELATIONSHIP QUALITY, PERSONALITY, AND RESPONSE TO RELATIONSHIP TRANSGRESSIONS** Yanna J. Weisberg<sup>1</sup>, Jeffrey A. Simpson<sup>1</sup>, <sup>1</sup>University of Minnesota –

Previous work in affective forecasting has demonstrated that individuals use the intensity of their negative feelings in response to a transgression to predict how long these feelings will last. In addition, the predicted intensity and duration of these feelings is greater when the transgressor is a prospective partner than when the transgressor is not (Gilbert, 2004). In close romantic partnerships, however, predictions of the duration of negative feelings after a transgression may be influenced not only by the initial level of distress but also by aspects of the relationship between the transgressor and target. Additionally, there are likely individual differences in prediction of both the intensity and duration of negative feelings. In the present study, 97 undergraduate psychology students currently involved in romantic rela-

tionships reported how they would feel after ten different transgressions by their relationship partner, and then predicted how they would feel a week after experiencing the transgression. The ten transgression examples varied in terms of severity as judged by independent raters. Results showed that predicted intensity and duration of negative affect were both predicted by the severity of the situation. Additionally, the effects of severity on both intensity and duration were qualified by interactions with neuroticism, relationship quality, relationship length, and investment in the relationship. Results suggest that the quality of the relationship between transgressor and target is an important factor in the prediction of reactions to and recovery from the offense.

### C120

#### **ONE OF THESE THINGS IS NOT LIKE THE OTHER: DIFFERENCES IN SEXUAL SATISFACTION IN FRIENDS-WITH-BENEFITS RELATIONSHIPS COMPARED TO LONG-TERM AND CASUAL SEX RELATIONSHIPS**

Heather Adams<sup>1</sup>, Joseph Gonzales<sup>1</sup>, Victor Luevano<sup>1</sup>; <sup>1</sup>California State

University, Stanislaus – Friends-with-benefits (FWB) relationships, which are sexual relationships between friends with no romantic expectation and no defined duration, are often classified as simply casual sexual (CS) relationships in the research. However, recent research suggests that FWB relationships differ substantially from other types of relationships. The aim of this study was to investigate whether FWB relationships produced different levels of sexual and emotional satisfaction than CS and long-term (LT) relationships. Seventy-nine participants (16 male, 63 female) who have engaged in at least one of these three relationship types (CS, FWB, LT) were surveyed on the topics of intercourse frequency, orgasm frequency, participant and partner placed orgasm importance, sexual satisfaction, and emotional closeness. A series of paired-sample t-tests revealed that participants experience more emotional closeness in FWB relationships than in CS relationships,  $t(14) = 3.11, p < .01$ , but less emotional closeness in FWB than LT relationships,  $t(32) = 3.81, p < .01$ . Additionally, compared to LT relationships participants in FWB relationships reported less sexual satisfaction,  $t(34) = 2.22, p < .05$ ; less frequency of orgasm,  $t(35) = 2.68, p = .01$ ; feeling as though their partner was less concerned about their reaching orgasm,  $t(35) = 3.28, p < .01$ ; and feeling that reaching orgasm was less important,  $t(34) = 2.66, p = .01$ . Exploratory analyses suggest that these effects are stronger for women than for men. Our findings suggest that more attention should be given to specific types of relationships, especially friends-with-benefits relationships given their recent rise in frequency.

### C121

#### **RELATIONSHIP QUALITY AND PERSONALITY SIMILARITY: DIFFERENTIATING DISTINCTIVENESS AND NORMATIVENESS**

Madison Barfield<sup>1</sup>, Carly P. Smith<sup>1</sup>, R. Michael Furr<sup>1</sup>; <sup>1</sup>Wake Forest University –

Psychologists and laypeople are interested in the idea that people who are similar to each other will have relatively good relationships. Unfortunately, many examinations of the "relationship quality and personality similarity" hypothesis suffer from two limitations that compromise previous findings: 1) defining 'similarity' between partners in a way that confounds similarity and normativeness (or social desirability), and 2) defining 'relationship quality' in terms of only one measure reported by one partner. The current study addresses both limitations. It addresses the first by differentiating partners' distinctive similarity (the degree to which partners' share unique patterns of non-normative personality attributes) from personality normativeness (Furr, 2008). It addresses the second limitation by having both partners describe their relationship and their relationally-based affective states along numerous dimensions (e.g., overall closeness, knowledge of each other's goals and overall time spent alone together engaged in various activities, etc). Each member of sixty opposite-sex pairs of acquaintances provided self-reports of personality, relational attributes, and immediate affective states (both pre- and post- an interaction with their partner). Results revealed that distinctive similarity (but not simple, unadjusted similarity) is associated with a host of positive relationship attributes and experiences, though these associations are more robust from females' perspectives than from males'

perspectives. In addition, normativeness is associated with one's immediate affective state with a partner. These results unconfound previous research by showing that it is having unique configurations of personality traits in common with one's partner that best predicts relationship satisfaction.

### C122

**SEXUAL SATISFACTION MEDIATES HUSBANDS' FEMININITY ON WIVES' MARITAL SATISFACTION** Carolyn Wenner<sup>1</sup>, James K. McNulty<sup>1</sup>; <sup>1</sup>University of Tennessee – Men's femininity appears to be important to intimates relationships. For example, women with more feminine partners report higher levels of satisfaction with the relationship (Antill, 1983). But how/why do such associations emerge? Given that the sexual context of intimate relationships is one in which partners exchange intimate affection and other relational, and traditionally feminine, behaviors, one mechanism through which partners' femininity may shape marital satisfaction is the sexual relationship. Using a sample of newlywed couples, the current study examined whether sexual satisfaction mediates the positive association between husbands' femininity and wives' marital satisfaction. Replicating previous research, husbands' femininity was positively associated with wives' marital satisfaction. Further, and consistent with predictions, husbands' femininity was also positively associated with wives' sexual satisfaction and those enhanced feelings of sexual satisfaction mediated the effects of husbands' femininity on wives' marital satisfaction. Interestingly, although unrelated to wives' marital satisfaction, husbands' masculinity was also positively associated with wives' sexual satisfaction. These findings contribute to our understanding of marital satisfaction by demonstrating that one way in which men's feminine characteristics contribute to women's relationship satisfaction is through the sexual relationship.

### C123

**MY ENEMY'S ENEMY IS MY FRIEND** Jonathan R. Weaver<sup>1</sup>, Jennifer K. Bosson<sup>1</sup>; <sup>1</sup>University of South Florida – Holding the same negative, as compared to positive, attitude about a third party has been shown to predict increased liking for a stranger (Bosson, Johnson, Niederhoffer, & Swann, 2006). However, Bosson et al. used a fictitious third party in their tests of the bonding power of similar negative attitudes, which is quite different from a third party someone has encountered in person. In the current study, ninety participants learned that they held the same positive or negative attitude of a professor with a future interaction partner, and then rated the closeness they felt to their future interaction partner. Results revealed an interaction in which a shared negative attitude toward a professor produced more closeness to a future partner than a shared positive attitude, but only when the attitude was strongly held. When the attitude was weakly held, attitude valence did not influence closeness to the future partner. These results differ from what Bosson et al. obtained, in which a shared negative attitude promoted closeness more effectively than a shared positive attitude only when the attitude was weakly held. The differing results might have been caused by the different targets (i.e., the third parties) used in each study. It is possible that the use of a college professor increased the ecological validity of the shared attitude manipulation in the current study. Discussion considers possible mediators of this effect.

### C124

**PLURALISTIC IGNORANCE AND INFIDELITY** Sarah J. Watkins<sup>1</sup>, Susan D. Boon<sup>1</sup>; <sup>1</sup>University of Calgary – Dating infidelity occurs frequently (e.g., Wiederman & Hurd, 1999) and can have devastating consequences for both the relationship and the individuals involved (e.g., Cano & O'Leary, 2000; Makepeace, 1981). The present study examined whether pluralistic ignorance occurs with respect to undergraduate students' beliefs about infidelity, that is, whether a discrepancy exists between students' own attitudes toward infidelity and those they attribute to students in general. Fifty three female and 47 male undergraduate students completed a self-report measure of pluralistic ignorance modeled after Prentice and Miller (1993). As hypothesized, participants believed their

peers thought it was more acceptable for students in serious committed relationships to cheat on their dating partners than they themselves thought it was. When asked how acceptable it is for them and for their dating partners to cheat on each other, males rated infidelity as more acceptable than females. Finally, both males and females estimated that the average student has cheated on a dating partner more often than they reported that they themselves had cheated on a dating partner. These results provide evidence of pluralistic ignorance in that students misperceive the social norms with respect to both the acceptability of infidelity and the frequency with which it occurs. Previous research has shown that pluralistic ignorance occurs with alcohol use (Prentice & Miller, 1993) and "hooking up" (Lambert, Kahn, & Apple, 2003); this study extends these findings to other risky behaviours in university students. Potential consequences of pluralistic ignorance will be discussed.

## Groups/Intragroup Processes

### C125

**I CAN DO IT, RIGHT MOM? SELF-VERIFICATION AS A MEDIATOR OF MOTHERS' SELF-FULFILLING EFFECTS ON CHILDREN'S EDUCATIONAL ATTAINMENT** Kyle Scherr<sup>1</sup>, Stephanie Madon<sup>1</sup>, Max Guyll<sup>1</sup>, Jenny Willard<sup>2</sup>, Richard Spoth<sup>1</sup>; <sup>1</sup>Iowa State University, <sup>2</sup>Kennesaw State University – A self-fulfilling prophecy is a false belief that leads to its own fulfillment. Myriad research has focused on mediators of this process by attempting to identify behaviors through which perceivers communicate their beliefs to targets. However, this literature has been criticized for lacking theoretical grounding. As an attempt toward redressing this limitation, this research examined whether self-fulfilling prophecy effects are mediated by self-verification processes. We examined the ability of self-verification to mediate self-fulfilling prophecy effects with longitudinal data obtained from families (mothers, fathers, and adolescents; N = 332), with adolescents' educational attainment as the outcome. Family members completed surveys relevant to family, peers, and school in multiple waves from when the adolescents were in the 6th grade to post-high school. After controlling for relevant background predictors (e.g., peer influence, motivation, academic self-concept), a regression analysis indicated that mothers' false beliefs had self-fulfilling effects on their adolescents' educational attainment,  $\beta = .28$ ,  $p < .001$ . To the authors' knowledge, this is the first evidence that mothers' false beliefs can have self-fulfilling effects on their adolescents' educational attainment. Results from the mediational analysis employing Preacher and Hayes (2008) bootstrapping method provided consistent support for self-verification processes as a mediator. There was a significant indirect effect of mothers' beliefs on adolescents' educational attainment through adolescents' academic aspirations,  $\beta = .04$ ,  $p < .05$ . Mothers' self-fulfilling effects occurred because adolescents internalized their mothers' false beliefs about their educational outcomes and engaged in behaviors that verified those internalized beliefs, thereby causing them to come true.

### C126

**CHANGING MORE THAN YOUR MIND: EXPLORING THE IMPACT OF MAJORITY AND MINORITY OPINION CHANGE ON JUROR SATISFACTION** Victoria Springer<sup>1</sup>, Markus Kimmelmeier<sup>1</sup>; <sup>1</sup>University of Nevada, Reno – In nearly 90% of trials, the majority opinion on the first ballot during deliberations becomes the verdict (Davis, Kerr, Atkin, Holt, & Meek, 1975). However, minority dissenters sometimes successfully convert majority members. Consistently holding a position, whether it is with the minority or majority, or changing one's stripes may have important social psychological consequences regarding engagement with the legal process and jury system. This concern is particularly salient in Arizona, where the supermajority rule requires only 75% juror agreement to render a verdict in civil trials. The experience of being outvoted by fellow jurors rather than working towards a unanimous consensus may impact juror satisfaction with jury service, breeding a sense of alienation and disengagement from the legal system. We hypothesize that juror satisfaction with the trial will partially depend on changes in

opinion position – based on the work of Moscovici (1980), Latané and Wolf (1981), and Baron and Bellman (2007). The data utilized include juror and case-level data from Arizona civil trials (168 juries, 1,385 jurors; Hannaford, Hans, & Munsterman, 1999). Employing multi-level modeling, and controlling for relevant demographic and case features, this study found that compared to jurors who were always in the majority, those jurors who managed to change others' minds and turn the verdict in their direction were more satisfied ( $b=39.08$ ,  $p=.02$ ). Even jurors who held steadfastly to their minority position but were outvoted seemed to be more satisfied than those who were with the majority (and the final verdict) all along ( $b=14.34$ ,  $p<.001$ ).

### C127

#### WHEN BEING A MODEL MINORITY HAS NEGATIVE CONSEQUENCES: IMPLICATIONS OF REALISTIC THREAT AND ETHNIC IDENTIFICATION

Jessica Kang<sup>1</sup>, Cheryl Kaiser<sup>2</sup>; <sup>1</sup>University of Washington, <sup>2</sup>University of Washington – Two studies examine White Americans' reactions towards Asian Americans of different ethnic identification levels. In study 1, 33 White American undergraduates were asked to consider the typical characteristics of either a strongly or weakly group-identified Asian American male student. Participants then rated the target on a series of model minority-relevant stereotypes. The strongly identified Asian American was seen as more competent than the weakly identified one. In study 2, White American students were exposed to a realistic threat (through imagining a competitive classroom scenario) or not. They were then told that they were going to evaluate a fellow classmate who was either a strongly or weakly group-identified Asian American. Participants expressed more envy and jealousy toward the strongly identified Asian American, regardless of whether or not they were in a realistic threat situation, consistent with the results of Study 1 that viewed the strongly identified target as more competent. Also there was an interaction between level of identification of the target and realistic threat situation. White participants were less willing to help and protect the strongly identified Asian American in the realistic threat situation. These findings suggest that the level of identification of an Asian American can affect perceptions of model minorities. Also that both level of ethnic identification and realistic threat situation may elicit less positive behavior tendencies towards Asian Americans. Thus, although Asian Americans are associated with positive attributes, the association may have negative consequences.

### C128

#### THE PROTECTIVE FUNCTION OF THE GROUP-SERVING BIAS

Paul Zarnoth<sup>1</sup>, Amanda Gourley<sup>1</sup>, Shawhin Moosavi<sup>1</sup>, Dean Alves<sup>1</sup>; <sup>1</sup>Saint Mary's College of California – Self-serving biases benefit individuals by minimizing self-esteem loss following a failure and by maximizing the enhancement of self-esteem following a success (Duval & Silvia, 2002). The group-serving bias (the tendency for group members to attribute success to the effort and ability of the group and failure to external factors) was hypothesized to operate in a similar way to protect collective self-esteem. Undergraduate participants completed a bonding exercise in three-member groups and then individually completed the state self-esteem scale (SSES) (Heatherton & Polivy, 1991) and the collective self-esteem scale (CSES) (Luhtanen & Crocker, 1992). The groups then worked on a timed puzzle task and were randomly assigned to either succeed or fail. Next, individuals reported the degree to which each of the following determined the success or failure of the group: the participant, the other group members, the group as a whole, and external factors. Finally, the participants completed the SSES and the CSES a second time. Participants assigned far more responsibility to themselves and to their groups in the success condition than in the failure condition. Those participants with stronger self-serving biases exhibited the greatest improvements in state self esteem following success and exhibited the least decline in state self esteem following failure. Consistent with our hypothesis, participants with stronger group-serving biases showed the greatest gains in group identification in the success condition and the

least decline in group identification in the failure condition. These findings suggest that group-serving biases help groups remain cohesive in both good and bad times.

### C129

#### EMOTION RECOGNITION: EVALUATIONS VERSUS STEREOTYPES

Gijsbert Bijlstra<sup>1</sup>, Rob W. Holland<sup>1</sup>, Daniel H. J. Wigboldus<sup>1</sup>; <sup>1</sup>Behavioural Science Institute, Radboud University Nijmegen – In the present contribution we tested the hypothesis that comparative context and social categorization are important moderating variables of emotion recognition processes. Earlier research has shown that evaluative connotations between social category members and emotional expression predict whether recognition of positive or negative emotional expressions will be facilitated (e.g. Hugenberg 2005). We hypothesized that this recognition advantage only holds for research paradigms in which positive and negative emotional expressions are directly tested against each other in a within subject design. In line with this notion, when participants in the present two studies were asked to classify positive versus negative emotional expressions (i.e. dual valence: happy versus anger, or happy versus sadness), valence congruency effects were found. Importantly, however, in a comparative context without differences in valence in which participants were asked to classify two distinct negative emotions (i.e. single valence: anger versus sadness) we found that recognition facilitation only occurred for stereotypically associated discrete emotional expressions. With this, the current results indicate that the valence of emotional expressions may overshadow the recognition of discrete emotions, but only when differences in valence are salient. The results of Study 2 effectively illustrate the core of our ideas. Although the same sad faces were shown in both conditions we found in the dual valence condition that sadness was faster recognized on the relatively negatively evaluated male social category, whereas, in the single valence condition sadness was recognized faster on stereotype consistent female social category.

### C130

#### WHEN WAR REWARDS: SOCIAL DOMINANCE AND REACTIONS TO

#### INGROUP-PERPETRATED VIOLENCE

John Rohrbach<sup>1</sup>, Paul K. Piff<sup>1</sup>, Andres G. Martinez<sup>1</sup>, Dacher Keltner<sup>1</sup>; <sup>1</sup>University of California, Berkeley – Some people believe that ingroup-perpetrated violence is indefensible. Others, however, consider such violence to be justified, even moral. In the current experiment, we explored the psychological processes underlying these divergent responses to violence and conflict. Specifically, we tested the influence of social dominance orientation (SDO) on reactions to ingroup-perpetrated violence. American participants ( $N = 88$ ) were instructed to write about a time when either America (ingroup) or a foreign country (outgroup) committed violence against another group. Participants then completed a measure of state self-esteem. Results showed that when reminded of violence perpetrated by the ingroup, high-SDO participants experienced boosts in their self-esteem relative to low-SDO participants. SDO did not affect responses to outgroup-perpetrated violence. These results indicate that it is not violence per se, but rather ingroup violence specifically that is "rewarding" for certain people. We argue that episodes of ingroup-perpetrated violence may serve to affirm the worldviews of people high in preferences for group-based dominance.

### C131

#### THE IMPACT OF SOCIETAL THREAT ON AUTHORITARIANISM, SOCIAL DOMINANCE, AND DECISIONS IN THE MINIMAL GROUP PARADIGM

Sean T. Stevens<sup>1</sup>, Alex Borowsky<sup>1</sup>, Dave Wilder<sup>1</sup>; <sup>1</sup>Rutgers University - New Brunswick – Mere categorization of persons into groups (minimal group paradigm/MGP) has been shown to be sufficient to trigger ingroup favoritism. Few studies, however, have examined stable individual differences that may enhance or diminish this bias. Two candidates were examined in this study: right wing authoritarianism (RWA) and social dominance orientation (SDO). Persons exhibiting high RWA and/or high SDO should be less tolerant of outgroups and should, therefore,

exhibit greater ingroup favoritism in a MGP paradigm. Furthermore, when threatened, high RWA or SDO individuals were expected to be even less tolerant of outgroups. To test these hypotheses, participants were divided into arbitrary groups on the basis of a trivial dot estimation task (MGP), completed RWA and SDO scales, and read a vignette that either depicted an American economic collapse in 2025 accompanied by social instability (high threat) or depicted relative stability in 2025 (no threat). Participants then completed measures that assessed perceived threat, ingroup favoritism, and modified versions of the RWA and SDO scales. Consistent with past findings, mere categorization was sufficient to induce ingroup favoritism. Although perceived threat was greater in the high threat condition, threat did not increase ingroup favoritism. However, threat did significantly increase authoritarianism (RWA), an interesting finding since RWA is considered to be a stable personality trait. Overall, results suggest that bias induced by social categorization is a robust phenomenon that is largely unaffected by individual differences in political values (RWA, SDO measures).

### C132

#### THE INFLUENCE OF SHARED REPRESENTATIONS ON FALSE MEMORIES

**IN GROUPS** Kevin R. Betts<sup>1</sup>, Verlin B. Hinsz<sup>1</sup>; <sup>1</sup>North Dakota State University – Groups are often asked to recall important information. An advantage of recalling information in groups is that members can discuss their recall and potentially correct one another's false memories. However, in some circumstances, discussion may instead encourage false memories. In the current study, we adopted a shared representations framework to identify circumstances that encourage false memories in collaborative groups. Shared representations refer to any task-relevant concept, perspective, or cognitive process that is shared among group members. We created the conditions necessary for groups to develop shared representations by presenting them with word lists consisting of items strong and weak in associative strength. Strong associative strength word lists encouraged strong shared representations and weak associative strength word lists encouraged weak shared representations. Groups were asked to reach consensus on their recall in comparison to individuals recalling alone. When shared representations were strong, groups falsely recalled significantly more information than individuals. When shared representations were weak, groups falsely recalled approximately the same amount of information as individuals. Still, groups correctly recalled more information than individuals in both the high and low associative strength conditions. These results indicate that despite general advantages of collaborative recall, select circumstances that allow for strong shared representations may lead to collaborative memory deficits.

### C133

#### YOU COPIED! THE NEGATIVE IMPLICATIONS OF UNIQUENESS

**VIOLATIONS** Jennifer Argo<sup>1</sup>, Katherine White<sup>2</sup>; <sup>1</sup>University of Alberta, <sup>2</sup>University of Calgary – Across four studies, the present research demonstrates 1) that certain types of individuals prefer products that set them apart from their in-group and, 2) the emotional and behavioral outcomes that arise when this uniqueness effort is threatened (i.e., they are copied). In an exploratory first study, high (vs. low) need for uniqueness (NFU) individuals are shown to own products atypical for their in-group (and that are instead associated with an out-group). In study 2, the least positive emotions are reported when high NFU individuals are copied by an in-group member (vs. out-group member and/or low NFU). In study 3, we argue that interdependent individuals have a low NFU and independent individuals have a high NFU. When self-construal is primed, those with situationally activated independent self-construals are most likely to dispose of a product if they are copied by an in-group member (vs. out-group and/or interdependents). In our final study we identify a condition under which those with independent self-construals will not be negatively influenced if they are copied by an in-group member: when the copied object is low in importance. In particular, independents are less likely to trade a copied product for a less desirable alternative when little (versus extensive) effort has been exerted to obtain the object

(whereas no differences are realized for those with interdependent self-construals activated). In sum, certain individuals prefer to distinguish themselves from their in-group through the products they own and violations to this uniqueness effort have negative ramifications for emotional and behavioral outcomes.

### C134

#### GAINING GROUP ENTRY: THE VALUE OF SUBMISSIVE BEHAVIOR IN

**HIRING SITUATIONS** Caitlin Hogan<sup>1</sup>, Rosalind Chow<sup>2</sup>, Larissa Tiedens<sup>3</sup>; <sup>1</sup>Stanford Graduate School of Business, <sup>2</sup>Tepper School of Business, <sup>3</sup>Stanford Graduate School of Business – Dominant behavior generally results in greater status acquisition than submissiveness, because observers perceive dominant actors as competent and intelligent and thus confer status to them. In the present research, we examine a situation in which submissiveness results in greater status conferral than dominance. We propose that considering an outsider for a position in an organization is quite different than considering an insider. Outsiders raise concerns about the outsider's willingness to accommodate group norms, and these concerns may supersede the desire for intelligent leaders. In a vignette study about a hiring situation, we predict and find that submissive outsiders are preferred over dominant ones because submissiveness signals a willingness to accommodate group norms.

### C135

#### PROMOTION OF COOPERATION AMONG COMMUNITY RESIDENTS: EFFECTS OF FAMILIARITY WITH LOCAL HISTORICAL HERITAGES AND COMMITMENT TO THE COMMUNITY.

Hikichi Hiroyuki<sup>1</sup>, Ken-ichi Ohbuchi<sup>1</sup>, Toshiaki Aoki<sup>2</sup>; <sup>1</sup>Tohoku University, <sup>2</sup>Tohoku Institute of Technology – This study examined the effect of residents' familiarity with local historical heritages on their commitment to community and cooperative attitude toward community activities. We constructed a theoretical model consisting of the following five hypotheses based on social identity theory (Tajfel & Turner, 1986) and self-categorization theory (Hogg, 1992): Residents who are familiar with the local historical heritages will have the sense of commonness with past inhabitants (H1) and they will catch on credit to historical heritages (H2); Because the past inhabitants are diachronic in-group member, residents recognizing commonness with them will have a strong commitment to their community (H3); As famous local historical heritage improve social valuation of community, residents perceiving those credits will have a strong commitment to their community (H4); And residents who commit to community will actively participate in community activities (H5). We conducted a questionnaire survey in Japanese communities which have a lot of historical heritages (404 respondents) and which have fewer of it (441 respondents). We asked the respondents to rate familiarity with local historical heritages, sense of commonness with past residents, evaluation of credit to local historical heritages, commitment to community, intention of participation into community activities. Multi-group SEM using Amos revealed that the theoretical model satisfactorily fitted the data ( $\chi^2 = 718.69$ ,  $p < .01$ , GFI = 906, CFI = 938), with all hypothesized causal relationships being significant. The results suggest that promotion of understanding of local historical heritages among residents is a useful way of fostering their commitment to community and cooperative attitude.

### C136

#### THE EFFECTS OF SELF-CONSTRUAL, SOCIAL CUES AND PERSONALITY TRAITS IN CHOOSING CONFRONTATIONAL STRATEGY IN CONFLICT SITUATIONS

Stephanie Foster<sup>1</sup>, Julie Chen<sup>1</sup>; <sup>1</sup>Gettysburg College – The current research examined the relationship between self-construal, sensitivity to social cues and confrontational tendency in two studies among European American participants. Study 1 found that interdependence was positively related to importance of being sociable through a correlational study. Study 2 examined how likely participant would choose confrontational strategy in conflict situations and manipulated self-construal, nationality of the interaction partner and group size of interaction partners. Self-construal was manipulated as a between subject factor through a pronoun circling task (Gardner, 1999). Then participants were

given eight conflict scenarios. The nationality of interaction partner (American vs. non-American) and number of interaction partner (single vs. group) were manipulated as within-subject factors. The results of Study 2 showed that participants were more likely to choose confrontational strategy when interacting with a single friend than with a group of friends. Also, they were more likely to choose confrontational strategy with American interactional partner's than with non-American partner's. This effect, however, was moderated by participants' openness to experience. Participants who were high on openness to experience scale were more likely to be equally confrontational with American or non-American partner. In other word, openness to experience helped participants to be color blind in conflict situations.

### C137

#### **WILL WORK HARDER FOR MONEY THAN FOR FRIENDS: MONETARY INCENTIVES INCREASE PERCEIVED MOTIVATION OF COLLABORATORS**

**Dana M. Wallace<sup>1</sup>, Verlin B. Hinsz<sup>1</sup>; <sup>1</sup>North Dakota State University** – Today's society emphasizes social networking. Use of social networking websites has surged; therefore, one might conclude that social networking is a strong motivating force. In contrast, money is historically a powerful motivator for performance. Previous research suggests that collaborative performance is better than individual performance, perhaps because of an increased accountability to others in spite of opportunities for social loafing. Alternatively, the illusion of group productivity suggests that group members believe they are more productive than objective task-performance measures suggest. This research explores differences in performance in dyads as a function of social and monetary incentives as well as retrospective judgments of the motivational impact of these incentives. Based on the illusion of group productivity, we hypothesize that even if social incentives do not improve task performance, collaborators may believe that improvements occur. A collaborative memory test was examined with dyads having no incentives, dyads under social incentives, and dyads under monetary incentives. Participants in the social incentive condition were reminded of their partner's reliance on them while participants in the monetary incentive condition were told that top performers would receive \$20. Participants completed a series of retrospective judgments assessing commitment and effort. No significant differences were observed on performance; however, participants in the monetary incentive condition expressed significantly more commitment and effort towards the task than those under no incentive or social incentives. These results suggest incentives have a differential impact on perceived motivation. Moreover, our modern conception of social networking may not overshadow the motivational influence of money.

### C138

#### **WHAT LIES BENEATH – COGNITIVE GROUNDWORK OF THE BLACK SHEEP EFFECT**

**Gerhard Reese<sup>1</sup>, Kai J. Jonas<sup>2</sup>, Melanie C. Steffens<sup>1</sup>; <sup>1</sup>Friedrich Schiller University, Jena, Germany, <sup>2</sup>University of Amsterdam, The Netherlands** – The black-sheep-effect (BSE) predicts deviate in-group members to be more strongly derogated than deviate out-group members. While motivational determinants of the effect are well investigated, it is important to identify the underlying cognitive processes leading to differential intergroup derogation. As motivational concerns can trigger a more systematic information-processing mode, we argue that the extent of information processing differs depending on the deviant's group membership. Deeper processing of the in-group deviant should explain differential derogation of in-group compared to out-group members, as stronger reflections about the in-group's image request means to restore the group's overall positivity. In Experiment 1, we measured derogation and information processing after participants received information about a deviant in-group or out-group member. Both a BSE and stronger systematic information processing of in-group information were found. The second experiment presented participants with a deviate in-group member while either being under cognitive load or not. When cognitive load constrained systematic processing, participants judged the deviate less negatively compared to the no load condition. In the third experiment, both group membership and cognitive load were

manipulated. Punishment was measured implicitly using a lexical decision task. As predicted, an implicit BSE was found in the no load condition but not under cognitive load. Moreover, in-group deviance was harder to ignore than out-group deviance when cognitive resources were available. These results show that in-group deviance elicits deeper information processing, which directly affects the extent of derogation. Besides motivational determinants, cognitive processes need stronger attention in explaining the BSE.

### C139

#### **ACADEMIC AND ETHNIC IDENTITY IN INTERRACIAL COLLEGE ROOMMATE RELATIONSHIPS**

**William Clay<sup>1</sup>, Natalie Shook<sup>1</sup>; <sup>1</sup>Virginia Commonwealth University** – Adjustment to college life can be difficult, especially for minority students at predominantly White universities. One factor that may facilitate this transition is intergroup contact. Cross-group friendships have been demonstrated to improve institutional belonging and satisfaction for minority students (Mendoza-Denton & Page-Gould, 2008; Levin et al., 2006). The purpose of the current study was to determine whether minority students in interracial roommate relationships would identify more readily with their university than their counterparts in same-race roommate relationships. Participants were minority, first-year students randomly assigned to live with either another minority student (same race room) or a White student (interracial room). During the last three weeks of their first semester or the first three weeks of their second semester at college, participants completed a questionnaire packet which included ratings of their roommate relationship, as well as identification with their university and racial/ethnic group. In general, interracial roommate relationships were less satisfactory and less friendly than same-race roommate relationships. However, minority students in interracial rooms displayed significantly less disparity between their university identity and racial identities, whereas minority participants in same-race rooms placed much greater weight on their racial identity than their identification with the university. Students in interracial rooms also rated themselves as slightly more typical of students at their university. These findings are particularly relevant considering past work that has indicated the importance of a sense of institutional belonging for minority students' academic success (Walton & Cohen, 2007) and suggest potential benefits of intergroup contact.

### C140

#### **THE PERCEPTIVE CHAMELEON: IMPACT OF EXPOSURE AND NON-HABITUAL GESTURES ON MIMICRY**

**Lia L. Emanuel<sup>1</sup>, Laurie T. Butler<sup>1</sup>, Natalie R. Hall<sup>1</sup>; <sup>1</sup>University of Reading** – Nonconscious behavioral mimicry is the finding that perceivers inadvertently and unconsciously copy the gestures and behavior of a person that they are interacting with (Chartrand & Bargh, 1999). Previous research has suggested a direct perception-to-behavior link as the mechanism supporting mimicry, whereby the mere perception of an individual's behavior automatically increases the probability of engaging in that behavior. While mimicry is thought to serve a functional purpose in social interactions, few studies have directly explored the impact of perceptual factors on the magnitude of mimicry observed. To address this, the present study manipulated both the amount of exposure to target gestures that participants received and the type of gesture. In Experiment 1 (n=85), using a video based photo description task in which an actor performed either no gestures or face-rubbing (16 times per minute), participants displayed significant levels of mimicry, relative to the control condition, regardless of whether they were initially exposed to face-rubbing for 3 minutes or 7 minutes. Using a similar paradigm in Experiment 2 (n=52), it was shown that non-conscious mimicry extended to a less habitually performed ear-touching gesture, albeit at a lower rate than for the face-rubbing gesture used in Experiment 1. Results suggest that the degree of nonconscious mimicry displayed by participants is not a linear function of the amount of prior exposure to gestures, and that mimicry generalizes across both common and uncommon gesture types. The theoretical implications regarding the perception-behavior link are discussed.

**C141****INTERGROUP AND INTRAGROUP PROCESSING IN SELF-STEREOTYPING: THE MODERATING EFFECT OF GROUP (GENDER) STATUS.** Iva

Katzarska-Miller<sup>1</sup>, Monica Biernat<sup>2</sup>; <sup>1</sup>Transylvania University, <sup>2</sup>University of Kansas – The moderating effect of group status on intragroup and intergroup processing and self-stereotyping, within the framework of gender, is examined. Self-stereotyping is “the perceptual interchangeability or perceptual identity of oneself and others in the same group on relevant dimensions” (Turner, 1984). Different lines of research (e.g. Lorenzi-Cioldi, 1995; Simon, 2004; Smith & Zarate, 1992) suggest that social status affects whether individuals engage in intragroup or intergroup processing. Membership in groups marked by low status is conducive to intergroup processing and therefore higher levels of self-stereotyping, while membership in groups marked by high status is conducive to intragroup processing and in turn less self-stereotyping. In two studies the effects of gender status on outgroup activation and self-stereotyping were examined. In both studies women tended to spontaneously mention men (intergroup processing) more often when describing what it means to be a woman than men spontaneously mentioned women. Women also rated themselves higher on warmth and lower on competitiveness than men did (self-stereotyping). In Study 2, a lexical decision task following activation of the ingroup (Gawronski et al., 2005) showed faster reaction times for masculine traits than feminine traits for women but no difference for men, further showing activation of the outgroup for the lower status gender. Direct manipulation of the comparative context in Study 2, did not influence outgroup activation and self-stereotyping measures. Implications, limitations and further directions are discussed.

**C142****DO CONSERVATIVES ABANDON THEIR OPPOSITION TO GOVERNMENT REPARATIONS WHEN REDRESS IS TARGETED AT MEMBERS OF THEIR OWN GROUP?** Jillian Banfield<sup>1</sup>, Craig Blatz<sup>2</sup>, Michael Ross<sup>1</sup>; <sup>1</sup>University of

Waterloo, <sup>2</sup>University of Massachusetts, Amherst – In many countries, members of previously victimized minorities are demanding government reparations for historical injustices. Majority group members often oppose such government redress, although their opposition is far from unanimous (Viles, 2002). The current studies explored when opposition to redress is fuelled by a conservative ideology. In previous research, conservatism was associated with increased opposition to government reparations, but the redress was always targeted at members of outgroups, and especially minorities (Dawson & Popoff, 2004). We examined whether or not conservatives abandon their opposition to government redress when injustices are committed against members of their own group. In Study 1, conservatism predicted the opposition of White but not African Canadians to government redress for earlier injustices against African Canadians. In Study 2, conservatism predicted the opposition of White and Native Americans to government redress for historical injustices committed against African Americans. Conservatism did not predict the response of Native and African Americans to government redress for historical injustices suffered by members of their own groups. Across both studies, higher conservatism predicted reduced support for redress, but mainly for members of an outgroup. There was one exception to this rule: conservative African Americans did not show increased opposition to redress for either members of their own group or Native Americans. We discuss the theoretical and practical significance of the findings.

**C143****PERCEPTUAL HARMONY IN JUDGMENTS OF GROUP PROTOTYPICALITY AND INTRAGROUP RESPECT** L. James Climenhage<sup>1</sup>, Michael T. Schmitt<sup>1</sup>;

<sup>1</sup>Simon Fraser University – We propose the existence of a folk psychology of social groups that leads people to assume that intragroup respect and ingroup prototypicality are positively correlated. In other words, people may infer a group member's level of prototypicality based on the respect that group member receives, or, conversely, infer a level of intragroup respect based on information about prototypicality. Four experiments

test predictions based on these assumptions. In Study 1, participants rated a group member as more prototypical if they read that the group member was highly respected rather than disrespected. Conversely, participants in Study 2 assumed a prototypical group member was more respected by the group than a non-prototypical group member. As a folk theory of groups, we reasoned that the perceived relationship between prototypicality and respect would be stronger for groups high in cohesiveness compared to groups low in cohesiveness. Indeed, we found that the effect of respect on perceptions of prototypicality (Study 3) and the effect of prototypicality on perceptions of respect (Study 4) were stronger for participants considering groups high in cohesiveness compared to those considering non-cohesive groups. Overall, the results suggest that people make inferences about respect and prototypicality within groups that maintain perceptual harmony. Discussion focuses on the implications of findings for research and theorizing on prototypicality and intragroup respect.

**C144****PERCEPTIONS OF EQUALITY AND "GOOD RELATIONS" BETWEEN AND WITHIN GROUPS** Hazel Wardrop<sup>1</sup>, Dominic Abrams<sup>1</sup>; <sup>1</sup>University of Kent –

This research, sponsored by the Equality and Human Rights Commission, is part of the UK Government's framework for evaluating equality and "good relations" across communities. We tested the predictions from a model of good relations which holds that positive intergroup and intragroup relations only promote social harmony in the absence of perceptions of inequality, and that positive intragroup relations can have a detrimental impact upon intergroup relations and vice versa (Abrams, 2008). In an experiment (N=150) participants evaluated two groups when intergroup equality was high or low, and intragroup and intergroup relations were positive or negative. On the basis of self-categorization theory and social identity theory it was predicted that positive intergroup and intragroup relations would be negatively related when the intergroup relationship was unequal. This hypothesis was confirmed. The research sheds light on ways of assessing good relations and also cautions against strategies that focus only on one level of analysis (i.e. either intra- or inter-group).

**C145****COMPASSIONATE LIBERALISM?: SOCIAL DOMINANCE ORIENTATION MEDIATES THE RELATIONSHIP BETWEEN POLITICAL ORIENTATION AND PROSOCIALITY** Laura Saslow<sup>1</sup>, Megan Neal<sup>1</sup>, Dacher Keltner<sup>1</sup>, Sarina M. Rodrigues<sup>2</sup>; <sup>1</sup>University of California, Berkeley, <sup>2</sup>Oregon State University –

Previous research has established that conservatives are less likely to use fairness, equality, nurturing, and empathy to reason about morality (Graham, Haidt, & Nosek, 2009). In the current study, we investigated if political orientation is related to prosociality: dispositional empathy, altruism, and affection; empathic accuracy; and feelings of compassion after a compassion induction. We also tested a mechanism to explain why political orientation might be related to prosocial correlates, by focusing specifically on the role of social dominance orientation, or the justification of inequality. We predicted that social dominance orientation would mediate the relationship between conservatism and prosociality. With multiple methods, we confirmed our predictions. This research contributes to a growing body of knowledge demonstrating the value of a simple one-item liberal to conservative political ideology self-rating in understanding a wide range of outcomes.

**C146****ADDING INJURY TO INSULT: UNEXPECTED REJECTION LEADS TO MORE AGGRESSIVE RESPONSES** Eric Wesselmann<sup>1</sup>, Fionnuala Butler<sup>2</sup>, Kipling

Williams<sup>1</sup>, Cynthia Pickett<sup>2</sup>; <sup>1</sup>Purdue University, <sup>2</sup>University of California – Davis – Social rejection is a painful event that many individuals experience. Research has demonstrated that those who experience the pain of rejection commonly aggress. Such aggression may play an important role in recovery from the pain of a rejection (Leary et al., 2006; Warburton et al., 2006). But are some rejection experiences more painful than others, and thus more likely to lead to aggressive responses? Sociometer

theory (Leary et al., 1995) suggests that people can detect rejection via others' reactions; a properly working sociometer affords a person predictive control over the outcome of an interaction. We hypothesized that individuals who are unexpectedly rejected should experience greater social pain and a loss of predictive control leading to more subsequent aggression compared to when rejection is predictable. Study 1 confirmed that a common rejection paradigm (i.e., get-acquainted paradigm; Twenge et al., 2001) leads to pain and threatens four fundamental needs (i.e., belonging, control, self-esteem, and meaningful existence). Results also indicate participants felt generally liked by their group members, suggesting rejected participants were blindsided by this feedback. Study 2 manipulated predictive control via confederate behavior towards participants before a rejection manipulation. Results replicated the general rejection-aggression link. More germane to our hypotheses, unpredictable rejection undermined participants' beliefs that they could predict other's behavior (i.e., led to the perception of a broken sociometer) and led to higher levels of aggression. Aggressive behavior appears to aid rejected individuals in refortifying threatened need levels.

#### C147

**THE EFFECTS OF ENTITATIVITY ON JUDGMENTS OF PARTICIPATION IN CORPORATE SOCIAL RESPONSIBILITY ACTIVITIES** Koichi Hioki<sup>1</sup>, Taku Konishi<sup>2</sup>, Rie Tanaka<sup>2</sup>, Satoko Itaya<sup>2</sup>, Shinichi Doi<sup>2</sup>, Kenji Yamada<sup>2</sup>; <sup>1</sup>Kobe University, Graduate School of Business Administration, <sup>2</sup>NEC Corporation, C&C Innovation Research Laboratories – Recently many companies encourage employees to participate in pro-social activities as Corporate Social Responsibility (CSR). However, the factors to motivate employees to participate in such activities are unclear. The present study aimed to investigate factors which facilitate participation in CSR activities. One of the most important factors we focused on was entitativity. The previous study of social conformity revealed that a member who highly depended on his/her group did greater conformity behavior than one who did not depend on their group (Jackson et al. 1958). Based on the previous study, we hypothesized that a high-entitative group member would feel debt in skipping CSR activity more than a low-entitative group member. Accordingly, a high-entitative group member would intend to participate in the activity more than a low-entitativity group member, particularly when other members were willing to participate. To test these hypotheses, we asked 156 undergraduate students to read a scenario describing CSR activity. Participants were asked to rate (1) the willingness to participate in it, (2) what extend they would feel debt if they were skipping it. The experimental design was 2 (group entitativity; high / low) x 2 (cost; high / low) x 3 (other's will; participate / skipping / no-information) between participant model. The results showed that feeling of debt in skipping the activity was greater in high-entitativity condition than low-entitativity condition. Additionally, participants had intentionality to participate voluntarily in CSR activity in high-entitativity condition more than low-entitativity condition. The relationship between entitativity and evaluated cost are also discussed.

#### C148

**TOLERATING DESTRUCTIVE LEADERS: THE INFLUENCE OF THE BUDGET POLICY AND WHO IS HARMED.** Stijn Decoster<sup>1</sup>, Jeroen Stouten<sup>1</sup>, Thomas M. Tripp<sup>2</sup>; <sup>1</sup>University of Leuven, <sup>2</sup>Washington State University at Vancouver – Although leaders are responsible for the organization's resources, they frequently act self-interested (e.g. stealing from the organization), and followers seem to tolerate this. What factors contribute to such tolerance? First, the organization's budget policy: if the organization pursues a "use-it-or-lose-it" policy, allocations not spent by the end of the year will be lost, this in contrast to carry-forward budget policies. Second, tolerance may be dependent on who is harmed. Our previous study pointed out that followers react if their group is harmed, but only in the carry-forward condition. The current study addressed the question of whether followers react because their group is harmed or because they themselves are harmed. This experimental study addressed how group members reacted with either a use-it-or-lose-it or a carry-forward policy,

when the leader used the budget either to benefit himself (at the expense of the group) or to benefit himself and the participant (at the expense of the other group members). Results showed that in the carry-forward condition group members' perceptions of fairness, justice, liking, and organizational commitment were lower when the leader harmed the participant in contrast to the other group members. In contrast, in the use-it-or-lose-it condition participants were tolerant even if the leader harmed the participant. These results suggest that people tolerate destructive leaders dependent on the groups' resource policy and whether they are harmed as an individual or not. In a carry-forward policy, group members are more deferential to leaders as long as they are not harmed themselves.

#### C149

**OVERPLAYING THE DIVERSITY CARD: WHEN A SUPERORDINATE GROUP OVERREPRESENTS THE PREVALENCE OF MINORITIES** Jennifer R. Spoor<sup>1</sup>, Jolanda Jetten<sup>1,2</sup>, Matthew J. Hornsey<sup>1</sup>; <sup>1</sup>University of Queensland, <sup>2</sup>University of Exeter – There is substantial payoff for organizations and groups to be perceived as demographically diverse (e.g., Crosby et al., 2003). Therefore, it is not surprising that promotional materials often focus on group diversity, to the point that the proportion of minorities is often exaggerated in both subtle (Matchett & Pippert, 2008) and overt ways (Conklin, 2001). Overrepresentation of minorities is often intended to convey the organization's commitment to diversity, but there may be psychological consequences for minorities when their group is blatantly overrepresented, especially if their everyday experiences in the group contradict the rosy picture of inclusion. Drawing on the role of perceived intragroup respect in group dynamics (Spears et al., 2006), we suggest that perceptions of the superordinate group's respect for minorities will mediate reactions to minority overrepresentation. Current students (50 White, 53 Asian) were presented with an ostensible flyer advertising their university. The flyer's photos were varied to have either low or high representation of Asian students. Participants indicated their perceptions of the university's respect for Asian students, evaluations of the flyer, and willingness to participate in majority and minority subgroup interactions. Compared to majority White participants, Asian participants perceived the high minority representation flyer as less respectful toward Asian students. Furthermore, perceived respect mediated Asian participants' less favorable evaluations of the flyer and lower willingness to engage in cross-subgroup interactions compared to White participants. Results are discussed in terms of the theoretical and practical importance of combining genuine respect for minorities with attempts to promote group diversity.

#### C150

**DO DIFFERENCES IN COLLECTIVISM MODERATE RESPONSES TO RELATIVE DEPRIVATION? A MULTI-NATIONAL META ANALYSIS.** Gina Pippin<sup>1</sup>, Silvana Bialosiewicz<sup>1</sup>, Heather Smith<sup>1</sup>; <sup>1</sup>Sonoma State University – As the current economic crisis continues to effect the socioeconomic status of people all over the world, predicting the response to relative deprivation (RD) becomes more important. But will responses to RD be the same across different countries? RD is a judgment that one is worse off compared to some standard leading to feelings of anger and resentment. One of the most important conceptual distinctions within RD theory is the distinction between individual and group RD. Individual RD is the product of interpersonal comparisons and should lead to individually oriented responses such as criminal or addictive behavior. Group RD is the product of intergroup comparisons and should lead to collectively oriented responses such as joining political organizations or rioting. However, people from different cultural backgrounds may be sensitive to different types of RD. Using Hofstede's (1981) classification of countries as more or less collective, we coded 108 effect sizes representing research projects from 29 countries including the U.S., China, Israel and Iraq. Intergroup comparisons predicted collective behavior more strongly in collectivistic countries than in individualistic countries. Interpersonal comparisons to outgroup members predicted collective behavior more strongly in individualistic countries than in collectivistic

countries. In contrast, temporal comparisons (between oneself and the past or an imagined future) predicted individual behavior, but only for samples collected in individualistic countries. If coding sample nationality can capture differences in people's relative sensitivity to different types of comparisons, it indicates how important cultural context can be for understanding how people will respond to perceived deprivation.

### C151

**GROUP IDENTITY BUFFERS THE ADVERSE CONSEQUENCES OF COLLECTIVE FAILURE: A SOCIAL DILEMMA EXPERIMENT** Jay W. Jackson<sup>1</sup>, Andrea Bangert<sup>1</sup>, Amanda Stryker<sup>1</sup>; <sup>1</sup>Indiana University - Purdue University Fort Wayne – In a social dilemma, each individual must choose a response that benefits the group as a whole (to cooperate) or one that maximizes personal benefits. If most people focus on personal gains, the group suffers a deficit. Studies of teamwork suggest that collective failure reduces team morale and increases selfish actions. Thus, members of failed groups should be less cooperative in response to a social dilemma than members of successful groups. However, from social identity theory, we predicted that a strong group identity would buffer the adverse consequences of group failure. To test this moderation hypothesis, we employed a 2 (group identity: low or high) x 2 (group performance: failure or success) experimental design with 304 participants (76 four-person groups). After the manipulations, group members were isolated to complete measures of group identity, mood, and other constructs. They then responded to a standard social dilemma involving the distribution of 100 chips, each worth 5¢, to a personal and group account. As predicted, there was a significant group identity x group performance interaction effect on amount contributed. Group identity had little effect on members of successful groups, but a large impact on those in failed groups. Collective failure reduced cooperation among members of low-identity groups, but not among high-identity groups. Additional analyses indicated that this effect was due primarily to group identity rather than mood or other potential mediators. In general, our findings support the social identity approach to social dilemmas and, more specifically, are consistent with the goal transformation hypothesis.

### C152

**WHAT'S IN A NAME?: CULTURAL UNDERSTANDING OF REACTIONS TO INSULTS AS EXPLAINED BY THE THEORY OF LOW STATUS COMPENSATION** Sarah Butler<sup>1</sup>, P. J. Henry<sup>2,1</sup>; <sup>1</sup>DePaul University, <sup>2</sup>New York University – The theory of low-status compensation (Henry, in press) holds that while everyone needs a minimal sense of social-worth to be a well-functioning person, culture sends messages to members of low-status groups that they have less social worth. In turn, members of low-status groups use a variety of strategies to compensate for their decreased sense of worth, such as defensiveness toward psychological threats. For example, members of low-status groups may be more likely to find slurs against their group offensive and respond strongly to such insults. Of course, members of low status groups do not live outside a cultural context and their especially negative responses may influence cultural norms such that all individuals understand that slurs can be more problematic for members of low-status groups. To test these ideas, participants rated the offensiveness of the most severe group-based slur they could think of for 15 social groups (including different ethnicities, genders, religions, and sexual orientations), and then indicated the relative status in society for those groups. As expected, a negative relationship was found between the perceived status of a group in society and the offensiveness of negative slurs against that group by members of both high- and low-status groups, while controlling for negative feelings towards the groups and the controllability of membership in the groups. Specifically, slurs against low-status groups were seen as most offensive, whereas slurs against high-status groups as less offensive. This research begins to explore the overall cultural recognition and understanding of low-status compensation strategies.

### C153

**CHARISMATIC LEADERSHIP AND LEADER FAVORITISM: THE MODERATING ROLE OF UNCERTAINTY AND IDENTIFICATION** David E. Rast, III<sup>1</sup>, Michael A. Hogg<sup>1</sup>, Steffen R. Giessner<sup>2</sup>; <sup>1</sup>Claremont Graduate University, <sup>2</sup>Erasmus University – The social identity theory of leadership (Hogg, 2001) posits that as people identify more strongly with a group, leader endorsement and perceived leadership effectiveness become more strongly influenced by how prototypical of the group follower perceive their leader. Prototypical leaders are trusted to act in the group's best interest and are paradoxically able to be innovative in defining the group's identity and in steering the group in new directions. However, from an uncertainty-identity theory perspective (Hogg, 2007), under times of uncertainty, people prefer groups that are ideologically orthodox, unchanging and stasis-oriented, and also have strong and influential leadership. The current study investigates these contradictory predictions. Participants (N = 207) read a short statement from an in-group leader in which we manipulated whether the leader was (un)charismatic and promoting (stasis) change. Participants were then primed to feel uncertain, with leader favoritism subsequently measured. Results indicate that leader favoritism is not influenced when a charismatic leader elevates or suppresses uncertainty, regardless of how strongly the followers identify with their group. Conversely, when the leader is uncharismatic, elevating uncertainty adversely affects leader favoritism only among followers who strongly identify with their group. This finding suggests that elevating uncertainty negatively affects the perception of non-charismatic leaders, but is potentially positive for charismatic leaders. In line with previous leadership research (e.g., Waldman et al., 2001), our results demonstrate that the relationship between charisma and uncertainty is key in leadership processes.

### C154

**COGNITIVE INDEPENDENCE AND COHESION IN DECISION MAKING GROUPS** Kelly Trindel<sup>1</sup>, Paul Paulus<sup>2</sup>; <sup>1</sup>Wingate University, <sup>2</sup>University of Texas at Arlington – Cognitive Independence (CI) can be defined as the tendency to form opinions and make decisions based on personal knowledge as well as additional information that appears to be valid and factual. CI implies a tendency away from normative influence and toward informational influence. In this project CI is investigated in multiple forms in terms of its effects on group decision-making. Over the course of four studies the construct is identified and defined, a scale is designed to measure it and its predictive power in state and trait variable forms are investigated on the Hidden Profile group-decision-making task (Stasser & Titus, 1985). General predictions throughout the project are that CI and group cohesion predict success on a Hidden Profile murder-mystery task. These predictions are supported by the results of the main study in which trait and state-level CI significantly predicted novel information exchange, and novel information exchange and group cohesion in turn significantly predicted decision-making success. Results are discussed in terms of their place in multiple literatures, including the study of group bias toward shared information, group personality research, the dissent and conflict literature, and the social influence literature.

### C155

**WHEN INGROUP TRANSGRESSIONS PROVOKE INTRAGROUP RETALIATION: DISTINGUISHING BETWEEN COLLECTIVE SHAME AND COLLECTIVE GUILT** Andres G. Martinez<sup>1</sup>, Paul K. Piff<sup>1</sup>, Dacher Keltner<sup>1</sup>; <sup>1</sup>University of California, Berkeley – Ingroup misdeeds can pose a direct threat to people's self-image. Individuals may seek to enact retribution to protect themselves against these threats. We investigated whether reminders of an ingroup transgression could motivate individuals to retaliate against their ingroup. We further tested whether collective shame or guilt—two emotions that arise in the face of ingroup transgressions—better explains this effect. American participants wrote about a time when either America (ingroup) or a foreign country (outgroup) was unnecessarily aggressive toward another group. We then assessed col-

lective shame, collective guilt, and desires to retaliate against the ingroup. Ingroup misdeed participants expressed significant elevations in collective shame, collective guilt, and intragroup retaliation, relative to outgroup misdeed participants. A multiple mediation analysis, with shame and guilt entered simultaneously, demonstrated that collective shame was a significant mediator of the ingroup misdeed-->intragroup retaliation link; collective guilt, however, was not. We argue that although shame and guilt can co-occur, intragroup retaliation is uniquely motivated by collective shame. Implications for intergroup emotion, social identity, and collective action are discussed.

### C156

#### EFFECTS OF SHARED COGNITIVE ORGANIZATIONS OF INFORMATION ON EVALUATIONS OF MEMBERS' TASK CAPABILITIES: MUTUAL ENHANCEMENT IN A NON-MULTIATTRIBUTE DECISION SETTING.

Masami Takada<sup>1</sup>, <sup>1</sup>Graduate School of Social Sciences, Hitotsubashi University, Tokyo, Japan – Groups tend to discuss and repeat information shared by all members before discussion instead of unique or unshared information only one member knows. One explanation of this common knowledge effect is the tendency of members to evaluate each others' task capabilities positively when shared information is mentioned. This mutual enhancement, the process whereby shared information is validated by other members and thus holders of shared information are evaluated as capable and knowledgeable, has been shown mainly in multi-attribute decision settings. This study explored mutual enhancement in a non-multiattribute setting where organizations or structures of information matters. As a non-multiattribute setting, a jury decision-making task was used with two types of cognitive organizations of trial testimony: Temporal organization by which testimony is categorized by each time-point that testimony refers to, or witness organization by which testimony is organized by each witness that testimony belongs to. Twenty-four students read 25 pieces of testimony (five witnesses referred to five time-points) in either temporal or witness organization presentations, and then exchanged their recall lists of that testimony with bogus partners, whose recall lists were organized either in temporal or witness way. Results indicated that when participants shared, with their partners, the same types of cognitive organizations of that testimony, they evaluated their partners as more knowledgeable and capable on that task than when they didn't share cognitive organizations, even though the testimony in list itself is the same. Implications are discussed in terms of social validation processes of shared cognition in group discussions.

### C157

#### THE DISRUPTIVE POWER OF DISRESPECT IN DYADIC INTERACTIONS

Sarai Blincoe<sup>1</sup>, Monica J. Harris<sup>1</sup>; <sup>1</sup>University of Kentucky – Existing research on respect and disrespect has revealed the importance of these interpersonal attitudes, but the nature of respect and disrespect (as distinct from attitudes such as liking and disliking), and their importance for everyday interactions, remains unexplored. In the present study, 260 undergraduates interacted in same-sex dyads on a problem-solving task and a getting-acquainted conversation. One person in the dyad, the goal person, was randomly assigned to convey respect, disrespect, liking or disliking to their partner over the course of the interaction. The second dyad member, the target, was instructed to "be yourself." Naïve judges coded the interaction videos on several subjective and objective scales. Participants completed measures of affect, nonverbal behavior and interaction quality. Results indicate that being disrespected significantly affects successful completion of a problem-solving task. Goal persons reported conveying disrespect by insulting their partner, rejecting or ignoring their partner's opinions and dominating the problem-solving task. Respect was conveyed more through agreement or acquiescence; whereas liking was demonstrated via compromise. Several gender differences were obtained. Women were more likely than men to convey respect and liking by talking more and smiling. In the disrespect condition, the goal person in the female interactions were rated as more hostile, less friendly and less involved than the male goal person. This study

serves as a first step in developing a behavioral profile for respect and disrespect, differentiating similar attitudes (i.e. respect vs. liking), and probing the impact of disrespect on successful interactions.

### C158

#### IS SIMILARITY IN BODY WEIGHT OR PHYSICAL ATTRACTIVENESS MORE IMPORTANT IN COLLEGE-AGED FEMALE FRIENDSHIP SELECTION?

Julia C. Fondren<sup>1</sup>, Sara Zachary<sup>1</sup>, Doris G. Bazzini<sup>1</sup>, Sara C. Smith<sup>1</sup>; <sup>1</sup>Appalachian State University – Previous research has shown that women prefer to be friends with other women who are similar in level of physical attractiveness to themselves. Given that contemporary views of physical attractiveness mandate "thinness" for women, it is unclear how much body weight influences women's friendship preferences. This study was designed to disentangle the constructs of physical attractiveness and weight with regard to determining which is most important in friendship selection and formation. In the experiment, female participants were shown a picture of either a moderately or highly attractive woman, whose photographs were morphed to be either average or over weight. Participants were then asked to imagine meeting this person and asked to assess the woman on her likeability, social attractiveness, and to anticipate whether they thought the person might be a social hindrance. Participants' own attractiveness and body mass index were measured. Median splits were performed on each variable as a means of assessing the participants' similarity to the target. Then within levels (low versus high) of participants' attractiveness and within levels (low versus high) of BMI, separate 2 (Target Attractiveness) X 2 (Target Weight) ANOVAs were conducted. Results demonstrated that attractiveness is more related to friendship decisions than weight, but strong support for the similarity-attraction hypothesis was not found with regard to weight.

### C159

#### WHEN INGROUPS AREN'T "IN": CHRISTIAN LIBERALS DON'T FAVOR THEIR RELIGIOUS INGROUPS

Carlee Beth Hawkins<sup>1</sup>, Brian A. Nosek<sup>1</sup>; <sup>1</sup>University of Virginia – Ingroup favoritism is pervasive and occurs in both preexisting groups and experimentally created minimal groups; however, it varies across group memberships. For example, conservatives are more likely to favor ingroups (Sidanius, Pratto, & Bobo, 1996) and higher-status groups (Nosek, Banaji, & Jost, 2008) than are liberals. One of the factors that may differentiate liberals and conservatives is liberals' greater tolerance of individual beliefs (e.g., Sniderman et al., 1989). Religious groups are unique because they serve functions as group identities and belief systems. We investigated whether Christian liberals were particularly likely to avoid ingroup favoritism in the context of religion. In two studies (N's = 1616, 1565), participants distributed \$1000 among 6 possible charities in a simulated donation task. The name of one of those charities was manipulated between participants to make reference to religion (e.g., Christian Community Service Center) or not (i.e., Community Service Center). A significant interaction between charity framing (as religious or not) and political ideology emerged in both studies ( $d = .22, p = .0005$ ;  $d = .30, p < .0001$ ), and this effect was not explained by differences in religiosity. Christian conservatives donated more money to the Community Service Center when it was described as religious compared to the control condition, but Christian liberals did not. In fact, Christian liberals demonstrated a pattern of giving more similar to agnostics and atheists than to Christian conservatives. Because freedom of individual beliefs is important to liberals, liberal Christians may be particularly resistant to favoring their religious ingroups.

### C160

#### TESTING THE BOUNDARIES OF OSTRACISM: WHEN DOES CONSTRUCTIVE INFORMATION EXCLUSION HURT?

Eric E. Jones<sup>1</sup>, Janice R. Kelly<sup>2</sup>; <sup>1</sup>Southern Illinois University Carbondale, <sup>2</sup>Purdue University – Being out of the loop, a form of partial ostracism (Williams et al., 2000) where one is included in group activities but excluded from certain information, leads people to experience deleterious effects (Jones et al., 2009). However, communicating a constructive motive beforehand for information exclusion mitigates these effects (Jones & Kelly, 2009). Two

studies examined the robustness of a constructive motive's buffering effect by delaying the feedback timing and changing the exclusion duration. **STUDY 1:** Participants completed a group task under one of four conditions: in-the-loop, destructively out-of-the-loop, constructively out-of-the-loop, or out-of-the-loop for no stated reason. In the destructive and constructive conditions, participants received reasons for their exclusion after learning of being uninformed. Compared to in-the-loop participants, out-of-the-loop participants reported less trust/liking of group members if left out for a destructive purpose or no reason. Nevertheless, participants who were constructively uninformed experienced no ill effects. **STUDY 2:** Participants imagined being uninformed for a destructive or constructive motive for a short (1 week) or long (9 months) period. An interaction occurred. When uninformed for 1 week, compared to participants left constructively uninformed, participants left out for destructive reasons liked/trusted group members less. Conversely, when uninformed for 9 months, out-of-the-loop participants disliked/distrusted group members equally, whether uninformed for a destructive or constructive reason, showing limits to a constructive motive's buffering effect. People infer their group standing from information exclusion (Jones & Kelly, 2009). While a constructive motive dampens these concerns for short-lived exclusion, extended exclusion heightens these concerns even for constructive reasons.

### C161

**FROM UNDERDOG TO TOP DOG: CHANGES IN EVALUATIONS OF COMPETITIVELY DISADVANTAGED INDIVIDUALS** Scott Allison<sup>1</sup>, James Beggan<sup>2</sup>, Melanie Waligura<sup>1</sup>; <sup>1</sup>University of Richmond, <sup>2</sup>University of Louisville – Does our liking for underdogs change as they begin to enjoy more success? Past research has shown people tend to like, root for, and sympathize with underdogs (Allison & Goethals, 2009; Vandello, Goldschmied, & Richards, 2007). Yet previous studies have also demonstrated that although we support underdogs, we don't respect underdogs (Allison & Burnette, 2009). Respect for underdogs appears to lag behind affective support for underdogs, and that consequently underdogs may have to enjoy considerable success over time before the stigma associated with underdog status is shed. In the present study, we asked 150 participants to evaluate an underdog mayoral candidate who sheds his underdog status over time by eventually surpassing the top dog mayoral candidate in the polls. Consistent with past research, we found that the underdog initially attracted significantly more liking, support, and sympathy than did the top dog. The underdog was also respected less than the top dog. As the underdog began to enjoy equal success with the top dog, liking and support increased, sympathy decreased, and respect remained just as low as before. When the underdog began to enjoy greater success than the top dog, liking, support, and sympathy significantly decreased, and respect continued to remain low. Only when the underdog enjoyed several years of success did participants' respect for him climb to levels originally associated with the top dog. We discuss these findings as they relate to theory and research on competition, momentum in group influence, and impression formation.

### C162

**CHILDREN'S SUSCEPTIBILITY TO THEIR MOTHERS' SELF-FULFILLING BELIEFS AND THE MODERATING INFLUENCE OF RELATIONSHIP AFFECTIVE QUALITY.** Jennifer Willard<sup>1</sup>, Stephanie Madon<sup>2</sup>, Kyle Scherr<sup>2</sup>, Max Guyll<sup>2</sup>; <sup>1</sup>Kennesaw State University, <sup>2</sup>Iowa State University – Researchers have proposed that individuals' beliefs can shape social reality through the self-fulfilling prophecy (i.e., a false belief that comes true through social interaction; Merton, 1948). Although there is support for the self-fulfilling prophecy, the modest effect sizes found raise questions concerning the extent to which this process could influence social reality (Jussim et al., 1996). However, researchers have noted that under certain circumstances the effect sizes can be larger. Experimental data seems to suggest that the relationship between perceivers and targets moderates perceivers' self-fulfilling influence on targets. We examined this possibility using long-term naturalistic data collected from mothers and their children (N = 429 dyads). We hypothesized that children's relationships

with their mothers would moderate their susceptibility to their mothers' self-fulfilling influence. Surveys assessed background predictors of children's alcohol use, mothers' beliefs about their children's alcohol use, children's perceptions relationship affective quality, and children's alcohol use. We identified the inaccuracy of mothers' beliefs by regressing mothers' beliefs on children's background predictors and saved the residuals. To test for moderation, we included the following variables in a regression model: children's background predictors, relationship affective quality, mother belief residuals, and relationship affective quality x mother belief residuals. Consistent with our hypothesis, relationship affective quality moderated the self-fulfilling influence of mothers' inaccurate beliefs. Mothers' inaccurate beliefs had a greater influence on their children's later alcohol use when children perceived the relationship as poor than when they perceived the relationship as good. Thus, under some situations individuals' beliefs can have meaningful effects.

### C163

**THE EFFECTS OF FLUCTUATING GROUP ACHIEVEMENT ON INDIVIDUAL MEMBER'S PERFORMANCE** Ako Agata<sup>1</sup>, Naoki Kugihara<sup>1</sup>; <sup>1</sup>Osaka University – Previous studies (e.g. Kerr, 1983) suggested that group success might lead to a perceived dispensability of effort. We hypothesized the following: 1) an individual would exert less effort (i.e., social loafing) when they received positive pseudo-feedback (PPF) that their group's achievement increased as time passed than when they received a negative pseudo-feedback (PNF) that the group's achievement decreased, 2) the perception of others effort would be higher in the PPF condition than in the PNF condition. The participants were required to press the "1" key on the PC key-board as much as they could. In the beginning, they individually performed the task for three minutes, followed by a three-minutes rest period, they performed the task as a group of three people for 15 minutes. In the group task, all the participants had to monitor a graph on a display, which showed the group achievement (PPF and PNF). The participants were also given a group goal where they had to work together to press the key 600 times per minute. The results showed that the participants in the PPF condition perceived their efforts as more dispensable when compared to those in the PNF condition, although there was no significant difference in the performances given by the two groups. The results also showed that those in the PPF condition perceived the effort of others to be higher than that those in the PNF condition.

## Norms and Social Influence

### C164

**ON ATTITUDES TOWARD FAT PEOPLE: LINKING LAY THEORIES OF SOCIAL NORMS TO EXPLICIT ATTITUDES TOWARD VIOLATORS OF NORMS** Raymond Y. M. Chun<sup>1</sup>, Connie S. K. Poon<sup>1</sup>, Grace W. M. Ip<sup>2</sup>, Charles W. K. Yip<sup>1</sup>; <sup>1</sup>The University of Hong Kong, <sup>2</sup>Hong Kong Shue Yan University – Individual differences in negative attitudes toward fat people have been linked to variations in beliefs about the controllability of fatness (Crandall, 1994). Although attitudes towards fat people may be influenced by societal standards, little is known with respect to how lay beliefs about social norms may affect attitudes toward fat people. We suggest that people who believe that social norms are fixed (entity norms theorists) differ from those who believe that social norms are malleable (incremental norms theorists) in their explicit attitudes towards violators of norms. To the extent that expressing opinions incongruent with social norms risks negative consequences, entity norms theorists, who believe that nothing can be done to change social norms, may tend to express a negative attitude toward norms violators. By contrast, incremental norms theorists, who tend to believe that social standards can be negotiated as the society evolves, may feel less pressed express a negative attitude toward norms violators (cf. Chiu et al., 1997). Thus, we hypothesized that entity (versus incremental) norms theorists would display more a negative explicit, though not necessarily implicit, attitude toward fat people, who violate societal standards of appearance. We developed a measure to assess uni-

versity students' beliefs about the malleability of social norms. We used the Dislike Subscale of Crandall's (1994) Antifat Questionnaire and an Implicit Association Test (cf. Greenwald et al., 1999) to measure their explicit and implicit attitudes toward fat people respectively. As expected, entity (versus incremental) norms theorists displayed more explicit, but not implicit, negative attitudes toward fat people.

**C165**

**REVISITING THE SELF-RELEVANCE OF ANTIFAT ATTITUDES** Kristin N. Dukes<sup>1</sup>, Keith B. Maddox<sup>1</sup>; <sup>1</sup>Tufts University – Previous research has revealed the pervasiveness of obesity stigma but a limited amount of this research has focused on how prejudice against overweight individuals may be related to body image. Contrary to conventional wisdom, Crandall (1994) suggests that prejudice against overweight individuals is not founded in self-relevant weight concerns. The current research investigated and extended this hypothesis by exploring the relationship between prejudice toward overweight individuals, self-relevant weight concerns, and body image. It was hypothesized that self-relevant weight concerns, and not prejudice, would be significantly related to measures of body image. Participants completed Crandall's (1994) Antifat Attitudes Questionnaire (AFA) as well as questionnaires that assessed body image (body dissatisfaction and body shape concerns) and attitudes about weight gain and loss. The AFA is composed of three subscales that map onto evaluations of overweight people (Dislike), beliefs about the controllability of weight (Willpower), and self-relevant concerns about being overweight (Fear of Fat). Consistent with predictions, analyses revealed significant positive correlations between body dissatisfaction, body shape concerns, unfavorable attitudes toward weight gain, and self-relevant concerns about being overweight (Fear of Fat). Also consistent with predictions, no relationship existed between these factors evaluations of overweight individuals (Dislike) and beliefs about controllability of weight (Willpower). In line with Crandall's previous research, these results suggest that prejudice against overweight individuals and beliefs about their ability to control weight are not based on self-relevant weight concerns.

**C166**

**UNDERSTANDING BEHAVIORAL COMMITMENT THROUGH VEGANISM** April McGrath<sup>1</sup>, Jakub Racek<sup>1</sup>, Rachele McGrath<sup>2</sup>; <sup>1</sup>Carleton University, <sup>2</sup>St. Thomas University – Some individuals partake in behavior consistent with their beliefs and values even when such behavior is challenging and requires high levels of persistence, whereas others are less willing to behaviorally commit to their principles. In an attempt to understand why people commit to challenging, but personally important, behavior, we examined narratives written by 30 individuals practicing veganism. Participants wrote narrative accounts about their motivations, challenges, and overall experiences in adopting and maintaining a vegan diet and completed several questionnaires. Narratives were coded by following the procedure of numerically aided phenomenology, which organizes participants' narratives based on similar shared meanings. Participants were then placed into one of three distinct groups based on a cluster analysis of the similarities of their narratives to the themes identified. Results indicated that vegan participants adopted their diets to either oppose animal cruelty and exploitation (Cluster I – ethical vegans), to improve their health (Cluster II – health vegans), or to positively influence the lives of animals and the environment (Cluster III – selfless vegans). Importantly, cognitive dissonance played a motivating role for participants in the adoption of their lifestyles, with one quarter of them writing explicitly about the discomfort experienced due to their discrepant values and actions. Lastly, statements made by participants suggest that the norm activation theory (Schwartz, 1977), or the value-belief-norm theory (Stern, Dietz, Abel, Guagnano, Kalof, 1999) may be helpful in understanding the adoption of veganism and other instances of behavioral commitment that appear challenging.

**C167**

**COMPLIANCE-ENHANCING MECHANISMS OF SCARCITY: THE ROLE OF ELABORATION** Naomi K. Grant<sup>1</sup>, Leandre R. Fabrigar<sup>2</sup>, Adelle Forzley<sup>3</sup>, Maia Kredentser<sup>2</sup>; <sup>1</sup>Mount Royal College, Calgary, Alberta, <sup>2</sup>Queen's University, Kingston, Ontario, <sup>3</sup>University of Calgary, Calgary, Alberta – The use of scarcity (i.e., that items are seen as more valuable to the extent that they are not widely available) is an effective compliance tactic, but there are competing views as to how it operates. One view is that scarcity is a cue (Cialdini, 1993). Another view is that scarcity acts as a signal that more thought is required (Brannon & Brock, 1992). The goal of the current research was to use the Elaboration Likelihood Model (Petty & Cacioppo, 1986) to reconcile these seemingly disparate points of view, as well as to suggest an additional mechanism by which scarcity might operate. Participants (N = 167) read about a study skills program that was either limited or widely available. Participants in the low elaboration condition retained a 7-digit number in memory as they read program information. Participants in the high elaboration condition retained 2 digits. Scarcity increased intentions to sign up for the program under low elaboration, but decreased intentions under high elaboration (ps < .05). Mediation analyses suggested that scarcity operated as a cue under low elaboration, and biased thoughts in a negative direction under high elaboration. This research is the first to demonstrate that scarcity can play multiple roles depending on elaboration levels, and that shifts in the role served by scarcity can sometimes reverse its effects.

**C168**

**THE EFFECTS OF IMPRESSION MANAGEMENT GOALS ON EATING BEHAVIOR** Abigail Remick<sup>1</sup>, Patricia Pliner<sup>1</sup>; <sup>1</sup>University of Toronto – Previous research suggests that women use eating as a means of impression management and eat less when they are motivated to make a good impression on their eating partner. However, past studies have assumed that certain kinds of people or specific traits in others (e.g. gender and attractiveness) will activate impression management concerns, but researchers did not directly manipulate impression management goals. The present study aimed to determine if women's eating behavior does in fact change as a result of self-presentation concerns by directly manipulating impression management goals. Participants were recruited under the guise of a "get-acquainted" experiment, ostensibly examining how people behave when meeting someone new. Participants were told that in order to make the situation more realistic, they would have a conversation over lunch with another participant. We then measured the amount of pizza taken by participants while they were under the assumption that they would be having lunch with a partner. Prior to taking their pizza, participants were given specific impression management instructions; they were told either to make a good impression, to avoid making a good impression, or were given no instructions. As hypothesized, participants in the good-impression and no-instructions conditions took less pizza than those in the avoid-good-impression condition. The results suggest that the impression management motive, which appears to be present naturally in social situations involving strangers, inhibits eating. Results are discussed in the context of the social facilitation literature, which suggests findings may differ when eating with friends or family.

**C169**

**REACTIONS TO EQUALITY NORM VIOLATIONS** Dana C. Leighton<sup>1</sup>, David A. Schroeder<sup>1</sup>, Katherine E. Banks<sup>1</sup>; <sup>1</sup>University of Arkansas – This research investigated reactions to, and consequences of, small versus large violations of the equality norm. Participants (N= 146) read scenarios describing a group of students who had worked together on a class project. Although everyone had objectively made equal contributions, one individual (the transgressor) did not give equal credit to others; therefore, a provision point that would have resulted in higher grades for everyone was missed. The transgressor was described as having deviated from equality by either a small or large amount. Furthermore, for half of the scenarios, other group members received lower class grades as a conse-

quence; in the other half, because of the instructor's actions, there was no negative consequence of the norm violation. Transgressors were judged to have shown greater respect and acted more fairly toward the group when there were no negative consequences following a minor equality norm violation compared to all other conditions. Participants thought group members would seek greater vengeance and want to impose harsher punishment for both large norm violations (regardless of the consequences), and when the group members suffered negative consequences for the equality norm violation. When a small equality norm violation did not result in negative consequences, the transgression was treated as "no harm, no foul;" no such discounting of equality norm violations was seen when significant negative consequences were suffered. Results demonstrate the need to unconfound the impact of norm violations per se from the consequences of those violations: all norm violations are not treated equally.

### C170

**COLLEGE STUDENTS' DATING PREFERENCES: "HOOKING UP" VERSUS DATING OR COMMITTED RELATIONSHIPS** Rebecca M. Warner<sup>1</sup>, Kristina Breton<sup>1</sup>, Heather D. Hussey<sup>1</sup>; <sup>1</sup>University of New Hampshire – Recent trends suggest that dating has become less common on college campuses and that "hooking up", uncommitted sexual activities with casual acquaintances, is on the rise. Hooking up is considered a risky sexual behavior usually involving alcohol and unprotected sex, and is often regretted by college students. One element contributing to this shift in behaviors is students' misperceptions regarding their peers' relationship preferences. The current study examined 339 undergraduate college students' (206 women and 133 men) perceptions of their peers' hooking up and dating behaviors, their own hooking up and dating behaviors and preferences as well as how they felt after such experiences. Consistent with social norms theory, students perceived that their peers hooked up more often than actual reported behaviors would suggest. Of those who did hook up, 33% did not enjoy the experience, 49% were not happy about the experience, and 71% did not feel emotionally fulfilled, with more women than men reporting emotional distress. Results suggest the majority of students (81%) would prefer dating relationships to hooking up and 82% find committed relationships as more rewarding. Furthermore, 73% of men and 93% of women would choose a date over a hookup. These results suggest that most students do not engage in uncommitted sex frequently although many perceive hooking up to be the norm, and that both male and female students would prefer to be involved in committed and/or dating relationships. Norm interventions should aim to correct these misperceptions and increase healthy dating behaviors.

### C171

**COMPARISON FOCUS IN INTERGROUP COMPARISONS: WHO WE COMPARE TO WHOM INFLUENCES WHO WE SEE AS POWERFUL AND AGENTIC** Susanne Bruckmüller<sup>1</sup>, Andrea Abele<sup>1</sup>; <sup>1</sup>University of Erlangen-Nuremberg – We can talk about differences between social groups in many different ways. Previous research has shown that who we compare to whom, i.e., which group becomes the norm and which group "the effect to be explained" (Miller, Taylor, & Buck, 1991) follows systematic principles. The present research investigates the consequences of these systematic biases in inter-group comparisons for the perception of the compared groups. In Experiment 1, participants read a text that either compared Law students to Economics students (Economics norm condition) or compared Economics students to Law students (Law norm condition). Participants attributed higher power and status, higher agency/ competence, and less communion/ warmth to the group that had represented the norm rather than the effect to be explained. Experiment 2 tested the same hypotheses with regard to two groups that participants had no prior knowledge about. Participants read a text comparing two fictitious cultures living on a South Pacific island. As in Experiment 1, participants perceived the norm group as more powerful, more agentic, and less communal than the comparison group. The ascription of agentic and communal traits was mediated by the attribution of power and status to the two groups. Overall, results show that the

comparison focus in inter-group comparisons implicitly carries information about power relations between social groups that perceivers are able to decode. An important implication is that systematic ways of explaining one group rather than another could serve as a subtle tool to perpetuate the status quo of power relations between social groups.

### C172

**THE ROLE OF TRANSPORTABILITY IN EXPLAINING RACIAL DIFFERENCES IN MEDIA INFLUENCE** John Kingsbury<sup>1</sup>, Rick Gibbons<sup>1</sup>, Meg Gerrard<sup>2</sup>; <sup>1</sup>Dartmouth College, <sup>2</sup>Dartmouth-Hitchcock Medical Center – Past research has shown that exposure to alcohol portrayals in movies is associated with escalation of drinking. One explanation proposed for this is that the media serve as "superpeers," providing adolescents with attractive, older models who engage in risk behavior that might not be acceptable among adolescents' peers. Research has also suggested a racial difference in this effect, such that Black adolescents are less receptive to media influence than White adolescents. The goal of the current study was to determine the factors that explain racial differences in media influence.

### C173

**GENDER DIFFERENCES IN THE PRESENCE AND CONSEQUENCES OF PERCEIVED DISCREPANCY FROM SOCIAL NORMS** Eliot Brockner<sup>1</sup>, Catherine A. Sanderson<sup>1</sup>; <sup>1</sup>Amherst College – This research examined whether college students feel discrepant from their peers regarding drinking and studying norms, the consequences associated with feeling discrepant, and how sex moderates both the nature and consequences of feeling discrepant. Men and women completed measures of their own attitudes and behaviors regarding drinking and studying norms, their perceptions of peers' attitudes and behaviors regarding those norms, and their feelings of connection to their college. Findings revealed that people do feel discrepant from both types of norms, and that men and women feel discrepant in different ways. In terms of drinking norms, men think that they drink more than other men, whereas women think that they drink less than other women. In contrast, men think that they study less and do less homework than other men, whereas women believe they study more and do more homework than other women. Feeling discrepant from such norms was also associated with distinct consequences, which again differed as a function of sex. Men who feel they drink less and study more than other men feel more connected to their college, whereas there was no effect of perceived discrepancy on drinking or studying norms on connection to their college for women. This research contributes to prior work by examining both the presence and consequences of feeling discrepant from two distinct types of social norms that are highly relevant to college students as well as the impact of sex on both the nature and consequences of feeling discrepant.

### C174

**POWER BY ASSOCIATION: THE VICARIOUS EXPERIENCE OF POWER** Nicholas Hays<sup>1</sup>, Noah Goldstein<sup>1</sup>; <sup>1</sup>UCLA – Previous research on power has focused on the firsthand experience of power (or powerlessness). This research, however, has overlooked how individuals are affected by their associations with powerful others. Based on evidence that those around us affect the way we see ourselves, we argue this oversight in the power literature is significant. The present research explores whether association with a powerful other elevates one's own sense of power, even when one cannot draw on the other's power. Empirically, we manipulated the power of an associate in a scenario and then measured the extent to which participants felt power over another peer described as equal in power. Compared to participants associated with a low-power other, those associated with a high-power other felt they had more power in their relationship with the equal-power peer. Furthermore, because power has been shown to increase optimism, we also measured participants' perceived likelihood of experiencing various positive and negative life events. Consistent with prior research, participants who were associated with a high-power other were more optimistic about the future than participants associated with a low-power other. This study demonstrates that power not only affects individuals directly, but also

indirectly and vicariously. Our conclusions suggest that even when individuals have no power of their own, they may behave as if they had power when associated with a powerful other, potentially leading to inappropriate behavior and irrational judgments.

**C175****THE INTERACTIVE EFFECTS OF MATERIALISM AND MONEY REMINDERS ON VALUES AND BELIEFS** Chad M. Danyluck<sup>1</sup>, Michael T. Schmitt<sup>1</sup>, Craig W. Blatz<sup>2</sup>, <sup>1</sup>Simon Fraser University, <sup>2</sup>University of Massachusetts, Amherst –

This study examined how money-reminders influence self-sufficiency values, as well as explored how individual differences in materialism moderate those effects. Participants viewed a screen-saver displaying either images of money or abstract graphics while completing measures to assess their endorsement of self-sufficiency values (e.g., endorsement of self-transcendent values, family and community involvement, and beliefs in symbolic racism). In line with our predictions, reminders of money affected participants' self-sufficiency values depending on their levels of materialism. Participants high in materialism when reminded of money evaluated the importance of family relationships, community ties and self-transcendent values more negatively than did participants low in materialism. A marginal interaction indicated that money-reminders led high materialists, but not low materialists, to increase their endorsement of symbolic racism. Our findings suggest that money steers people towards specific psychological outcomes, but the kinds of consequences brought forth depend on the values to which people ascribe. The results of the current study point to a new avenue of research looking into how money-reminders and material values influence intragroup and intergroup relationships. Implications are that interpersonal disharmony may be reduced when materialism is reduced and that minority groups might be disadvantaged in contexts where money and material values are salient. Future research on the effects of money-reminders could benefit from focusing on the processes that lead individuals to rank materialism high or low in their hierarchy of values.

**C176****SOCIAL AND PERSONAL POWER - PARALLEL AND OPPOSITE EFFECTS**

Joris Lammers<sup>1</sup>, Janka I. Stoker<sup>2</sup>, Diederik A. Stapel<sup>1</sup>; <sup>1</sup>Tilburg University, <sup>2</sup>Rijksuniversiteit Groningen – How does power affect behavior? We posit that this depends on the type of power. We distinguish between social power (power over other people) and personal power (freedom from other people). Social power is characterized by interdependence and responsibility over others. Personal power is characterized by independence and own goals. We propose that social and personal power have opposite effects if this distinction between independence and interdependence is relevant, but parallel effects if it is not relevant. We test in two studies the effect of social and personal power on two important variables associated with power: Stereotyping and Behavioral Approach tendencies. We do this because the distinction between independence and interdependence is relevant for stereotyping, but irrelevant for behavioral approach. We therefore expect social and personal power to have opposite effects on stereotyping, but parallel effects on approach. An experiment (N = 113) orthogonally manipulates social and personal power (together with a control condition). A large-scale field study (N = 3082) among real high- and low-power employees measures social and personal power. In both studies we find the predicted effect: social and personal power have opposite effects on stereotyping, but parallel effects on behavioral approach. That is, personal power increases but social power reduces stereotyping, but both personal and social power increase behavioral approach. This study advances our understanding of the concept of power itself. It shows that power should not be treated as a monolithic, but rather as a multifaceted construct.

**C177****THE IMPACT OF APPEARANCE-FOCUSED MEDIA IMAGES ON A STRESS BIOMARKER IN WOMEN** Lisa Mask<sup>1</sup>, Céline M. Blanchard<sup>1</sup>, Shiva Adel<sup>1</sup>,

Amanda Baker<sup>1</sup>, Zorana Tasovac<sup>1</sup>, Catherine Bielajew<sup>1</sup>; <sup>1</sup>School of Psychology, University of Ottawa – Research indicates that exposure to the media's "thin-body ideal" is related to women's preoccupations with their own appearance, negative affect, and dysfunctional eating behaviors (Grabe et al.2008). Few studies have investigated whether these cognitive, affective, and attitudinal outcomes are also linked to a physiological stress response in women. Grounded in the framework of Objectification Theory (Fredrickson & Roberts, 1997), we hypothesized that exposure to an appearance-focused video designed to induce a state of self-objectification would result in greater body shame, restrained eating, and physiological stress as indexed by a salivary cortisol increase. A sample of undergraduate women (N = 35) was randomly assigned to view one of three experimental videos: an appearance-focused video, an instrumentality-focused video, or a neutral video. Saliva samples were collected at four different time intervals: immediately upon waking in the morning, 30 minutes following waking, immediately prior to viewing the video, and 30 minutes following exposure to the video. Cortisol levels were measured using the enzyme-linked immunosorbent assay technique. Results indicated that women who viewed the appearance-focused video reported greater body shame compared to women who viewed the instrumentality-focused and neutral videos. Within-group analyses revealed a significant salivary cortisol increase for 30 % of the women who were exposed to the appearance-focused video. This subgroup of women scored lower on measures of general autonomy, competence, and relatedness. These findings suggest that the subtle objectification of women in the media can be a stressful experience for women who feel less fulfilled in their basic psychological needs.

**C178****COMING CLEAN ABOUT (NOT) BEING GREEN: VALUE ASSERTIONS INCREASE ADMISSIONS OF ENVIRONMENTALLY-UNFRIENDLY BEHAVIOR** Anna Merritt<sup>1</sup>, Benoît Monin<sup>2</sup>; <sup>1</sup>Stanford University – Three

experiments investigated how value assertion makes individuals feel more comfortable admitting to environmentally harmful behaviors. In Study 1, participants either wrote about their environmental values, their environmentally friendly behaviors, or a control topic, and later listed their personal behaviors that negatively impact the environment. Those who first wrote about their values admitted significantly more negative behaviors than people in the other two conditions. In Study 2, we controlled for fluency effects by manipulating the number of values or positive behaviors participants could list; regardless of survey length, people who wrote about their values again later admitted to significantly more negative behaviors than people who wrote about their positive behaviors. Study 3 showed that this effect is specific to admitting negative behaviors, even when the admission is preceded by other related questions. Overall, our results suggest that people are more likely to admit to undesirable behavior when they have had a chance to express values that contradict that behavior, but not when they have merely listed good behaviors that might make up for their bad deeds.

**C179****A GOOD STUDENT IS EASY TO MENTOR: A SOCIAL INFLUENCE PERSPECTIVE ON SCIENTIFIC INTEGRATION** Maria Aguilar<sup>1</sup>, Mica

Estrada-Hollenbeck<sup>1</sup>, Randie Chance<sup>1</sup>, Alix Sanchez<sup>1</sup>, Anna Woodcock<sup>2</sup>, Paul Hernandez<sup>3</sup>, P. Wesley Schultz<sup>1</sup>; <sup>1</sup>California State University San Marcos, <sup>2</sup>Purdue University, <sup>3</sup>University of Connecticut, Storrs – A social influence framework was utilized to test how mentors (agents of social influence) contribute towards the integration of science student mentees (targets of social influence). Data come from an ongoing longitudinal study of 1420 minority science students, recruited from 38 campuses nationwide. Our analyses were conducted as a cross-lagged panel design at two time points, a year apart, examining quality of mentorship and integration into the sciences. Results showed a significant relationship between

quality of mentorship (Time 1) and integration (Time 2),  $b = .24$ ,  $t = 4.37$ ,  $p < .05$ . Additionally, perceived quality of mentorship (Time 1) was predictive of scientific integration (Time 1;  $b = .27$ ,  $t = 6.31$ ,  $p < .05$ ). The relationship between mentorship (Time 1) and future integration (Time 2) diminished after controlling for initial feelings of integration,  $b = .08$ ,  $t = 1.79$ ,  $p = .07$ . The second set of cross-lagged analyses revealed a significant relationship between integration (Time 1) and mentorship (Time 2),  $b = .24$ ,  $t = 4.76$ ,  $p < .05$ . This effect persisted after controlling for initial perceptions of mentorship quality. Taken together, these results show that individuals who feel an initial sense of integration into the scientific community perceive mentors to be of quality and helps further mentees' integration. Traditional models of mentorship regard the mentors as integral to the socialization of mentees. These results demonstrate that the mere presence of an agent of social influence does not explain later scientific integration. The existing characteristics of the mentees better account for successful future integration into the sciences.

### C180

**PERCEIVED SIMILARITY AS A MODERATOR OF SOCIAL COMPARISON EFFECTS ON WOMEN'S BODY IMAGE** Rebekah Wanic<sup>1</sup>, James Kulik<sup>1</sup>, <sup>1</sup>University of California, San Diego – Recent body image research has generated evidence of an asymmetrical social comparison effect, whereby women who view a fit peer show a decrement in self-ratings while those who view an unfit peer do not differ from controls. Similarity between perceiver and target has been identified as a factor that may moderate social comparison outcomes. Therefore, we sought to determine whether perceived similarity would influence body image related comparisons. College women ( $N = 160$ ) viewed an image of a fit, control, or unfit-appearing peer before responding to questions about their body image, self-satisfaction, and perceived similarity. Controlling for participant BMI, results revealed the expected asymmetrical comparison effect, which was qualified by perceived similarity. Specifically, perceived similarity to the unfit target and dissimilarity to the fit target resulted in self-ratings that were significantly lower than control ( $ps < 0.007$ ), while perceived dissimilarity to the unfit target produced heightened self-ratings ( $p = 0.014$ ). Results support Mussweiler's (2003) selective accessibility model (SAM).

### C181

**IMPLICATIONS OF NORM-BASED REJECTION SENSITIVITY AND NORM-BASED SOCIAL REJECTION ON CONSUMPTION DECISION** Grace Ip<sup>1</sup>, Chris Yau<sup>1</sup>, Ka-ye Wong<sup>1</sup>, <sup>1</sup>Hong Kong Shue Yan University – As social norms and peer group are important factors influencing individuals' decision, so we postulate that individuals who anxiously expect rejection if they don't follow group norms (norm-based rejection sensitivity) would put more emphasis on peer's preference when making consumption decision (Study 1). Similarly, when individuals are rejected by new acquaintances because being labeled as deviants, they would put more emphasis on peer's preference in making immediate consumption decision (Study 2). In Study 1, 108 undergraduates filled in questionnaires on rejection sensitivity (RS), norm-based RS, self-esteem and consumption consideration (CC) consisting of four domains on peer preference, product prestige, product function and general consumption consideration. Regression analysis showed that only norm-based RS significantly predicted peer preference in CC but not RS nor self esteem. In study 2, modified on Baumeister et al. (2005)'s rejection paradigm, 40 undergraduates participated in small group (4 or 5 participants) discussion were randomly assigned to acceptance or rejection group (i.e. they were told as being rated by other participants as a cooperative or deviant member), then filled in CC questionnaire and participated in a consumption game with other participants or alone respectively. Results indicated that those in the rejection group have a significantly higher rating on peer preference than those in the acceptance group. To conclude, both studies supported the present predictions that individuals who are high in norm-based rejection sensitivity or are recently rejected by peers would put more emphasis on peer's preference when making consumption decision.

### C182

**WHEN BAD BEHAVIORS LEAD TO GOOD ONES: THE INFLUENCE OF NORM VIOLATION ON BEHAVIORAL REGULATION** Benjamin Giguère<sup>1</sup>, Richard N. Lalonde<sup>2</sup>, <sup>1</sup>McGill University, <sup>2</sup>York University – An idealized world of self-regulation is one where all behaviors are regulated. In that world, never would we indulge in that extra piece of cake. Unfortunately, in reality, blunders of behavioral regulation are relatively common occurrences. Social norms can act as signals of these regulatory failures and may thus contribute to the regulatory process. The current research aimed to explore how violation of social norms that result from regulation failure may influence future regulation. Two multi-time studies were conducted. Study 1 showed that when norms help signal a lapse in regulation of alcohol consumption, they may lead to enhanced regulation in the future. Specifically, the social emotional outcomes (e.g., guilt) from the perception that a failure to regulate one's drinking lead to violating social norms resulted in changes in the expected outcomes associated with this behavior. These changes then decreased the likelihood the same behavior would be repeated during the following week. Study 2 conceptually replicated these findings by demonstrating that the same social psychological processes observed in Study 1 operated to decrease procrastination. Findings from these two studies offer a novel perspective on behavioral regulation by proposing a psychological mechanism for normative influences.

### C183

**NORM-BASED REJECTION SENSITIVITY: ITS AFFECTIVE, BEHAVIORAL, AND COGNITIVE CONCOMITANTS WHEN PERSONAL PREFERENCES COLLIDE WITH SOCIAL NORMS** Connie S. K. Poon<sup>1</sup>, Charles W. K. Yip<sup>1</sup>, Grace W. M. Ip<sup>2</sup>, <sup>1</sup>University of Hong Kong, <sup>2</sup>Hong Kong Shue Yan University – When people's personal preferences collide with group norms, people may choose to follow the group norms or act on their true preferences. Past research has focused on situational forces that affect how people act in these situations. Although individual differences have been observed, the sources of such differences have yet to be identified. We suggest that some individuals have anxious expectations of rejection based on non-conformity to group norms (i.e., high norm-based rejection sensitivity or norm-based RS) (cf. Feldman & Downey, 1996). High (vs. low) norm-based RS individuals may be expected to feel more nervous as they consider the repercussions of not following group norms inconsistent with their preferences. We hypothesize that, motivated to avoid rejection, high (vs. low) norm-based RS individuals will have stronger intention to conform to group norms that violate their true preferences. As they intend to adhere to group norms, high (vs. low) norm-based RS individuals may be expected to more closely monitor how other group members act. Undergraduates completed the Norm-based Rejection Sensitivity Questionnaire developed by Yip and colleagues (2009). We measured participants' affective, behavioral, and cognitive reactions in six hypothetical scenarios in which their personal preferences collide with group norms. As expected, norm-based rejection sensitivity predicted their nervousness about the repercussions of non-conformity, intention to follow group norms, and monitoring of other group members' actions, even after controlling for the effects of self-esteem, neuroticism, and personal rejection sensitivity. Motivation to avoid rejection mediated the relation between norm-based RS and intention to follow group norms.

## Self/Identity

### C184

**THE IMPACT OF ROLE MODELS ON SCHOOL BELONGING FOR NATIVE AMERICAN MIDDLE-SCHOOL STUDENTS** Rebecca Covarrubias<sup>1</sup>, Stephanie A. Fryberg<sup>1</sup>, <sup>1</sup>The University of Arizona – Native American (NA) students encounter limited exposure to positive representations of their group in the academic domain. This underrepresentation may threaten students' identities in the classroom, subsequently decreasing feelings of school belonging and negatively impacting academic performance (Wal-

ton & Cohen, 2007). Two studies examined the impact of role models on school belonging for underrepresented NA students. In Study 1, 90 NA middle-school students read about a successful in-group (Native American), out-group (European American), ethnically ambiguous, or no role model, and then completed a belonging measure. Analyses revealed that NA students in the in-group role model condition reported higher belonging relative to students in the out-group, ambiguous, or no role model (control) conditions. No differences were found between the out-group, ambiguous, and control conditions. In Study 2, 71 NA and 46 European American (EA) middle-school students were randomly assigned to list many, a few, or no successful role models and then completed a belonging measure. Analyses revealed that NA students who listed many role models reported higher belonging than those who listed a few or no role models and reported similarly high levels of belonging as EA students across all conditions. NA students who listed a few role models also reported higher belonging than those who listed no role models. These findings suggest that positive, in-group representations help facilitate identity-safe contexts for underrepresented NA students, but have no effect on EA students who seemingly encounter a plethora of positive representations in the classroom.

### C185

#### **SOCIAL ATOMIZATION THEORY AND ITS IMPLICATIONS FOR PSYCHOLOGICAL AND PHYSICAL HEALTH**

Sara Konrath<sup>1</sup>, <sup>1</sup>University of Michigan – Social atomization theory highlights the importance of considering the orthogonality of agency and communion-related variables (e.g. self-construal, individualism/collectivism; see Konrath et al, 2009) rather than seeing them as unipolar dimensions. Examining the four quadrants of self and other-focus may allow for more predictive power by including cases which are high in both (Balanced), low in both (Detached), and unmitigated in self-focus (Atomized) or other-focus (Dependent). In this study I test whether those who are high in self-focus and other-focus (Balanced) will be the healthiest on a number of variables, while those who are low in self-focus and other-focus (Detached) will be the least healthy. Data from the 2006 Health and Retirement Study were used to test these predictions. Two proxy measures were created: self-focus reflected people's sense of independence from others, while other-focus reflected people's embeddedness within social groups. A median split was used to create four self-other groups: Balanced, Atomized, Dependent, and Detached. Preliminary analyses indicate that those are high in both self and other-focus (Balanced) generally scored the highest in psychological (e.g. life satisfaction, well-being, anxiety, depression), cognitive (e.g. memory performance), and physical health outcomes (e.g. self-ratings of health, presence of chronic health conditions), while those who were low in both self and other-focus (Detached) generally scored the lowest in psychological, cognitive, and physical health outcomes. As in any correlational study, direction of causality and third variables are potential interpretive problems and these will be addressed in my poster through more detailed analyses.

### C186

#### **PREDICTING PSYCHOLOGICAL WELL-BEING FROM SELVES AND SELF-DISCREPANCIES: EXAMINING THE DOMAINS OF MORALITY, INTELLIGENCE, AND PERSONALITY**

Brenda L. McDaniel<sup>1</sup>, James R. Daugherty<sup>1</sup>, <sup>1</sup>Kansas State University – Past research has used the actual and ideal selves (i.e., who we are and who we want to be, respectively) and discrepancies between selves to predict self-esteem, anxiety, and depression (McDaniel & Grice, 2008). The present study expands existing research by using ratings of morality, intelligence, and Big Five traits to predict psychological well-being. Participants completed a repertory grid (Grice, 2004) consisting of 15 bipolar traits for their actual and ideal selves. Participants also completed measures of shame and guilt (Tangney, 1990), self-esteem (Rosenberg, 1965), anxiety (Hamilton, 1959), depression (Radloff, 1977), and anger rumination (Sukhodolsky, Golub, & Cromwell, 2001). Our results suggest that when self and ideal self ratings, across morality, intelligence, and Big Five traits, are simultaneously allowed to predict variance in psychological well-being, self ratings

uniquely predict shame, self-esteem, anxiety, depression, and thoughts of revenge. Ideal self ratings uniquely predict guilt. Both self and ideal self ratings uniquely predict angry afterthoughts and angry memories. Actual-ideal self-discrepancies significantly improved predictions of self-esteem and depression above and beyond self and ideal self ratings. Further, when self and ideal self ratings were analyzed at the domain level (morality, intelligence, and Big Five separately), ratings of Big Five personality and morality were the strongest predictors of psychological well-being. Our findings suggest that psychological well-being is most strongly related to self ratings of personality, but ideal self ratings and discrepancies between selves also provide predictive knowledge within specific domains.

### C187

#### **IN THE NAME OF SELF-LOVE: INTERPERSONAL IMPLICATIONS OF PRIDE IN COMPETITIVE CONTEXTS**

Armand Munteanu<sup>1</sup>, Christopher Burris<sup>1</sup>, <sup>1</sup>St. Jerome's University – A conceptual distinction has been made between Alpha or "hubristic" pride, defined as a global sense of pride in the self, and Beta or "authentic" pride, defined as pride in specific actions (see Tracy & Robins, 2004, 2007). Alpha pride has been linked to a variety of maladaptive attitudes and behaviors, whereas Beta pride has been characterized as inherently more prosocial and productive of a stable sense of self-esteem. To our knowledge, research has yet to examine the interpersonal consequences of Beta versus Alpha pride in competitive contexts wherein the achievement focus of the former is most likely to be relevant, however. Thus, 99 undergraduates completed Alpha and Beta pride measures from the TOSCA-3 (Tangney & Dearing, 2002) on-line and subsequently engaged in a word-definition task with an ostensible competitor to earn tickets for a cash draw. Upon receiving bogus feedback that they either won or lost the competition, participants divided the allocated tickets between themselves and their ostensible competitor and indicated how they justified their allocation decision. As expected, Alpha pride predicted self-serving ticket allocation and self-focused justifications regardless of outcome; Beta pride also predicted self-focused justifications. Moreover, both Alpha and Beta pride predicted increased use of other-focused justifications following a loss (but decreased use following a win), and this pattern was primarily driven by Beta pride. Thus, when dealing with competitive failure, Beta pride in particular may motivate justifications for self-serving behavior that denigrate the other and/or deny the impact of one's harmful actions upon him/her.

### C188

#### **CONFLICTS OF INTEREST: RELATIONAL SELF-CONSTRUAL AND DECISION-MAKING IN INTERPERSONAL CONTEXTS**

Jonathan Gore<sup>1</sup>, Susan Cross<sup>2</sup>, <sup>1</sup>Eastern Kentucky University, <sup>2</sup>Iowa State University – Three studies investigated the moderating effect of relational self-construal on decision-making during interpersonal conflicts of interest. In Studies 1 (n = 161) and 2 (n = 294), participants completed a measure of relational self-construal, read hypothetical conflicts of interest then evaluated courses of action based on the degree to which doing so would benefit or harm to each person involved. Results indicated that zero-sum perceptions were stronger among people with a low relational self-construal than for high relationals. In Study 3, 173 participants described and evaluated their a past conflict of interest of their own with either a close or a distant other. Results revealed that high relationals evaluated the outcome positively when their decision was in favor of the close other. These results suggest that interpersonal conflicts of interests can be viewed as situations that can involve mutual gain, particularly if a person has a highly relational self-construal.

### C189

#### **VICARIOUS COLLECTIVE SELF-VERIFICATION**

Maya Kuehn<sup>1</sup>, Lindsay Shaw Taylor<sup>1</sup>, Serena Chen<sup>1</sup>, <sup>1</sup>University of California, Berkeley – The phenomenon of self-verification has been documented at both the individual and collective levels of identity (e.g., Chen, Shaw, & Jeung, 2004). At the collective level, people are motivated to seek verification from fellow ingroup members for the most certain and important components of

their collective identity. The present research investigated the vicarious experience of collective self-verification (CSV), and sought to examine how a fellow ingroup member's receipt of collective self-verification impacts an individual's own collective identity processes. Participants were highly and lowly gender-identified women who were recruited based on their self-views with respect to a prototypically female, somewhat negative characteristic, the need for approval. Participants saw this trait as descriptive and central to themselves as an individual, themselves as a woman, and women in general. After arousing all participants' CSV needs by providing inaccurate feedback regarding their need for approval from a supposed personality measure, participants were given a chance to satisfy their own CSV needs vicariously by sending further feedback to an ingroup member. This feedback included several dimensions of personality, including the need for approval; participants rated their likelihood of sending each dimension's feedback to the target. Although all participants were likely to send feedback for the need for approval, highly gender-identified women exhibited greater evidence of receiving vicarious collective self-verification following this experience than lowly gender-identified women, including feeling more understood as a woman. Results suggest that vicarious collective self-verification processes indeed have consequences for one's collective identity.

### C190

#### THE GROUP'S ROLE IN THE SELF-DETERMINATION OF NEGATIVE BEHAVIORS

Sophie Sansfaçon<sup>1</sup>, Catherine E. Amiot<sup>1</sup>, Simon Lapointe<sup>1</sup>; <sup>1</sup>Université du Québec à Montréal – Self-determination theory (SDT) is a motivational theory which usually applies to socially constructive behaviors, like volunteering (Deci & Ryan, 2000). However, SDT could also be applied to more destructive and negative behaviors. In fact, some people may freely choose to emit negative behaviors. These individuals appear to be self-determined with regards to the emission of these negative behaviors. Social groups may have an impact on the self-determination of the behaviors. Social identity theory (SIT) proposes that when individual identify with their social group, they endorse and internalise their group's norms and behaviors, regardless of whether these are positive or negative. We adapted a self-determination scale to test whether negative behaviors can be self-determined, and whether belonging to a group that endorses such behaviors can facilitate the internalization of negative behaviors. Participants (N=269) completed a questionnaire presenting a list of negative behaviors (i.e., aggression and addictions). The questionnaire assessed why participants engaged in such behaviors and whether these negative behaviors were endorsed by a social group participants belonged to. The psychometric properties of the self-determination scale were acceptable. Moreover, participants whose group endorsed the negative behavior were more self-determined in emitting this behavior than participants who did not belong to a group that endorsed this behavior. Also, among participants who belonged to a group that endorsed the negative behavior, the more these participants agreed with their ingroup's reasons for endorsing the behavior, the more they were self-determined for doing this behavior. Results are interpreted in light of SDT and SIT.

### C191

#### EXPERIENCE DOESN'T ALWAYS COUNT: THE ROLES OF SELF-INVESTMENT AND MARKET EXPERIENCE IN THE ENDOWMENT EFFECT

Michael Buhrmester<sup>1</sup>, William B. Swann<sup>1</sup>; <sup>1</sup>The University of Texas at Austin – Previous work on the endowment effect, the tendency for sellers to value an owned good more than potential buyers, has shown that market experience can reduce or eliminate the effect (List, 2003; 2004). Presumably, experts are able to learn through experience to no longer treat endowments as psychological losses. Implicit in this explanation is the importance of psychologically distancing one's personal self from the market good. We argue that feelings of self-investment in a good are central to explaining the moderating role of market experience on the endowment effect. To investigate this proposal, we created a hypothetical vignette about home selling experiences. 110 participants, consisting of both experienced real estate agents and less experienced non-agents,

were randomly assigned to complete one of two home selling scenarios. In one, participants acted as sellers for their own home. In the other, participants acted as selling agents for another person's home. Inconsistent with some previous research, market experts acted similarly to those who were inexperienced. However, consistent with our self-investment account, personal homeowners, compared to selling agents, were more likely to both resist dropping the price of their home following a lack of offers and to resist accepting a lowball offer. Furthermore, when forced to sell at a lower than initial price, homeowners, more so than agents, reported feeling as though selling the home was like losing a part of themselves. These results underscore the importance of considering the role of the self when making judgments about value.

### C192

#### IMPELLING ACTION AND QUELLING STRESS: MULTIPLE IDENTITIES AS A RESOURCE IN THE FACE OF CHALLENGES

Janelle M. Jones<sup>1</sup>, Jolanda Jetten<sup>2,1</sup>; <sup>1</sup>University of Exeter, <sup>2</sup>University of Queensland – Past research suggests that multiple identities may act as a resource (e.g., Correll & Park, 2005), conferring psychological benefits (i.e., well-being) on individuals by giving them the existential security (Thoits, 1983) and social capital (i.e., social, informational, and financial support; Putnam, 2000) needed to manage different challenges (e.g., life transitions; Iyer et al., 2009). The aim of the present research was to examine whether multiple identities might also confer behavioural benefits (i.e., persistence, resilience) on individuals when faced with challenges. Across three studies we hypothesized that access to a greater number of identities would predict increased persistence and resilience for individuals engaged in difficult mental and physical tasks. Results from two lab-based studies indicated that participants for whom a greater number (i.e., one, three, or five) of randomly presented social identities (i.e., gender, age, nationality, major, occupation) were activated, persisted for longer on an unsolvable anagram (Study One) and on keeping their hand submerged in an ice bath (Study Two). A subsequent field study found that novices who reported having many identities available to them demonstrated higher levels of resilience (i.e., faster heart rate recovery) after engaging in a dangerous sport (i.e., bobsleigh, luge, skeleton; Study Three). These findings suggest that multiple identities may impel action and quell stress in the face of mental and physical challenges. The psychological and behavioural benefits of multiple identities, and the implications of this resource for psychological health and well-being, are discussed.

### C193

#### SOCIAL IDENTITY AND GENDER: A SWEDISH VERSION OF THE GENDER COLLECTIVE SELF-ESTEEM SCALE

Hanna Li Kusterer<sup>1</sup>, Emma Bäck<sup>1</sup>, Torun Lindholm<sup>1</sup>; <sup>1</sup>Stockholm University – According to Social Identity Theory (Tajfel & Turner, 1986), people possess both personal and social identities. In order to measure aspects of social identity, Luhtanen and Crocker (1992) developed the Collective Self-Esteem Scale, consisting of four subscales: Membership, Identity, Public and Private. The present study was the first validating a Swedish translation of the Collective Self-Esteem Scale adapted to one's gender group, and one of few examining gender CSE in relation to feminist identity and attitudes toward women (c.f., Burn, Aboud, & Moyles, 2000; Carpenter & Johnson, 2001; Smith, 1999). In a student sample (n=295), as expected, men reported higher levels of Public CSE. Also, women had higher levels of Identity CSE. In a community sample (n=151), no significant differences between men and women were found on any of the subscales. For women in both samples, Membership CSE was negatively correlated with Classical and Modern Sexism, and Public CSE was positively correlated with Modern Sexism. For men in both samples, Public CSE was negatively correlated with Classical Sexism. Among students, women self-labeled as anti-feminists had lower Membership CSE than feminists and women in the middle, mixed category, and feminist women had lower Public CSE than the other two groups (c.f. Smith, 1999). In sum, although not extensively studied to date, the gender Collective Self-Esteem Scale appears as a use-

ful tool to investigate differences between women and men in how they shape and make use of their social identities, also in a Scandinavian context.

**C194****THE IMPACT OF A FAUX CONCEALABLE STIGMA: A NEW METHODOLOGICAL APPROACH FOR STUDYING CONCEALABLE STIGMATIZED IDENTITIES** Kimberly J. McClure<sup>1</sup>, Diane M. Quinn<sup>1</sup>;

<sup>1</sup>University of Connecticut – Examining the experience of people with concealed stigmatized identities (e.g., mental illness) in laboratory research presents many ethical challenges. The goal of the current study was to test a new methodological approach for studying processes involved with concealable stigmatized identities (CSIs) by demonstrating the utility of a temporary faux stigma. False personality feedback was given to participants (N = 102). To create a faux stigma, half of the participants received the type of negative personality feedback often associated with stigmatized identities (e.g., moral failings, instability); the other half received neutral feedback. Participants were then either told to specifically conceal their personality feedback in an interaction, or to more generally conceal anything personal about the self. After an interaction with a confederate, participants completed several questionnaires and were debriefed. Results demonstrated that those who were given the temporary faux stigma reported higher anticipated stigma prior to the interaction [ $F(1,98) = 28.47, p < .001$ ] and felt afterwards that their interactions had gone less smoothly [ $F(1,98) = 5.10, p = .03$ ]. Moreover, there was a stigma by concealment type interaction, such that within the faux-stigmatized group only, trying to conceal more generally led to worse mood compared to the more specific concealment of the new personality feedback. This research is an important first step in demonstrating the potential of creating a faux stigma in the laboratory to answer questions about the processes behind stigma and types of concealment.

**C195****DO SELF-COMPASSIONATE PEOPLE AGE MORE GRACEFULLY?** Ashley

Allen<sup>1</sup>, Mark Leary<sup>1</sup>; <sup>1</sup>Duke University – Americans have a life expectancy of over 80 years, but with increasing lifespan come physical problems, mental decline, and social loss. Despite the challenges associated with aging, people who are higher in self-compassion may experience the aging process more positively. If so, understanding how self-compassionate people think about aging may inform the development of interventions to help older individuals adopt a self-compassionate perspective. Because people who are high in self-compassion are less likely to be defensive about their personal shortcomings, older adults who score high in self-compassion should be more likely to admit when they are having difficulties, take better care of themselves, seek assistance for their problems, and be less resistant to receiving help when needed. In this study, 72 adults over the age of 60 completed a questionnaire assessing self-compassion, attitudes toward aging, depression, physical impairment, use of assistive devices, and how much using assistance bothered them. Results of multiple regression analyses showed that older adults who were higher in self-compassion were less depressed, had more positive attitudes toward aging, and reported being less physically impaired. High self-compassion participants were also less bothered when they needed physical or cognitive assistance. These findings show that self-compassion is related to a more positive experience of aging. In addition, the relationship between self-compassion and use of assistance suggests that encouraging older people to be more self-compassionate might lead them to take better care of themselves, thus slowing less physical and mental decline.

**C196****MAPPING THE SELF: A MULTIDIMENSIONAL SCALING ANALYSIS OF SELF-RELATED TERMS** Adrian F. Ward<sup>1</sup>, Daniel M. Wegner<sup>1</sup>; <sup>1</sup>Harvard

University – "Who am I?" This fundamental question of identity, repeated through the ages by everyone from Plato to oily-faced adolescents struggling to understand exactly what business hair has being there, seems to standing at a perpetual impasse. Myriad theories of "self" seem to be

talking about wildly disparate phenomena, and terms such as "mind," "will," and "consciousness" fly through the scientific atmosphere with little regard for agreement in cause or consequence. We explored how people think about the concept of "self" by using multidimensional scaling (MDS) techniques to produce a conceptual map of the domain of self-related terms. MDS relies on pair-wise similarity judgments rather than comparisons based on externally provided criteria; participants are therefore free to use their own intuitive criteria for comparing targets. Thus, latent dimensions are uncovered rather than imposed. In this study, 46 participants made similarity judgments between 15 terms selected by a prior sample as relevant to the concept of self: you, soul, essence, spirit, self, consciousness, will, mind, brain, body, heart, personality, conscience, feelings, and desires. Results indicate that people think of self-related terms on two major dimensions – a physical-metaphysical dimension, anchored by the terms "body" and "spirit," and a feeling-thinking dimension, anchored by the terms "heart" and "brain." "Self" lies at the center of both dimensions, indicating that people perceive the idea of self per se as equal parts physical and metaphysical, feeling and thinking.

**C197****IF ONLY YOU KNEW THE REAL ME: PREDICTED EVALUATIONS DIVERGE FROM SELF-VIEWS FOLLOWING NEGATIVE FEEDBACK** Gregory S.

Preuss<sup>1</sup>, Mark D. Alicke<sup>1</sup>; <sup>1</sup>Ohio University – The effect of negative social feedback on changes in self-views and metaprojections was studied. Metaprojections refer to people's predictions about how they will be evaluated by large samples of people in the future. After describing themselves in a video resume, participants received (or did not receive) negative feedback on a series of desirable traits. As hypothesized, negative feedback led to a significant decrease on the metaprojection composite, but not the self-view composite. In the no feedback control condition, scores on the self-view composite and metaprojection composite did not significantly differ from one another, suggesting that participants expected to be evaluated in a manner that was consistent with their stable and enduring self-views. In contrast, scores on the metaprojection composite were significantly lower than scores on the self-view composite in the negative feedback condition. A likely explanation for these findings is that in the absence of explicit and unambiguous evaluative feedback, people project their self-views onto others by "guesstimating" that others view them as they view themselves (Jussim et al., 1992). When people do receive explicit and unambiguous evaluative feedback, however, they have additional information (beyond their self-views) on which to base their predictions of how other people will evaluate their video presentation in the future. This additional information may propel some people to consider the possibility that other people do not see them as they see themselves.

**C198****MINDFULNESS REDUCES THE CENTRALITY OF THE SELF AND AIDS EXECUTIVE FUNCTIONING IN THE FACE OF THREATENING FEEDBACK.**

Robert J. Goodman<sup>1</sup>, Ernest S. Park<sup>1</sup>; <sup>1</sup>Cleveland State University –

Theorists suggest mindfulness, an open and receptive form of present-centered awareness, is beneficial because the centrality of the self is reduced and situations are experienced with fewer self-biases. While mindfulness has been shown to relate to many positive outcomes, several theoretical assumptions have not been tested. This study investigated whether a lab-induced mindful state reduces the salience of self-relevant concepts. Participants first completed a personality inventory, then performed a lexical-decision task (LDT) that included these items. This measure was designed to assess the accessibility of self-descriptors. Results show those induced with mindfulness were significantly slower than controls in identifying words that were self-rated as personally descriptive, suggesting the self is indeed less salient. If the self is less salient, then ego-threatening feedback should have less negative impact on subsequent attempts to self-regulate. So we hypothesized mindful participants would be better able to regulate after negative feedback. All participants received feedback indicating they would be lonely later in life, per-

formed a dichotic listening task to evaluate executive control, and completed a mood measure. Interestingly, mindful participants felt more negative affect, suggesting a greater willingness to confront rather than avoid the feedback. Furthermore, when integrating scores from the LDT, a significant interaction was found when analyzing self-control. Mindful participants whose self was less accessible performed significantly better at the dichotic listening task. For controls, self-salience had no impact on self-regulation. Our results demonstrate mindfulness can aid executive functioning, and highlights the importance of a decreased centrality of self.

### C199

#### COMPARING ASIAN AMERICAN ETHNIC AND RACIAL IDENTITIES

Jennifer Wang<sup>1</sup>, Sapna Cheryan<sup>1</sup>; <sup>1</sup>University of Washington – Psychologists often use race and ethnicity interchangeably when referring to distinctively meaningful categories for various groups. Markus (2008) proposed that race is associated with power dynamics whereas ethnicity is seen in terms of culture, practices, and conferring a sense of belonging and identity. In this study we examined how ethnic (e.g., Vietnamese American) and racial identities (e.g., Asian American) are understood. We hypothesized that racial identity is more associated with experiences of discrimination/prejudice while ethnic identity is more associated with culture and personal importance among Asian American college students. Two-hundred and five Asian Americans (50% US-born, 70% female) participated in the survey. Participants rated their agreement on 38 items generated from a pilot study (N = 161) examining identity factors framed within both ethnic and Asian American prompts (e.g., "To me, being Asian American means..."). These items focused on self-identification strength, practices, discrimination/prejudice, belonging, and other identity factors. Our findings suggest that when participants were prompted to think about their racial identity, they rated higher on items focusing on the experience of discrimination, prejudice, and exclusion compared to their ethnic identity. When prompted to think about their ethnic identity, they rated higher on the importance of self-identification with their ethnic group, respecting family, and pride compared to their racial identity. US-born Asian Americans reported that the Asian American identity was more important, unique, and was associated with greater pride compared to foreign-born Asian Americans. The conceptualization of these identities may have implications for group involvement and behavior among Asian Americans.

### C200

#### NEUROTICISM DETERMINES SUBJECTIVE SOCIAL STATUS THROUGH MULTIPLE MECHANISMS

Giuseppe Alfonsi<sup>1,2</sup>, Micheael Conway<sup>1,2</sup>; <sup>1</sup>Concordia University, <sup>2</sup>Centre for Research in Human Development – Subjective social status is an individual's self-perceived social rank, and accurately reflects objective status differences (i.e., in education, occupation, and income). Subjective status seems important in its own right as individuals with lower subjective status experience poorer health outcomes, above and beyond the contribution of objective status differences. The present hypothesis was that greater neuroticism may lead to lower subjective status, and may do so through multiple mechanisms, including lowered objective status, increased illness, and increased acute negative affect. In turn, lower subjective status was expected to lead to further increased illness. Participants (N = 354) in a longitudinal study completed measures of neuroticism, salary, subjective status, recent illness, and acute negative affect over 2 years. The hypothesis was tested as paths in structural equation modeling, and the proposed mechanisms for objective status and illness were observed, but no effect of negative affect was observed. As well, neuroticism directly led to lower subjective status. Furthermore, the findings indicate that illness and subjective status mutually influenced each other, with participants who experienced more illness going on to experience lower subjective status, which in turn predicted greater future illness. The model provided a good fit ( $S-B\chi^2(12) = 8.89, p = .71, CFI = 1.00, RMSEA = .001, CI = .00 - .04$ ). In sum, the results

suggest that neuroticism plays an important part in determining subjective status, and this determination may explain the association between subjective status and some of its observed correlates.

### C201

#### CAN THE BENEFITS OF SELF-DEFINING MEMORIES BE OBTAINED FROM A CLOSED MEMORY?

Travis Crone<sup>1</sup>, Denise Beike<sup>1</sup>; <sup>1</sup>University of Arkansas – Self-defining memories are key scenes that represent substantial markers in growth and understanding (Singer & Moffitt, 1991). Self-defining memories are marked not only by understanding, but also the high level of emotion associated with recall (Schwartz, Weinberger, & Singer, 1981). The pairing of emotionality with meaning across time appears to contradict that memories obtain more closure over time (Beike & Wirth-Beaumont, 2005). Open memories are associated with high emotionality and closed memories are associated with increased meaning. The current study's design was to determine if the positive outcomes of self-defining memories could be obtained from closed memories. Ninety-two students wrote about an unpleasant life event. Participants either wrote about a memory considered self-defining, closed, or open. Next, participants rated the memory on intensity, closure, insight, and other measures. Self-defining memories were not clearly closed or open, but continued to display a mixture of traits associated with both. Effects were seen for closure,  $p < .001$ ; intensity now  $p = .023$ ; and insight  $p = .019$ . Participants reported equal levels of insight for self-defining and closed memories, but less on open. Participants also reported less intensity at recall for closed memories than self-defining and open memories, which did not differ. Self-defining memories fell in the middle of the closure scale, different than both open and closed memories. The current research outlines how understanding, a major outcome of self-defining memories, can be obtained on equal levels from closed memories without the need for the emotionality associated with self-defining memories.

### C202

#### SELF-STRUCTURE AND PARENT-CHILD RELATIONSHIPS

Jenna Thomas<sup>1</sup>, Carolin Showers<sup>1</sup>; <sup>1</sup>University of Oklahoma – Explores the possible impact of parent-child relationships on self-structure, specifically whether evaluative integration of positive and negative self-beliefs may stem from poor parent-child relationships or the presence of significant positive or negative parental figures. In Showers's (2000) model of self-structure, evaluative integration occurs when both positive and negative attributes exist within a specific self-aspect category. Compartmentalization occurs when positive and negative attributes appear in different self-aspect categories. Participants completed a self-descriptive card sorting task to assess compartmentalization or integration and a set of parental relationship measures emphasizing attachment and satisfaction of needs: Emotional Reliance Questionnaire (Ryan et al., 2005), Need Satisfaction Scale (NSS; La Guardia et al., 2000), Adult Attachment Scale (cf. Cook, 2000). The strongest effects were found for NSS, with parent relationship types based on median splits of NSS ratings for mothers and fathers: two high NSS parents (N = 45); one low NSS parent and one high NSS parent (N = 59); or two low NSS parents (N = 60). ANOVA results showed a main effect,  $F(2, 148) = 3.06, p < .05$ , such that participants with two high NSS parents were relatively compartmentalized, whereas participants with two low NSS parents were relatively integrative. When gender of child and gender of parent were considered, the most integrative participants were males with two low NSS parents and females with high NSS mothers and low NSS fathers,  $F(3, 142) = 2.618, p < .053$ . Additional analyses examine the role of emotionally significant non-parental relationships as moderators of these effects.

### C203

#### EXPLORING THE BOUNDARIES OF THE EXTENDED SELF: DOES ATTACKING A BRAND THREATEN THE SELF?

Monika Lisjak<sup>1</sup>, Angela Y. Lee<sup>1</sup>, Wendi L. Gardner<sup>1</sup>; <sup>1</sup>Northwestern University – A wealth of research has found that close relationships can be included in the self. In this paper we explore the idea proposed by James (1890) that objects may

become part of the self such that individuals will be motivated to defend them when they are under attack. Drawing from extant literature in psychology and marketing, we posit that individuals who feel connected to a brand (e.g., Starbucks) will evaluate the brand more positively after being exposed to negative publicity about the brand. We predict that the defensive responses will be accentuated among those individuals with low implicit self-esteem when their self-concept is made salient. We tested this prediction in two studies by first measuring participants' implicit self-esteem (name-liking measure in Study 1; name-letter task in Study 2), the extent to which participants included the brand (Facebook in Study 1; Starbucks coffee in Study 2) in the self, and brand consumption. Then, participants were randomly assigned to write an essay that either activated or not the self. Finally, participants were presented with an unfavorable editorial about the brand and then asked to report how their attitude toward the brand might have changed. Across two studies, we found that after controlling for brand consumption, low implicit self-esteem individuals whose self-concept was activated and who included the brand in the self reported a positive attitude change. These results offer preliminary evidence that brands, when under attack, can elicit the same defensive processes as the self under attack.

### C204

**IN PURSUIT OF EXISTENTIAL LIBERTY: DIFFERENTIAL EFFECTS OF MORTALITY SALIENCE AND DEATH REFLECTION ON DESIRES FOR FREEDOM** Philip J. Cozzolino<sup>1</sup>, Panagiotis Rentzelas<sup>1</sup>, Nick R. Cooper<sup>1</sup>, Laura E. R. Blackie<sup>1</sup>, Nicolas Geeraert<sup>1</sup>, Lawrence S. Meyers<sup>2</sup>; <sup>1</sup>University of Essex, <sup>2</sup>California State University, Sacramento – Five studies explore the liberty-seeking consequences of considering death in a specific and individuated manner, as part of a new theoretical framework derived from the dual-existential systems model (Cozzolino, 2006). The model posits that unspecific reminders of death (mortality salience; MS) focus attention on external representations of the self, such as cultural worldviews, and thereby facilitate adherence to external control; alternatively, individuated mortality reminders (death reflection; DR) focus attention internally on self-specific structures such as personal values/goals, and thereby facilitate self-direction and desires for freedom. Study 1 examined the EEG alpha-band activity of MS, DR, and control participants as numerous studies link alpha to participants directing attention internally, as opposed to externally (Cooper et al., 2003); DR participants evidenced significantly greater alpha oscillations post-manipulation, compared to MS or control participants. Studies 2 and 3 demonstrated that DR participants, across multiple contexts, were significantly more likely to choose for themselves opportunities that promised self-direction, compared to MS or controls. Study 4 revealed that this liberty-seeking effect persists over time, as DR participants evidenced a greater willingness to determine their own path in a map-based game that offered numerous opportunities to be controlled by an external source. Finally, Study 5 participants read a news story about Governmental restrictions of civil liberties in the UK; results revealed the lowest levels of support for the Governmental policies among DR participants who also revealed high levels of attachment to the ideals of freedom and democracy. Theoretical and practical implications of the results will be discussed.

### C205

**HOME PERFORMANCE IN DECISIVE CHAMPIONSHIP GAMES: AN UPDATE** Kurt A. Boniecki<sup>1</sup>, Stephen T. Phillips<sup>2</sup>, Barry R. Schlenker<sup>3</sup>; <sup>1</sup>University of Central Arkansas, <sup>2</sup>Broward College, <sup>3</sup>University of Florida – Baumeister and Steinhilber (1984) reported that professional baseball and basketball teams performed poorly at home in the decisive games of championship series (World Series, NBA Finals and Semifinals) relative to their home performance in earlier games of the series, suggesting that home teams choked under the pressure of winning the championship before a supportive audience. Schlenker, Phillips, Boniecki, and Schlenker (1995) updated and reanalyzed the data, and concluded that there was no convincing evidence for the home-choke hypothesis. Baumeister

(1995) criticized Schlenker et al.'s conclusions on the basis that home teams still only won 47% of the decisive games of the World Series (though not significantly different from the teams' home performances in early games) and that the updated World Series results did not significantly differ from those reported by Baumeister and Steinhilber. To address the criticism, we updated Schlenker et al.'s analysis and found that home teams won 52% of all decisive games and 53% of seventh games in the World Series, and that this performance did not significantly differ from the home performance in the first two games,  $ps > .25$ . Furthermore, the differences between the current results and those reported by Baumeister and Steinhilber were marginally significant,  $ps < .09$ . Including updated data from the American and National League Championships, the NBA Finals, and the NBA Semifinals, our current analysis supports the conclusions of Schlenker et al. A quarter century after Baumeister and Steinhilber, we still find no convincing evidence of the home-choke hypothesis.

### C206

**THREATENED POLITICAL IDENTITY: PERCEIVED SIMILARITY TO THE "WRONG CANDIDATE" ELICITS COGNITIVE DISSONANCE** Deborah L. Hall<sup>1</sup>, Wendy Wood<sup>2</sup>; <sup>1</sup>Duke University, <sup>2</sup>University of Southern California – Classic research in social psychology suggests that perceived similarity to a political candidate will increase the likelihood that voters come to view the candidate in a positive light. Perceived similarity may, however, be problematic when voters identify with a candidate nominated by a different political party. That is, feeling similar to the "wrong candidate" may pose a threat to one's political identity. The present research investigated whether feeling similar to an opposition party's candidate elicits feelings of cognitive dissonance. Data were collected in the month prior to the 2008 U.S. Presidential election. Registered voters watched a film clip of Democratic Presidential nominee, Barack Obama, giving a speech. Participants' electrodermal activity was recorded while they watched the speech, and perceived similarity to Obama and self-reported affect were measured immediately after the speech. As predicted, perceived similarity to Obama was dissonance-provoking for self-identified opponents of the Democratic Party. Democratic opponents who felt similar to Obama reported significantly more dissonance-related affect and showed heightened electrodermal activity during the speech compared to those who felt dissimilar to Obama. No such effect emerged for voters with more favorable feelings towards the Democratic Party. These findings indicate that group identity can be a potent source of cognitive dissonance. The implications of identifying with members of an outgroup are discussed.

### C207

**"I THOUGHT YOU WERE JAPANESE:" THE EFFECTS OF ETHNIC MISATEGORIZATION ON IDENTITY ASSERTING BEHAVIOR** Matthew Trujillo<sup>1</sup>, J. Nicole Shelton<sup>1</sup>; <sup>1</sup>Princeton University – Three studies were conducted examining the effects of ethnic miscategorization. Ethnic miscategorization is defined as the process of having one's ethnicity incorrectly categorized by another. A sample of undergraduates and adults were surveyed about the frequency of which they experience ethnic miscategorization and their affective reactions to this experience. Individuals of Latin and Asian heritage reported the highest frequency of experience and reported feelings of negative affect associated with ethnic miscategorization. Study 2 was conducted online and involved priming participants to believe that ethnic miscategorization was either prevalent or rare in society. Participants then rated their liking for products that were associated with their ethnic in-group, a similar ethnic group, or ethnically neutral products. Participants who were primed to believe that ethnic miscategorization is prevalent expressed less liking for in-group products compared to participants in the control condition. This finding was replicated in Study 3. Participants in the experimental condition in Study 3 were led to believe that an interaction partner had ethnically miscategorized them. These participants expressed less liking for both ethnic in-group and a similar ethnic group products as compared participants in the control condition. Moreover, ethnic centrality was found to

moderate this effect, with participants who experienced ethnic miscategorization expressing lesser liking for in-group and similar out-group products as they increased in ethnic centrality. Findings from the three studies indicate that the experience of ethnic miscategorization may lead to distancing behaviors from one's ethnic group and ethnic groups similar to one's own.

### C208

**INFLUENCE OF INTERPERSONAL SKILL AND COMMITMENT TO A GROUP ON IDENTITY FORMATION** Yuri Seo<sup>1</sup>, Minoru Karasawa<sup>1</sup>; <sup>1</sup>Nagoya University – On the basis of view that interpersonal relationship plays a key role in identity formation (e.g., Erikson, 1959), the present study examined how interpersonal skills and commitment to a significant in-group contribute to identity formation. Guided by Allen & Meyer (1990), the present study distinguished three facets of commitment (i. e., affective, normative, continuance) and examined how these facets of commitment influenced the level of identity formation. A total of 120 Japanese undergraduates completed a questionnaire survey. The questionnaire consisted of 40 items assessing: (a) interpersonal skills, (b) commitment to their university, and (c) identity formation. A structural equation modeling analysis revealed that the level of perceived interpersonal skills elevated the affective and normative commitment, which contributed to forming positive and stable identity. In addition, perceived interpersonal skills did not influence identity formation directly. These findings illustrate the important role of interpersonal skills identity formation, although it was not the only factor influencing identity formation. Drawing from the findings, it was concluded that regardless of the level of interpersonal skills, it may be difficult to form a positive identity without having social roles or obligations in the group. Furthermore, the level of continuance commitment to the group, which was not predicted by interpersonal skills, contributed to identity formation. This finding highlights a possibility that one might develop a positive identity just by belonging to a group even when interpersonal skills is not learned well. Strategies for effective intervention and social training for adolescents suffering diverse problems of identity are discussed.

### C209

**AUTOBIOGRAPHICAL EVENT-RELATED SELF-EVALUATIONS MEDIATE THE FADING AFFECT BIAS** Timothy D. Ritchie<sup>1</sup>, John J. Skowronski<sup>2</sup>, Constantine Sedikides<sup>3</sup>; <sup>1</sup>University of Limerick, <sup>2</sup>Northern Illinois University, <sup>3</sup>University of Southampton – The intensity of emotions associated with memory of pleasant life events fades more slowly than the intensity of emotions associated with memory of unpleasant life events. This phenomenon has been termed the Fading Affect Bias (FAB). Over the past decade, autobiographical memory research has established the reliability and validity of the FAB and its moderators; however, its mediators are unknown. We addressed this issue in five studies. In Study 1, participants (N = 81) retrospectively recalled either positive or negative autobiographical events, and then rated how pleasant or unpleasant each event felt both at occurrence and at recall. Participants also rated the extent to which each event increased self-esteem. Self-esteem partially mediated the FAB. In Study 2 (N = 64), using a within-subjects design, the extent to which each event increased a sense of meaning in life partially mediated the FAB. This finding was replicated in Study 3 (N = 39), which used a between-subjects design. In Study 4 (N = 26), the self-importance of events at the time of recall fully mediated the FAB. Finally, in Study 5 (N = 56) which used a diary-keeping method, event self-importance partially mediated the FAB, thus ruling out the possibility that previous findings are attributable to retrospection biases. Collectively, these findings illuminate the importance of event-related self-evaluations to emotional judgments about autobiographical events.

### C210

**SOCIAL DISAGREEMENT AND THE SELF: ATTITUDINALLY DIVERGENT SOCIAL NETWORKS AND SELF-CONCEPT CLARITY** Alysson E. Light<sup>1</sup>, Penny S. Visser<sup>1</sup>, Jon A. Krosnick<sup>2</sup>, Sowmya Anand<sup>3</sup>; <sup>1</sup>University of Chicago, <sup>2</sup>Stanford University, <sup>3</sup>University of Illinois – Previous research has shown that experiencing disagreement with social network members on attitude issues results in individuals holding their attitudes more weakly. The present studies expand upon these findings to investigate the effects of such social exposure to divergent attitudes on the strength and coherence of one's self beliefs, or self-concept clarity. Given the centrality of attitudes to the self, we anticipated that disagreeing with social network members would not only decrease attitude strength, but also decrease the confidence and clarity of one's self-beliefs. In Study 1, students from the University of Chicago reported their attitudes on a target issue, and also the attitudes of up to five close others. Participants who reported greater divergence between their own attitude and the attitudes of their social network members reported experiencing lower self-concept clarity. These effects were fully mediated by individuals' general confidence in their judgments. In Study 2, a nationally-representative panel survey was conducted in which participants reported their attitudes and their network members' attitudes on a target issue, responding to items assessing self-concept clarity, subjective well-being, and perceived stress. Individuals whose attitudes differed more from their network members' reported lower subjective well-being and higher perceived stress. These effects were fully mediated by self-concept clarity. These results suggest that being embedded in social networks that reflect a diversity of attitudes has effects not only on attitude strength, but also on the structure of the self-concept and psychological well-being.

### C211

**EXPANDING BICULTURALISM: THE IMPACT OF CULTURAL IDENTITY AND EXPERIENCE ON SELF-COMPLEXITY** Kelly A. Hirsch<sup>1</sup>, Kristy K. Dean<sup>2</sup>; <sup>1</sup>California State University, San Bernardino, <sup>2</sup>Grand Valley State University – Greater self-complexity – the degree to which the self-concept is comprised of many, non-redundant self-aspects – has been associated with better social and physical functioning (e.g., Linville, 1985). Prior research (Hong, Morris, Chiu, & Benet-Martinez, 2000) evidences cognitive benefits (e.g., frame-switching) as a result of identification with two cultures (i.e., biculturalism), suggesting that biculturals may display greater self-complexity than monoculturals. Alternatively, individuals that identify with the ethnic group only (i.e. separation) or the dominant culture only (i.e., assimilation) may have developed more complex self-concepts due to the conflict of living in a society that does not encourage these acculturation strategies (Berry, 2001). The current study is the first to examine cultural differences in self-complexity and their underlying mechanisms. Ninety self-identified bicultural Hispanic-Americans and monocultural White participants completed a trait-sorting task (e.g., Linville, 1985) and a questionnaire assessing cultural identity and experience (Chung, Kim, & Abreu, 2004). The latter hypothesis was supported. Individuals, regardless of ethnicity, demonstrated greater self-complexity when they identified less with American culture and more with Hispanic culture (i.e., separation), or when they identified more with American culture and less with Hispanic culture (i.e., separation),  $\beta = -.23$ ,  $t(86) = -2.16$ ,  $p = .03$ . Similar findings emerged when cultural experience was examined,  $\beta = -.23$ ,  $t(86) = -2.22$ ,  $p = .03$ . Discussion will center on implications for social and physical functioning and future directions for experimental research on biculturalism.

### C212

**THE EMBODIED SELF: STEREOTYPIC MOVEMENTS CHANGE THE SELF** Nikki Harleen Mann<sup>1</sup>, Kyle Nash<sup>1</sup>, Kerry Kawakami<sup>1</sup>, Curtis Phillips<sup>1</sup>; <sup>1</sup>York University – A growing body of research has investigated effects related to the embodiment of cognitions (Niedenthal, 2007). Two studies tested the hypothesis that sensation and movement could also impact the way we perceive a particularly important concept: the Self. Participants were made to unobtrusively move in ways stereotypic of overweight people

or strong people. In Study 1, participants were randomly assigned to one of three conditions; i) an overweight-movement condition, ii) a no-movement control condition, iii) a free-movement condition. In Study 2, we replaced the third condition with a strong-movement condition. In both studies, participants then completed body silhouette questionnaires and self/other implicit association tests (IATs) related to weight and strength. Results demonstrated that overweight movements caused people to choose more overweight body silhouettes and to associate themselves with the concept of overweight, whereas strong movements caused people to choose stronger body silhouettes and to associate themselves with the concept of strong. We conclude that, consistent with theories of embodied cognition, there is a close relationship between bodily feedback and cognitions – including cognitions of the self.

### C213

#### THE ROLE OF PLACES IN SUBJECTIVE IDENTITY CONTINUITY Mhairi

**Bowe<sup>1</sup>, Fabio Sani<sup>1</sup>; <sup>1</sup>University of Dundee** – Subjective continuity is a critical feature of personal identity but recent research has shown that other identity elements, such as social groups, can be sources of perceived identity continuity (Sani et al., 2007, 2008). Environmental Psychology suggests places also provide a sense of self-continuity by offering a link to personal past and perceptions of self-congruency (Twigger-Ross & Uzzell, 1996). However, unlike the social psychological studies it neglects to acknowledge their role in providing a sense of connection with the future. In Study 1, twenty interviews were conducted to reveal the nature of place-related identity continuity (PIC) and explore its psychological functions. Thematic analyses suggested that most participants experience a strong attachment to at least one significant place and that these places do indeed fulfil a need for subjective self-continuity. Crucially, this is achieved through the provision of a link to personal and social past, and by allowing the projection of these identities into the future. Study 2 (N=274), provided quantitative evidence of this multi-dimensional nature of PIC and investigated the consequences of experiencing an ongoing relationship with significant places such as one's home, town or city. Results showed that PIC has a positive impact upon place attachment and that this relationship is mediated by place identity strength. These studies demonstrate the significance of a sense of continuity as a feature of relationships with places, suggesting the importance of maintaining stable place identifications under diverse social conditions such as immigration or urban redevelopment, and during periods of conflict or natural disaster.

### C214

#### EXAMINING THE RELATIONSHIP AMONG IDENTIFICATION, WORLD VIEWS, AND ACCEPTANCE IN A MINORITY SAMPLE Lucia Guillory<sup>1</sup>, Brian Lowery<sup>2</sup>; <sup>1</sup>Academy of Management, <sup>2</sup>Academy of Management, Society of Experimental Social Psychology, Society for the Psychological Study of Social Issues

– In the present study we use an African American sample to examine the relationship among prejudice, minority group identification and the endorsement of status legitimizing worldviews (SLWs e.g. the belief that American society is fair). Our study was geared toward discovering how identification and worldviews would influence the way minorities were perceived by members of their in-group. We showed African American participants the fabricated personal profile of an in-group member. We varied the person in the profile's identification level and degree of SLW endorsement and asked participants to evaluate the individual in the profile on various dimensions of liking and make predictions about how they might interact with the person if they were to meet him. We found an interaction between identification and worldviews such that the more minorities accepted the idea that American society is fair and identified with African American culture the more African American participants liked and accepted these individuals. The less the subject accepted the idea that American society is fair and identified with African American culture the less African American participants like and accepted the individual. We also found that the more

educated a minority participant is, the more positively he or she feels toward other minority group members who accept the idea that American society is fair.

### C215

#### PROTECTING THE SELF THROUGH CONSUMPTION: STATUS GOODS AS AFFIRMATIONAL COMMODITIES Nathan Pettit<sup>1</sup>, Niro Sivanathan<sup>2</sup>;

<sup>1</sup>Cornell University, <sup>2</sup>London Business School – Individuals conspicuously consume to signal their wealth. As a variant to this economic explanation, three experiments explored individual's psychological need for self-integrity as a potential motivating force for these consumption decisions. Employing multiple instantiations of high-status goods and self-threat, three studies demonstrated that individuals consume these status-infused products for their reparative effects on the ego. Individuals under self-threat sought ownership of high status goods to nurse their psychological wounds (Experiment 1), and when afforded an alternate route to repair their self-integrity, sought these products less (Experiment 2). Furthermore, high-status goods act as a shield to protect an individual's ego from future self-threats (Experiment 3). The compensatory role of high-status goods have important implications for consumer decision-making and public policies aimed at reducing consumer debt.

### C216

#### THE MULTICULTURAL IDENTITY INTEGRATION SCALE: A VALIDATION STUDY Maya A. Yampolsky<sup>1</sup>, Catherine E. Amiot<sup>1</sup>, Roxane De la Sablonniere<sup>2</sup>; <sup>1</sup>Universite de Quebec a Montreal (UQAM), <sup>2</sup>University of Montreal (UdeM)

– Having more than one cultural identity necessitates the cognitive management of these identities within one's general sense of self. According to the Multiple Social Identity Integration Model (MSIIM; Amiot et al., 2007), there are different stages of identity organization: categorization, where people identify with one cultural identity over all others; compartmentalization, where individuals maintain multiple, separate identities within the self; and integration, where people interconnect their multiple cultural identities. Study 1: Interviews were conducted to explore the identity configuration of multicultural individuals and to account for the antecedents of their identity organization. Participants (N=10) constructed cultural identity narratives, and questions were asked in relation to each strategy posited in the MSIIM. MSIIM strategies were reflected in participants' experiences, with 5 reporting compartmentalization strategies and 5 reporting integration strategies. Frequency analyses revealed that, in comparison to participants who compartmentalized their multiple cultural identities, participants who integrated their cultural identities experienced less discrimination and reported greater linguistic competence and social support within their cultural groups. Study 2: The reliability and validity of the Multicultural Identity Integration Scale (MIIS) was tested. Participants (N=73) were administered the MIIS, along with previously validated measures of cultural identity compatibility. EFA analyses provided preliminary partial support for the subfactorial structures of categorization, compartmentalization, and integration. Sufficient convergence and divergence from existing measures was found, with significant, moderate, positive correlations with bicultural identity integration (Benet-Martinez & Haritatos, 2005), and significant, negative, moderate correlations with cultural chameleonism (Downie & Koestner, 2005). Implications for future research will be discussed.

### C217

#### THREAT OR CRITICISM: WHAT MOTIVATES GROUP IDENTIFICATION Zachary Hohman<sup>1</sup>, Robert Blagg<sup>1</sup>, Michael Hogg<sup>1</sup>; <sup>1</sup>Claremont Graduate University

– Past research indicates that criticism evokes more defensive reactions when it comes from an outgroup member than when they it is attributed to an in-group member (Hornsey & Imani, 2004). However, few studies have focused on reactions to threats from an outgroup member or the relationship between threat and criticism. The current work seeks to elucidate the relationship between threat and criticism on group identification and support for the group's ideological beliefs. Participants were randomly assigned to a condition in which they read a pas-

sage of an Internet blog ostensibly written by a person from a country outside the United States. The blog either contained neutral language about America (control condition), a criticism of America (high criticism, no threat condition), a threat towards America (high threat, no criticism condition), or both a criticism and threat towards America (high criticism, high threat condition). Participants then answered questions measuring their strength of identification with America and support for militaristic foreign policies. As expected, participants identified stronger with America under high rather than low criticism. This effect was qualified by a significant interaction with threat – identification was strongest in the criticism and no threat condition. Further, participants had the strongest support for military policies under the high threat and high criticism condition. Overall, the findings suggest that when people's groups are threatened and criticized they not only identify stronger with their group but also demonstrate more support for group-based policies and ideologies.

### C218

**WHEN PRAISE FALLS ON DEAF EARS: IS THE HEDONIC IMPACT OF A COMPLIMENT MUTED WHEN IT MATTERS MOST?** Shana Cole<sup>1</sup>, Emily Balcetis<sup>1</sup>; <sup>1</sup>New York University – When do the nice things people say to us fall on deaf ears? In what may be an unfortunate paradox, compliments often feel least good when they come from those people most likely to offer them. In early studies, we found that compliments from loved ones were less emotionally impactful than compliments from strangers, but only in some domains. In other domains, compliments felt equally good no matter who they came from. In the present study, we proposed that source differences emerge when the praise is about something important to a person, but not when it refers to something unimportant. We chose two groups of people for whom a particular domain varied in importance: casual bowlers and league bowlers. The bowlers imagined being complimented on their bowling game by a friend, stranger, or their mom, and indicated what their mood and self-confidence would be like. League bowlers anticipated experiencing less positive emotional consequences when the compliment came from their mom than when it came from friends or strangers. For casual bowlers, however, compliments felt equally good coming from moms as they did from strangers. This research suggests that in important domains when we most care about how well we're doing, the people who are most likely to say things to make us feel good are the least likely to actually be effective at doing so. We discuss the results as evidence of a desire for accurate feedback and underscore their importance in understanding how people process positive social feedback.

### C219

**BE HERE NOW (AND THERE, AND THEN): SELF-CONTINUITY INDUCED BY OPTICAL-ACOUSTIC STIMULATION** Christopher Burris<sup>1</sup>, Mellissa Howard<sup>1</sup>; <sup>1</sup>St. Jerome's University – The phenomenological intransigence of consciousness (PI), as manifest by the inability to imagine one's non-existence as a conscious being, may be one source of motivation to secure a sense of self-continuity by identifying with entities, such as social groups, that transcend one's individual physical existence. The PI experience itself may be difficult to apprehend directly amidst the sensory capture of everyday life, however. Thus, in an on-line pretest session, 40 participants first completed an 11-item PI measure that included items referring to an experiential sense that one has always, and will always, exist. Then, in a separate lab session at least one day later, experimental condition participants completed a 25-minute "Deep Tranquility" session (predominant frequency from 4-8 Hz) with a Mindplace Sirius optical-acoustic brain wave stimulator, followed by a second administration of the PI scale and self-report ratings concerning their experience during the brain session. In the control condition, the order of the Mindplace session and the PI scale was reversed. In the experimental but not the control condition, increases in PI were associated with participants' self-reports of "floating," of "thoughts quieting down," and of being able to "hear themselves think," and with a greater reported desire to "anchor" oneself to one's social groups. Thus, at least for some, social identifica-

tion may be one manifestation of the motivation to seek "evidence" that is consonant with one's experience of the individual self as transcending the limits of life in a physical body.

## Self-Regulation

### C220

**EXPOSURE TO ALCOHOL CUES LEADS TO SUBSEQUENT SOCIAL DISINHIBITION** Nicholas Freeman<sup>1</sup>, Ron Friedman<sup>1</sup>, Bruce Bartholow<sup>2</sup>, Elga Wulfert<sup>1</sup>; <sup>1</sup>University at Albany, SUNY, <sup>2</sup>University of Missouri-Columbia – Previous research has illustrated that even in the absence of actual or placebo consumption, exposure to rudimentary alcohol cues (i.e., priming) can influence subsequent non-consumptive behavior. In the current investigation, we extended this line of research to the social disinhibition domain by examining whether mere exposure to alcohol-related cues can lead individuals to subsequently act in a disinhibited manner. In three similar experiments, after initial exposure to either alcohol or control stimuli, participants completed an ostensibly unrelated free-association task that required them to type the first word that came to their mind upon seeing a stimulus word. A subset of the words were provocative (e.g., feces, penis), which we reasoned would elicit slower (i.e., more inhibited) responses from participants concerned with saying something embarrassing, and/or faster responses from those who were relatively disinhibited. In all three studies, participants primed with alcohol responded significantly faster to the provocative words than control participants, an indication that they were less socially inhibited. Further, these effects were only found under conditions of evaluative pressure (i.e., with an experimenter present), suggesting that they can not be attributed to cognitive associations between alcohol concepts and the provocative words. These results may have important practical implications for understanding and predicting disinhibited behavior, particularly given the ubiquity of alcohol-related stimuli (e.g., advertisements) in our daily environment. Further, by using an implicit dependent measure as opposed to self-report, the current findings provide the strongest evidence to date that alcohol priming effects are not an artifact of experimental demand.

### C221

**TOO WEAK TO RESIST: THE INFLUENCE OF SELF-REGULATION ON INFIDELITY** Natalie Ciarocco<sup>1</sup>, Jessica Echevarria<sup>1</sup>, Gary Lewandowski<sup>1</sup>; <sup>1</sup>Monmouth University – Infidelity is a common part of romantic relationships. Relationship infidelity is the leading cause of marriage dissolution and 60-75% percent of college students in serious romantic relationships admit to engaging in infidelity during their relationships (Barta & Klein, 2005). Given the frequent occurrence of infidelity, the potential factors that impact the likelihood of infidelity are important to identify. One potential explanation for infidelity is weakened self-control. According to Baumeister and Heatherton (1996), self-control is a limited resource. When the environment demands self-regulation, self-control weakens like a fatigued muscle, hindering one's ability to regulate on subsequent activities requiring self-control. Based on this model, the current research investigates whether failures in self-control are a partial explanation for infidelity. Thirty-two college students in exclusive romantic relationships interacted through a private chat room with an opposite-sex confederate. The interaction was a "getting acquainted" type of activity where the confederate purposefully showed romantic interest toward the participant. Prior to this interaction, half the participants were depleted of self-control by resisting a tempting food (freshly baked chocolate chip cookies). As predicted, behavioral measures indicated that depleted levels of self-regulation increased the likelihood of infidelity. Specifically, depleted participants were significantly more likely to both accept a coffee date from and supply a personal telephone number to the confederate. While behavioral measures indicated intent to cheat, self-reports of infidelity likelihood did not differ by condition. This suggests that weakened self-control is one potential cause for the levels of infidelity occurring in romantic partnerships today.

**C222****THE INFLUENCE OF SELF-PRESENTATION AND ACCURACY GOALS ON THE RELATIONSHIP BETWEEN CAUSAL UNCERTAINTY AND SELF-REGULATION**

Jennifer Passey<sup>1</sup>, Jill A. Jacobson<sup>2</sup>; <sup>1</sup>University of Alberta, <sup>2</sup>Queen's University – Greater causal uncertainty (i.e., confidence about one's ability to understand social events; Weary & Edwards, 1994) is associated with enhanced self-regulation performance following a social interaction (Jacobson et al., 2006). The current set of studies investigated two potential explanations for this relationship. Perhaps high causally uncertain people, who also are more likely to be socially rejected (Passey, 2006), have come to believe that engaging in effortful self-presentation during social interactions is fruitless. Alternatively, high causally uncertain people, who engage in more vigilant processing of social information, may fail to self-regulate their own behavior during the social interaction because they are instead focused on creating an accurate impression of their interaction partner. If high causally uncertain people engage in less self-presentation and/or are more focused on accuracy during social interactions, they may be less depleted by such activities, leaving more resources available for a subsequent self-regulation assessment. To test these explanations, we manipulated participants' goals for self-presentation (Study 1; N = 88) or their goals for accuracy (Study 2; N = 112) before a social interaction. In Study 1, higher causal uncertainty was again associated with better self-regulation performance, but self-presentation goals did not moderate this relationship. In Study 2, high causally uncertain participants' self-regulation performance was consistent regardless of goals for accuracy; whereas for low causally uncertain participants, self-regulation performance improved with instructions to create accurate impressions of their partner. These results, however, were obtained only for participants with lower self-esteem; no self-regulation differences were observed for higher self-esteem participants.

**C223****EFFECTS OF EGO DEPLETION ON MOTIVATION AND ATTENTION**

Raymond N. Serra<sup>1</sup>, Brandon J. Schmeichel<sup>1</sup>; <sup>1</sup>Texas A&M University – Self-control appears to rely on a limited and depletable resource. The self-control resource has been linked to the performance of a variety of tasks requiring executive control, including tests of working memory and response inhibition. The present investigation examined the effects of a depleted resource for self-control (i.e., ego depletion) on more basic motivational states and attentional processes. Experiment 1 tested the hypothesis that ego depletion increases self-reported approach motivation. Experiment 2 hypothesized that ego depletion alters attentional breadth (local versus global). Both experiments used a writing task to manipulate depletion (borrowed from Schmeichel, 2007). In the no depletion condition, participants wrote about a recent trip they had taken. In the depletion condition, participants wrote about a recent trip but were prohibited from using two common letters while writing. Experiment 1 found that participants in the depletion condition reported higher approach motivation, as measured by the BAS subscale of Carver and White's (1994) behavioral inhibition and activation (BIS/BAS) scales. (BIS scores were unaffected.) In Experiment 2, participants in the depletion condition showed an increase in global attentional focus as measured by a standard local/global task developed by Kimchi and Palmer (1982). Moreover, individual differences in BAS interacted with the depletion manipulation such that higher BAS predicted more global attentional focus under depletion. Together, the results of these experiments link ego depletion to increased approach motivation and to a global attentional bias, suggesting that depleted individuals scan the environment in an approach-motivated mindset, as though they are seeking opportunity for reward.

**C224****INDIVIDUAL DIFFERENCES AND SELF-REGULATORY FATIGUE; THE CASE OF OPTIMISM AND CONSCIENTIOUSNESS**

Lise Solberg Nes<sup>1,2</sup>, Charles R. Carlson<sup>1</sup>, Leslie J. Crofford<sup>1</sup>, Reny De Leeuw<sup>1</sup>, John Wilson<sup>1</sup>, Suzanne C. Segerstrom<sup>1</sup>; <sup>1</sup>University of Kentucky, <sup>2</sup>Mayo Clinic – Ability to self-regulate is an essential component of the human self. Research indicates that capacity to self-regulate varies, however, and self-regulatory strength appears to be a limited source that can be depleted or fatigued. People vary in the way they approach and cope with situations, and individual differences could potentially impact ability to self-regulate. Dispositional optimism and conscientiousness have for example been associated with engagement and persistence aimed at achieving goals and overcoming challenges, potential indicators of self-regulatory strength. Research on the impact of individual differences on self-regulatory capacity is scarce at this point, and the current study sought to examine whether personality factors such as optimism and conscientiousness can buffer self-regulatory fatigue. Participants (N = 100) were randomly assigned to either a high or low self-regulation task, followed by a persistence (anagram) task. Supporting previous research, higher dispositional optimism predicted longer persistence (p = .04), and there was also a trend towards the same effect for conscientiousness (p = .08). The optimism by self-regulation interaction was significant (p = .01), but took on a different form than expected. Rather than persisting despite self-regulatory fatigue, optimists persisted longer only when they did not experience self-regulatory fatigue. There was also a trend towards a similar conscientiousness by self-regulation interaction (p = .06). These results suggest that the well-established positive impact of optimism and conscientiousness on engagement and persistence may be diminished or reversed in the presence of self-regulatory fatigue, adding an important new chapter to the self-regulation, and personality, literature.

**C225****THE COGNITIVE BENEFITS OF SHAKING ONE'S HEAD**

Severine Koch<sup>1</sup>, Rob W. Holland<sup>1</sup>, Ad van Knippenberg<sup>1</sup>; <sup>1</sup>Radboud University Nijmegen – The current research investigated the cognitive benefits of head shaking compared to nodding, based on the underlying assumption that head shaking is strongly associated with situations of disagreement that require greater cognitive effort. Research in the domain of embodiment has shown that performing an action may in itself activate the psychological states and processes associated with it. Clearly, disagreeing on an issue habitually requires further elaboration, whereas agreement renders further clarification superfluous. In two studies, we tested the hypothesis that head shaking mobilizes the extra cognitive resources that are generally required under conditions of disagreement. Overt head movements were induced unobtrusively beforehand, and cognitive functioning was gauged by means of two cognitive tasks tapping into different aspects of cognitive control. Study 1 examined the effects of head movements on a task switching paradigm that measures the cognitive ability to switch focused attention. In Study 2, a Stroop color naming task was administered. In both studies head shaking significantly enhanced performance compared to head nodding. These findings contribute to the embodiment literature by highlighting the regulatory function of motor actions that usually coincide with specific situational processing demands. Presumably due to its associative links with contexts that habitually require more cognitive resources, head shaking seems to enhance cognitive control relative to head nodding, even outside an actual disagreement context.

**C226****WHEN INTENTIONS FAIL: AMBIGUOUS EXCLUSION INCREASES STIGMA-REINFORCING EATING BEHAVIOURS AMONG WOMEN WITH WEIGHT CONCERNS**

Paula Brochu<sup>1</sup>, Donna Garcia<sup>2</sup>, Heather Smith<sup>1</sup>, Victoria Esses<sup>1</sup>; <sup>1</sup>University of Western Ontario, <sup>2</sup>University of Guelph – An emerging body of research suggests that the awareness of stigma can lead stigmatized individuals to engage in self-defeating, stigma-reinforcing behaviors. This study investigated whether ambiguous exclusion may,

ironically, increase self-defeating eating behaviors among highly weight-focused individuals. Participants were 44 women registered in an introductory psychology course at the University of Western Ontario who first completed the Dietary Restraint Scale in an online mass testing session. Upon arrival at the laboratory, participants engaged in a computerized game of catch (Cyberball) with two thin, female confederates. In the game, participants were randomly assigned to be blatantly excluded (receive 2 of 30 throws), ambiguously excluded (receive 6 of 30 throws), or included (receive 10 of 30 throws). After the game, participants completed a cookie taste and rate task, with the weight of cookies consumed serving as a measure of self-regulation. Results revealed a significant interaction between dietary restraint and exclusion condition. As dietary restraint increased, ambiguously excluded participants consumed a greater quantity of cookies. In contrast, dietary restraint was unrelated to cookie consumption in the blatant exclusion and inclusion conditions. These results demonstrate that not all forms of exclusion have the same consequences, as only ambiguous exclusion increased stigma-reinforcing eating behaviors among those with weight concerns. Implications for understanding the behavioral consequences of ambiguous weight discrimination are discussed.

### C227

#### MOOD AS A RESOURCE IN FEEDBACK-SEEKING: THE ROLE OF SELF-REGULATORY FUNCTIONS OF POSITIVE MOOD Tomoe Tanaka<sup>1</sup>, Masayuki Harashima<sup>2</sup>; <sup>1</sup>Showa Women's University, <sup>2</sup>Chiba University

Previous researches show that positive mood induced by personal experience may enable people to have interest in negative feedback (Trope & Neter, 1994), and process negative self-relevant information (Raghunathan & Trope, 2002). In the present research, we specifically examined the possibility that mood induced by a task irrelevant to personal experience can have same effects in feedback-seeking. For this purpose, mood (positive or negative) and the self-relevance of feedback (low or high) were independently manipulated. We hypothesized that positive mood participants would pay attention to negative feedback more than negative mood participants, but this effect would be weaker in low relevance condition. The experiment consisted of three parts. First, participants took a personality test on the Web which was introduced as the test for undergraduates (high relevance) or elderly (low relevance). Next, they watched either positive or negative mood inducing video clips as part of an unrelated experiment. Finally, participants received the results of the personality test. On the computer screen, there were 5 boxes labeled "Virtues" and 5 boxes labeled "Weaknesses", and participants could read each feedback by clicking these boxes. The number of times they clicked these boxes, the latency they read each feedback, and the value ratings of feedback were measured. Consistent with the predictions, only in the high relevance condition, positive mood participants clicked more negative boxes, read negative feedback longer, and rated negative feedback more valuable than negative mood participants. These findings demonstrate the self-regulatory functions of positive mood when people face self-relevant information.

### C228

#### MINDFULNESS FOSTERS STRESS RESISTANCE: EVIDENCE FROM THE TRIER SOCIAL STRESS TASK Melissa Holt<sup>1</sup>, Kirk W. Brown<sup>1</sup>; <sup>1</sup>Virginia Commonwealth University

Mindfulness – a receptive attentiveness to present events and experience – has been associated with numerous indicators of psychological well-being and preliminary evidence suggests that mindfulness promotes more adaptive emotion regulation (Brown, Ryan, & Creswell, 2007). To better understand the emotion regulatory potential of a mindful disposition, we examined whether it predicts stress resistance in a controlled laboratory context using a well-validated social evaluative threat paradigm, the Trier Social Stress Task (TSST; Kirschbaum et al., 1993). In the TSST, participants perform speech and arithmetic tasks before a panel of critical evaluators. Emotional responses to the TSST were measured at pre-TSST baseline and at 4 times post-TSST using both self-reported negative affect and endocrine (cortisol) indicators. In Study 1, 44 college students completed a trait

mindfulness measure and were randomly assigned to complete the TSST or a control task. TSST participants higher in mindfulness showed lower emotional responses (e.g., lower salivary cortisol levels) at 4 times post-task – soon after the tasks (reactivity) and at 3 recovery points. There was no relation of mindfulness to emotion responses in the control condition. In Study 2, 66 healthy adults completed two trait mindfulness measures and completed the TSST. Both mindfulness measures again predicted reduced emotional responses to the TSST. These findings provide evidence that more mindful individuals show reduced reactivity to, and quicker recovery from, social stress. Together with past research, the results support theory on the emotion regulatory potential of mindfulness, and suggest one means by which this quality conduces to higher psychological well-being.

### C229

#### SELF-CONCEALMENT AND SELF-CONTROL Ahmet Uysal<sup>1</sup>, Helen Lin<sup>1</sup>, C. Raymond Knee<sup>1</sup>; <sup>1</sup>University of Houston

Self-concealment is the tendency to conceal distressing or negative personal information from others (Larson & Chastain, 1990). Past research has shown that self-concealment is negatively associated with self-control. Researchers have suggested that keeping secrets depletes regulatory resources and results in low self-control. However, the associations among these three variables have not been tested yet. In the present study, we investigated the relationship between self-concealment, self-control, and a regulatory resource (operationalized as subjective vitality). Students from undergraduate psychology classes (N = 180) completed the self-concealment scale, self-control scale, and subjective vitality scale. Participants' ages ranged from 18 to 59 (M = 23.89, SD = 6.83). Self-concealment was negatively associated with both self-control (r = -.34, p < .001) and vitality (r = -.49, p < .001). Furthermore, we hypothesized that self-concealment would predict lower self-control only for individuals who do not have sufficient regulatory resources (i.e., low vitality). A significant interaction effect was found; however, the findings were in the opposite direction. Simple slope analyses indicated that self-concealment was negatively associated with self-control for high-vitality individuals ( $\beta = -.49, p < .001$ ), whereas it was not associated with self-control for low-vitality individuals ( $\beta = -.15, ns$ ).

### C230

#### REGULATORY FOCUS AND PREDICTIONS OF TASK COMPLETION TIMES: DIFFERENT SENSITIVITY TO A TIME LIMIT Yuka Ozaki<sup>1</sup>, Osamu Higuchi<sup>2</sup>; <sup>1</sup>Tokai University, <sup>2</sup>Hitotsubashi University

This study examined the effect of regulatory focus on people's predictions of task completion times. Participants estimated how long it would take them to complete an academic task (i.e., writing a mid-term report). In the near future condition, the deadline of the task was in two weeks, while in the far future condition it was thirteen weeks ahead. We hypothesized that people in prevention focus should perceive the deadline as a risk factor and change their achievement plan accordingly: (a) if the deadline is approaching, they plan to finish the task quickly so as not to exceed the time limit, (b) if the deadline is far ahead, they plan to spend much time to carefully complete the task without mistakes. Meanwhile, we hypothesized that when people are promotion-focused, they should be comparatively indifferent to the deadline as a potential risk factor, and predict their task completion time with little concern to the time limit. Results supported the hypotheses and the prevention-focused participants planned to spend less time on the task than the promotion-focused participants in the near future condition, and vice versa in the far future condition. Time resource management strategies concerning regulatory focus and perception of time limit is discussed.

### C231

#### ACADEMIC GOAL ATTAINMENT: THE INFLUENCES OF HOPE AND SELF-CONTROL Chloe A. Nicksic<sup>1</sup>, Kevin L. Rand<sup>1</sup>, Courtney B. Johnson<sup>1</sup>; <sup>1</sup>Indiana University-Purdue University Indianapolis

Although hope and optimism have been linked to adaptive self-regulation, their relative contributions and mechanisms of action in goal pursuits remain unclear.

The goal of this study was to examine these personality traits and two potential mechanisms of action (self-control and executive functioning) in the context of academic goal pursuits. A total of 69 undergraduate students participated in this laboratory study. Upon arrival to the lab, participants completed self-report measures of trait hope, optimism, neuroticism, and demographic information. Subsequently, an experimenter administered tests to measure verbal intelligence (i.e., WASI Vocabulary subtest) and executive functioning (i.e., Wisconsin Card Sorting Test; WCST). Finally, self-control was assessed by timing how long participants could squeeze a hand-grip. Semester GPAs for study participants were obtained from the registrar. A hierarchical multiple regression was conducted with end-of-semester GPA as the dependent variable. Participants' gender, high school GPA, and verbal intelligence scores were entered in the first step. Hand-grip time and number of categories completed on the WCST were entered in the second step. Hope, optimism, and neuroticism were entered in the third step. Greater self-control predicted higher end-of-semester GPA ( $\beta = .28$ ), but executive functioning did not. Additionally, higher hope predicted higher end-of-semester GPA ( $\beta = .28$ ), whereas optimism and neuroticism did not. These results suggest that hope, but not optimism or neuroticism, is an important personality trait in the context of academic goals. Although self-control does not mediate the relationship between hope and academic goal achievement, it is an important predictor in its own right.

### C232

#### **EGO DEPLETION IN TEST SITUATIONS: SELF-CONTROL STRENGTH AS MODERATOR OF THE RELATIONSHIP BETWEEN ANXIETY AND COGNITIVE PERFORMANCE**

Alex Bertrams<sup>1</sup>, Christoph Englert<sup>1</sup>, Oliver Dickhäuser<sup>1</sup>; <sup>1</sup>University of Mannheim, Mannheim, Germany – As meta-analyses show, the assumable inverse relationship between anxiety and cognitive performance is unexpectedly low. Moreover, the evidence is inconsistent: Some studies revealed either no or more puzzling, a positive relationship between anxiety and cognitive performance, indicating additional variables may be moderating this relationship. We examined whether the present level of self-control strength is such a moderator variable. We assumed that anxious people with depleted self-control strength are unable to deliberately direct their attention away from distracting worries about their achievement, resulting in weak cognitive performance. However, anxious people whose self-control strength is not depleted should be able to direct their attention actively to the cognitive task at hand and away from distracting worries. Therefore, the latter are supposed to not experience decrements in cognitive performance, and might even experience an increase in performance since motivational processes related to anxiety might have an impact. In a laboratory experiment, participants' ( $N = 96$ ) self-control strength was either depleted or not, using a writing task. Afterwards, participants' current anxiety level was assessed using the State-Trait Anxiety Inventory. Finally, we measured cognitive performance by the number of mentally solved math problems (e.g.,  $773 \times 2$ ). Multiple regression analysis revealed the expected interaction: For depleted participants, there was an inverse relation between anxiety and cognitive performance while for non-depleted participants, there was a positive relation between anxiety and cognitive performance. The results suggest that ways to overcome self-control depletion that have been identified by research may help to avoid anxiety-related performance decrements.

### C233

#### **INVESTIGATING SELF-REGULATORY FATIGUE USING THE FRAMEWORK OF THE BIOPSYCHOSOCIAL MODEL**

Debra P. Bunyan<sup>1</sup>, Jayne E. Hurst<sup>1</sup>, Jim J. Blascovich<sup>1</sup>; <sup>1</sup>University of California, Santa Barbara – Study 1 investigates self-regulatory fatigue in the context of the biopsychosocial model. The biopsychosocial model posits that motivational states result from resource and demand evaluations. The motivational states of challenge and threat can be distinguished by patterns of cardiovascular reactivity. Because self-regulatory fatigue is said to occur when a person's resources have been depleted and, thus, can no longer meet the demands of the situation, we argue the biopsychosocial model is an important empirical

framework for furthering our understanding of self-regulatory fatigue. We hypothesized that individuals experiencing self-regulatory fatigue would exhibit a cardiovascular pattern consistent with threat, whereas, those individuals who did not experience self-regulatory fatigue would demonstrate a cardiovascular pattern consistent with challenge. Our hypothesis was supported, such that, participants who were asked to tell a story without using words that begin with the letters t or w demonstrate the physiological response associated with threat while persisting on a subsequent anagram task while those who were asked to tell a story without restrictions demonstrate the physiological pattern consistent with challenge. Implications for the mechanism of self-regulatory fatigue are discussed. Study 2 furthered this investigation by adding a second baseline between tasks. Results demonstrate the mechanism of self-regulatory fatigue, such that, the actual ratio of resources and demands can be observed during an initial depleting task versus the task in which participants fail to self-regulate. Preliminary analysis shows that participants do demonstrate a lack of resources during the initial task, as well as the subsequent activity. Theoretical implications are discussed.

### C234

#### **LITTLE COFFEE SHOP OF HORRORS: REMINDERS OF DEATH INCREASE PREFERENCE FOR RISKY OPTIONS**

Leah E. James<sup>1</sup>, Daphna Oyserman; <sup>1</sup>University of Michigan – Terror management theory suggests that reminders of one's own mortality ("mortality salience") invite efforts toward self preservation. Paradoxically, existing work shows that mortality salience primes in the laboratory can increase intention to take risks in some individuals, specifically those for whom risk-taking is central to self-esteem and those with an external locus of control (Ben-Ari, Florian, & Mikulincer, 1999; Miller & Mulligan, 2002). However, little is known about how reminders about the possibility of death affect momentary behavior urges in real world contexts. In the current study, college-age adults waiting in line at a coffee shop were exposed to a staged conversation about the death of another young person in a car accident. They were then approached by a confederate who administered a survey about what one desires in their coffee shop experience. Participants who overheard the death conversation reported less interest in coffee shops with quiet study space and organized social activities, and marginally more support for the sale of alcohol and cigarettes in coffee shops than control group participants who were not exposed to a conversation. Results suggest that reminders of death similar to those encountered on a daily basis can momentarily reduce interest in future-focused behaviors like studying and heighten interest in potentially self-destructive behaviors such as substance use. Further, these effects may apply to a broader population than that suggested by previous work.

### C235

#### **HOW DO WE TRULY FORGIVE OURSELVES?**

Kyli Hedrick<sup>1</sup>, Michael Wenzel<sup>1</sup>; <sup>1</sup>Flinders University, Adelaide, Australia – Recent attempts to study self-forgiveness have been unable to capture genuine self-forgiveness where offenders accept responsibility for their wrongdoing while they overcome self-punitive tendencies and restore a positive view of themselves. Research has typically measured self-forgiveness solely via the outcome of positive self-regard, which is commonly negatively related to acceptance of responsibility, remorse or guilt. Previous studies thus seem to confound self-forgiveness with a downplaying of the incident. Instead of a mere focus on the outcome, we need to consider the process through which offenders restore their self-regard. For genuine self-forgiveness this involves the severance of the negative link between responsibility acceptance and positive self-regard. Crucial in this process, we argue, is the reaffirmation of the violated values, which conciliatory behaviours such as confessions facilitate. In a role-play study ( $N = 90$ ) it was experimentally manipulated whether participants confessed their wrongdoing to the victim or not. While responsibility acceptance was strongly negatively related to reported self-forgiveness (i.e., self-regard), this relationship was tempered when participants confessed their wrongdoing to the victim. The offender's reaffirmation of values showed a parallel moderation that accounted for this effect: when

offenders reaffirmed the violated values the negative relationship between responsibility acceptance and self-reported forgiveness (i.e., positive self-regard) was mitigated. Value reaffirmation appeared to be the key ingredient of confession and essential to the process of genuine self-forgiveness, allowing offenders to accept responsibility without this having deleterious consequences for their own self-regard.

### C236

**CONTINGENCIES OF SELF-WORTH AND EGO-DEPLETION** Miranda Farley<sup>1</sup>, Salena Schapp, Amara Brook, Jennifer Crocker<sup>2</sup>; <sup>1</sup>Santa Clara University, <sup>2</sup>University of Michigan – Previous research has shown that people try harder to succeed in areas of life on which they base their self-esteem – contingencies of self-worth (CSW). Other studies have found that controlling behavior on one task can impair self-regulation on a subsequent task. This study sought to learn whether investing self-esteem in academic performance predicts increased persistence on an academic task, and whether this effect differs for people whose self-control has or has not been depleted by attempting a previous difficult task related to another CSW – appearance. More specifically, women who did or did not base their self-esteem on appearance and/or academics were given the opportunity to sample numerous fattening snack foods (challenging task for women who base self-esteem on appearance) or music (easy task). Then, they attempted to complete an impossible academic task, and we measured their persistence on this second task. Academic CSW predicted spending more time on the impossible academic task only for non-appearance contingent participants in the food condition. Academic CSW predicted spending significantly less time on the impossible task for appearance contingent participants in the food condition, predicted marginally less time for appearance contingent participants in the music condition, and did not predict time for non-appearance contingent participants in the music condition. These results suggest that contingent self-worth is a fragile source of motivation because it only helps self-regulation on the rare occasion when people are not already depleted from a previous task.

### C237

**HOPE AND OPTIMISM IN LAW STUDENTS: LONGITUDINAL ASSOCIATIONS WITH ACADEMIC PERFORMANCE AND LIFE SATISFACTION** Amanda Shea<sup>1</sup>, Kevin Rand<sup>1</sup>, Allison Martin<sup>2</sup>; <sup>1</sup>Indiana University-Purdue University Indianapolis, <sup>2</sup>Indiana University School of Law-Indianapolis – Attorneys and law students are notoriously distressed. Research has implicated the unique rigors of law school in the etiology of this distress (Sheldon & Krieger, 2004). Personality characteristics, such as trait hope (Snyder, 1994) and optimism (Scheier & Carver, 1985), have been shown to mitigate the deleterious effects of stress and to predict better performance and well-being under adverse conditions (Snyder & Lopez, 2007). The goal of this longitudinal study was to examine the differential relationships of trait hope and optimism with academic performance and life satisfaction among first-year law students. At the beginning of the academic year, 86 law students completed self-report measures of trait hope, trait optimism, LSAT scores, and undergraduate GPA. During the last week of the semester, students completed a self-report measure of life satisfaction. Additionally, participants' law school GPAs were obtained from the registrar at the end of the semester. In partial support of our hypotheses, measured-variable path analysis using structural equation modeling showed that higher hope ( $\beta = .25$ ), but not optimism ( $\beta = -.07$ , n.s.), predicted higher law school GPA, while controlling for LSAT score and undergraduate GPA. Both higher hope ( $\beta = .39$ ) and optimism ( $\beta = .38$ ) predicted greater end-of-semester life satisfaction, accounting for 44% of the variance. These results suggest that positive personality traits, such as hope and optimism, are important predictors of performance and psychological well-being during arduous undertakings such as law school.

### C238

**DISTRACTION AS A MEANS TO PRESERVE SELF-CONTROL** Jeremy Tost<sup>1</sup>, Ashley E. O'Hearn<sup>1</sup>; <sup>1</sup>New Mexico State University – The strength model of self-control (Muraven, 1998, Baumeister, 1999) proposes that our ability to control impulses and persist at tasks is like muscular strength in that it becomes depleted from use. The current study evaluates the extent to which self control performance is influenced by attentional control, defined as how and where we direct our attention during an activity. Ninety seven participants engaged in a commonly used self-control task (the hand-grip task) in which they were instructed to hold the pegs of the hand-grip together as long as they could. After obtaining a baseline measure, all participants were randomly assigned to one of three conditions at which point they performed the hand-grip task a second time. In the focus condition participants were instructed to direct their attention on the squeezing hand while doing the grip task. In the distraction condition participants were instructed to perform the Star Counting Task (De Jong, 1990) while doing the grip task. In the control condition participants received the same instructions as in the baseline measurement. While participants in the focus condition performed comparable to the control condition  $t(50) = .83$ ,  $p > .05$ , those in the distraction condition performed significantly better than controls  $t(67) = 2.66$ ,  $p < .05$ . Results are discussed in terms of practical application, that is, to what extent attentional control can be useful in dealing with daily self-control pressures.

### C239

**THE INTERACTIVE EFFECTS OF POTENTIAL REJECTION AND ATTACHMENT ANXIETY ON SELF-REGULATION** Sandra Marques<sup>1</sup>, Tara K. MacDonald<sup>1</sup>, Lorne Campbell<sup>2</sup>, John Lydon<sup>3</sup>; <sup>1</sup>Queen's University, <sup>2</sup>University of Western Ontario, <sup>3</sup>McGill University – Rejection can be an extremely painful experience affecting one's well-being and interpersonal functioning (Ayduk et al., 2001). Given the investment that goes into romantic relationships, they provide the ideal situation where rejection can be especially distressing. Baumeister and colleagues (2005) demonstrated that following rejection, individuals experience self-regulation failure and subsequently tend to make deleterious health choices. We hypothesized that the relationship between rejection by a romantic partner and self-regulation failure manifested would be moderated by attachment anxiety. Using the Secret Self manipulation devised by Murray and colleagues (2002), participants in the experimental condition were led to believe that their partners would eventually find out any information they try to keep secret, leading to conflict in the relationship. Participants in the control condition did not receive this feedback. Following this manipulation, in an ostensibly unrelated task, individuals were given a bowl of jelly beans and were asked to complete a taste-test sheet. The ability to self-regulate was operationalized by assessing the number of jelly beans consumed. Using multiple regression analyses, number of jelly beans eaten was predicted from condition, gender, attachment anxiety, and the interaction terms. Results indicated a significant condition x gender x anxiety interaction, such that in the rejection condition, females high in attachment anxiety ate significantly more jelly beans than those low in attachment anxiety. No significant effects were found in the control condition. These results suggest that for females, attachment anxiety might be an important moderator of the relationship between perceived rejection and self-regulation in romantic relationships.

### C240

**ANTICIPATED AND CURRENT EMOTIONS AS PREDICTORS OF BEHAVIORAL SELF-REGULATION** Christina M. Brown<sup>1</sup>, Allen R. McConnell<sup>2</sup>; <sup>1</sup>Saint Louis University, <sup>2</sup>Miami University – Discrepancies between one's current and desired states evoke negative emotions (Phillips & Silvia, 2005), and it is thought that these emotions guide self-regulation. However, rather than emotions motivating (Duval & Wicklund, 1972) or signaling the need for self-regulation (Carver, 2004), it is possible that people self-regulate based on how they expect to feel (i.e., anticipated emotions; e.g., Baumeister et al., 2007). Thus, the current work

tested the role of both current and anticipated emotions in self-regulation. A self-discrepancy was induced in participants ( $N=206$ ) via failure feedback about an important ability, after which they could self-regulate by practicing problems intended to improve that ability. Participants reported both their current emotions and how they expected to feel if their ability did not improve. After practicing, they again received false feedback and reported their emotions. Contrary to classic theories of self-regulation, negative emotions did not predict greater self-regulation (i.e., practice). If anything, self-regulation tended to increase as emotions became more positive,  $Beta=.23$ ,  $p=.11$ . Moreover, self-regulation was predicted by anticipated emotions, such that the worse participants expected to feel following failure, the more they self-regulated,  $Beta=-.30$ ,  $p<.05$ . Participants also demonstrated overestimation biases (e.g., Gilbert et al., 1998) such that they anticipated both failure experiences would make them feel worse than they actually did. However, the overestimation bias was smaller after the second, compared to the first, failure experience  $t(205)=4.07$ ,  $p<.001$ . These results suggest that anticipated emotions, not current emotions, guide behavioral self-regulation and that these affective forecasts become more accurate following experience.

#### C241

##### UNDERSTANDING SEEMINGLY FICKLE FORGIVENESS: HOW REGULATORY NONFIT CAN INFLUENCE DECISIONS TO FORGIVE

Alexander G. Santelli<sup>1</sup>, C. Ward Struthers<sup>2</sup>, Careen Khoury<sup>2</sup>; <sup>1</sup>Columbia University, <sup>2</sup>York University – Prior research has demonstrated that regulatory fit can influence the forgiveness process (Santelli, Struthers, & Eaton, 2009). According to regulatory focus theory (Higgins, 1997; 1998), individuals self-regulate using either a promotion or a prevention focus, and when individuals pursue a goal in a manner that sustains their regulatory focus, they experience regulatory fit (Higgins, 2000). Santelli et al. established that victims are more forgiving when they receive apologies that emphasize a regulatory focus that is congruent to their own; however, the effect of regulatory fit, independent of apology, was never explored. Given that the "feeling right" experience associated with regulatory fit is known to transfer to value judgments (Higgins, Freitas, Idson, Spiegel, & Molden, 2003), the current experiments sought to determine whether these feelings would also transfer to victims' forgiveness of transgressors. In three experiments, participants completed a regulatory fit manipulation (Freitas & Higgins, 2002), imagined being victims of a transgression, and completed items measuring forgiveness. Participants in the regulatory nonfit condition were less forgiving than participants in the fit condition and the control condition when transgression severity was mild. However, this result was reversed when severity was high. The moderating effect of severity was mediated by the extent to which participants felt right about their interaction with the transgressor. Finally, the effect of fit on forgiveness was shown to be the result of a misattribution process. Thus, experiencing regulatory nonfit in one situation may have unintended interpersonal consequences in another.

#### C242

##### THE EFFECT OF CONSTRUAL LEVELS AND DELIBERATIVE/IMPLEMENTAL MINDSETS ON SOCIAL SELF-REGULATION

Chika Harada<sup>1,2</sup>, Koji Tsuchiya<sup>1</sup>, Toshikazu Yoshida<sup>1</sup>; <sup>1</sup>Nagoya University, <sup>2</sup>Research Fellow of the Japan Society for the Promotion of Science – Past studies in construal level theory and deliberative/implemental mindsets indicated that the activation of high-level construals and implemental mindsets promote self-control and self-regulation behaviors (e.g., Fujita et al., 2006; Brandstätter & Frank, 2002). While they have uncovered particular cognitive states affecting subsequent behaviors and evaluations, they have not examined any similarities and differences in these effects. This study investigated the effect of construal levels and mindsets on self-regulation within social settings, and placing a focus on the similarities and differences in these effects. Participants were induced high- vs. low-level construals (study 1,  $N=97$ ) or deliberative vs. implemental mindsets (study 2,  $N=95$ ), using previously validated priming procedures. They were then

asked to complete measures about "value", "cost", "evaluation of temptations", and "intention" of the behavior in each conflict scenario that social self-regulation ability was required (self-assertiveness, patience, and emotion/desire inhibition scene in social settings). Results of study 1 showed that participants who were activated high-level construals had higher primary behavioral value ratings, lower evaluation of behavioral cost, and stronger intentions than their low-level construals counterparts. No difference in evaluations of temptations was found. In study 2, mindsets had no effect on the evaluation of behavior. These results indicated that the activation of high-level construals contributes to self-regulation in the context of social conflict, while mindsets had no effect on conflict behaviors within social settings. The differences between construal levels and mindsets, along with implications of these findings were discussed.

#### C243

##### IDENTITY VS. REGULATORY CAPACITY: EXAMINING TWO EXPLANATIONS

OF PERSEVERANCE Michael B. Kitchens<sup>1</sup>, Michael P. Fleming<sup>1</sup>, Ashley M. Omdorff<sup>1</sup>; <sup>1</sup>Lebanon Valley College – Perseverance is explained by at least two self-related processes. First, people persevere because they are motivated to behave in a way that is consistent with their self-image. For example, previous research showed that participants who were publically informed that they were expected to perform well on an upcoming anagram task spent more time trying to solve the anagrams than participants who were publically informed that they were expected to perform poorly on the task. Additionally, perseverance can be explained by self-control capacity. Research shows that engaging in self-control reduces the capacity to engage in further acts of self-control, such that participants who previously engaged in emotion regulation spent less time solving anagrams than participants who had not regulated their emotions. The purpose of this study was to begin examining whether these explanations are competing or interactive mechanisms of perseverance. To test this, participants completed either a regulatory-depleting task or a non-depleting task. Participants were then led to believe that they were either expected to perform well or poorly on an upcoming anagram task, or they were given no expectations about their performance. Results showed that participants persevered more when they completed the non-depleting task than when they completed the regulatory-depleting task. The feedback had no statistically significant effect. In short, these data indicate that self-regulation capacity explains perseverance better than self-consistency motives. However, these data in the context of the broader literature may suggest that self-control capacity accounts for private perseverance, but self-consistency motives account for public displays of perseverance.

#### C244

##### FOREWARNED IS FOREARMED: CONSERVING SELF-CONTROL STRENGTH TO RESIST SOCIAL INFLUENCE

Loes Janssen<sup>1</sup>, Bob M. Fennis<sup>2</sup>, Ad Th. H. Pruyn<sup>3</sup>; <sup>1</sup>Tilburg University, <sup>2</sup>Utrecht University, <sup>3</sup>University of Twente – Why is it often so difficult to resist (unsolicited) persuasion? Recent research has shown that resisting persuasion often involves active self-regulation. Resisting an influence attempt consumes self-regulatory resources, with the inevitable consequence that when these resources are low, one's attempts at resistance are more likely to fail (e.g., Fennis, Janssen, & Vohs 2009). Hence, a state of self-regulatory resource depletion (Baumeister et al., 1998) increases susceptibility to influence, but the present research shows that, under certain conditions, depleted individuals successfully conserve their resources to be put into action when subsequently confronted with an influence attempt. In three experiments we show that forewarning of an impending influence attempt promotes self-regulatory efficiency and prompts depleted individuals to conserve what is left of their regulatory resources. After performing a self-control task, depleted participants who were forewarned about an upcoming persuasive encounter performed worse on an intervening self-control task (conserving their resources), than participants who were either not depleted, or not forewarned (cf. Muraven et al., 2006). As a result, when these individuals were subsequently confronted with a persuasive request, they

complied less (Experiments 1 and 2), and generated more counterarguments (Experiment 3) than their depleted counterparts who were not forewarned and did not conserve their resources, and they were as able as non-depleted individuals to resist the influence attempt. The current research shows that self-regulatory efficiency may play an important role in resisting social influence. Moreover, it provides insight into the self-regulatory dynamics underlying 'classic' effects of forewarning on persuasion.

#### C245

**BEYOND GROUP IDENTITY: THE COGNITIVE COSTS OF STIGMA THREAT IN NON-IDENTIFYING INDIVIDUALS** Sarah A. Flores<sup>1</sup>, Heather C. Lench<sup>1</sup>, <sup>1</sup>Texas A&M University – Identifying with a stigmatized group has been shown to have a detrimental impact on cognitive processing in situations that threaten that group. This study investigated whether the regulation of impulses causes these cognitive deficits rather than group membership or social threats. LGB (lesbian, gay, bisexual) individuals often experience discrimination and hostility from others and identifying with this group is associated with stigma threat effects. The purpose of this study was to explore the consequences of overriding emotional impulses in people who do not necessarily identify as LGB but are attracted to same sex individuals. Participants who did not identify as LGB completed an IAT measure of same sex attraction and then wrote for five minutes about the attractive characteristics of a picture of a male, a female, or a neutral object. Participants then reported their current emotions and completed measures of cognitive processing. Greater implicit attraction to the same sex decreased performance on cognitive tasks when participants wrote about the attractive qualities of a person versus an object and self reported anxiety mediated this relationship. These results suggest that anxiety elicited by considering attraction to another person is sufficient to cause cognitive deficits in individuals attracted to same sex individuals. These findings have implications for understanding the potential cognitive and emotional costs of stereotypes even in those who do not self identify with the stigmatized group. Theories of stereotype and stigma threat can be broadened to understand when and why individuals will experience cognitive deficits in a potentially threatening environment.

#### C246

**MANAGING OTHERS LIKE YOU WERE MANAGED: HOW PREVENTION FOCUS MOTIVATES COPYING INTERPERSONAL NORMS** Shu Zhang<sup>1</sup>, E. Tory Higgins<sup>1</sup>, <sup>1</sup>Columbia University – Four studies investigated the relation between regulatory focus and the tendency to copy a role model's managing behaviors when later taking on the same role as the model. We predicted that the tendency to copy will be greater for individuals with a prevention focus on duties and obligations (oughts) than for individuals with a promotion focus on aspirations and advancements (ideals), because enacting role-related behaviors fulfills interpersonal norms that fit prevention concerns. We also predicted that prevention-focused individuals would even copy managing behaviors they disliked when they received them earlier. These predictions were first supported in two experimental studies, where prevention focus was measured as a chronic disposition (Study 1) and situationally induced as a temporary state (Study 2). We used a grader-student paradigm to examine people's tendency to copy, that is, whether they would choose a grading method they received earlier from a grader and use it to evaluate others' performance when later taking on the grader role. Further, it was normativeness of a managing behavior that underlay the tendency to copy among prevention-focused individuals (Study 3), which was based on how they were managed before rather than how effective the behavior was (Study 4). Taken together, these findings indicated an important role of prevention focus in perpetuation of interpersonal behaviors across similar relationships.

#### C247

**ACCEPTANCE AND ADJUSTMENT AS COMPONENTS OF SECONDARY CONTROL:** Raymond P. Perry<sup>1</sup>, Robert H. Stupnisky<sup>1</sup>, Tara L. Haynes<sup>1</sup>, Judy G. Chipperfield<sup>1</sup>, Reinhard H. Pekrun<sup>2</sup>, <sup>1</sup>University of Manitoba, <sup>2</sup>University of Munich – Following Rothbaum et al. (1982), secondary control has received intensive scrutiny concerning its functional role in the absence of primary control, most recently Morling and Evered's (2006) reconstrual of secondary control (SC) involving acceptance and adjustment. Absent from their analysis is whether acceptance and adjustment occur simultaneously in response to loss of primary control, or sequentially. If the latter, then in what order? We examined these issues in unpredictable learning conditions involving school-to university transitions in which heightened competition, frequent failure, poor instruction, unfair grading, etc., threaten primary control. First-year students (n=679), selected from a longitudinal database containing 13 one-year cohorts (N~10,500), were assessed two times in the academic year on psychosocial measures, including general-life and achievement-related SC acceptance and adjustment. Confirmatory factor analyses of the acceptance and adjustment measures in October (Time 1) and March (Time 2) produced adequate fit indices: CFIs>.95, RMSEAs<.05. Cross-lag structural equation models (covariates=age, ethnicity) indicated that, for general-life SC, acceptance positively predicted adjustment ( $\beta=.20$ , CFI=.93, RMSEA=.05). A multi-group model showed this linkage was stronger in students with lower rather than higher general primary control ( $\beta$  low = .29 vs.  $\beta$  high = .10, CFI=.92, RMSEA=.04). For achievement-related SC, adjustment negatively predicted acceptance ( $\beta= -.14$ , CFI=.93, RMSEA=.06). A multi-group model indicated this linkage was stronger for students with higher rather than lower achievement primary control ( $\beta$  high = -.28 vs.  $\beta$  low = -.03, CFI=.94, RMSEA=.04). Results supported Morling and Evered's perspective in unpredictable learning conditions, but qualified the nature of their analysis.

#### C248

**EXPLORING THE MECHANISM OF MINDFULNESS: FROM ATTENTION TO SELF-INTEGRATION** Jen Ho Chang<sup>1</sup>, Yi Cheng Lin<sup>1</sup>, Chin Lan Huang<sup>2</sup>, <sup>1</sup>National Taiwan University, <sup>2</sup>National Taiwan University of Science and Technology – Recently, mindfulness-based activities and psychotherapy have been widely adopted to improve medical and psychological treatments. However, on such a wide range of medical applications, the potential mechanism of mindfulness has not been clearly explained. Therefore, this study intends to explore the inner mechanisms of mindfulness through an attention experiment (emotional flanker task) and a self-integration task (card sorting in different self domains) which correspond to the two main characteristics of mindfulness: "action awareness" and "non-judgment". At first, we did a preliminary study to validate the mindfulness measurement (FFMQ; Baer et al, 2006, Assessment, 13:27-45, 2006) in an university sample (n=269). The factor analysis supported the same factor structure as the FFMQ and the most of mindfulness facets were positivity related to well-being and negativity related to psychological symptoms. For the main study, 60 undergraduates participated in exchange for extra credit in several general psychology courses. Participants completed FFMQ which contained action awareness and non-judgment scales, the emotional flanker task and the card sorting task individually in a single session. Result revealed that the person with higher action awareness was influenced less by emotional target (positivity and negativity) than the person with lower ones. At the same time, the degree of being non-judgmental positively correlated to the degree of self-integration which corresponded with the ability to accept both the positive and negative aspects of self domains. The present findings shows that the action awareness influenced the external attention process and non-judgment influenced internal self-integration, indicating both processes might be the key psychological mechanism of mindfulness.

**C249****PERFECTIONISM AND SELF-REGULATION: MOTIVES FOR PERFECTION INVOLVE DIFFERENT FACETS OF THE SELF'S RESOURCES** Matthew

Findley<sup>1</sup>, Kristine M. Kelly<sup>2</sup>, Andrew R. Hull<sup>2</sup>; <sup>1</sup>University of Oklahoma, <sup>2</sup>Western Illinois University – The Strength Model of self-regulation (Baumeister, Bratslavsky, Muraven, & Tice, 1998) states that the self is dependent on an internal energy reserve that becomes depleted with successive acts of self-regulation. Many factors have been found to contribute to the exhaustion of self-regulatory reserves. One factor that has not been examined is perfectionism which requires a great deal of cognitive effort, and therefore would likely deplete self-regulatory resources. Perfectionism consists of a positive, healthy type and a negative, unhealthy type (Terry-Short, Owens, Slade, & Dewey, 1995). This study attempted to examine the effects that the two types of perfectionism might have on self-regulatory resources. It was hypothesized that perfectionists would have greater self-regulatory depletion than would non-perfectionists. Further, we expected that negative perfectionists would experience greater self-regulatory depletion than would positive perfectionists. Participants were college students who were randomly assigned to a perfectionism condition (positive perfectionist, negative perfectionist, or non-perfectionist control group) by receiving different instructions to trace an unsolvable figure. Blood glucose and handgrip strength measurements were taken before and after the task to assess self-regulatory depletion. Results indicated that, as expected, non-perfectionists were the least depleted for both handgrip and blood glucose measures. However, negative perfectionists were the most depleted on the handgrip measure, and positive perfectionists were the most depleted on the glucose measure. The results suggest that perfectionism causes self-regulatory depletion, but positive and negative perfectionists may draw upon different aspects of the self's resources.

**C250****TWO TYPES OF VALUE-AFFIRMATION: IMPLICATIONS FOR SELF-REGULATION FOLLOWING SOCIAL EXCLUSION** Aleah Burson<sup>1</sup>, Jennifer

Crocker<sup>1</sup>; <sup>1</sup>University of Michigan – Past research shows that self-regulation typically decreases following social exclusion. Considering the findings that affirming important values reduces destructive responses to self-threatening experiences, we hypothesized that affirming an important value sustains self-regulation following social exclusion. Furthermore, we predicted that the benefits of value-affirmation depend on the type of value participants affirm. Affirming values related to supporting others (self-transcendent values) were expected to reduce the negative effects of exclusion on self-regulation more than affirming values related to maintaining one's self-image (self-enhancement values). After experiencing social exclusion or not, 92 undergraduate participants wrote about the personal importance of a self-transcendent value, a self-enhancement value, or their daily routine (control). Self-regulation was then measured. As hypothesized, we found a significant interaction ( $F(2, 86) = 5.45, p = .006$ ) between the type of value affirmed and social exclusion on self-regulatory effort. Excluded participants who were not value-affirmed showed less self-regulation than excluded participants who affirmed either a self-enhancement value ( $p = .016$ ) or a self-transcendent value ( $p < .001$ ). Additionally, excluded participants exerted more self-regulation if they affirmed a self-transcendent value than if they affirmed a self-enhancement value ( $p = .041$ ). Non-excluded participants did not show significantly different self-regulation as a function of which value they affirmed. Not only does this study's findings support the idea that value-affirmation prevents typical decreases in self-regulation following social exclusion, it also provides evidence that the type of affirmed value makes a difference in the extent of its diminishment.

**C251****SELF-AFFIRMATION IN CHINA: FAMILY-DEPENDENT BUT NOT FRIENDS-DEPENDENT SELF MATTERS** Lixin Jiang<sup>1</sup>, Chenjun Wang<sup>1</sup>, Huajian Cai<sup>1</sup>;

<sup>1</sup>Sun Yat-Sen University – Although numerous self-affirmation studies have been conducted in the West, little about it is known in the East. In three studies, we examined whether affirmations of the independent self, family-dependent self, or friends-dependent self function similarly in an East-Asian culture (China). Affirmation of the independent self produces null effects. However, affirmation of the family-dependent versus friend-dependent self produced different results. In particular, affirmation of the family-dependent (but not friends-dependent) self led to (a) more openness to threatening information about one's weakness following failure feedback (Study 1), (b) better performance in a stereotype-relevant domain following stigmatization as a member of a negatively stereotyped group (Study 2), and (c) less existential anxiety following mortality salience (Study 3). These studies provide converging evidence that, in an East-Asian culture, affirmation of the family-dependent self functions differently than affirmation of the friends-dependent (or independent- self).

**C252****THE RELATIONSHIP BETWEEN MINDFULNESS, SELF-REGULATION, AND REPETITIVE THOUGHT** Daniel Evans<sup>1</sup>, Suzanne Segerstrom<sup>1</sup>; <sup>1</sup>University of

Kentucky – Mindfulness, defined as non-judgmental and non-reactive attention to one's present experiences, has properties of a self-regulatory technique. The nature of this regulation, however, is less clear, particularly with regard to repetitive thought (RT), which encompasses constructs such as worry, rumination, reflection, and emotional processing. Some aspects of mindfulness (e.g., nonreactivity) suggest a decreased propensity for RT of all types, whereas others (e.g., nonjudging) suggest control over the quality of RT. In an undergraduate sample ( $N = 199$ ), multidimensional scaling of a battery of trait RT measures replicated the typical 2-dimensional solution with valence (positive versus negative) and purpose (searching versus solving) dimensions (Segerstrom et al., 2003). Total mindfulness was associated with more positively valenced RT ( $r = .52, p < .001$ ) and searching RT ( $r = .23, p = .001$ ), while the mindfulness facets of non-judging and acting with awareness were negatively related to total RT ( $r = -.42$  and  $-.32$ , respectively,  $p < .001$ ). In contrast, trait self-control measures were related to more positively valenced RT ( $r$ 's =  $.31$  to  $.42, p < .001$ ), but mixed in their relationships with total RT ( $r = -.01, ns$ ;  $r = -.22, p = .002$ ). Mindfulness appears to contribute to two qualities of regulation of RT: lower propensity to engage in RT of all types and higher propensity to engage in positively valenced, searching RT. Furthermore, trait mindfulness and trait self-regulation appear to be distinct constructs based on their different relationships to the dimensions and total amount of RT.

**C253****RETAIL THERAPY: CONTROL DEPRIVATION AND COMPENSATORY SPENDING** Charlene Y. Chen<sup>1</sup>, Leonard Lee<sup>1</sup>, Andy J. Yap<sup>1</sup>; <sup>1</sup>Columbia

University – Desiring control over the environment is a fundamental human motive. Perceived uncontrollability drives individuals to restore control via compensatory strategies. We propose that shopping is an avenue in which control-deprived individuals attempt to recover their sense of control. Specifically, we demonstrate in two studies that control deprivation can influence buying behavior. Study 1 was a field experiment conducted at a supermarket. In exchange for a discount coupon, shoppers before shopping were asked to recall an episode where they had felt either a sense of control (HC) or a loss of control (LC). Results indicated that LC shoppers spent more than HC shoppers. Study 2 was designed to conceptually replicate this main effect and investigate how it is moderated by individuals' chronic desire-for-control. Control was manipulated using the ease-of-retrieval paradigm (Schwarz et al., 1991): Lab participants had five minutes to describe either two (HC) or ten (LC) past scenarios whereby they had experienced a sense of control; they had also earlier completed the desire-for-control scale (Burger & Cooper,

1979). Finally, participants shopped with real cash at a store set up in the lab. Results showed a significant main effect of control manipulation on expenditure qualified by a significant interaction of control manipulation and desire-for-control scores. Specifically, LC participants with high desire-for-control spent the most at the store. These findings suggest that control-deprivation increases spending, especially among individuals who have high desire-for-control, and illuminate the psychological underpinnings of the popular notion of “retail therapy.”

#### C254

**SHEDDING LIGHT ON BEHAVIORAL PROCRASTINATION: DIFFERENT PREDICTORS FOR DIFFERENT OPERATIONS** Anthony Hermann<sup>1</sup>, Jill Schroeder<sup>1</sup>; <sup>1</sup>Bradley University – Research on procrastination is dominated by individual difference measures of the construct. Studies that do emphasize behavioral operationalizations (e.g., behavioral postponement) do not typically distinguish between procrastination on different types of tasks. Fifty-three college students who completed individual difference measures of the Big Five personality traits and self-doubt at an initial experimental session, were then required to 1) email the experimenter to receive another task, and 2) complete the task, a measure of verbal reasoning, and return it via email to the experimenter within 10 days. Although individual differences in procrastination were correlated with both behavioral measures of procrastination, the behavioral measures were unrelated to each other. Furthermore, longer times to email the experimenter were associated only with low conscientiousness and low neuroticism, while longer times to return the reasoning task were only associated with high self-doubt about one’s abilities. These findings suggest that procrastination on one task is not necessarily linked to procrastination on another, and that motives for procrastination can vary dramatically depending on the type of task.

#### C255

**CAN YOU RESIST THE TEMPTATION OF FACEBOOK: ASYMMETRICAL FACEBOOK-STUDY ASSOCIATION PREDICTS ACADEMIC PERFORMANCE** Lile Jia<sup>1</sup>, Edward Hirt<sup>1</sup>; <sup>1</sup>Indiana University Bloomington – Facebook has become a temptation college students need to resist in their pursuit of academic excellence. The current research combined the perspective of asymmetrical temptation-goal association (Fishbach, Friedman, & Kruglanski, 2003) and implicit attitude (Fazio et al., 1995) to investigate whether and how these two types of implicit cognition predict a consequence of one’s self-control success—academic performance. Using a sequential priming paradigm, we indexed the magnitude of the asymmetrical association between one’s mental representation of Facebook (the temptation) and that of study (the overarching goal), i.e. the former facilitates the activation of the latter while the latter inhibits the activation of the former, as well as one’s implicit attitudes toward Facebook. It was found that when college freshmen viewed Facebook as a temptation to study, the asymmetrical Facebook-study association and the implicit attitude toward Facebook interacted to predict their SAT/ACT score. Specifically, the more negative one’s implicit attitude toward Facebook was, the more Facebook-study facilitation and study-Facebook inhibition predicted better academic performance. Besides being the first evidence showing that measured asymmetrical temptation-goal association can predict self-control success, the present findings also suggest that one role implicit attitudes play in self-control process is to orient the recruitment of automatic self-control mechanisms (such as asymmetrical temptation-goal association) toward negative stimuli, as opposed to positive ones. In addition, the fact that one’s implicit cognition can predict a dependent variable as distal as one’s performance on standardized exams attests to the practical utility of researching implicit cognition in self-control processes.

#### C256

**SELF-REGULATORY FOCUS AND DEPRESSION: CORRELATIONAL AND EXPERIMENTAL EVIDENCE** Johannes Keller<sup>1</sup>, Ayse Uskul<sup>2</sup>, Susanne Pauls<sup>1</sup>; <sup>1</sup>University of Mannheim, <sup>2</sup>University of Essex – Depression has been argued to be a disorder closely connected to self-regulatory mechanisms (Straumann, 2002). Using a self-regulatory focus (SRF) framework (Higgins, 1997), we tested the relationship between SRF and depression in 5 studies. We observed that prevention SRF correlates positively and promotion SRF negatively with self-reported depression. We also examined the association between SRF and specific correlates of depression (sensitivity to positive/negative information, optimism/pessimism) and found that prevention correlates positively with sensitivity to negative information and pessimism whereas promotion SRF correlates positively with sensitivity to positive information and optimism. In a further study, we established that sensitivity to negative and positive information reliably mediates the SRF-depression link. These studies established that, although promotion is modestly negatively correlated with depression, the prevention SRF-depression link is more substantial. Focusing on this latter link, we examined causal pathways using retrospective data and by manipulating prevention SRF. These studies established that the current prevention-depression link cannot be accounted for by self-reported past depression. Also, past depression does not account for the relationship between past prevention SRF (as reported by parents) and current depression. We finally demonstrate that a prevention prime is associated with increased state depression scores compared to a control condition. In sum, findings from five studies converge to demonstrate that prevention SRF is reliably positively associated with depression and its psychological correlates. Findings suggest that depression is a functional disorder that is reliably related to the prevention self-regulatory system whereas the link to the promotion self-regulatory system is much less reliable.

## Culture

### D1

**DUTIFUL CHOOSING: CULTURE AND THE SUBJECTIVE EXPERIENCE OF MEETING EXPECTATIONS** Emma Buchtel<sup>1</sup>, Steven J. Heine<sup>2</sup>, Ara Norenzayan<sup>2</sup>; <sup>1</sup>Hong Kong Polytechnic University, <sup>2</sup>University of British Columbia – Are there cultural differences in our sense of obligation? Past research has suggested that while Westerners prefer to have their actions motivated only by a sense of personal choice, East Asians do not need this sense of personal agency, instead being happily motivated by close others' expectations. The current research shows that rather than this either-or distinction, East Asians are more likely than Westerners to feel a sense of agency when they fulfill the expectations of others. In two studies using daily diary and situation sampling methods, we examine cultural differences in the congruency between one's sense of agency and obligation to help others. Comparing participants from East Asian and Western European cultural backgrounds, we find that a) East Asians are more likely than Westerners to feel a sense of congruency between agentic and obligated motivations to help others; b) these cultural differences are partially mediated by positive attitudes towards hierarchy and filial values; and c) East Asians are more likely to have positive emotional associations with both obligated and agentic motivations to help others. The studies suggest that East Asians, in comparison to Westerners, are more likely to feel that their obligations are self-endorsed and involve a positive emotional experience. While Confucian "virtue ethics" promote feeling unity between one's desires and social obligations, the autonomy-seeking philosophies of the post-enlightenment West may have encouraged a disassociation of duties from self-endorsement. Implications for theories of motivation, in particular Self-Determination Theory (Ryan & Deci, 2000), are discussed.

### D2

**CULTURAL IDENTITY CLARITY, SELF-CONCEPT CLARITY AND PSYCHOLOGICAL WELL-BEING AMONG CHINESE NORTH AMERICANS** Esther Osborne<sup>1</sup>, Donald M. Taylor<sup>1</sup>; <sup>1</sup>McGill University – Clarity of personal identity has been positively associated with psychological well-being (Baumgardner, 1990; Campbell, 1990; Stinson, Wood & Doxey, 2008). However, Taylor (1997, 2002) argues that without a clear cultural identity, a person has no normative template against which to even construct a clear personal identity, and by extension, to achieve positive self-esteem and well-being. Individuals negotiating Eastern and Western cultural identities simultaneously may face particularly poignant cultural identity challenges. Among Chinese North Americans, we predicted that a combined Chinese North American identity that is perceived by the individual as clearly defined could potentially act as a guiding normative framework and would thus be associated with a clear personal identity and personal self-esteem and well-being. One-hundred and thirty self-identified Chinese North Americans completed a questionnaire assessing the relationships among cultural identity clarity, self-concept clarity, self-esteem and life-satisfaction. Regression analyses revealed that the perceived clarity of participants' Chinese North American identities was positively related to self-concept clarity, self-esteem and life satisfaction. Furthermore, self-concept clarity significantly mediated the relationship between cultural identity clarity and self-esteem, and the relationship between cultural identity clarity and life-satisfaction. Having a clearly defined perception of one's combined Chinese North American identity was associated with the experience of a clear personal identity, which in turn was associated with increased self-esteem and

life-satisfaction. Exercises designed to clarify cultural identity might be effective for increasing psychological well-being among individuals negotiating two cultural identities.

### D3

**CULTURE, SOCIAL EXCLUSION AND STRESS: CROSS-CULTURAL DIFFERENCES IN THE PSYCHOLOGICAL AND PHYSIOLOGICAL RESPONSE TO BEING EXCLUDED BY ONE'S PEERS** Sasha Kimel<sup>1</sup>, Yukiko Uchida<sup>2</sup>, Shinobu Kitayama<sup>1</sup>; <sup>1</sup>University of Michigan, <sup>2</sup>Kyoto University – Theory and research in social psychology suggests that the desire for positive social relationships is one of the most fundamental of human needs. People who experience ostracism, rejection and other forms of social exclusion tend to suffer both psychologically and physically. Although this tendency to feel distressed when left behind may be a basic feature of human experience, we argue that the degree to which this experience is detrimental depends on one's culture. Here we provide the first direct evidence for how culture affects the experience of acute social rejection and acceptance by peers. European-Americans and Japanese participants played cyberball—a well-established laboratory exclusion task in which subjects tossing a virtual ball with two actual players who they do not know and do not expect to meet. Half of participants receive the ball an equal amount of time as the other players ("acceptance" condition) whereas the other half only received the ball only two times before the other players proceeded with the game ("exclusion" condition). After completing the ball-tossing game, participants rated their mood and their current satisfaction levels with their sense of belonging, self-esteem, meaningful existence, and control. They also provided salivary cortisol samples before and after the social rejection/acceptance manipulation. Japanese showed significantly less positive mood in the exclusion condition than European-Americans. Furthermore, salivary cortisol levels were consistent with the behavioral data. Implications for current understandings of culture and social rejection will be discussed.

### D4

**CULTURAL DIFFERENCES IN STRESSOR FREQUENCY AND INFLUENCES ON DISTRESS IN JAPAN AND THE U.S.** Takeshi Hashimoto<sup>1</sup>, Heejung Kim<sup>2</sup>; <sup>1</sup>Shizuoka University, <sup>2</sup>University of California, Santa Barbara – The purpose of this study was to examine cultural differences in interpersonal stress experiences in Japan and the U.S. Four hundred eighty-six undergraduates in Japan (120 males and 169 females) and the U.S. (72 males and 125 females) completed a questionnaire that included measures of interpersonal stressors, the value of expression, cultural self-construal (independent versus interdependent), the behavior inhibition/activation system (BIS/BAS), and psychological distress. The frequencies of the two stressors, interpersonal blunders (causing someone trouble because of one's own failure) and interpersonal friction (taking care to avoid conflict with others), were higher in Japan than in the U.S., whereas the frequencies of the stressor interpersonal conflict did not differ across cultures. Interdependent self and BIS correlated positively with interpersonal blunders and friction, whereas independent self correlated negatively with these stressors. The association between stressors and distress was slightly stronger in Japan than U.S., and this association was partially buffered by assertiveness only in Japan.

### D5

**ARE AFFECTIVE FORECASTING ERRORS CULTURE SPECIFIC?** Priyanka Joshi<sup>1</sup>, Vivek Belhekar<sup>2</sup>, Prabha Shete<sup>3</sup>; <sup>1</sup>University of Southern California, <sup>2</sup>University of Mumbai, India, <sup>3</sup>Tatwajna Vidyapeeth, India – Affective forecasting (Wilson & Gilbert, 2003) refers our ability to predict our emotions in future hypothetical situations. Our affective forecasts are usually

subject to error such that individuals overestimate the intensity and duration or 'impact' of events on their general sense of happiness and wellbeing which is referred to as impact bias and occurs for both positive and negative events. These forecasting errors occur partly due to 'focalism' or our tendency to focus on a single event and not take into account the possibility that other co-occurring events will influence our thoughts and feelings and sense of happiness. Previous research suggests that Asians who are holistic thinkers do not show these affective forecasting errors or impact bias (Lam et al., 2005). In the current research on a community sample in India, participants completed an affective forecasting measure which included an item about their levels of happiness on successfully solving and not being able to solve a difficult puzzle. Later the same participants completed a moderately difficult puzzle and were randomly given success or failure feedback and were then asked to rate their experienced feelings. There was a significant discrepancy between predicted and experienced emotions for both positive,  $t(48) = 1.79$ ,  $p < .05$ , and negative events,  $t(42) = 1.72$ ,  $p < .05$ , suggesting that affective forecasting errors seem to commonly occur even in an Asian sample. Age and gender related trends were similar in an Indian sample as compared to previous research in the Western nations.

#### D6

**DIFFERENCE IN SELF-FACE RECOGNITION BETWEEN CHRISTIAN AND NON-RELIGIOUS CHINESE** Shihui Han<sup>1</sup>, Yina Ma<sup>1</sup>; <sup>1</sup>Peking University, China – Our recent brain imaging studies suggest that Christian belief and practice affect self-referential processing by weakening encoding of self-relevance of trait words. The current work extended the previous research by assessing whether Christian belief and practice influence self-related processing during face recognition. Experiment 1 tested the hypothesis that Christian belief and practice weaken self advantage during face recognition. We showed that, while non-religious Chinese participants responded faster to self-face compared to a familiar face in both an implicit face recognition tasks that required identification of face orientations and an explicit face recognition task that required identification of face owners, reaction times did not differentiate between self-face and the familiar face in Christian participants. Using implicit association test, Experiment 2 showed evidence for an implicit positive association with self-face in non-religious participants who responded faster to self-face that was associated with positive than negative items. However, the implicit positive association with self-face was significantly decreased in Christian than non-religious participants. Our findings suggest that Christian belief that repudiates the distinctness of the self decreases the implicit positive association with the self and results in elimination of self-face advantage in the believers.

#### D7

**THE CULTURAL SELF AND MOTIVATION FOR COOPERATION AND COMPETITION** Asuka Komiya<sup>1</sup>, Yusuke Karoji<sup>1</sup>, Yuji Ogihara<sup>1</sup>, Takayuki Goto<sup>1</sup>; <sup>1</sup>Kyoto University – A recent survey by the Japan Productivity Center reported that cooperation among workers has decreased and competition has been gaining emphasis in the working environment. Yet by which tactic are Japanese actually motivated? Since Japan is an interdependent culture in which dominant emphasis is placed on social harmony, working through cooperation with others may be more motivating than competition. The present study investigated whether Japanese were more motivated by cooperation or competition. In this study, 35 pairs of Japanese students completed an Implicit Association Test (IAT) which measured their cultural identity (interdependent vs. independent). Then they performed two creativity tests. In the first test, participants worked individually, whereas in the second test, each pair worked in either a cooperative or a competitive condition. After each test, the participants rated the degree to which they would be willing to take the same test again. The results showed that individuals who were relatively interdependent were more motivated in the cooperative condition than in the competitive condition, whereas individuals who were relatively independent were equally motivated in both conditions. Moreover, individuals in the interdependent group were more motivated to

work in the cooperative condition but less motivated to work in the competitive condition, compared to working individually. We discuss the possibility that the current problems among Japanese workers, such as mental illness, are at least partially caused by recent radical changes of working environment.

#### D8

**A SENSITIVE WINDOW FOR ACCULTURATION: IDENTIFICATION WITH MAINSTREAM CULTURE DECREASES AS A FUNCTION OF AGE OF IMMIGRATION** Benjamin Y. Cheung<sup>1</sup>, Maciek Chudek<sup>1</sup>, Steven J. Heine<sup>1</sup>; <sup>1</sup>University of British Columbia – Acculturation is a process of adjustment in one's ways of thinking following exposure to a new culture. We hypothesize that acculturation is more easily accomplished while at younger ages due to greater brain plasticity. We tested this hypothesis with a large sample of Hong Kong immigrants to Canada who completed both the heritage and mainstream subscales of the Vancouver Index of Acculturation (Ryder, Alden, & Paulhus, 2000). Results indicated that the younger an immigrant was at the time of immigration, the greater was their identification with the mainstream culture. This effect was independent of the number of years spent in Canada. Curiously, age of immigration did not influence participants' identification with their heritage culture. It appears that, like the acquisition of language, learning a new culture is most effective when it occurs within a sensitive window.

#### D9

**FINDING PSYCHOLOGICAL CHANGE ON THE RADIO: LINGUISTIC MARKERS OF SELF-FOCUS AND MISERY INCREASE OVER TIME IN POPULAR US SONG LYRICS** Richard S. Pond, Jr.<sup>1</sup>, C. Nathan DeWall<sup>1</sup>, W. Keith Campbell<sup>2</sup>, Jean M. Twenge<sup>3</sup>; <sup>1</sup>University of Kentucky, <sup>2</sup>University of Georgia, <sup>3</sup>San Diego State University – U.S. culture is filled with many cultural products. Yet few studies have investigated how changes in cultural products correspond to changes in psychological traits, emotions, and goals. The current research filled this gap by testing the hypothesis that one cultural product—word use in popular song lyrics—changes over time in a manner similar to cultural changes in individualistic traits and emphasis on intrinsic goals. Linguistic analyses of the 10 most popular songs for each year between 1980 and 2007 ( $N = 280$ ) demonstrated changes in word use that mirror psychological change over the same time period. Over time, use of words related to self-focus and anti-social behavior increased, whereas words related to other-focus, social interactions, positive emotion, and leisurely activities decreased. These findings offer novel evidence regarding the need to investigate how changes in tangible artifacts of the sociocultural environment can provide a window into understanding cultural changes in psychological processes.

#### D10

**EFFECTS OF MESSAGE FRAMING, SELF-CONSTRUAL, AND DESIRABILITY FOR CONTROL ON RESPONSES TO GIVING MESSAGES** Paul M. Connell<sup>1</sup>, Wendy Attaya Boland<sup>2</sup>, Michael A. Kamins<sup>1</sup>; <sup>1</sup>Stony Brook University, <sup>2</sup>American University – Corporate social responsibility messages are often framed from the perspective that an individual is actively making a difference by purchasing. Because individuals with an independent self-construal are likely to be motivated by individual achievements, they ought to prefer messages framed such that they are given credit for giving. Interdependents, being more socially oriented, ought to be indifferent between message frames. In experiment 1, in a 2 (individual/company gives) X 2 (interdependent/independent) design, 67 participants read a scenario framed either as the company or the individual giving to a cause for every purchase. Participants appraised affect toward the company as the dependent measure, and completed a self-construal measure. We observed a significant two-way interaction, where independents preferred the individual-gives message and independents were indifferent between messages. In experiment 2, we explored the role of desire for control (DFC) on preference for message frames. High-DFC individuals can actually react negatively to increased control due to self-presentation concerns. Because interdependents are

less motivated to take credit for actions and are more socially motivated, we believe that individual-gives frames could backfire for high-DFC interdependents. In a 2 (individual/company gives) X 2 (interdependent/independent) X 2 (low/high DFC) between subjects design, 117 participants repeated the procedure used in experiment 1 and also completed a DFC measure. We observed a significant 3-way interaction between message frame, self-construal, and DFC. High-DFC independents preferred the individual-gives message frame, consistent with experiment 1. However, high-DFC interdependents preferred the company-gives message frame, indicating that a "you give" message can sometimes backfire.

#### D11

##### **ASSIMILATION VERSUS REACTANCE TO CULTURAL NORMS IN CREATIVE EXPRESSION: THE ROLE OF CULTURAL CUES AND BICULTURALS' IDENTITY CONFLICT** Aurelia Mok<sup>1</sup>; <sup>1</sup>Columbia University – Bicultural

individuals differ in the degree to which their cultural identities are integrated versus conflicting- Bicultural Identity Integration (BII). Past research finds that BII moderates the effect of cultural cues on self-expressions: whereas integrated biculturals assimilate to the cued cultural norm, conflicted biculturals contrast. We investigate whether this effect extends to creative expressions. Two priming experiments with Asian-American participants showed that cultural cues have different effects on creative generation depending on the level of BII. As hypothesized, cues to American (vs. Asian) culture enhanced novel idea generation (Experiment 1) and divergent thinking (Experiment 2) for integrated biculturals, yet repressed that for conflicted biculturals. Implications for research in bicultural identity, creativity, and organizational behavior are discussed.

#### D12

##### **WHEN YANG IS YIN AND YIN IS YIN: AN EXAMINATION OF THE ORGANIZATION OF POSITIVE AND NEGATIVE EMOTIONS IN MEMORY AMONG ASIANS** Christie Scollon<sup>1</sup>; <sup>1</sup>Singapore Management University –

A well-replicated finding in the subjective well-being literature is that Asians report lower levels of SWB than European Americans. Cultural differences are especially pronounced in global or retrospective reports of emotion and attenuated or non-existent in comparisons of experience sampling (Oishi, 2002; Scollon et al., 2004), leading researchers to believe that cultural differences in SWB are mainly due to differences in the way people recall their emotional experiences. Two studies examined the organization of positive and negative emotions in memory in a sample of Singaporeans. Study 1 examined autobiographical memories. 37 participants wrote about their "most significant positive event." Experts content coded the narratives. While all but one story was positive, 75% of the narratives were also infused with negative content. Over half spontaneously mentioned negative feelings. 1/3 mentioned the positive being the absence of the negative (e.g., not stressed or worried as usual). 1/4 included negative events such as failure or illness. By contrast, a separate sample (N = 37) wrote about their "most significant negative event" which contained little positive emotion. Study 2 (N = 83) used a reaction time paradigm to examine the organization of emotional knowledge (Robinson, 2007). Replicating American studies, Singaporeans showed a positive priming effect such that positive primes facilitated responses to positive stimuli (Robinson & Kirkeby, 2005). However, unlike Americans, Singaporeans also displayed a negativity priming effect such that negative primes facilitated responses to negative targets. The negative priming effect has previously only been found among neurotic Americans (Robinson et al., 2007).

#### D13

##### **THE MEAN(ING) OF LEARNING ACROSS CULTURES: A CROSS-CULTURAL STUDY OF STUDENTS' CONCEPTS OF LEARNING** Marieke van Egmond<sup>1</sup>,

Ulrich Kühnen<sup>2</sup>, Jin Li<sup>3</sup>; <sup>1</sup>Bremen International Graduate School of Social Sciences, <sup>2</sup>Jacobs University Bremen, <sup>3</sup>Brown University – Culture influences social cognitive processes involved in the learning process. Students from Asia and the West differ on achievement motivation (Ho &

Hau, 2008) self-concept (Markus & Kitayama, 1991) and cognition (Nisbett, Peng, Choi & Norenzayan, 2001). Lacking from the field so far is a theoretical framework about the meaning that is attached to the concept of learning in different cultures. A survey was conducted at an international university in Germany (N=294) to develop such a theory. The survey was based on the theory that due to different philosophical traditions, Western students have a 'mind oriented' approach to learning and Asian students have a 'virtue oriented' approach (Li, 2003). At the core of the 'mind orientation' is doubt towards pre-existing knowledge. Learning is seen as the perfection of critical thinking skills. In the 'virtue orientation' learning is seen as the pursuit of moral and social development, with respect and diligence as guiding principles. Results show a significant cultural difference between Western and East-Asian students. Asians score significantly higher on the virtue orientation ( $F(1,104) = 3.85$ ;  $p=.05$ ). Reliability of the developed scale was high ( $\alpha=.91$ ). Whereas mind orientation significantly correlates with academic satisfaction for Western-European students ( $r=.28$   $p=.023$ ), this correlation is absent for East-Asian students. Additionally, an intercultural change over time is observed for East-Asian students. Cross-sectional results indicate an increase in mind orientation over time ( $F(1,100) = 2.830$ ;  $p<.05$ ). This development towards the Western meaning system does however not occur at the expense of the virtue orientation, which remains equally highly endorsed.

#### D14

##### **CULTURAL GROUNDING OF EXPLICIT VS. IMPLICIT COMMUNICATION IN CLOSE RELATIONSHIPS** Amanda Eggen<sup>1</sup>, Yuri Miyamoto<sup>1</sup>, Yukiko Uchida<sup>2</sup>;

<sup>1</sup>University of Wisconsin - Madison, <sup>2</sup>Kyoto University – This study explores communication media across cultures and how they are related to relationship quality. Cross-cultural studies have shown that in independent cultures, people often use words to explicitly communicate thoughts and feelings (i.e., low-context; Hall, 1976), while in interdependent cultures, people often attend to implicit subtle, contextual cues in order to elude messages and to understand the other person's thoughts and feelings (i.e., high-context; Hall, 1976). Although cultural differences in ways of communication have been documented, how they are related to relationship quality is not well understood. We hypothesized that explicit communication should be more important for relationships in Western cultures than in Eastern cultures. Alternately, implicit communication should be more important for relationships in Eastern cultures than in Western cultures. In two studies, European American and Japanese undergraduates read vignettes that depict interactions between two communication pairs – one pair who primarily explicitly communicates, and one pair who primarily implicitly communicates. The communication pairs were married couples in study 1 and friends in study 2. Participants then indicated how satisfying they found the relationships. As hypothesized, Americans rated explicit communication pairs as having higher relationship quality than Japanese did, and Japanese rated implicit communication pairs as having higher relationship quality than Americans did. The results suggest that explicit communication is linked to higher perceived relationship quality for Americans than Japanese, while implicit communication is linked to higher perceived relationship quality for Japanese than Americans.

#### D15

##### **FREE WILL OR CULTURALLY CONSTRUCTED IDEAL? - COMPARING AMERICAN AND CHINESE SELF-PERCEIVED AUTONOMY IN DECISION MAKING PROCESS** Julie Chen<sup>1</sup>, Valerie Martin<sup>1</sup>, Rebecca Tarvin<sup>1</sup>;

<sup>1</sup>Gettysburg College – A cross-cultural study of perceived decision making autonomy was conducted between 172 American and 216 Chinese participants. Participants were asked to allocate the decision making accountability in six important life domains to members in their life (self, professors/advisors, romantic partner, friends, family, media). Then they repeated the process from a friend's perspective and a stranger's (from the opposite culture) perspective. Results showed that American participants had significantly higher perceived decision autonomy for themselves by allocating higher decision making accountability to self

when taking the self perspective, relative to the friend perspective. Chinese participants, on the contrary, perceived themselves to be equally autonomous as their friends. American participants perceived Chinese to be less autonomous than themselves and their friends. Chinese participants perceived Americans to be more autonomous than themselves and friends. Cultural priming manipulation, using American and Chinese cultural icons revealed marginally significant contrast effect from the American participants.

#### D16

**CULTURAL DIFFERENCES IN SELF-CRITICISM: DIFFERING REACTIONS TO THOSE WHO AGREE WITH OUR SELF-ASSESSMENTS** Quan Lam<sup>1</sup>, Jill A. Jacobson<sup>1</sup>; <sup>1</sup>Queen's University – In this research, we sought to investigate whether the self-critical behavior that East Asians typically display to others (cf. Heine et al., 1999) is genuine self-criticism or simply a self-presentational style. According to Goffman's (1955) facework hypothesis, individuals self-criticize to elicit support and reassurance from others. Furthermore, social norms dictate that when other people are down, we should not attack them, but instead we should attempt to make them feel better. In light of Goffman's work, we wondered if East Asians self-criticize for the purpose of pre-empting negative feedback from others. If so, they should react differently depending on how their self-criticisms are received by others. European-Canadian and East Asian-Canadian participants made the first attempt at completing a puzzle before transferring it to their partner (actually a confederate) to finish. Upon transferring the puzzle, participants also indicated to their partner how well they thought they did, to which the confederate partner responded either by giving the participants positive or negative feedback about their performance. No cross-cultural differences in liking were observed when participants self-criticized and were given positive feedback or when they self-enhanced and were given positive or negative feedback, although the partners in the latter condition were liked less than those in the other two conditions. The only cross-cultural difference was observed when participants' self-criticisms were met with negative (i.e., agreeing or counternormative) feedback. In this condition, Asian-Canadians rated their partner as more likable than did European-Canadians, which would seem more supportive of a genuine than a self-presentational explanation.

#### D17

**CULTURAL VARIATION IN THE EFFECTIVENESS OF SOLICITED AND UNSOLICITED SOCIAL SUPPORT** Taraneh Mojaverian<sup>1</sup>, Heejung S. Kim<sup>1</sup>; <sup>1</sup>University of California, Santa Barbara – Research has shown that Asian/Asian Americans (AAs) are less likely to use social support to deal with stressful situations than European Americans (EAs). Concerns with maintaining group harmony and the possibility of disrupting social ties among AAs are considered as contributors to this cultural discrepancy. This research examined the effectiveness of two types of social support: support that is sought directly (solicited support) and support received without prompting from the recipient (unsolicited support). With emphasis on maintaining personal agency for EAs, unsolicited social support may negatively impact self-efficacy and self-esteem, while actively soliciting social support may not. Given the importance of interdependence in Asian cultures, receiving unsolicited social support may reinforce social belonging and relational ties for AAs, and soliciting social support may have the negative social ramifications discussed in previous studies. The current study examined the impact of culture (EA v. AA) and mode of social support (solicited v. unsolicited) on stress responses to a task. Participants performed a stressful task in an experimental setting with the option of seeking support from a confederate participant (solicited support) or were automatically given support from the confederate (unsolicited support). Results supported our hypothesis, with EAs benefiting more from solicited support, reporting lower levels of stress, more success with the task, and higher state self-esteem. Unsolicited support was more effective for AA participants, who reported

lower levels of stress, more success with the task and more liking for the confederate. Implications for cultural differences in coping styles and their effectiveness are discussed.

#### D18

**THROUGH TIME AND SPACE: VARIATION OF INDIVIDUALISM-COLLECTIVISM IN JAPAN** Hidehumi Hitokoto<sup>1</sup>, Toshiyuki Murabe<sup>1</sup>, Kenichi Narita<sup>2</sup>, Junko Tanaka-Matsumi<sup>2</sup>; <sup>1</sup>Kwansei Gakuin University, <sup>2</sup>School of Literatures, Kwansei Gakuin University – Cross-cultural studies of Individualism-Collectivism (IC) have expanded its focus into rich within culture variation (Vandello & Cohen, 1999) that may have resulted from the historical underpinnings of the region (Markus & Lachman, 2002). We measured regional variation of IC within Japan by using prefecture (N=47) level indicators collected from the Japanese census archive covering the period between 1960 and 2005. We derived the IC score by submitting the parameters of living such as the size of the family, type of residence, divorce rate, parameters of industry into ecological factor analysis (Hofstede, 2001). IC score showed convergent validity with the regional score of subjective culture (e.g. importance of privacy, number of friends and voluntary relationships, well-being explained by relationship satisfaction independent of self-esteem in the region) that we obtained in different studies. Using the IC score, we were able to map the whereabouts of IC, from high individualism (low collectivism) (Kitayama, Ishii, Imada, Takemura, & Ramaswamy, 2006) to low individualism (high collectivism) prefecture in Japan. We further searched for the antecedents that can explain this regional variation using regression analysis and cross-lagged effect model. We found that approximately 70% of the IC score variance in 2005 could be explained by 1) the amount of people's mobility (Oishi, Lun, & Sherman, 2007), 2) mortality rate by tuberculosis after the World War II (Fincher & Thornhill, 2008), 3) levels of humidity (Watsuji, 1931), and 4) some variable related to the economic growth period. Stability and changes of Japan are discussed.

#### D19

**STRENGTH OF WEAK TIES ACROSS CULTURES: CROSS-CULTURAL EXAMINATION OF ACQUAINTANCESHIP** Takeshi Hamamura<sup>1</sup>; <sup>1</sup>The Chinese University of Hong Kong – Individuals' social relations consist of strong ties (e.g., family, friends) and weak ties (e.g., acquaintances) (Granovetter, 1973). Although the importance of strong ties is obvious, weak ties are also important for well-being by ensuring variety and diversity in our social exchanges. For instance, through acquaintances people are able to access information they would not otherwise come across. Strength of weak ties, however, may differ across cultures. Prior research shows that cultures differ in the nature of social relations. In some societies such as North American societies, social relations tend to be relatively open, and individuals frequently and voluntarily enter into and terminate their social relations. In contrast, in other societies such as societies in East Asia, social relations tend to be less open, and individuals in these societies are embedded in relatively fixed and long-lasting social relations. This theorizing suggests cultural differences in acquaintanceship. Two studies were conducted to examine acquaintanceships across cultures. These studies found that although Chinese and Western participants were similarly approach-focused toward their friends, toward acquaintances Chinese were much less approach-focused compared to Westerners. The similar culture and relationship-type interaction was found on relationship satisfaction as well. Implications are discussed.

#### D20

**CULTURAL DIFFERENCES BETWEEN ASIAN AND WHITE AMERICANS: A STUDY ON FAMILY STRAIN AMONG COLLEGE STUDENTS** J. Mendiola<sup>1</sup>, K. A. Cotter<sup>1</sup>, H. Valdez<sup>1</sup>; <sup>1</sup>California State University, Sacramento – Culture can influence the experience of social interactions. A collectivistic versus an individualistic cultural background can influence the experience of social strain from family members. In a cross-sectional survey of 125 undergraduates (72% women), we compared Asian (n = 42) and White (n = 83) Americans on perceived and received family strain. Asian Americans (M = 2.50, SD = .70) reported more perceived family strain than

Whites ( $M = 2.10$ ,  $SD = .60$ ),  $F(1, 121) = 3.83$ ,  $p = .05$ ,  $\eta^2 = .03$ . However, gender moderated this effect such that Asian women ( $M = 2.57$ ,  $SD = .71$ ) reported more perceived family strain than Asian men ( $M = 2.28$ ,  $SD = .64$ ), whereas White men ( $M = 2.28$ ,  $SD = .61$ ) reported more family strain than White women ( $M = 2.03$ ,  $SD = .58$ ),  $F(1, 121) = 3.98$ ,  $p = .05$ ,  $\eta^2 = .03$ . The same main effect of race was found for received family strain: Asian Americans ( $M = 2.41$ ,  $SD = .85$ ) reported more received family strain than Whites ( $M = 1.99$ ,  $SD = .69$ ),  $F(1, 111) = 14.26$ ,  $p < .001$ ,  $\eta^2 = .11$ . Race interacted with cohabitation status, such that Asian Americans living with their romantic partner ( $M = 3.28$ ,  $SD = 1.16$ ) reported more received family strain than Asian Americans not cohabiting ( $M = 2.32$ ,  $SD = .78$ ) and Whites (not cohabiting  $M = 2.01$ ,  $SD = .71$ ; cohabiting  $M = 1.92$ ,  $SD = .64$ ). Implications for culturally sensitive relationship counseling are discussed.

### D21

**COMMITMENT TO ONE'S ETHNIC IDENTITY AND WELL-BEING: THE ROLE OF AUTONOMY SUPPORT FROM FRIENDS** Yuna Ferguson<sup>1</sup>, Neetu Abad<sup>1</sup>, Kennon M. Sheldon<sup>1</sup>; <sup>1</sup>University of Missouri-Columbia – Much research has examined ethnic identity, which refers to acceptance of and commitment to one's ethnic group and the exploration of one's heritage, as a predictor of various psychological outcomes, including lower depression and suicide and higher well-being. However, surprisingly few studies have examined factors that influence minority individuals' ability to form an ethnic identity. To address this gap, the current study investigated the role of autonomy support from friends, particularly when the friends are ethnically divergent from the target individuals. Past research on self-determination theory demonstrates that having one's autonomy supported within close relationships predicts well-being and positive identity formation, perhaps because such support fosters unconditional self-acceptance and self-expression. Based on this research, the current study hypothesized that ethnic minority individuals' experience of autonomy support within close peer relationships would be positively associated with their own ethnic identity, which would then positively predict their well-being. To test this model, 48 college students of minority or bicultural status completed self-report measures of well-being, Phinney's (1992) Multi-Group Ethnic Identity Measure, and the experience of autonomy support from ethnically divergent friends. Results showed that autonomy support positively predicted minority individuals' identification with their ethnic group, even after controlling for alternative explanatory variables such as relationship closeness and duration. Furthermore, ethnic identity commitment partially mediated the relationship between autonomy support and well-being. When close friends support minority individuals' right to make their own choices, they are more likely to embrace their heritage and experience well-being benefits as a result.

### D22

**CULTURAL DIFFERENCES IN ATTITUDINAL AMBIVALENCE** Andy Ng<sup>1</sup>, Michaela Hynie<sup>1,2</sup>, Tara MacDonald<sup>3</sup>; <sup>1</sup>York University, <sup>2</sup>York Institute for Health Research, <sup>3</sup>Queen's University – The antecedents and consequences of attitudinal ambivalence have been widely studied among North Americans (see Petty & Krosnick, 1995). However, attitudinal ambivalence has not received much cross-cultural study. We compared the amount of potential attitudinal ambivalence toward everyday objects among Canadian students of 3 cultural backgrounds: East Asian ( $N = 94$ ), South Asian ( $N = 170$ ), and European ( $N = 260$ ). Because East Asians exhibit naive dialecticism and thus tolerate contradictions (Peng & Nisbett, 1999), we hypothesized that East Asian Canadians (EAC) would exhibit more ambivalent attitudes than European Canadians (EC). South Asian culture does not endorse dialectical philosophy but is a highly collectivist society, so South Asian Canadians (SAC) are an interesting comparison group. EACs, SACs, and ECs rated their overall attitudes, attitude strength, and separate positive and negative attitudes toward 16 everyday objects (e.g., flowers, exams). An ambivalence score for each object was then calculated (Thompson, Zanna, & Griffin, 1995). ANOVAs indicated that EACs were significantly higher than ECs and SACs

on their average ambivalence level, collapsed across all objects. There was also no one object for which EACs exhibited lower levels of ambivalence than their EC and SAC counterparts. In contrast, SACs and ECs did not differ in ambivalence. In addition, positive attitudes were moderately correlated with attitude strength for ECs and SACs whereas negative attitudes were moderately correlated with attitude strength for EACs, suggesting positivity bias for ECs and SACs but negativity bias for EACs in their attitude strength. Implications of these findings are discussed.

### D23

**SOCIETAL DIFFERENCES IN THE IMPORTANCE OF BEING UNIQUE: INDIVIDUALISM AS AN ADAPTIVE TOOL FOR "OPEN" SOCIETIES** Kosuke Takemura<sup>1</sup>; <sup>1</sup>Kyoto University – The current research examined the hypothesis that a high Need for Uniqueness (NfU) is more positively associated with Subjective Well-Being (SWB) in "open" societies, where people have opportunities to form new social relationships, than in "closed" societies, where relationships are predetermined and stable. In open societies such as the US, one must be attractive to form social relationships with desirable individuals, since others also seek desirable partners. As a result, competitive interpersonal markets can emerge. However, it may sometimes be costly to participate in inflated competitions. Thus, being unique or creating one's own unique niche can be a good strategy for individuals to develop "selling points." On the other hand, in closed societies, being ostracized from current relationships can be fatal. Thus, conformity is important since it may lower the risk of being ostracized. This rationale suggests that having a high NfU may bring success in social life for individuals in particular societies, but not in others. Thus, NfU may be positively correlated with SWB in open societies, but not in closed societies. The current study tested this hypothesis by examining the regional differences within Japan. A secondary analysis of representative social survey data within Japan (the Japan Survey on Information Society, Naoi, 2004) was performed and found that, as predicted, the NfU-SWB association was greater in regions of Japan where people were more willing to expand their network of contacts. Implications for studies of individualism are discussed.

### D24

**THE CULTURE OF BACTERIAL AVOIDANCE IN THE U.S.** Ilan Shrira<sup>1</sup>; <sup>1</sup>University of Florida – Cultures with high pathogen levels exhibit norms, values, and behaviors that minimize the transmission of disease. In these cultures, a collectivistic approach to relationships should therefore be adaptive. People in collectivistic cultures tend to maintain strong ties to in-groups (e.g., family), hold a suspicion of out-groups, and exhibit greater discrimination between in-group and out-group members. Xenophobia (fear of out-groups) may function to reduce the risk of disease transmission, while ethnocentrism (favoring one's own group) creates a mutually supportive network should someone in the group fall ill. When parasite threat is low, however, there are fewer costs and more benefits to cultivating a larger social network and trusting out-groups. Without the threat of disease, fluid contact between strangers and acquaintances will lead to fitness-enhancing rewards such as broader coalitions, novel information, and innovations – all markers of individualistic cultures. These predictions are supported by recent cross-cultural research (Fincher et al., 2008). The present study examined whether these patterns would also exist in a modernized country, the United States, where mortality from infectious diseases is low. Specifically, this research tested whether the incidence of common infections (e.g., Chlamydia, hepatitis) was related to collectivistic behavior patterns – such as living with extended family, carpooling to work, fewer divorces – at the state level. The data revealed that infection rates strongly predicted collectivism, and these patterns held within regions of the country as well. The results suggest that even in relatively benign environments, pathogen levels influence how people approach relationships and structure their environment.

**D25****WHEN DO PEOPLE INTERNALIZE CULTURALLY DOMINANT WAYS OF SEEING THINGS? A DEVELOPMENTAL STUDY OF JAPANESE ELEMENTARY SCHOOL CHILDREN'S DRAWING STYLES** Sawa Senzaki<sup>1</sup>, Takahiko Masuda<sup>1</sup>; <sup>1</sup>University of Alberta – Findings of research into culture and attention indicate that traditional Japanese landscape paintings tend to have a horizon placed significantly higher, and to include a greater number of objects than traditional Western paintings. These findings suggest that the Japanese paintings present a more holistic view of the landscape.

Furthermore, the authentic preferences of contemporary college students in East Asian and Western cultures reflect the patterns found in traditional paintings in the students' respective cultures (Masuda, Gonzalez, Kwan, & Nisbett, 2008, PSPB), suggesting internalization of a culturally dominant way of seeing. The current study further examined the precise period during which this internalization processes took place, by investigating drawing styles of children in first through sixth grades in a public elementary school in Kamakura, Japan. Children were asked to either freely draw a landscape picture or make a collage of a landscape, and the placement of the horizon and the number of objects included were measured. The results indicated that Japanese elementary school children gradually developed an understanding of the concept of a horizon, and most of them showed a complete understanding by the fourth grade. More importantly, after children acquired the concept of a horizon, they placed the horizon within the top 25% of the frame. In addition, whereas the number of objects included by children in first through third grades was inconsistent, the fourth graders and their seniors consistently included a large number of objects.

**D26****INDIVIDUALISM/COLLECTIVISM AND THE PIONEER SPIRIT** Steven

Hoekstra<sup>1</sup>; <sup>1</sup>Kansas Wesleyan University – At SPSP in 2009, Kitayama presented Japanese data relating patterns of individualism and collectivism to historical voluntary settlement trends. His data endeavored to test the theory that "American individualism owes importantly to voluntary settlement by Europeans in the formative years of the United States" and that "the subsequent expansion of the territory to the west must have also fostered the ethos of independence." The present study revisited the latter portion of this hypothesis by reanalyzing data from two state-based studies (Vandello & Cohen, 1999; Allik & Realo, 2004) with the addition of the founding dates for each state. The resulting correlations and regressions showed that "pioneer states" showed greater levels of individualism, as operationalized by Vandello and Cohen's (1999) archival assessment of that construct. Interestingly, while the "pioneer spirit" appears to be associated with greater individualism, it simultaneously is also positively correlated with indicators of social capital (community engagement, group membership, interpersonal trust). In fact, it appears that these latter variables are substantial mediators of the predictive relationship of states' founding dates on individualism/collectivism. Future studies should replicate with broad-based cross-country sampling using individual self-report/trait assessments of individualism/collectivism. It would also be worthwhile to explore the apparent paradox between individualism and measures of community investments.

**D27****CULTURE AND ESCAPE: ALTERNATIVE WAYS OF DEALING WITH THE PROBLEM OF MORTALITY** Christine Ma-Kellams<sup>1</sup>, Jim Blascovich<sup>1</sup>;

<sup>1</sup>University of California, Santa Barbara – Four studies focused on terror management by exploring cultural differences in the use of escapism as an alternative way of dealing with the problem of death. Findings show that: 1) East-Asians do not demonstrate the same defensive responses post-mortality salience (MS) that European-Americans typically demonstrate; 2) East-Asians, when given the opportunity to use an alternative form of escapist (in our case, humor) responding to MS, prefer to use the escapist response more than European-Americans; 3) East-Asians, when given the opportunity to choose from a variety of possible responses (both escapist and defensive) post-MS, prefer the escapist responses

more so than European-Americans; and 4) East-Asians do not prefer escapist coping responses in general but specifically to mortality salience. Implications for terror management and the psychological functionality of escape are discussed.

**D28****FEELING GOOD OR FEELING BAD ABOUT THE RESULTS? MOOD ATTRIBUTION MATTERS IN SELF-REGULATION: CULTURAL PERSPECTIVE** Meng Zhang<sup>1</sup>, Susan Cross<sup>1</sup>; <sup>1</sup>Iowa State University – Americans and Chinese tend to behave differently in response to success or failure. The purpose of this study is to investigate whether mood attribution moderates these differences. American and Chinese participants were given critical thinking tasks in the lab and were given feedback (positive or negative) afterward. Half of the participants were led to misattribute their moods (positive or negative) to music rather than the task feedback (positive or negative). Participants' persistence on a second similar task was measured. Results revealed that there was a significant three-way interaction. American participants who received positive feedback from their previous task persisted more only if they attributed their positive moods to the successful performance. The pattern for Chinese participants was different. Chinese participants who received negative feedback will persist more only if they attribute their negative moods to their previous failure. In short, mood attribution moderated the relationship between the feedback valence and self-regulation among different cultural groups.

American participants who received positive feedback from their previous task persisted more only if they attributed their positive moods to the successful performance. The pattern for Chinese participants was different. Chinese participants who received negative feedback will persist more only if they attribute their negative moods to their previous failure. In short, mood attribution moderated the relationship between the feedback valence and self-regulation among different cultural groups.

**D29****CULTURE OF HONOR AND SUICIDE** Lindsey L. Osterman<sup>1</sup>, Ryan P.

Brown<sup>1</sup>; <sup>1</sup>University of Oklahoma – Joiner's (2004) theory of suicide posits that suicidality is characterized by three psychological factors: a sense of burdensomeness, feeling of isolation, and desensitization to hurting oneself. This theory has been empirically supported at the individual level, and we suggest that it can also be usefully applied at a cultural level. Although there exist individuals in all cultures who experience suicidality, we suggest that cultures of honor (Nisbett & Cohen, 1996) might foster values that put males at a particular risk for suicide. Namely, cultures of honor place a particularly high premium upon males' ability to protect and provide for family, promote the value of self-sufficiency, and sanction the use of retaliatory violence, all of which might heighten male risk for experiencing the psychological states that Joiner describes. We examined the hypothesis that both culture of honor and state-level variables conceptually analogous to Joiner's three factors uniquely predict male suicide rates. To do so, we obtained state-level data on economic factors (i.e., median income and an income inequality index), indices of social connectedness (i.e., divorce rates, transiency, collectivism, and proportion of population living in rural areas), gun ownership, culture of honor status, and suicide rates for males and females. A linear regression revealed that culture of honor status, economic factors, and social connectedness variables all uniquely predicted interstate variance in male suicide rates ( $R^2=.690$ ). Female suicide, though predicted strongly by some social connectedness variables, was only weakly related to economic factors and not at all related to culture of honor ( $R^2=.476$ ).

**D30****GLOCALIZATION AND CULTURAL REAFFIRMATION: FACTORIAL STRUCTURE OF CULTURAL VALUES FOR VIETNAMESE VS. VIETNAMESE AMERICANS** Angela-MinhTu D. Nguyen<sup>1</sup>, Que-Lam Huynh<sup>2</sup>, Veronica Benet-Martinez<sup>1</sup>;

<sup>1</sup>University of California, Riverside, <sup>2</sup>San Diego State University – Cultural reaffirmation occurs when bicultural individuals endorse their heritage values to a greater extent than do monocultural individuals in the native country (Kosmitski, 1996). A possible explanation is cultural encapsulation (Kim-Jo, Benet-Martinez, & Ozer, in press), which purports that the heritage culture brought by immigrants to their host country becomes crystallized and transmitted in an unaltered form. Meanwhile, the heritage culture in the native country remains dynamic (Matsumoto, 2000). To further test these propositions and understand the conception of "heritage culture" by bicultural and monocultural

samples, we collected data from 245 Vietnamese American undergraduate students in the US and 150 Vietnamese undergraduate students in Viet Nam regarding Vietnamese (16 items) and Western (specifically American; 17 items) cultural values. Items were written based on traditional Vietnamese values, such as the five cardinal values (Do, 1999), and traditional American values, such as the Horatio Alger myth (Weiss, 1969). Supporting the cultural reaffirmation effect, Vietnamese Americans (regardless of country of birth and age of migration) endorsed Vietnamese values to a significantly greater extent than Vietnamese in Viet Nam. Furthermore, factor analyses indicated that there were differences in the structure of Vietnamese and American values. Specifically, whereas Vietnamese and American values loaded on separate factors for Vietnamese Americans, they loaded together for Vietnamese participants. These findings support the glocalization phenomenon, or the integration of globally dominant Western cultures and local native cultures (Chiu & Hong, 2006). Furthermore, this study contributes to research on group-level acculturation (Berry, 2003) and cultural integration (Benet-Martinez & Haritatos, 2005).

### D31

#### BEYOND CULTURAL PREFERENCE: CULTURE-SPECIFIC BEHAVIOR AS A DEFAULT ADAPTIVE STRATEGY Hirofumi Hashimoto<sup>1,2</sup>, Yang Li<sup>1</sup>, Toshio Yamagishi<sup>1</sup>; <sup>1</sup>Hokkaido University, <sup>2</sup>The Japan Society for the Promotion of Science research fellow DC

— In an experiment with 61 Japanese participants, we successfully replicated Yamagishi, Hashimoto and Schug's (2008) finding in a vignette study that choosing a majority-colored pen (as observed in Kim and Markus' (1999) study) is a reflection of a default strategy (used in situations of which nature is not clearly defined) for avoiding negative reputation, rather than a reflection of their preference for conformity. The experiment was run in five-person groups, each consisting of two real participants and three confederates. One of the participants picked up a pen from a can containing five pens, one of which was a unique colored and the others were majority colored, and passed the can with the remaining pens to the other participants (first choice condition). All the five pens disappeared before the can reached the second participant (because one of the confederates secretly took two pens from the can), and a new can containing the same set of five pens was brought to the second participant (last choice condition). While very few initial choosers (7%) chose a unique pen, about half of the last choosers (48%) chose a unique pen. These results suggest: 1) Japanese participants preferred the unique pen to the majority pen when they were not concerned with other participants' reactions (last choice), and yet, 2) they avoided to choose a unique pen when it might incite negative responses from others. The choice of the majority pen was shown to be a means to avoid negative responses from others.

### D32

#### DOES THE PRESENCE OF SOCIAL OTHERS AFFECT THE FACIAL EMOTION EVALUATION?: CROSS-CULTURAL COMPARISON Kenichi Ito<sup>1</sup>, Takahiko Masuda<sup>1</sup>, Koichi Hioki<sup>2</sup>; <sup>1</sup>University of Alberta, <sup>2</sup>Kobe University

— Past research suggests that people commonly use contextual information to understand facial emotions (Carroll & Russell, 1996). However, few studies systematically tested whether or not people from different cultural backgrounds similarly use contextual information to understand facial emotions. To test the generalizability of the effect across cultures, in Study 1, we used the affective priming paradigm, in which Canadian and Japanese participants categorized happy or sad facial expressions (target) after a brief presentation of congruent or incongruent facial emotions (prime). In Study 2, Canadian and Japanese participants categorized happy or sad facial emotion while simultaneously presented with congruent or incongruent facial emotions. We superimposed the facial expressions used in Study 1 in the way that the faces used as targets were surrounded by the faces used as primes. In both studies, we recorded participants' response latency and their accuracy of categorization. The results indicate both similarity and difference between two cultural groups. Canadian participants and Japanese participants were similar to the extent that both groups categorized the facial emotions

congruent with prime/background faster than the ones incongruent with prime/background. In contrast, Canadian participants were different from Japanese participants that they evaluated facial emotions relatively slower than Japanese participants when contextual information succeeded facial emotions (Study 1). Furthermore, Canadian participants evaluated facial emotions relatively slower than their Japanese counterparts when facial emotions and contextual information were presented simultaneously (Study 2). Cultural differences in context sensitivity and its effect on the facial emotion evaluation are discussed.

### D33

#### EXAMINING THE CROSS-CULTURAL DIFFERENCES OF ATTACHMENT STYLES WITHIN MARRIAGE TYPES BETWEEN ASIAN INDIANS AND AMERICANS Melissa Chan<sup>1</sup>, Ashley K. Randall<sup>1</sup>, Deepti Duggi<sup>2</sup>, Shanmukh V. Kamble<sup>2</sup>, Emily A. Butler<sup>1</sup>; <sup>1</sup>University of Arizona, <sup>2</sup>Karnatak University, India

— Adult attachment styles describe the way in which individuals in romantic relationships relate to each other. Most research on attachment has been conducted in the context of Western style "love" marriages in which partners choose each other, but the majority of marriages in the world are arranged, in which the extended family plays a central role. To investigate whether culture and marriage type influence attachment style, we compared Asian Indian couples living in India (n = 100 couples) with American couples (n = 30). We hypothesized that the Indians would report more anxious and avoidant attachment than the Americans due to cultural values of social harmony and emotional restraint. Specifically, emphasis on social harmony may lead individuals to be more concerned with others' opinions and thus more prone to attachment anxiety. Emotional restraint, on the other hand, might discourage individuals from sharing their problems and thus make them more prone to attachment avoidance. In addition, we hypothesized that individuals in Indian arranged marriages would be more anxious and avoidant than both those in Indian "love" marriages and those in American marriages because arranged marriages hinge on familial approval and require emotional restraint. As predicted, Indian participants reported more avoidance as assessed by the Experiences in Close Relationships scale. Although there was no country difference in anxiety, as predicted, results revealed the highest anxiety levels among Indian arranged marriages. These results demonstrate the importance of cross-cultural research in understanding relationship functioning in our global society.

### D34

#### DOES MONKEY GO WITH PANDA OR BANANA? CULTURAL DIFFERENCES IN THE CATEGORIZATION OF OBJECTS Andrea Zo-Rong Wucherpfennig<sup>1</sup>, A. Timur Sevincer<sup>1</sup>, Hyekyung Park<sup>2</sup>, Shinobu Kitayama<sup>3</sup>; <sup>1</sup>University of Hamburg, <sup>2</sup>Hokkaido University, <sup>3</sup>University of Michigan

— The categorization of objects is a basic cognitive principle to mentally organize the world. Objects can be classified into categories either according to their causal, spatial, or temporal relationships (i.e., relationship-based classification), or according to the similarity of their attributes (i.e., category-based classification). For example, some people may classify a monkey within a category comprising things related to its environment (e.g., bananas, trees, and lianas), whereas other may classify a monkey within a category comprising other mammals (e.g., pandas, lions, and dolphins). Importantly, culture has an influence on people's cognitive structures. Interdependently-oriented people think holistically and focus on relationships between people or objects, whereas independently-oriented people think analytically and focus on the attributes of people or objects (Nisbett, Peng, Choi, & Norenzayan, 2001). Hence, we expected interdependently-oriented people (e.g., Asians) to classify objects based on relationships, while more independently-oriented people (e.g., Europeans) to classify based on categorical memberships. We compared style of categorization of Korean and German participants. Participants were presented with twenty word triads consisting of three objects (e.g., monkey-panda-banana) adopted from Ji, Zhang, and Nisbett (2004), and were asked to group two out of three together. Eight triads were critical

such that two items in each triad shared relational features (e.g., monkey-banana) and that another two shared categorical memberships (e.g., monkey-panda). As expected, results revealed that Koreans used more of relationship-based rule compared with Germans. Our study adds evidence to the cultural influence on basic cognitive principles.

### D35

#### WHY IS IT BAD IF PEOPLE KNOW I CHEATED ON MY SPOUSE? A CROSS-CULTURAL INVESTIGATION OF THE INFLUENCE OF NEGATIVE MORAL JUDGMENTS ON UNRELATED DOMAINS

Jennifer Stellar<sup>1</sup>, Kaiping Peng<sup>1</sup>, Wang Lei<sup>2</sup>; <sup>1</sup>University of California-Berkeley, <sup>2</sup>Peking University – Moral

transgressions have consequences beyond moral judgments. Learning that a person has committed an immoral act not only affects general evaluations about his/her moral character, but also influences judgments about seemingly unrelated domains. One's cultural upbringing may heighten or diminish the extent to which an individual allows moral judgments to cloud non-moral evaluations. We hypothesize that (1) moral transgressions contaminate non-moral evaluations in both collectivist and individualist cultures, but (2) that this phenomenon is stronger in collectivist cultures because, at its core, immoral behavior is a stronger affront to collectivist values. American and Chinese undergraduates read scenarios about three different characters and made evaluations about the characters' future job performance. These evaluations were made both before and after they learned that the characters had committed moral transgressions in their private lives. Immoral behavior negatively impacted evaluations of future job performance in all three scenarios in both cultures. However, evaluations of future job performance dropped significantly more for Chinese participants than for Americans. Potential mediators and moderators are examined. Overall, the results suggest that while immoral behavior universally contaminates judgments of an individual in other non-moral domains, it does so more strongly in collectivist cultures. This study provides indirect evidence for a stronger sensitivity in collectivist cultures to immoral behavior.

### D36

#### AN EXPERIMENTAL TEST OF THE IMPACT OF RELATIONAL MOBILITY ON CASUAL ATTRIBUTION

Masaki Yuki<sup>1</sup>, Kengo Kamaya<sup>1</sup>; <sup>1</sup>Hokkaido University – Research on culture and causal attribution has shown that

North Americans tend to make internal attributions, whereas East Asians tend to make external attributions. From the socio-ecological perspective, we propose that these culturally-bounded tendencies are in fact ecologically valid in the respective societies, varying in the level of relational mobility. In societies high in relational mobility, such as North America, people can choose one's relationships and groups more freely, and their behaviors should actually reflect their internal factors, such as attitudes and personality more strongly. Thus, internal attribution is mostly valid. On the contrary, in societies low in relational mobility, such as East Asia, people are confined within the current relationships and groups, so they must behave in accordance with the expectations from others. Thus, external attribution is, in most cases, accurate. The current study aimed at testing this hypothesis conceptually, using a situational priming method. Ninety-four Japanese undergraduates were asked to read an essay that maintained that the Japanese society was either still low in relational mobility, or had become dramatically high in relational mobility recently. Then they were asked to write down what kinds of behaviors are adaptive in such a society, followed by the distraction task. Then, they were asked to indicate how much they agreed with the statements that human behaviors are determined by internal attributes. As predicted, participants who read the high relational mobility essay endorsed the internal attribution statements more strongly than did those who worked on the low relational mobility essay.

### D37

#### UNPACKING CULTURAL DIFFERENCES IN ALEXITHYMIA: A CROSS-CULTURAL EXAMINATION OF THE ASSOCIATION BETWEEN CULTURAL VALUES AND EXTERNALLY ORIENTED THINKING

Jessica Dere<sup>1</sup>, Carl F. Falk<sup>2</sup>, Steven J. Heine<sup>2</sup>, Andrew G. Ryder<sup>1,3</sup>; <sup>1</sup>Concordia University, <sup>2</sup>University of British Columbia, <sup>3</sup>SMBD-Jewish General Hospital – Alexithymia,

a multi-faceted personality construct, refers to a general deficit in the ability to identify emotional states and to describe these states to others (Taylor, 2004). Three main components of this construct are difficulty identifying feelings (DIF), difficulty describing feelings (DDF), and externally oriented thinking (EOT). Ryder and colleagues (2008) found that higher overall levels of alexithymia among Chinese as compared to Euro-Canadian outpatients were explained by group differences in EOT. They proposed that EOT might be encouraged in a Chinese cultural context, which places greater focus on interpersonal relationships than on inner emotional experiences. The current study sought to test the hypothesis that EOT is more strongly shaped by culture than are DIF and DDF, by examining associations between the components of alexithymia and cultural values. Chinese-Canadian (n=159) and Euro-Canadian (n=290) undergraduates completed the Toronto Alexithymia Scale (Bagby et al., 1994), the Asian Values Scale-Revised (Kim & Hong, 2004) and the Euro-American Values Scale for Asian-Americans-Revised (Hong et al., 2005). Chinese-Canadian participants reported higher levels of alexithymia, attributable entirely to higher levels of EOT ( $p < .01$ ). EOT was significantly predicted by Asian values ( $\beta = .235$ ,  $p < .01$ ) and Euro-American values ( $\beta = -.297$ ,  $p < .01$ ) among Chinese-Canadians and by Euro-American values ( $\beta = -.215$ ,  $p < .01$ ) among Euro-Canadians, after controlling for DIF and DDF. Neither DIF nor DDF were significantly predicted by values. In addition, Asian and Euro-American values taken together fully mediate the relation between group membership and EOT. These results indicate that inclusion of EOT introduces a cultural bias to the measurement of alexithymia.

### D38

#### ABORIGINAL METIS IDENTITY: THE LINKS BETWEEN CULTURAL IDENTITY, SELF-ESTEEM AND COPING SKILLS

Christine Hole<sup>1</sup>, Jessica J. Cameron<sup>1</sup>; <sup>1</sup>University of Manitoba – Although members of minority

groups have experienced negative treatment and discrimination (Feagin, 1991; Landrine & Klonoff, 1996), identifying with one's minority group is beneficial (Phinney, et al., 1997; Zimmerman, et al., 1996). Group membership can provide a sense of belonging that reflects positively on how members of these groups view themselves (Abrams, 1992). The Canadian Aboriginal population may be particularly relevant for studying the influence of cultural identity due to the fact that this population has become inflicted with both hidden and observable barriers of personal, institutional and systemic bias, discrimination, racism and a general lack of socioeconomic equality (Canadian Council on Social Development, 2000; CERD Report, 2002). Although previous studies on other ethnic groups (Grossman & Davids, 1985; Martinez & Dukes, 1997) has demonstrated that cultural identity has positive effects, the historical and current climate of the Aboriginal population may make cultural identification problematic. The present study examined the extent to which cultural identity bolsters one's self-esteem level and in turn predicts increases in coping ability. Data was gathered through Statistics Canada on a weighted sample of 340,440 Canadian Aboriginal Adults from the Métis population. Overall, path-analytic results indicate that self-esteem partially mediates the link between cultural identity and coping for Métis adults. Participants who reported stronger identification with the Métis culture exhibited higher self-esteem which in turn was associated with better coping abilities. Reciprocal influences of coping and self-esteem will be discussed along with the potential implications of the present findings for counseling, prevention programs and policy change.

**D39**

**PROTOTYPES OF HONOR IN TURKEY AND THE UNITED STATES** Berna Gercek Swing<sup>1</sup>, Susan Cross<sup>1</sup>, Ayse Uskul<sup>2</sup>, Cansu Akozkan<sup>3</sup>, Zeynep Sunbay<sup>4</sup>, Bilge Ataca<sup>5</sup>, <sup>1</sup>Iowa State University, <sup>2</sup>University of Essex, <sup>3</sup>Istanbul Bilgi University, Turkey, <sup>4</sup>University of Southampton, UK, <sup>5</sup>Bogazici University, Turkey – What does it mean to be an "honorable person"? Three studies address that question using a prototype approach. American and Turkish participants responded to open ended questions pertaining to the meaning of honor. Turkish participants generated 70 concepts, 59% of which were simultaneously generated by 5% or more of the sample. The most common concepts were "honesty" (mentioned by 40% of the sample), and "chastity" (namus; mentioned by 20% of the sample). American participants generated 75 concepts, 45% of which were simultaneously generated by 5% or more of the sample. The most common concepts were "to be respected" and "doing the right thing" (mentioned by 19% of the sample). These results imply greater consensus in the definition of honor in Turkey than in America. In Study 2, a sample of Turkish participants rated the importance of the original 70 Turkish concepts. The most important concept was "not to be unjust", whereas the least important concept was "to fit into customs and traditions". Similarly, a sample of American participants rated the importance of the original 75 American concepts. The most important concept was "honesty", whereas the least important concept was "being smart". In Study 3 Turkish and American participants rated the importance of the combined words generated in Study 1. The concepts generated by Turks were considered equally important by Turks and Americans, whereas the concepts generated by Americans were considered more important by Americans. These findings are important first steps in explicating Turkish and American lay conceptions of honor.

**D40**

**PATHWAYS TO PATHOLOGIZING: DO PERCEPTIONS OF ABNORMALITY DIFFER ACROSS CULTURES?** Lauren Ban<sup>1</sup>, Nick Haslam, Yoshi Kashima; <sup>1</sup>Concordia University, <sup>2</sup>The University of Melbourne – Abnormal behavior seems common (Ahn, Novick & Kim, 2003) and morally acceptable (Meehl, 1973) to the extent it is understood. Evidence for cultural differences in cognitive style suggests there may be variations in this 'reasoning fallacy'. If East Asians think holistically and Western Europeans, analytically (Nisbett, 2005), the effect of understanding on perceptions of abnormality may differ according to culture. Moreover, Haslam's (2005) theory of 'folk psychiatry' suggests there are multiple criteria by which people judge abnormality. Two studies examined the differential bases on which people from East Asian and 'Western' cultural backgrounds judge abnormality. Fifty-one students from a 'Western' cultural background and 51 students from an East Asian cultural background read descriptions of abnormal behaviour featuring either causal or non-causal information. The results indicate that for 'Westerners', behavior is seen as common ( $p = 0.01$ ) and morally acceptable ( $p = 0.03$ ) to the extent it is understood. By contrast, understanding had no effect on the extent to which East Asians saw behavior as common ( $p = 0.22$ ) and morally acceptable ( $p = 0.79$ ). In a reversal of the 'reasoning fallacy', understanding made abnormal behavior seem more worthy of stigma in the East Asian context (social distance:  $p = 0.01$ , authoritarianism:  $p = 0.05$ , social restrictiveness:  $p = 0.06$ ). Attributions of moral responsibility were partially explainable through cultural differences in traditional social values ( $p = 0.02$ ). Cultural variations in pathologizing style were attributed to the differential salience of normative frameworks, which are grounded in culturally specific conceptions of the person.

**D41**

**DETECTING AND EVALUATING DIFFERENTIAL ITEM FUNCTIONING OF THE ROSENBERG SELF-ESTEEM SCALE IN THE U.S. AND CHINA** Huajian Cai<sup>1</sup>, Hairong Song<sup>2</sup>, Jonathon D. Brown<sup>3</sup>, Kevin J. Grimm<sup>2</sup>; <sup>1</sup>Henan University, <sup>2</sup>UC Davis, <sup>3</sup>University of Washington – Using an item response theory based approach (i.e., likelihood ratio test with an iterative procedure), we examined the equivalence of English- and Chinese-language versions

of the Rosenberg Self-Esteem Scale (RSES) in a sample of American ( $N = 551$ ) and Chinese college students ( $N = 380$ ). Results from differential item functioning analysis (DIF) showed that these two language versions of the RSES were not fully equivalent at the item level as well as at the scale level. The two cultural groups did not use the scale comparably, with American students showing more extreme responses than the Chinese students. Moreover, we evaluated the practical impact of DIF and found that cultural differences in average self-esteem scores disappeared after the DIF was controlled. We discuss the implications of our findings for cross-cultural research and provide suggestions for future studies using the RSES in China.

**Emotion****D42**

**EMOTIONAL VALUES AND EMOTIONAL RESPONSE: DOES IDEAL AFFECT INFLUENCE HOW PEOPLE EXPERIENCE EMOTIONAL EVENTS?** Louise Chim<sup>1</sup>, Alice Moon<sup>2</sup>, Jeanne L. Tsai<sup>1</sup>; <sup>1</sup>Stanford University, <sup>2</sup>University of California, Berkeley – Previous findings suggest that people's ideal affect (the affective states they value and ideally want to feel) predicts what types of activities people engage in to feel good. For example, people who value excitement states are more likely to participate in physically rigorous sports than people who value calm states. Does ideal affect influence how people actually experience emotional events? We hypothesize that the more people value the affective states that are elicited by an event, the more positively and less negatively they experience that event. In Study 1, 31 European Americans, 29 Asian Americans, and 30 Mainland Chinese participants watched calm film clips and reported their emotions after each clip. Across cultural groups, the more people valued calm states, the more relaxed they felt; conversely, the more people valued excitement states, the less happy and more bored they felt. Participants also watched exciting clips, but they were not effective in eliciting excitement. Therefore, in Study 2, 41 European Americans and 40 Asian Americans played an exciting (boxing) and calm (yoga) video game. Immediately after, participants described the game using one emotion word and reported their emotions. Across cultural groups, the more people valued calm states, the more likely they were to describe the yoga game as calm or pleasant, the less likely they were to describe the boxing game as exciting or pleasant, and the more they felt negative emotions during the boxing game. As predicted, these findings suggest that ideal affect shapes how people experience emotional events.

**D43**

**THE EFFECTS OF IDEAL BODY MEDIA ON RESTRAINED EATERS' IMPLICIT MOOD** Jessica Boyce<sup>1</sup>, Roeline Kuijer<sup>1</sup>, David Gleaves<sup>1</sup>; <sup>1</sup>The University of Canterbury, New Zealand – Idealized body media (IBM), such as thin images of women in advertising and the media, appears to negatively affect women's emotional state, including their mood. To our best knowledge, however, all experimental studies that have assessed their participants' mood following IBM exposure have used explicit measures (e.g., VAS; POMS). Some propose that explicit (conscious and controllable) and implicit measures tap into different parts of self-knowledge (e.g., Banaji, 2001). Moreover, if a participant links IBM exposure to the dependent variables the study may be more vulnerable to demand characteristics and produce inflated negative responses (Mills et al., 2002). Thus, we examined the effect of IBM on a subtle/implicit mood measure (developed by Hass et al., 1992). Also, because research suggests that IBM can more negatively affect restrained eaters (i.e., chronic dieters, Herman & Polivy, 1980), we assessed this individual difference as a potential moderator. Disguised as an investigation of 'Hunger and Memory', we measured restraint (embedded among filler items), and then in a follow-up session female participants ( $N = 118$ ) were exposed to IBM (vs. control) and completed the implicit mood test – disguised as a memory test – twice, pre and post exposure. We also assessed body-satisfaction in a "second, unrelated study." Among restrained eaters, exposure to IBM increased negative mood as measured implicitly, i.e., this occurred

without using explicit measures or prompting negative responses. Exposure to IBM also decreased their body-satisfaction. This is the first indication that IBM can affect implicit mood measures and is an important addition to this literature.

#### D44

**PATTERNS OF EMOTIONAL EXPERIENCE AS IMPLICIT MEASURES OF ACCULTURATION: MEXICAN AND KOREAN MIGRANTS IN THE US, AND TURKISH MIGRANTS IN BELGIUM** Jozefien De Leersnyder<sup>1</sup>, Batja Mesquita<sup>1</sup>, Heejung Kim<sup>2</sup>, Gabby Gomez<sup>2</sup>; <sup>1</sup>University of Leuven, Belgium, <sup>2</sup>UC Santa Barbara – A person's emotions tend to embody the central meanings and practices of the cultural contexts in which he/she engages. In most cases, emotions as socialized thus help a person to interact and relate to others in ways that are valued and effective. The question addressed by the studies here described is what happens if a person moves from one cultural context to another or between cultures, as is the case in immigrant groups. Two studies investigated the concordance of emotional experiences between immigrant and cultural mainstream community samples. Emotional patterns across eight types of self-described situations were obtained from Mexican (n=106) and Korean (n=74) minorities in the US (Study 1) and Turks (n=167) in Belgium (Study 2). These individual emotional patterns were compared to the average patterns of a cultural mainstream sample (Belgians n=99, European Americans n=78) for each type of situation. This method provided emotional concordance scores for each participant. Multiple hierarchical regressions were conducted in order to predict migrants' emotional concordance scores with other acculturation-indices. Whereas migrants' emotional concordance could not be predicted by explicit measures of acculturation (attitudes, self-reported behavior), implicit measures reflecting engagement in mainstream culture (language proficiency, social relationships with members of mainstream culture) predicted an individual's emotional concordance well. These findings support the existence of 'emotional acculturation,' and suggest that the changes in experienced emotion are implicit measures of acculturation that are not necessarily associated with the more consciously subscribed changes, such as those in values and identity.

#### D45

**REGULATION OF MEANING IN EVERYDAY LIFE: PRO-SOCIAL CONSEQUENCES OF BOREDOM** Wijnand A. P. van Tilburg<sup>1</sup>, Eric R. Igou<sup>1</sup>; <sup>1</sup>University of Limerick – Boredom is an experience that most people have experienced at one point or another. The literature suggests that boredom raises people's uncertainty with regard to the meaningfulness of their behaviors (e.g., Barbalet, 1999) and it often promotes anti-social behaviour (e.g., aggression, racism; e.g., Dahlen et al., 2006). We investigate how anti-social consequences of boredom can be turned into pro-social consequences. We argue that one of the goals that bored people have is to re-establish a sense of personal meaningfulness. As a result, bored people engage in responses that are instrumental for the pursuit of this goal. We tested the hypothesis that charity support increases after experiencing boredom, but that this effect of boredom is limited to situations in which pro-social behaviour is instrumental for re-establishing personal meaningfulness. A series of four experiments is presented that reveals the crucial role of people's need to feel meaningful in displaying pro-social responses when bored. In addition, we manipulated the usefulness of charity support for achieving a sense of meaningfulness. We found that boredom reduced a sense of personal meaningfulness. In addition, boredom promoted charity support when it was useful for establishing a sense of meaningfulness of one's behaviour, but this pro-social effect was not observed when charity support was not useful for meaning re-establishment. The results suggest that boredom promotes charity support as a way to re-establish meaningfulness. Our approach has implications for the effects of boredom and how people regulate behaviour in order to establish a sense of meaningfulness.

#### D46

**THE MISERY-IS-NOT MISERLY EFFECT IN INTERTEMPORAL CHOICE** Viral Gandhi<sup>1</sup>, Jennifer Lerner<sup>1</sup>, Elke Weber<sup>2</sup>; <sup>1</sup>Harvard University, <sup>2</sup>Columbia University – The Misery-is-not-Miserly effect refers to the tendency for incidentally sad people to pay higher buying prices in order to acquire a commodity (Lerner, Small & Loewenstein, 2004; Cryder, Lerner, Gross & Dahl, 2008). The question now becomes: Does incidental sadness also make decision makers willing to pay a premium for acquiring goods now versus later? We predicted that it would. Drawing on established methods (e.g., Lerner et al., 2004), subjects experienced a sadness, disgust, or neutral mood induction and then made a series of intertemporal choices, modelled on a paradigm by Kirby, Petrel and Bickel (1999). The experiment included disgust as an additional control condition, allowing us to test the alternative possibility that negatively valenced emotions might increase discount rates in general. Based on prior studies (e.g., Han, Lerner & Zeckhauser, 2009), we expected that disgust would not do so. Results revealed that sad subjects had a significantly higher discount rate than neutral subjects ( $t(39) = 2.21, p < .01$ ). Indeed, sad subjects' discount rate was 92% higher than that of neutral subjects, a large and costly difference of which decision makers were unaware. This effect was significant for all sizes of reward (small, medium and large). The sadness impatience effect was particularly acute for small rewards, resulting in a 111% increase in the discount rate, ( $t(39) = 2.45, p < .01$ ). As hypothesized, disgust did not increase discount rates.

#### D47

**DISGUST SENSITIVITY AS A PREDICTOR OF RELIGIOUS ORIENTATION** John Terrizzi Jr.<sup>1</sup>, Larry Ventis<sup>2</sup>, Natalie Shook<sup>1</sup>; <sup>1</sup>Virginia Commonwealth University, <sup>2</sup>The College of William & Mary – Disgust is a human emotion that has evolved to protect us against the ingestion of toxic substances. However, more recent evidence suggests that disgust can also inform our moral judgments and decision-making (Haidt, 2003). Along these lines, disgust sensitivity has been demonstrated to positively correlate with religious obsessions, particularly preoccupations with fear of sin (Olatunji, Tolin, Huppert, & Lohr, 2005), and with religious fundamentalism (Terrizzi, Ventis, & Shook, 2009). The purpose of the current research was to explore the relationship between disgust sensitivity and religious orientation. Psychologists have identified three distinct religious orientations: (1) extrinsic, which is using religion to achieve an end, (2) intrinsic, which is using religion as an end within itself, and (3) quest, which is characterized by open-mindedness and a willingness to confront existential questions (Allport & Ross, 1967; Batson, Schoenrade, & Ventis, 1993). For the current study, participants completed a battery of questionnaires including measures of disgust sensitivity, the religious life inventory, and the post critical belief scale. The results indicate that global disgust sensitivity, as well as sexual disgust and pathogen related disgust, were positively correlated with the intrinsic religious orientation. There was no relationship between disgust sensitivity and the extrinsic or quest orientations. Disgust sensitivity was also correlated with religious orthodoxy and the affirmation of a religious realm. These results suggest that intrinsically oriented people may be more concerned with moral contamination than extrinsic and quest oriented people because for them, religion provides a stable internal structure for interpreting their social worlds.

#### D48

**THE EFFECT OF POSITIVE EMOTIONS ON MORAL DECISION MAKING** Frederieke van Dongen<sup>1</sup>, Eric Igou<sup>1</sup>; <sup>1</sup>University of Limerick – We assume that specific positive emotions differ regarding their influence on moral decision making. More specifically, we argue that positive emotions with a greater impact on the self raise more self-interest than emotions with less impact on the self, leading to less moral behavior for the first than for the latter type of emotions. We examined situations with a moral conflict between self-interest and other-interest (e.g., distribution of money when sharing is morally normative, giving up personal benefits in order to protect the environment). Study 1 made a distinction between positive emotions based upon their relative impact (influence and duration) on a

person's life: high-impact (e.g., love, happiness) and low-impact emotions (e.g., optimism, euphoria). Study 2 tested the influence of positive emotions on moral decision making in two economical dilemmas. The first moral measure examined tendencies to illegitimately profit from a common good (e.g., evading taxes, illegitimately profiting from social welfare). The second dilemma consisted of a scenario on moral decision making in times of the financial crisis. Consistently, we found that high-impact emotions (e.g., love, happiness) led to less moral decisions (i.e., decisions only based on self-interest, ignoring other's interests) than low-impact emotions (e.g., optimism, euphoria). Study 3 tested our hypothesis in the context of pro-environmental behavior. Again, high-impact emotions led to less moral decisions, that is, damaging the environment to increase own benefits, than low-impact emotions. The implications for the influence of specific positive emotions on moral decision making will be discussed.

#### D49

##### **I'M EMBARRASSED FOR YOU: DIFFERENTIAL EFFECTS OF PERSPECTIVE TAKING ON VICARIOUS EMBARRASSMENT AND EMPATHIC CONCERN**

**Eric Stocks<sup>1</sup>, David Lishner<sup>2</sup>; <sup>1</sup>University of Texas at Tyler, <sup>2</sup>University of Wisconsin Oshkosh** – Much research has investigated the cognitive-perceptual factors that promote one form of empathy, empathic concern. However, little research has investigated such factors for a related empathic emotion, vicarious embarrassment. We tested the hypothesis that different forms of perspective taking elicit different emotional responses to a target in an embarrassment-eliciting situation. In our experiment, participants heard a target recount an embarrassing event while they adopted one of three perspective-taking sets (remain objective and detached vs. imagining how the target feels vs. imagining yourself in the target's situation) as well as an opportunity to either approach or avoid the target. Results revealed that, compared to those who remained objective and detached, those who imaged the target's thoughts and feelings experienced heightened empathic concern (but not heightened vicarious embarrassment and the desire for further exposure to the target, whereas those imagining themselves in the target's situation experienced heightened vicarious embarrassment (but not heightened empathic concern) and did not seek further exposure to the target. This suggests that different manifestations of vicarious emotions may be associated with different motivational orientations.

#### D50

##### **FORGIVENESS IN REAL-TIME: COGNITIVE AND CARDIOVASCULAR REACTIONS TO OFFENSE**

**Ryan S Darby<sup>1</sup>, Britta Larsen<sup>1</sup>, Nicholas Christenfeld<sup>1</sup>, Christine R Harris<sup>1</sup>; <sup>1</sup>University of California, San Diego** – Previous research has demonstrated that imagined forgiveness of an offense is associated with decreases in cardiovascular reactivity compared to holding grudges, though this has yet to be studied with actual real time offenses. The current study examined the effects of primed forgiveness on cardiovascular recovery from an offense, and also explored the potential relationship between a forgiving disposition, forgiving cognitions, and cardiovascular reactivity. Participants (N = 96) filled out dispositional measures of forgiveness and were then randomly assigned to list the benefits of either forgiveness or studying and write about a time when they received benefits from that activity. This forgiveness intervention was done to maximize the probability of forgiveness occurring naturally. In the second half of the experiment, participants did a brief math task with a confederate who rudely harassed the participant. Heart rate and blood pressure were monitored before, during, and after the offense. The data revealed a significant interaction between intervention type and dispositional forgiveness on systolic and diastolic blood pressure over time. Individuals high in trait forgiveness who underwent a forgiveness intervention, did show decreased blood pressure after 5 minutes, but not during the offense. Finally, self-report ratings of how much the participant liked the offender and how well the pair got along were positively correlated with dispositional forgiveness. This study suggests that previous findings relating forgiveness to decreased cardio-

vascular reactivity are generalizable. It also suggests there is a positive relationship between dispositional forgiveness, pro-social behavior, and, tentatively, faster cardiovascular recovery.

#### D51

##### **SOCIAL AND DEVELOPMENTAL FACTORS IN EMOTION REGULATION IN ADOLESCENCE**

**Jennifer A. Silvers<sup>1</sup>, Katherine A. Remy<sup>1</sup>, Kevin N. Ochsner<sup>1</sup>; <sup>1</sup>Columbia University** – Recent research suggests that adolescence is a "make or break" time for the development of effective emotion regulation skills. Yet, little empirical work has examined how emotion regulation capacity changes over the course of typical adolescent development. Moreover, although anecdotal evidence suggests that adolescents are more sensitive to negative social cues than adults, this hypothesis has not been formally tested. The present study investigated whether 1) emotion regulation success increases and 2) reactivity to negative social emotional stimuli decreases over the course of adolescence. Individuals at the beginning (10-13 years), middle (14-17 years) and end of adolescence (18-22 years) completed an emotion regulation task. On each trial, participants viewed a negative or neutral picture and were instructed to either draw themselves closer to the emotional details of the picture ("close") or to mentally distance themselves from such details ("far") and then rated their negative affect. Half of the pictures viewed contained social content. Across and within age groups participants reported less negative affect in response to negative stimuli on "far" trials than "close" trials. A significant interaction between age, strategy and valence was observed suggesting that older individuals were more effective at using the "far" strategy when viewing negative stimuli than younger individuals. An additional interaction between age, valence and social content revealed that younger participants reported more negative affect in response to negative social stimuli than older participants. These findings suggest that emotion regulation success improves over adolescence as emotional reactivity to negative social cues attenuates.

#### D52

##### **COVETING WHAT IS THY NEIGHBOR'S: WHEN ENVY BREEDS DESIRE**

**Jan Crusius<sup>1</sup>, Thomas Mussweiler<sup>1</sup>; <sup>1</sup>Universität zu Köln** – Envy is an unpleasant emotion that arises after an unfavorable social comparison, such as when we lack another person's superior good. A central component of envy seems to be the desire for this fortune. Despite its important implications, experimental evidence on the psychological underpinnings of envious desire is lacking and the conditions that foster its emergence are unclear. Assuming that people are motivated to control spontaneous envious reactions, we predicted that envy and envious desire are strongest when resources to exert self-control are taxed. To evoke envy, we invited participants to a taste test. Some of them completed this test in the presence of another person who tasted a more desirable food. In Experiment 1, participants were assigned to taste a chewy candy and deprived of a box of chocolate. Those who were in the presence of a better-off neighbor experienced more envious discontent the more intoxicated they were. In Experiment 2, participants who were deprived of a desirable ice cream having to taste an inferior biscuit envied their better-off neighbor most intensely under high cognitive load. Furthermore, they reported the highest willingness to pay for the ice cream. In Experiment 3, participants were most likely to spontaneously purchase the better food under these circumstances. In Experiment 4, under high cognitive load, automatic approach behavior towards the more desirable food of the neighbor was highest. These findings help to unravel the complexities of envy and contribute to a more complete understanding of emotional determinants of economic judgments and behavior.

#### D53

##### **THE IMPACT OF ANTICIPATED VERSUS EXPERIENCED FEELINGS OF REGRET AND RELIEF ON BARGAINING DECISIONS**

**Elizabeth Dyczewski<sup>1</sup>, Keith Markman<sup>1</sup>; <sup>1</sup>Ohio University** – In light of recent theorizing that anticipated, but not experienced, emotions should directly influence behavior (Baumeister, et al., 2007), and that upward counterfactuals should promote riskier behavior than should downward counterfactuals

(Markman et al., 2006), we hypothesized: a) that anticipated regret and relief would be felt more strongly than experienced regret and relief; and b) that anticipated regret would promote riskier decision-making whereas anticipated relief would elicit more conservative decision-making. To test these predictions, participants played two rounds of the Ultimatum Game, in which the "proposer" must offer some proportion of drawing tickets to the "responder." If accepted, the tickets are divided accordingly, but if rejected, neither player receives any tickets. In essence, then, the proposer must offer as little as possible to maximize gains, while not offering so little that the offer is rejected. All participants were ostensibly randomly assigned to the role of the proposer. Those in the "experience" condition learned that an even lower offer would have been accepted than what they offered, whereas those in the "anticipate" condition were simply asked to imagine that a lower offer would have been accepted than what they offered. As predicted, anticipated reactions were stronger than experienced reactions. Moreover, and as hypothesized, anticipated regret predicted riskier decisions (i.e., lower second offers), whereas anticipated relief predicted more conservative decisions (i.e., higher second offers). Experienced regret and relief, on the other hand, did not predict subsequent behavior.

#### D54

##### WHAT LOOKING PROUD SAYS ABOUT YOU: EFFECTS OF THE NONVERBAL PRIDE EXPRESSION ON PERCEPTIONS OF MORAL VALUES E. J.

Horberg<sup>1</sup>, Dacher Keltner<sup>1</sup>, Serena Chen<sup>1</sup>; <sup>1</sup>University of California, Berkeley – Interest in the emotion of pride is flourishing, with research now confirming a universal nonverbal pride expression (Tracy & Robins, 2004), and demonstrating that the expression of pride communicates information about one's social status (Tiedens, Ellsworth, & Mesquita, 2000). The present experiment extends this literature by investigating whether the nonverbal pride expression communicates the possession of certain moral values. Specifically, because pride conveys the belief that the self deserves high social status, we predicted that people would infer that a person who expresses pride will value status hierarchies, and will not value egalitarianism. In an experiment, 195 participants viewed a photograph of a target stranger who wore either an expression of pride or joy. Participants then estimated how much the target values social hierarchy and egalitarianism, and how much pride the target experiences during everyday life. As expected, participants who saw the target express pride believed the target values hierarchy more, egalitarianism less, and experiences more pride during everyday life, compared to participants who saw the same target express joy. Finally, estimates of the target's tendency to experience pride mediated the effect of expression on both hierarchy and egalitarianism values. Effects held across target gender. These findings suggest that the nonverbal pride expression communicates hierarchy-based moral values, and more broadly, that people use an individual's positive emotions as information about his or her values. Implications regarding the function of pride, and the emotion-morality link are discussed.

#### D55

##### EXERCISING THE BODY FOR A HAPPY MIND: ASSOCIATIONS BETWEEN PHYSICAL ACTIVITY, AFFECT, AND PERSONAL RESOURCES Candice

Lowdermilk<sup>1</sup>, Susanne Scheibe<sup>1</sup>, Jutta Mata<sup>1</sup>, Barbara Fredrickson<sup>2</sup>; <sup>1</sup>Stanford University, <sup>2</sup>University of North Carolina at Chapel Hill – Physical activity has been shown to improve affect, increase psychological resources such as wellbeing and optimism, and reduce symptoms of depression. One possible mechanism underlying this relation is that physical activity increases physiological reactivity and flexibility essential to the experience and regulation of emotions. So far, most studies have focused on reduction of negative emotions. In this study we investigate whether these improvements result not only from reduced experience of negative emotions, but also from increased positive emotions, linking physical activity, positive emotions, and personal resources. We also tested whether positive emotions mediate the relation between physical activity and psychological resources. A community sample of 477 participants aged 19 to 65 completed self-report measures of physical

activity, emotional experience, and psychological resources such as resilience, optimism, and flourishing. More active participants reported more positive and less negative emotions in everyday life, fewer symptoms of depression and anxiety, as well as more psychological resources. Engagement in vigorous exercise was most strongly related to higher positive and lower negative affect followed by moderate and light activity. Additionally, the relations between physical activity and personal resources and between physical activity and symptoms of depression and anxiety were mediated by positive emotions. These findings suggest that physical activity affects both positive and negative emotions and lays the groundwork for laboratory and intervention studies aimed at establishing causal links between physical activity and positive emotions.

#### D56

##### THERE IS A FIRE BURNING IN MY HEART: THE ROLE OF ATTRIBUTION IN AFFECTIVE PRIMING EFFECTS Masanori Oikawa<sup>1</sup>, Henk Aarts<sup>2</sup>, Haruka

Oikawa<sup>3</sup>; <sup>1</sup>Research Fellow of the Japan Society for the Promotion of Science, <sup>2</sup>Utrecht University, <sup>3</sup>Teikyo University – The role of attribution process in affective priming effects was addressed by examining the consequences of expressing one's emotions towards the primes within the framework of the affect misattribution procedure (AMP: Payne, Cheng, Govorun & Stewart, 2005). Eighty-six undergraduate students performed an adapted AMP which varied the expression of their responses towards the primes. Consistent with the previous findings in the affective priming literature, pleasant or unpleasant picture primes influenced subsequent evaluations of unrelated neutral targets, despite blatant warning to ignore the primes. Affective priming effects occur we argue because primed affect is unexpressed and not bound to an object and hence capable of coloring subsequent evaluative judgments of ambiguous stimuli. Thus we predicted that when people express their feelings towards the primes, the affect is bound to an object, and becomes less capable of coloring subsequent judgments. Supporting this notion, the affective priming effects disappeared when participants expressed their affective responses towards the primes. These findings suggest that affective priming effects ensue when activated affect is kept unexpressed and sustained active. Implications of relationship between attribution and affect that lingers on and colors subsequent evaluative judgments are discussed.

#### D57

##### HAPPY EXPRESSION IMPROVES MEMORY FOR FACIAL IDENTITY, WHEREAS DISGUST EXPRESSION IMPROVES MEMORY FOR FACIAL EXPRESSION Kristen VonWaldner<sup>1</sup>, Marilyn Mendolia<sup>1</sup>; <sup>1</sup>University of

Mississippi – A recent model of facial decoding posited that recognition of particular persons and recognition of particular emotional expressions involve similar visual analysis pathways (Calder & Young, 2005), suggesting that cues extracted for facial identity recognition may influence facial expression recognition and vice versa. D'Argembeau and Van der Linden (2007) found that identity recognition was better when actors were initially seen displaying happy rather than angry expressions; however, expression recognition was the same for happy and angry expressions. The latter finding may point to a further complexity in facial decoding processes for particular emotions—specifically, whether decoding is based on all features of an expression (holistic), as has been demonstrated for both happy and angry expressions, or on individual features (part-based), as has been demonstrated for disgust expressions (Mendolia, 2007). The present study explores memory for facial identity and facial expression by using emotions associated with each decoding process. After viewing photos of actors displaying happy or disgusted expressions, participants completed a recognition task containing neutral expressions, half from actors previously seen. After each photo, participants indicated whether they recognized the person and, if so, what expression the person had displayed. Participants were better at and more confident in recognizing actors initially seen displaying happy rather than disgusted expressions, but were better at and more confident in recognizing disgusted rather than happy expressions. This investiga-

tion has implications for understanding cognitive and perceptual mechanisms underlying facial identity and facial expression recognition, as well as practical applications in psychology, law, and criminal justice.

#### D58

**IMPLICIT THEORIES OF EMOTION: BELIEFS ABOUT EMOTION PREDICT AFFECT REGULATION AND EXPERIENCE** Kimberly Angelo<sup>1</sup>, Sanjay Srivastava<sup>1</sup>; <sup>1</sup>University of Oregon – Past research has demonstrated the importance of implicit theories of intelligence and personality in predicting personal development, mastery, and well-being (Dweck, 1999). Recent research has shown that people also differ in their implicit theories of emotion (Tamir et al., 2007), such that some believe emotion is fixed (entity theory) and others believe that emotions may be changed (incremental theory). The goal of the current research was to investigate the relationships between implicit theories of emotion, emotion regulation, and trait- and state-level affect. Study 1 (N = 276) used questionnaires to examine trait-level correlations between implicit theories, emotion regulation, and well-being variables. We found that incremental (vs. entity) theorists showed greater use of mood repair and cognitive reappraisal. Incremental theorists also experienced greater positive and less negative trait affect, a relationship partially mediated by emotion regulation. These effects held when controlling for extraversion, neuroticism, and emotional intensity. Study 2 (N = 177) replicated these findings, and used the Day Reconstruction Method (Kahneman et al., 2004) to examine concurrent emotion regulation and affect. Though implicit theory did not predict use of emotion regulation at the state level, it moderated the effects of attentional deployment on positive and negative affect: This emotion regulation strategy predicted more positive and less negative state affect when a person held an incremental theory. Together, this research suggests that those who believe that emotions are malleable (vs. fixed) are more likely to attempt to regulate their emotions and to be more successful when they do so.

#### D59

**CHILDREN LABEL FACIAL AND POSTURAL CUES TO EMOTION BETTER THAN VOCAL CUES** Nicole Nelson<sup>1</sup>, James Russell<sup>1</sup>; <sup>1</sup>Boston College – In everyday life, emotional expressions are multi-faceted, although the majority of literature examining children's understanding of emotion focuses on facial expressions, meaning our understanding of how children interpret emotional expressions is incomplete. This study addresses this knowledge gap by examining preschoolers' knowledge of facial, postural and vocal emotion cues. Preschoolers (3-5 years, N=114) were presented with three sets of audiovisual clips in which an actress displayed one emotion cue (Facial, Postural or Vocal) and a fourth Complete set (always presented last) in which all three cues were present. For each set of audiovisual clips, children freely labeled the emotion presented (happiness, sadness, anger and fear). Children's performance was high for Complete(.83), Facial(.82) and Postural(.73) presentations, but low for Vocal(.45) presentations. For all emotions, children labeled the Facial and Complete audiovisual clips equally well, indicating children received no additional benefit from viewing all cues over only facial cues. In addition, the Postural and Facial clips were labeled at similar levels for sadness and fear ( $p > .08$ ). For the Vocal clips, children's labeling of sadness was high (.74), while labeling of happiness(.35), anger(.51) and fear(.18) was moderate to low. Adults labeling of the Vocal clips, however, was high for all emotions presented (.84-.98), suggesting that preschoolers are still learning to interpret vocal emotion cues. The current study expands the literature by suggesting a potential developmental pattern in children's understanding of cues to four basic emotions: children understand facial expressions and complete displays early, followed by postural displays, with vocalizations lagging behind.

#### D60

**WHERE'S THE TERROR? EXPLORING THE ROLE OF ANXIETY IN TERROR MANAGEMENT THEORY WITH A MORTALITY SALIENCE MANIPULATION DESIGNED TO FACILITATE "SELF-AWARENESS"** Guy Leboeuf<sup>1</sup>, Gaëtan F. Losier<sup>1</sup>; <sup>1</sup>Université de Moncton – Terror management theory (TMT) stipulates that humans face terrifying anxiety from their combined innate propensity toward self-preservation and awareness of mortality. Culture serves to protect us by providing meaning and the promise of symbolic or literal immortality. Research based on TMT have typically used a mortality salience manipulation that initiates a culture (or worldview) defense without apparent conscious anxiety or negative affect. The present study aims to examine the role of anxiety in TMT by using a mortality salience manipulation that will facilitate access to self-experience (i.e., by asking participants to be attentive to "here and now self-experience") and potentially creates more conscious anxiety. Undergraduate students (n=184) were randomly assigned to either the experimental condition (i.e. looking at five images related to death) or the control condition (i.e. looking at five images related to visiting the dentist). All participants completed questionnaires prior to and following each condition. Results confirmed that the manipulation produced the intended effect (i.e. making anxiety explicit or conscious). Results also supported the typical TMT main effects with self-esteem serving as a buffer to anxiety. However there was not evidence of worldview defense. Affect and cognitive processes associated with mortality salience effects are discussed.

#### D61

**HOT OR NOT: HOT COGNITION AND POLITICAL PARTY IDENTIFICATION** Shea Robison<sup>1</sup>, Kathleen McCulloch<sup>1</sup>; <sup>1</sup>Idaho State University – In political psychology, recent research using implicit attitude priming demonstrates that affect is activated automatically by mere exposure to political concepts. However, this research focuses exclusively on reports of feelings towards political figures and concepts without addressing their relation to political party identification. In surveys conducted as part of our experiment we found that while feelings towards political figures were significantly correlated with party identification, this correlation is 'only' .52, which suggested the need to consider both feeling reports and party identifications in assessing the effects of affect on political decisions. Hence, our experiment is the first to use party identification with an implicit attitude priming paradigm. In our experiment, participants were primed with pictures of Presidents Bush and Obama, as well as other normed black and white faces, followed by positive, negative and neutral target words. The participants' task was to indicate as quickly and accurately as possible whether the target words were good or bad. We found significant differences between Democrats and Republicans in their patterns of automatic responses following the critical primes: Bush primes elicited unequivocal positive and negative reactions along party lines, while Obama primes evoked significant reactions among Republicans, but ambiguous affective responses among Democrats. Other research in social psychology suggests fundamental differences between liberals and conservatives, with conservatives demonstrating more motivated social cognition than liberals. Using party identifications in our study we are able to extend this research by demonstrating that Democrat support for Obama is less affective than is Republican support for Bush.

#### D62

**YOU WON'T GET AWAY WITH IT... THE PROMISE AND PERIL OF DIMINISHING NEGATIVE EMOTIONS IN ECONOMIC EXCHANGE** Cynthia Wang<sup>1</sup>, Jayanth Narayanan<sup>1</sup>, Niro Sivanathan<sup>2</sup>, Deshani Ganegoda<sup>3</sup>, Keith Mumighan<sup>4</sup>; <sup>1</sup>National University of Singapore, <sup>2</sup>London Business School, <sup>3</sup>University of Central Florida, <sup>4</sup>Kellogg School of Management – The precursory role that negative emotions play in punishment is well-established in the negotiations literature. In six experiments, we examined factors that diminish and exacerbate negative emotions. Specifically, we investigated (1) how a time delay between a monetary offer and a pun-

ishment decision is mediated by negative emotions, and (2) how this mediation is moderated by the ruminative thought patterns of responders. Our results showed a time delay between an offer and a decision reduced punishments, but this effect depended on how responders ruminated during the delay. This pattern occurred both in the form of ultimatum rejections ('A' experiments) and third-party punishments ('B' experiments). Following a time delay, responders reported less negative emotions and were more likely to punish actors perceived to have acted unfairly (Experiments 1A and 1B). Rumination increased negative emotions and punishments (Experiments 2A and 2B); however, responders who ruminated about their feelings about the offer during a time delay punished negative actors more than those who ruminated about their thoughts of the offer and those who ruminated about an incident unrelated to the task. Ultimatum rejections are often described as having a limited impact on reinforcing cooperative norms; third-party punishment are often described as a mechanism that reinforce social norms and helped maintain cooperation. Thus, negative emotions within the ultimatum game context produced detrimental effects, but in a third-party context, they could potentially produce beneficial outcomes. This suggests that negative emotions can play a positive role, even in contentious, seemingly negative interactions.

### D63

**THE ROLE OF EMOTION REGULATION IN FORGIVENESS** Kai-Yun Luo<sup>1</sup>, Ruey-Ling Chu<sup>1</sup>; <sup>1</sup>National Taiwan University – Literature shows that emotional management associates with the ability to forgive. In addition, forgiveness is considered as an important approach in physical and psychological health. This study investigated the effect of emotional regulation strategies on forgiveness and well-being, as well as examined the mediation effect of social skills between emotional regulation strategies and forgiveness. There were 162 fifth-grade elementary school students who participated in the study. The result showed that "reappraisal" might influence children's attitude of forgiveness. Nevertheless, there were no correlation between "suppression" and forgiveness. Forgiveness could predict well-being of the children. Consequently, students who used "reappraisal" to regulate their emotions might forgive their offenders more easily, and feel happier. However, forgiveness did not mediate the relationship between emotional regulation strategies and well-being. Furthermore, the relationship between emotional regulation strategies and forgiveness was mediated by social skills.

### D64

**BOYS DON'T CRY, BUT WHY? THE ROLE OF NON-CONSCIOUS GOAL PURSUIT IN EMOTION REGULATION** Daniella Shidlovski<sup>1</sup>, Ran R. Hassin<sup>1</sup>; <sup>1</sup>The Hebrew University, Jerusalem, Israel – Is it possible that dirty diapers are less unpleasant for those of us who want to become parents? Similarly, is it possible that the mere desire to be masculine reduces men's emotional reactions (because men are supposed to be tough)? Our research suggests not only a positive answer to the above questions, but also a mechanism: Non-conscious goal pursuit, we show, regulates emotions in goal-compatible ways. In two experiments, we examined the influence of goal priming on emotion regulation. In the first experiment, male participants were either primed or not with a masculinity goal, and then rated their negative emotional response to unpleasant pictures. We hypothesized that participants primed with a masculinity goal will express decreased emotional response to the unpleasant stimuli, which is exactly what happened. This effect was moderated by participant's explicit goal to be masculine. In our second experiment, female participants rated unpleasant pictures of various types, including babies' pictures, after either being primed (or not) with a motherhood goal. Results show that goal-primed participants expressed reduced emotional response only to the goal relevant stimuli (babies' pictures) but not to other, goal-irrelevant stimuli. Interestingly, females that were during their period days (and therefore were biologically incapable of pursuing the goal with which they were primed) showed the opposite pattern. Results from these two studies suggest that automatic goals can affect

emotions and emotion regulation. The strength and direction of the effect depends not only on the desirability but also on the applicability of the primed goal.

### D65

**BEING MOVED: VALENCE FACILITATES APPROACH-AVOIDANCE BEHAVIOR INDEPENDENT OF EVALUATION AND APPROACH-AVOIDANCE INTENTIONS** Regina Krieglmeyer<sup>1</sup>, Roland Deutsch<sup>1</sup>, Jan De Houwer<sup>2</sup>, Rudi De Raedt<sup>2</sup>; <sup>1</sup>University of Wuerzburg, <sup>2</sup>Ghent University – Theories from diverse areas of psychology postulate that affective stimuli facilitate approach or avoidance behavior, because they elicit motivational orientations that prepare the organism for appropriate responses. Recent evidence casts serious doubt on this assumption. Instead of motivational orientations, evaluative coding mechanisms may be responsible for the effect of stimulus valence on approach-avoidance responses. Two studies tested contrasting predictions derived from the two accounts. In support of the motivational orientation view, stimulus valence facilitated compatible approach-avoidance responses even though participants had no intention to approach or to avoid and the valence of the response labels was dissociated from the approach-avoidance movement (Study 1). This was also true when participants were not required to process the valence of the stimuli (Study 2). These findings are at odds with the evaluative coding account and support the notion of a unique automatic link between the perception of valence and approach-avoidance behavior.

### D66

**NEUTRAL AFFECT: MANIPULATION, MEASUREMENT, AND PERSONALITY CORRELATES** Cinnamon Danube<sup>1</sup>, Karen Gasper<sup>1</sup>; <sup>1</sup>The Pennsylvania State University – Affectively neutral states are commonly used as control conditions in research; however, it is problematic both methodologically and theoretically that researchers have not established defining criteria for such states. To address these issues, we had several goals: (1) establish criteria that characterize the state of neutrality, (2) establish that neutrality exists as a distinct affective state, and then (3) make recommendations for both the manipulation and measurement of neutral affect. In Study 1, baseline ratings of 67 affect adjectives were collected along with ratings following several commonly used methods for manipulating affect (Velten Statements, film clips, Life Event Inventory). The adjectives included commonly rated affective states (e.g., happy, sad, glad, tired) and adjectives that assess more neutral states (e.g., neutral, indifference, emotionless). We also assessed typicality, boredom, and calmness, as they are sometimes equated with neutrality. Results revealed that neutrality was best represented as indifference; differentiable from positive and negative affect; experienced at relatively high levels by participants; differentiable from typicality, boredom, and calmness; and created as a result of neutral mood manipulations. In Study 2, we validated our measure of neutral affect by examining how neutrality was related to several individual difference measures (e.g., affect intensity, emotional expression/experience, affect repair, approach/avoidance). Results indicated that neutrality reflected less affect intensity, expressivity, and repair, and was not associated with approach/avoidance. Lastly, we make recommendations for the manipulation and measurement of neutral states in research and stress the importance of using set criteria for these states to eliminate theoretical murkiness.

### D67

**SOCIABILITY AND MOOD: DO POSITIVE MOODS MAKE YOU SOCIAL OR DO NEGATIVE MOODS MAKE YOU UNSOCIAL?** Deanna C. Whelan<sup>1</sup>, John M. Zelenski<sup>1</sup>; <sup>1</sup>Carleton University – The broaden-and-build theory (Fredrickson, 1998) suggests that positive emotions help build social resources. Prior studies support this notion by linking positive (compared to negative) moods and preferences for social behavior. Because social situations are generally more pleasant than non-social situations (Lucas & Diener, 2001), it is difficult to ascertain if these situational preferences are due to the social or pleasant features of situations (c.f., a mood-congruity explanation). To address this, we developed a ques-

tionnaire that carefully balanced the pleasantness of social and non-social situations. This study also included a neutral condition to clarify whether sociability preferences depend on the presence of positive emotions or the absence of negative emotions. Participants ( $N = 99$ ) were randomly assigned to watch an emotional film clip (positive, negative, or neutral), and then rated current sociability (adjectives) and desire to participate in a series of situations. Results indicated that participants in the positive mood condition reported feeling more sociable compared to both negative and neutral conditions (which did not differ). Furthermore, participants in the positive condition preferred social over non-social situations whereas those in the negative condition preferred non-social over social situations. Interestingly, this pattern held for both pleasant and unpleasant situations. Therefore, although negative moods seem to bias participants towards non-social situations, positive moods also seem to increase preferences for social situations, when compared to neutral moods. Thus, the broaden-and-build model is supported in highlighting a distinct role for positive emotions in making people more social.

#### D68

**VALENCE FROM CONFLICT: ITS INFLUENCE ON LIKEABILITY OF PERCEPTIBLE AND SUBLIMINAL STIMULI** Tanaz Molapour<sup>1</sup>, Margaret T. Lynn<sup>1</sup>, Pareezad Zarolia<sup>1</sup>, Travis A. Riddle<sup>2</sup>, Ezequiel Morsella<sup>1,3</sup>; <sup>1</sup>San Francisco State University, <sup>2</sup>Columbia University, <sup>3</sup>University of California, San Francisco – It has been hypothesized that it is adaptive for organisms to avoid situations associated with cognitive conflict by generating a negative valence toward such 'inefficient' situations (Lewin, 1935). Consistent with the law of least work and recent theorizing, Study 1 revealed that, in a variation of the Stroop paradigm, urges to quit were greater following incongruent than congruent trials,  $F(1, 18) = 5.078$ ,  $p < .05$  ( $\eta^2 = .22$ ), but only during early/novice phases of performance, when responding is inefficient. Study 1 is thus the first demonstration of an avoidance response toward cognitive conflict. To assess whether the effect stemmed from negative valence, in Study 2 ( $n = 24$ ) we evaluated whether the Stroop conflict condition could influence the valence (likeability) toward incidental, neutral (non-biologically-significant) figures that were presented subliminally. Subliminal presentation was used to diminish the influence of explicit knowledge of the figure-Stroop condition pairings on judgments. Stroop stimuli were presented 3,500 ms following presentation of the subliminal figures. Following the block of Stroop trials, participants rated how much they liked the figures that had been presented subliminally. Stroop condition had no effect on likeability judgments,  $p > .05$ . In Study 3 ( $n = 24$ ), Stroop stimuli followed the subliminal figure by only 200 ms (an interval critical for classical conditioning), leading to a different pattern of results. Inspired by Lewin (1935), these findings begin to illuminate the relationship between a processing dynamic (cognitive conflict) and the emergence of valence.

#### D69

**DIADIC SOCIAL COORDINATION: CAN POSITIVE EMOTIONS DIFFERENTIALLY IMPACT HOW TWO PEOPLE WORK TOGETHER?** Tanya Vacharkulksemsuk<sup>1</sup>, Barbara L. Fredrickson<sup>1</sup>; <sup>1</sup>University of North Carolina, Chapel Hill – Social coordination is a phenomenon that plays out in a host of everyday instances (e.g., flight crew, sports teams), characterized by multiple actors working toward one goal. This study examines the role of emotions in facilitating social coordination among dyads. We hypothesize that the experience of positive emotions within a social interaction can facilitate social coordination and effective teamwork, particularly by way of broadened thinking and increased interpersonal connectedness. Eighty participant pairs of same-sex strangers were recruited for the study. Prior to the study, each pair was randomly assigned to an interaction task condition: pairs assigned to the positive social interaction task asked each other provided self-disclosing question prompts (e.g., "What is the greatest accomplishment of your life?", "Given the choice of anyone in the world, whom would you want as a dinner guest?"; adapted from Aron, et al., 1997), and control pairs proofread an article of emo-

tionally-neutral text together. Following the interaction task, the pair played a cooperative card game developed as an experimental-laboratory measure of social coordination (Cohen & Bacdayan, 1994). Results are consistent with the hypothesis described above. Findings underscore the functionality and role of positive emotions, particularly in a setting of interdependent relationships. Also, the present research examines emotions at the individual and dyadic level, and encourages avenues for new research in larger interpersonal contexts, such as business teams and sports teams.

#### D70

**THE EFFECT OF EMBODIED EMOTIVE STATES ON COGNITIVE CATEGORIZATION** Thomas F. Price V<sup>1</sup>, Eddie Harmon-Jones<sup>1</sup>; <sup>1</sup>Texas A&M University – Research has uncovered that positive affect broadens cognitive categorization. The motivational dimensional model, however, posits that positive affects vary in approach motivational intensity and that positive affects lower in motivational intensity should broaden cognitive processes, whereas positive affects higher in motivational intensity should narrow cognitive processes. Consistent with these predictions, high approach positive affect has been shown to narrow attention, whereas low approach positive affect has been shown to broaden it (Gable & Harmon-Jones, 2008, Psychological Science). High approach positive affect, therefore, might narrow categorization. Two experiments investigated this possibility by having participants respond to cognitive categorization tasks in three body postures designed to elicit different levels of approach motivation: (1) reclining backward, which should evoke low approach motivation; (2) sitting upright, which should evoke moderate approach motivation; and (3) leaning forward, which should evoke high approach motivation. Participants smiled while in each posture in order to experience positive affect. Experiment 1 provided initial support for the idea that high approach positive affect narrows categorization and low approach positive affect broadens categorization. Experiment 2 replicated these findings with improved smiling instructions. These results extend previous work by showing that the motivational model's predictions hold for basic attentional processes as well as higher level cognitive processes such as categorization.

**INFANT DETECTION OF INAUTHENTIC EMOTION: IT'S FUNNY WHEN MOMMY IS HURT** Eric A. Walle<sup>1</sup>, Joseph J. Campos<sup>1</sup>; <sup>1</sup>University of California, Berkeley – Detection of authentic vs. inauthentic displays of emotion is an important skill that adults use in everyday social interactions. This skill is crucial for the development of trust in human interactions, yet the ontogeny of this skill has not been investigated empirically. We recently initiated research on this topic with infants 18-20 months of age who were presented with either authentic or inauthentic emotion displays. The study was a variant of work by Zahn-Waxler and colleagues, wherein infants witness their caregivers apparently hurting themselves. We used this paradigm to manipulate whether the caregiver's expressed emotion was appropriate to the context (i.e., authentic) or not. Forty infants witnessed either (a) the authentic emotion event, wherein the parent actually hits his/her hand with a toy hammer and reacts with pain, or (b) the inauthentic emotion event, wherein the parent, perceptibly to the infant, misses his/her hand with the toy hammer and reacts similarly with pain. The child's behavioral responses to the parent's pain display were then observed for 30 seconds and results analyzed by MANOVA. The inauthentic emotion display led to more positive affect and aggressive behaviors and fewer pro-social and empathetic concern behaviors than was observed in the authentic condition. Findings suggest infants may detect inauthentic emotion – an emotion inappropriate to the circumstance – at a surprisingly early age and behaviorally respond to the perceived authenticity of an emotion accordingly.

**D72**

**THE EFFECTS OF PERCEIVED DEMOGRAPHIC CHANGES ON INTERGROUP EMOTIONS AND RACIAL IDENTIFICATION AMONG WHITES IN NORTH AMERICA** H. Robert Outten<sup>1</sup>, Michael T. Schmitt<sup>1</sup>, Daniel A. Miller<sup>2</sup>, Amber L. Garcia<sup>3</sup>; <sup>1</sup>Simon Fraser University, <sup>2</sup>Indiana University-Purdue University Fort Wayne, <sup>3</sup>The College of Wooster – Growing racial minority populations are a social reality in North America, particularly in urban areas. We conducted two studies to examine how the anticipation of such demographic changes affect Whites' feelings toward minorities and their racial group. In Study 1, White American participants either viewed: 1) current racial demographic figures for the U.S. or 2) they saw current figures and projections for 2060. Participants who saw the projections for 2060 reported feeling more anger and fear towards racial minorities as well as more sympathy towards Whites compared to those who only saw the current figures. In Study 2 White Canadians either viewed: 1) bogus projections for Vancouver, BC in 2058 where Whites remain the racial majority or 2) accurate projections for 2058 where Whites become a numerical minority. Based on Intergroup Emotions Theory (Mackie, Smith, & Ray, 2008) we predicted a replication of Study 1, especially for those highly identified with their racial group. We expected that emotional responses to anticipated racial demographic changes would be strongest among highly identified Whites. Group identification significantly moderated the effects of condition, such that highly identified Whites felt more anger toward and fear of minorities in the future white minority condition than in the future white majority condition. Whites low in group identification did not show these effects. These results suggest that for Whites in North America considerations of racial demographic changes can affect intergroup emotional responses and racial group identification can heighten the impact. The implications of these findings are discussed.

**D73**

**THE ENDEARING PAIN: OSTRACISM ELICITS LIKING** Michael C. Philipp<sup>1</sup>, Eric J. Vanman<sup>1</sup>, Ottmar V. Lipp<sup>1</sup>; <sup>1</sup>The University of Queensland – This study investigates whether the aversiveness of ostracism, which has been likened to physical pain, conditions negative reactions towards those who ostracize. Thirty-three participants first played 3 successive games of a computerized ball-tossing exercise in which the participant and two other players threw a ball between one another. A unique avatar picture was displayed next to each of the other two players in each game. The first two games were always inclusive (the participant receiving 33% of the throws) and the final game was always ostracizing (the participant receiving only one throw at the game's beginning). An affective priming task measured implicit evaluations of both the inclusive and ostracizing players' avatars. 200ms picture primes (avatar pictures) preceded either a positive or negative target word. Participants were instructed to categorize each target word as pleasant or unpleasant within 1000ms of its appearance. An ostracizing avatar prime resulted in faster categorizing of pleasant words than did an inclusive avatar prime. Responses to unpleasant words were not affected by either avatar prime. Thus participants showed more implicit positivity towards those who ostracized them in the ball-tossing game than those who were inclusive. These findings imply that the social cognitive effects of ostracism are more complex than are those of other forms of pain—the aversiveness of ostracism does not condition negative responses towards ostracizers. Future studies will investigate whether similarities between ostracizers and those who are ostracized moderate this ostracizer-positivity effect.

**D74**

**EMOTION ADJUDICATION: THE DIFFERING EFFECTS OF POSITIVE EMOTIONS ON THE USE OF STEREOTYPE INFORMATION IN JUDGING GUILT** Samantha Neufeld<sup>1</sup>, Michelle N. Shiota<sup>1</sup>; <sup>1</sup>Arizona State University – The effects of global positive and negative affect on social cognition are well known: Positive mood increases heuristic-based processing, whereas negative mood boosts systematic processing. However, an approach defining emotions as functional responses to distinct, fit-

ness-relevant opportunities and threats suggests that different emotions should have different cognitive effects. Although researchers have begun to differentiate the effects of specific negative emotions, little work has been done on differentiating the positive emotions. The present study examined the effects of several positive emotions on one social cognition process: stereotyping. Participants (N = 602) first completed an emotion task designed to elicit Awe, Nurturant Love, Pride, "Happiness" or Neutral affect. They then completed a social judgment task, rating the likelihood of guilt of a target who had been accused of a crime. Half of the participants rated a target representing a group stereotypically associated with the crime; the other half did not. A significant Emotion x Stereotype interaction indicated that different positive emotions led to different responses to the stereotype information  $F(4, 582) = 4.40, p < .01$ . Compared with the effects of stereotype information in the Neutral condition, including stereotype information led to higher guilt ratings in the Happiness and Awe conditions, lower guilt ratings in the Nurturant Love condition, and had no effect in the Pride condition. These effects are interpreted in terms of the theorized functions of each emotion, and implications for positive emotion research are discussed.

**D75**

**EFFECTS OF SELF-RELEVANCE OF A NEGATIVE EVENT ON TWO HINDSIGHT COMPONENTS** Ema Kuwayama<sup>1</sup>, Koji Murata<sup>1</sup>; <sup>1</sup>Hitotsubashi University – Hindsight bias is the tendency to believe falsely that "I knew it all along" after an event has occurred. Blank, Nestler, von Collani, & Fischer (2008) recently proposed that hindsight bias consisted of three separable components; memory distortions, impression of foreseeability, and impression of necessity. Blank & Nestler (2006) has indicated that people who perceived an event as negative overestimated the necessity, but not the foreseeability. On the basis of this research, we examined if level of self-relevance would moderate impression of necessity but not impression of foreseeability even when the negativity of experience was controlled. In a questionnaire, 126 participants (59 males and 67 females) ranked five areas in order of effort they had exerted in last half year, then they remembered the most negative experience in the area ranked the first (high self-relevance condition) or third (low self-relevance condition). To measure negativity of the experience, they evaluated the intensity of negative feelings at the time. Then, they evaluated necessity and foreseeability of the experience. As predicted, even when the negativity of experience was statistically controlled, participants in high self-relevance condition evaluated greater necessity than those in low self-relevance condition did. On the other hand, no significant difference was observed in evaluation of foreseeability. These results indicated that self-relevance increased impression of necessity but not impression of foreseeability. In line with previous researches, our findings suggested that two separable hindsight components could lead to different hindsight effects.

**D76**

**AFFECTIVE FORECASTING AND MOTIVATION FOR DISASTER PREPAREDNESS** Masayo Noda<sup>1</sup>; <sup>1</sup>Tokai Gakuin University – The present study aimed to examine how affective forecasting influences motivation for disaster preparedness among people at risk. In the experiments, participants (N=256) reported on their actual disaster preparedness, and their motivation for it. One week later, participants were asked to predict what they would think and how they would feel if a major earthquake occurred within a month, and then respond to the motivation measure one more time at the end of the experiment. Those participants who scored below the mean plus one standard deviation on their preparedness scores were selected, and analyses were performed on affective forecasting (prediction / control) x time (Before (B) / After(A)) on motivation. A significant two way interaction was revealed. While there was no substantial difference Before (B) vs. After (A) in the control group, higher motivation scores were seen for After (A) in the prediction group. People often overestimate the intensity of their emotional reaction to future events, which is defined as impact bias (Wilson & Gilbert, 2003). The results demonstrated that strong predicted emotional reactions have

an impact on motivation for disaster preparedness. It was presumed that people at risk of a disaster become more prepared by their affective forecasting. In other words, people become motivated to protect themselves against disaster once they are able to foresee their affective states in a situation where a major earthquake has occurred.

**D77**

**EMOTIONS AS A BASIS FOR THE STRUCTURE OF CONTRASTIVE VALUES** William Montgomery<sup>1</sup>, Henry Montgomery<sup>2</sup>, Tommy Gärling<sup>1</sup>; <sup>1</sup>Goteborg University, <sup>2</sup>Stockholm University – In previous research we have shown that a set of eight contrastive basic values (prioritize others - prioritize self, adaptation - own will, get help - management by your own, security - courage) form a circumplex structure (Montgomery, Montgomery, & Gärling, 2008) both in between and within subjects data. In the present investigation we examine whether the circumplex follows from how the values are related to emotions. It was assumed that contrastive values are organized such that any pair of contrasting values (e. g., security - courage) is related to corresponding pairs of contrasting positive and negative emotions (e. g., feel safe - feel anxious, feel bored - feel excited). Two studies showed that multidimensional scaling of ratings of positive and negative emotions related to specific values yielded basically the same circumplex of the values as was obtained with other types of value ratings in our previous research. In Study 1 specific emotions were rated in relation to each of the eight values. In Study 2 participants rated how non-specific positive and negative emotions were related to all possible pairs of the eight values. It was concluded that the circumplex structure of contrastive values may be closely related to emotional reactions.

**D78**

**GENDER DIFFERENCES IN THE RELATIONSHIP BETWEEN PARENTS' DISTRESS AND REACTIONS TOWARDS CHILDREN'S DOMINANT AND SUBMISSIVE NEGATIVE EMOTIONS** Ashley Craig<sup>1</sup>, Rebecca Stelter<sup>1</sup>, Amy Halberstadt<sup>1</sup>; <sup>1</sup>North Carolina State University – Emotion socialization is a multifaceted process through which children learn about emotions, primarily during interactions with their parents. A number of factors can influence the socialization messages parents communicate to their children including parent gender, child gender, emotion type, as well as more complex variables such as parents' beliefs and cognitions. For example, Cassano and colleagues (2007) examined the reactions mothers and fathers have towards their children's sadness and found that parents' responses were contingent upon parent and child gender and parents' perceptions of children's ability to regulate sadness. The present study examined the influence that mothers' and fathers' distress about children's negative emotions had on their reactions towards these emotions. The study examined an ethnically diverse sample of parents with children ages 4 to 12 years old. Moderation analyses tested the hypothesis that the parents' distress about their children's negative emotions, both submissive and dominant, would be related to their reactions towards these emotions and that the influence of distress would differ based on parent gender. In general, mothers reported a greater use of supportive reactions towards children's negative emotions when they were experiencing low distress, but as mothers' distress increased, their supportive reactions declined to levels more similar to that of fathers. This pattern was only true of submissive negative emotions, highlighting the need to consider negative emotions in a more nuanced way. In sum, these findings highlight the importance of considering not only emotion type but also parent gender and their cognitions about emotion socialization.

**D79**

**MORAL ELEVATION ELIMINATES THE "MORAL LICENSING" EFFECT** Jean Roper<sup>1</sup>, Simone Schnall<sup>1</sup>; <sup>1</sup>University of Plymouth, United Kingdom – In the domain of positive moral emotions elevation is the emotional response to observing acts of moral goodness (Haidt, 2003). This emotion has been shown to motivate individuals to behave prosocially (Schnall, Roper & Fessler, in press). The current study examined the

effect of prior self affirmation. Self affirmation has been shown to reduce helping behaviour, possibly as a result of "moral licensing," namely the feeling that it is acceptable to refrain from moral behaviour or even to behave immorally (Sachdeva, Ilic & Medin, 2009). In this study participants were given the opportunity to complete a self affirmation writing task or a control writing task before watching an elevation eliciting or a control film clip. They were then free to leave or to help the experimenter on a boring maths task. Replicating our initial findings (Schnall et al., in press) participants in the elevation condition helped more than participants in a neutral control condition. Further, participants who first self affirmed and then watched an elevation eliciting clip spent longer helping the experimenter on a boring task than those who self affirmed but watched a control clip. Helping was especially pronounced when participants in the elevation condition had affirmed a personal quality related to being a person who does good things for others. These findings suggest that elevation may provide a buffer against the negative effect of "moral licensing" involved in self affirmation on helping behaviour.

**ARE HAPPY PEOPLE MORE SOCIABLE?: BEHAVIORAL EVIDENCE OF THE SOCIAL BENEFITS OF POSITIVE EMOTION** Portia S. Dyrenforth<sup>1</sup>, Michael J. Doane<sup>1</sup>, Richard E. Lucas<sup>2</sup>, Marjorie Maxwell<sup>1</sup>; <sup>1</sup>Hobart & William Smith Colleges, <sup>2</sup>Michigan State University – Theories of positive emotion suggest that people who feel good are more likely to engage in and be successful in social interactions (e.g., Lyubomirsky, King, & Diener, 2005). This is supported by trait-level evidence showing that happy people experience a variety of positive social outcomes. However, the exact mechanisms by which positive emotion influences specific social behaviors are still unclear. To investigate these mechanisms, we used an experimental design to test for behavioral indicators of sociability after a laboratory mood induction. Participants (n=94) were randomly assigned to complete either a positive or a neutral mood induction and assigned an interaction partner. These previously unacquainted dyads worked together for ten minutes on a semi-structured computer task. Videotapes of the interactions were coded for behavioral indicators of sociability at both the individual (e.g., initiating conversation) and dyad level (e.g. friendliness, social inhibition). Results indicated that individuals induced to feel positive emotion were rated as significantly less socially inhibited and less socially awkward than participants in a neutral mood condition. The effects of positive mood also extended to interaction partners such that dyads with one positive mood participant were rated as having significantly friendlier and more enjoyable interactions than dyads with two neutral partners, even when controlling for trait Extraversion. This study provides new behavioral evidence of increased sociability during positive emotion and suggests that many of the social benefits of positive emotion may result from reducing socially undesirable tendencies (e.g., awkwardness) rather than from increasing desirable social behaviors (e.g., initiating conversation).

**D81**

**EMOTIONS AND COUPLE CONFLICTS: MEN'S AGGRESSIVE BEHAVIOR IN CONFLICTIVE SITUATIONS AGAINST THEIR PARTNERS** Inmaculada Valor-Segura<sup>1</sup>, M. Carmen Herrera<sup>1</sup>, Francisca Expósito<sup>1</sup>, Miguel Moya<sup>1</sup>; <sup>1</sup>University of Granada – Emotions play an important role in intimate relationship and couple conflicts. Some negative emotions can serve to enhance the risk of couple violence. In the study 1 we explored the emotions generated by some intimate relationships conflicts. Using a mixed factorial design with type of interpersonal conflicts as within subject variable (10 different conflicts were presented) and sex as a between group variable, a total of 253 undergraduated participants rated the emotions felt on each conflictive situation. Results showed that emotions such contempt, anger and disappointment predicted the intention to be physically aggressive in conflictive situations. According to these results, the main goal of our study 2 was to analyze men's behavior against women when they were involved in a couple conflicts. A total of 83 undergraduates students (only men) must work with a woman virtual (simulated) partner, and answered a decision-making task about family

relationships. Independent variable was manipulated: conflict (woman disagreement of man's decision) / no conflict (woman agreement). Dependent variables included different measures related to how men participants reacted to woman's behaviour (emotions, evaluation of woman, etc.). Results showed a main effect of conflict / no conflict: reactions were more negative in almost all the dependent measures when there was conflict.

#### D82

**LESS NEGATIVE OR MORE POSITIVE? EXPLORING THE POSITIVITY EFFECT IN AGING** Kristin Wood<sup>1</sup>, Catherine Norris<sup>1</sup>; <sup>1</sup>Dartmouth College – Previous research has shown that people exhibit both a positivity offset (responding more positively than negatively to emotionally neutral stimuli) and a negativity bias (responding more negatively than positively to very emotional stimuli) in emotional responses. Furthermore, other research has demonstrated emotional benefits in aging, such that older adults report more emotional control and more pleasant emotional experiences than younger adults. This study sought to determine if this positivity effect results from decreased negativity, increased positivity, or both. Older (ages 65-80) and younger (ages 18-25) females viewed and made ratings of their emotional responses to IAPS images that ranged in valence from very negative to very positive. Although there was no difference in the negativity bias between age groups, older adults demonstrated a greater positivity offset to mild stimuli, such that older adults rated mildly pleasant pictures more positively than younger adults. Moreover, older adults were slower to rate unpleasant pictures than younger adults, whereas younger adults were slower to rate pleasant pictures. In addition, longer response times for mildly unpleasant pictures were associated with more positive ratings; longer response times for mildly pleasant pictures were associated with more negative ratings. Together, these results suggest that older adults attempt to find the positive rather than avoid the negative in life, while younger adults can not find the positive as easily. Thus, the positivity effect in aging may be due to increased positivity toward mildly emotional stimuli, suggesting that older adults more fully appreciate life's simple pleasures.

#### D83

**AGE AND CULTURE DIFFERENCES IN THE BENEFIT OF CONGRUENT FACIAL EXPRESSIONS ON EMOTION RECOGNITION ACCURACY** Jennifer Stanley<sup>1</sup>, Xin Zhang<sup>2</sup>, Helene Fung<sup>2</sup>, Derek Isaacowitz<sup>1</sup>; <sup>1</sup>Brandeis University, <sup>2</sup>Chinese University of Hong Kong – Past research suggests that older adults are less accurate at recognizing facial expressions than young adults. However, most of these studies used facial expressions devoid of context. In the present study, we sought to investigate the influence of contextual facial expressions on the accuracy of young (aged 18-30 years) and older (aged 60-86 years) adults from two different cultures: Americans (n = 42 young adults; n = 44 older adults) and Hong Kong Chinese (n = 40 young adults; n = 44 older adults). Participants identified the emotion expressed (anger, disgust, fear, happy, sad, or surprise; 36 randomly ordered trials of each) by a target face either surrounded by different faces expressing the same emotion (congruent trials) or different faces expressing a different emotion (incongruent trials). We expected that members of a more collectivist culture, such as Hong Kong, would be more influenced by contextual information than a more individualistic culture, such as America. We also expected older adults to be influenced by contextual information more than young adults. Consistent with our hypothesis, Chinese participants benefited more than Americans from congruent information for happy and surprised faces. Conversely, however, for fear recognition it was American participants who gained the most from congruent contextual information. Interestingly, older adults, more than young, recognized angry faces better on incongruent trials (vs. congruent trials). Overall, these results suggest that all groups can benefit from contextual information, although whether congruent or incongruent information is more helpful depends upon the group and the specific emotion.

#### D84

**EMOTIONAL EXPRESSION AND CONTROL WITH FRIENDS AND STRANGERS** Jeffrey Kahn<sup>1</sup>, Renee Tobin<sup>1</sup>, Daniel Fienup<sup>1</sup>, Julie Herbstrith<sup>1</sup>; <sup>1</sup>Illinois State University – Efforts to control emotions generally translate to diminished observable emotion displays. Although emotional control is more likely for negative than for positive emotions, audience effects in emotional communication are less clear (Tobin, Graziano, Vanman, & Tassinari, 2000). We examined the intraindividual relation between efforts to control emotions and observable displays to friends versus strangers. Participants (N = 210) were pairs of friends who were partnered with either their friend or a stranger participant. Participants viewed nine IAPS slides (Center for the Study of Emotion and Attention, 1995) selected to elicit positive, negative, and neutral emotions (3 each, order counterbalanced) for 30 sec each. After each slide, participants completed the Affect Grid (Russell, Weiss, & Mendelsohn, 1989) and Slide Reaction Questionnaire (Tobin et al., 2000) to measure emotional reactions and regulation. Participants also verbalized their reactions to the slides to their partners via video cameras (verbalization-questionnaire order counterbalanced). Although the video camera was not connected to their partner, participants were videotaped, and their emotion displays were coded using the Emotional Expressive Behavior Coding System (Gross, 1996). Results revealed that participants reported greater efforts at controlling emotions in response to negative slides than to positive ones. Random coefficients regressions using HLM (Raudenbush & Bryk, 2002) revealed significant intraindividual relations between control and expression, such that emotional control was associated with lower expressed pleasure and higher expressed intensity, yet this was not moderated by partner condition. Additional results from this multimodal experiment will be presented and discussed in the context of emotion-regulation theories.

#### D85

**THE VISUAL IMPACT OF GOSSIP** Eric Anderson<sup>1</sup>, Eliza Bliss-Moreau<sup>2</sup>, Lisa, F Barrett<sup>1,3</sup>; <sup>1</sup>Boston College, <sup>2</sup>California National Primate Research Center, University of California, Davis, <sup>3</sup>Massachusetts General Hospital / Harvard Medical School – Gossip can be thought of a form of affective information about who is friend or foe. Recent evidence indicates that, as a way of learning about the "value" of a person, gossip influences how human beings evaluate each other. In the current paper, we show that gossip does not just impact how a face is evaluated – it impacts whether or not a face is seen in the first place. Structurally neutral faces were paired with negative, positive, or neutral gossip. When viewed later, faces previously paired with negative (but not positive or neutral) gossip were prioritized in consciousness using a binocular rivalry procedure. These findings demonstrate gossip as a form of affective information can influence vision in a completely top-down manner, independent of the basic visual features of a face.

#### D86

**POSITIVE AFFECT BIASES PERCEPTIONS OF PROCESSING FLUENCY** Scott Ode<sup>1</sup>, Michael Robinson<sup>1</sup>; <sup>1</sup>North Dakota State University – The mere exposure effect is such that repeated stimuli are judged more pleasant. A prominent explanation for this relationship is that stimulus repetition facilitates processing fluency and indeed several recent studies have shown that manipulations of processing fluency (e.g., figure-ground contrast) lead to greater liking for stimuli. Given that many mental associations have a bidirectional element, we hypothesized that positive stimuli would prime perceptions of fluent processing related to early sensory experience. In three studies, participants were primed with positive, neutral, or negative words, after which they completed a perceptual fluency judgment. In Study 1, positive primes led individuals to judge subsequently presented boxes as larger, relative to neutral or negative primes. In Study 2, participants were asked to estimate the size of one of two subliminal boxes, neither of which was actually presented. Following positive affective primes, individuals were more likely to think that a larger box had presented. To insure that the findings were related to pro-

cessing fluency in general rather than size estimations in particular, Study 3 examined fluency in a duration judgment paradigm. Positive words were thought to occur for a longer duration than were neutral or negative words, though this was not actually the case. Our results establish the bidirectional nature of the fluency-liking relationship and specifically show that positive affect primes perceptions of greater fluency at low levels of sensory processing.

**D87****EMOTION REGULATION STRATEGIES AND THE PROCESSING OF EMOTIONAL IMAGES: AN ERP INVESTIGATION** Erika Henry<sup>1</sup>, Theresa Becker<sup>1</sup>, John Kerns<sup>1</sup>, Bruce Bartholow<sup>1</sup>; <sup>1</sup>University of Missouri – Past

research has shown that experimentally manipulating emotion regulation strategies such as suppression or reappraisal leads to differences in the processing of emotional stimuli, as indicated by the amplitude of the P300 component of the event-related brain potential (ERP). However, little is known regarding whether stable individual differences in the use of these emotion regulation strategies also results in differences in the spontaneous processing of emotional stimuli. In the present study, 50 undergraduates were shown a series of emotional images within the context of a cognitive control task while ERPs were recorded. Individual differences in emotion regulation strategies were assessed via the emotion regulation questionnaire (ERQ; Gross & John, 2003). A frontal negative deflection in the ERP waveform, occurring approximately 260 ms after picture onset, largest for negative images and maximal at FCz, differentiated individuals who typically use reappraisal strategies from those who typically use suppression. Implications for the effects of individual differences in emotion regulation on spontaneous emotional processing are discussed.

**D88****NEURAL CORRELATES OF THE RELATIONSHIP BETWEEN MENTALIZING, SOCIAL COMPLEXITY AND FACE MEMORY** Robert G. Franklin Jr.<sup>1</sup>, Reginald B. Adams Jr.<sup>1</sup>; <sup>1</sup>The Pennsylvania State University – The ability to

decode others' mental states based on facial cues is remarkable. Based on cues within the structure of a face, we are able to read what others are thinking with great consistency. Group process research shows that people vary in the degree to which they attribute either basic mental states or complex, human, mental states to an outgroup or ingroup member, respectively. Extending this, we propose that ostensibly neutral faces vary in the degree to which they others attribute basic versus complex mental states, a construct we term social complexity. In this experiment, we first show that neutral faces do systematically vary in the degree to which others attribute either basic or complex mental states to them and that faces that have more complex mental states are better remembered. Second, we examined the neural correlates of this relationship. In an fMRI encoding task, faces related as more socially complex versus those rated as less socially complex evoked greater activation of brain regions involved with face memory, such as the hippocampus and dorsolateral prefrontal cortex. However, areas involved with mental state decoding that are not usually involved in face memory tasks were also more active to socially complex faces. These included the temporoparietal junction and ventromedial prefrontal cortex. This suggests that activity in areas involved in decoding others' mental states may moderate memory for faces in memory tasks, potentially by evoking deeper processing of those faces that are more socially complex.

**D89****SPATIAL METAPHOR VIOLATIONS ENHANCE RECOGNITION AND FREE RECALL OF VALENCE WORDS** Stephanie M. Cohn<sup>1</sup>, Shannon Henry<sup>2</sup>, Skye M. Margolies<sup>3</sup>, L. Elizabeth Crawford<sup>2</sup>; <sup>1</sup>Yeshiva University, <sup>2</sup>University of

Richmond, <sup>3</sup>Virginia Commonwealth University – Recent work on spatial representation of affect has established an association between valence and verticality. This appears in metaphoric language, which describes negative feelings as DOWN and positive ones as UP, but also in the metaphor congruency effects found in other cognitive tasks. For example, shifts of attention upward or downward are facilitated after viewing a

positive or negative stimulus, respectively (Meyer & Robinson, 2004), and positive images are remembered as having appeared higher in space than did comparably located negative images (Crawford, Margolies, Drake & Murphy, 2006). We extend this work by examining the impact of metaphor congruence on memory for stimulus content, rather than location. Three experiments examined memory for valenced words studied or tested in higher or lower vertical space. All three showed a memory advantage for negative over positive words. In both free recall and recognition memory tasks, there was an advantage for words that originally had been studied in metaphor incongruent locations (positive low on the screen and negative high), relative congruent locations. There was no such incongruency advantage when location was varied at the testing phase of a recognition task, suggesting that the effect is due to encoding rather than retrieval processes. The findings suggest that, even when incidental to the task, spatial location provides an encoding context for valenced words, strengthening the memory trace for those that violate the GOOD is UP metaphor.

**D90****MOTIVATED TO LOVE: A DAILY DIARY STUDY OF COMMUNAL STRENGTH, SACRIFICE, AND RELATIONSHIP SATISFACTION IN ROMANTIC COUPLES** Aleksandr Kogan<sup>1</sup>, Emily Impett<sup>2</sup>, Christopher Oveis<sup>3</sup>, Dacher Keltner<sup>2</sup>; <sup>1</sup>University of Hong Kong, <sup>2</sup>University of California, Berkeley,

<sup>3</sup>Harvard University – Recent research has begun to explore whether communal strength, defined as the extent to which people are motivated to respond to a partner's needs, predicts helping behavior in friendships and relationship satisfaction in romantic couples. However, no research has investigated whether communal strength is related to the experience of positive emotions while responding to the needs of others; additionally, the mechanism by which communal strength is related to relationship satisfaction is unexplored. The present study examined both of these questions within the context of romantic relationships. We conducted a 14-day online daily experience study of both members of 69 dating couples. Participants completed a background measure of communal strength (Mills et al., 2004), and then reported on their daily relationship quality as well as the emotions that they experienced when they made a sacrifice for their partner and when they were the recipient of a daily sacrifice. Multilevel modeling analyses revealed that participants with high communal strength experienced more positive emotions when they made sacrifices for their partner, in turn contributing to enhanced feelings of satisfaction in the relationship. In addition, people with high communal strength had partners who experienced more positive emotions when they were the recipient of sacrifices, in turn contributing to increased feelings of appreciation for the sacrifices. Our results suggest that communal strength is related not only to whether an individual will respond to their partner's needs, but also to the emotional experience of giving for both the giver and recipient.

Our results suggest that communal strength is related not only to whether an individual will respond to their partner's needs, but also to the emotional experience of giving for both the giver and recipient.

**D91****THE POWER OF POSTURE AND EXTERNAL SITUATION OVER FACIAL EXPRESSION ON ATTRIBUTIONS OF EMOTION** Sherri C. Widen<sup>1</sup>, Jennifer Gallucci<sup>1</sup>, James A. Russell<sup>1</sup>; <sup>1</sup>Boston College – Traditionally, it has been

assumed that people read emotion from facial expressions irrespective of context (e.g., Ekman, 1994). Aviezer et al. (2008) showed that people's interpretation of the "disgust face" is influenced by its context, but in their study, context sometimes meant both posture and external situation: The disgust and sadness contexts included both, whereas the fear and anger contexts were limited to posture. In the current study, the effects of external situation and posture were separated. Participants (N=48) each labeled two sets of stimuli (counterbalanced order): In one set (posture-only), a "disgust face" was paired with postures conveying anger, sadness, fear, or disgust. In the second set (posture-with-situation), a disgust face was paired with both posture and external situation both conveying anger, sadness, fear, or disgust. When labeling the emotion, more people relied on the emotion of the context than the "disgust" face. This effect increased when postures were paired with external situation: more people relied on context than on the posture-only stimuli

(male stimuli,  $F[1, 46]=9.44$ ,  $p=.004$ ; female stimuli,  $F[1, 46]=16.46$ ,  $p<.001$ ). This effect held for every face/posture pairing; the interaction was not significant. This study extends Aviezer's finding by showing that external situation increases the likelihood that emotion attribution will agree with the context rather than the face. This study thus joins the growing number of studies that raise questions about what exactly facial expressions of "basic" emotions communicate.

#### D92

**SOCIAL IDENTITY SALIENCE AFFECTS GROUP-BASED EMOTIONS THROUGH GROUP-BASED APPRAISALS** Toon Kuppens<sup>1</sup>, Vincent Y. Yzerbyt<sup>1</sup>; <sup>1</sup>Université catholique de Louvain at Louvain-la-Neuve, Belgium – Group-based emotions have been conceptualized as rooted in the social identity of the perceiver. Consistent with that idea, research has shown that social identity salience affects group-based emotions. Here we show that group-based emotions affected by social identity salience are linked to group-based appraisals (which we measured with an open response format). Two ways in which social identity salience can be achieved are (1) explicitly reminding people of their group identity and (2) letting group members interact with each other; both have been shown to lead to stronger group-based emotions. In two studies we replicate these effects of social identity salience on group-based emotions and assess the content of people's thoughts with a thought-listing procedure. In the first study, explicitly reminding people of their group identity leads to the predicted change in group-based anger, an effect that is mediated by group-based (and not individual) appraisals of goal incongruence. In a second study participants either discussed a group-relevant scenario in small groups, or a related topic irrelevant to the scenario. The first condition led to stronger indignation (in response to the group-relevant scenario) and in this condition the perceived presence of group-based (and not individual) appraisals of goal incongruence during the discussion was related to participants' reports of indignation. These results provide further evidence for the group-based nature of group-based emotions.

## Lifespan Development

#### D93

**RELATIONS BETWEEN CHANGES IN PERSONALITY AND CHANGES IN HEALTH** Tera D. Letzring<sup>1</sup>, Clifford C. Rone<sup>1</sup>, Sarah E. Hampson<sup>2,3</sup>; <sup>1</sup>Idaho State University, <sup>2</sup>Oregon Research Institute, Eugene, Oregon, <sup>3</sup>University of Surrey, Guildford, UK – Relationships between personality and self-rated health were examined, including the relationship between changes in personality and changes in health, using data from the Hawaii Personality and Health cohort. As adults, over 1000 participants completed questionnaires at four time-points (T1-T4) over about a ten-year period from mean age 40-50. The Big Five were assessed at T1 and T2, current health was assessed at T1-T4, and health compared to 5 years ago was assessed at T1. Conscientiousness, emotional stability, and openness accounted for unique variance in current health and agreeableness accounted for unique variance in comparative health. People with better or the same comparative health increased in extraversion from T1 to T2 and people with somewhat worse comparative health decreased in extraversion. Furthermore, when controlling for T1 health, emotional stability and openness at T1 predicted better health at T2 and T3; agreeableness predicted worse health at T3; and extraversion predicted better health at T4. Relationships between personality change and health change were examined with regression by entering T1 traits in step one and health change from T1 to T2 in step two to predict T2 traits. People with better or the same health increased in emotional stability and stayed about the same in openness, while people with worse health decreased in emotional stability and openness. These findings suggest that there is a link between personality and self-rated health and that changes in some of these variables are also related.

#### D94

**PARENTAL ALLOWANCE OF ADOLESCENT DRINKING IN THE HOME AS A PREDICTOR OF PROBLEMATIC ALCOHOL USE IN YOUNG ADULTHOOD** Ash Levitt<sup>1</sup>, M. Lynne Cooper<sup>1</sup>; <sup>1</sup>University of Missouri – Many parents believe that allowing their children to drink in a controlled home environment is beneficial, whereas other parents believe that this practice is harmful both in the short and long term. Previous research provides mixed results, and is limited in terms of its sole reliance on the child's report and on cross-sectional or short-term longitudinal designs. The present study sought to address these issues by examining trajectories of drinking and related problems in a racially mixed, community sample of 818 adolescents (mean age = 15.1 years; response rate = 94%) and their parents across five assessments spanning 15 years. Results of growth curve analyses using hierarchical linear modeling showed that drinking in the home was unrelated to both initial levels and change over time in typical amounts consumed as well as in the frequency of heavy consumption. However, individuals who drank at home had significantly lower initial levels of drinking problems, but had faster growing trajectories that indeed remained elevated into young adulthood compared with their counterparts who were not allowed to drink in the home. These effects remained after controlling for other demographic variables (e.g., gender, race) as well as differences in maternal drinking problems, maternal family history of alcoholism, and parenting practices. Results suggest that adolescent drinking in the home might be developmentally risky for problems related to drinking in young adulthood, but does not affect later amounts of consumption.

#### D95

**LOW INCOME WOMEN'S TRANSITION TO PARENTHOOD: THE EFFECTS OF RELATIONSHIP STATUS ON THE EXPERIENCE OF MOTHERHOOD** Rudabeh Nazarinia<sup>1</sup>, Farrell Webb<sup>1</sup>, Walter Schumm<sup>1</sup>; <sup>1</sup>Kansas State University – The transition to parenthood is a well explore phenomenon with middle class, married Caucasian couples. There remains a gap in our knowledge on the experiences of couples from different racial/ethnic and social economic classes. As more couples experience the transition to parenthood outside of marriage it is important to explore how their relationship status relates to this transition. This study evaluates the experiences of 1,195 racially/ethnically diverse population of low income women's transition to parenthood. Utilizing data from the Fragile Families and Child Wellbeing Study we explore women's experience of motherhood one year after the birth of their child. The sample in this study consist of White, Black Non-Hispanic and Mexican mothers ranging in age from late teens to early forties. Through ANOVA and multiple regression analyzes we examine between and within group differences with regards to relationship statuses and how these statuses impact mothers' experiences. Findings indicate differences in the experiences of mothers from different relationship statuses across the transition to parenthood. Relationship status is an important variable when evaluating new mothers' parenting experiences from different racial/ethnic groups. As more couples have children outside of marriage it is important to recognize how relationship status can impact a mother experience of motherhood

#### D96

**PERSONALITY TRAITS, CHRONIC STRESS, AND CHANGES IN SELF-REPORTED SMOKING BEHAVIOR** Andrew Pfeiffer<sup>1</sup>; <sup>1</sup>Institute for Social Research – Prior research regarding smoking resumption and cessation has focused largely on young adult and adolescent populations. This research neglects the importance of studying the phenomena in older populations who are more likely to experience imminent deleterious effects of smoking on their health and mortality. Personality traits and stress are known to be key factors in smoking behavior, however, their relationship to changes in smoking behavior in late life remains unclear. The present research examined the relationship between "Big Five" personality traits (openness, extraversion, neuroticism, conscientiousness, and agreeableness), chronic stress, and change in self-reported smoking

behavior in older populations, controlling for socioeconomic status and demographics. Health and Retirement Study (HRS) data were used for respondents between ages 43 - 89 reporting either a cessation of smoking, or resumption of smoking between the years 2004 and 2006. Personality traits were measured in 2006 using a self-administered questionnaire containing the Midlife Development Inventory (MIDI) personality scale. In addition, the aforementioned questionnaire included items assessing exposure to chronic stressors and stressful events. Results showed that high scores on the personality trait "Openness to New Experience" was associated with smoking cessation in this population. However, no "Big Five" personality traits were significant in predicting smoking resumption, which was largely predicted by chronic stress. This suggests that programs and policy promoting smoking cessation in older populations should assess personality and consider traits like "Openness to New Experience" in their design. Programmatic attempts to decrease incidence of smoking resumption should address tactics for coping with chronic stress.

**D97****INTRA-INDIVIDUAL CHANGE IN STABILITY AND AGE** Antonio

Terracciano<sup>1</sup>, Paul Costa<sup>1</sup>, Robert McCrae<sup>1</sup>; <sup>1</sup>National Institute on Aging, NIH – The stability of individual differences in personality traits is typically examined at the group level. We computed individual coefficients from sequential assessments to evaluate intra-individual (i.e., within-person) change in stability over time. The analyses address the question of the age at which personality stability reaches a plateau, a question not addressed before from an intra-individual perspective. Participants (N = 684; age range 17 to 76) completed the Guilford-Zimmerman Temperament Survey (GZTS) three times, with an average interval between assessments of about ten years. Results indicate that individual stability coefficients increased over time only among those younger than age 30 at baseline. An increase up to age 30 and then a plateau was also found for a measure of profile (ipsative) stability. The results were confirmed when the analyses accounted for differences in retest interval, sex, ethnicity, education, and secular trends. Neither demographic variables, nor the standing on the five major dimensions of personality, were predictors of change in trait stability. These findings provide new support for the notion that personality stability plateaus early in adulthood.

**D98****SUCCESSFULLY NAVIGATING SOCIAL ROLE LIFE TRANSITIONS**

Caroline A. Lemoine<sup>1</sup>, Elizabeth A. Majka<sup>1</sup>, Alysso E. Light<sup>1</sup>, Elizabeth Shockley<sup>1</sup>, Penny S. Visser<sup>1</sup>; <sup>1</sup>University of Chicago – Social roles provide individuals with structure and meaning by establishing traits and behaviors that are expected given the positions we hold in society. In addition, these roles help us meet fundamental needs by providing us with a sense of purpose, helping us to decipher a clear sense of self, enabling us to feel connected and valued, and enhancing our sense of control (e.g., Ashford & Taylor, 1990). While some individuals flourish through role transitions, others are met with distress as they abandon their old, stable social roles or take on newer, less structured roles. In this work, we examined what factors serve as buffers against the deleterious consequences of social role transitions. In a nationally representative survey (N = 1,624 adults), participants indicated how many role entries (e.g., becoming a parent) and role exits (e.g., retiring) they had endured during the last five years. In addition, they completed measures of successful functioning (e.g., perceived stress level, subjective well-being, etc.). Finally, participants indicated their memberships in a variety of groups (e.g., religious group) and whether or not they volunteer. Analyses revealed that social role transitions were indeed associated with a variety of psychological outcomes. Interestingly, while role exits were associated with lower well being, role entries were actually associated with greater well-being. In addition, certain types of involvement (e.g., volunteering) buffered individuals against some of the negative outcomes associated with role transitions.

**D99****THE AGE-RELATED POSITIVITY EFFECT IN AUTOBIOGRAPHICAL MEMORY: A DIARY STUDY** Emily Schryer<sup>1</sup>, Mike Ross<sup>1</sup>; <sup>1</sup>University of

Waterloo – Healthy aging is associated with improved emotional self-regulation and the pursuit of goals that enhance well-being. Researchers have found that relative to younger adults, older adults show better recall of positive than negative stimuli such as pictures and words. Presumably, autobiographical memories could have a stronger influence on well-being than memories for pictures or words. The present research examined older (67-83) and younger (17-26) adults' recall of emotional autobiographical events in daily life. For five consecutive days, participants described one pleasant and one unpleasant event in an online diary questionnaire and rated the vividness, frequency, and valence of each memory. A week later participants were asked to recall the same events they had reported during the diary week. During the diary week, older adults were able to report a pleasant event each day but could not produce an unpleasant event on 40% of the daily diary questionnaires. A week later, however, older adults were equally likely to recall the pleasant and unpleasant events that they had reported in the diary week. Younger adults were able to report one pleasant and one unpleasant event on every diary questionnaire and were equally likely to recall both types of events in Session 2. Older adults rated all of their memories as more vivid and their pleasant events as occurring more frequently than did younger adults. We suggest that the motivation to self-regulate emotion may affect older adults' experience and interpretation of emotional events but not their long-term recall of autobiographical memories.

**D100****FORGIVINGNESS ACROSS ADULTHOOD: DIFFERENT BIG FIVE DETERMINANTS AT DIFFERENT AGES?** Mathias Allemand<sup>1</sup>; <sup>1</sup>University of

Zurich – Cross-sectional age differences in forgivingness, defined as an enduring tendency to forgive others, were investigated in a representative sample (N = 450). The study aimed at clarifying the role of the Big Five personality traits (Neuroticism and Agreeableness) as determinants of forgivingness across adulthood. Participants, who ranged in age from 20 to 83 years, completed the Tendency to Forgive Scale (Brown, 2003) and the Big Five Inventory (John & Srivastava, 1999). Results from structural equation modeling indicate that older adults were, on average, more willing to forgive others than younger adults. Consistent with previous research, Neuroticism was negatively related to forgivingness and age, whereas Agreeableness showed positive associations with forgivingness and age. Moreover, the influence of Neuroticism on forgivingness decreases with age, whereas the association between Agreeableness and forgivingness increases with age. Future directions concerning the meaning and possible implications of the differential effect of personality traits on forgivingness are discussed.

**Methods/Statistics****D101****DO THIN SLICES PREDICT BEHAVIOR ACROSS LONGER BEHAVIORAL STREAMS? RELIABILITY AND VALIDITY OF THIN SLICES OF NONVERBAL BEHAVIOR** Judith A. Hall<sup>1</sup>, Nora A. Murphy<sup>2</sup>; <sup>1</sup>Northeastern University,

<sup>2</sup>Loyola Marymount University – More and more, it is shown that perceivers can glean accurate information about target persons' states, traits, and personal characteristics from very short excerpts—thin slices—of their behavior or appearance. However, when investigating nonverbal behavior and when designing judgment studies, researchers rely on guesswork more than empirical evidence when deciding on how much behavior to code, and they are often challenged by journal reviewers and editors to defend their use of short excerpts. In this research, the goal was to provide some guidance for researchers facing methodological decisions with respect to measuring nonverbal behavior. We investigated the reliability and validity of rating nonverbal behavior on the basis of 30-s excerpts of silent video. Smiling, gazing, nodding, gestur-

ing, and self-touching were rated by naïve raters every 30 s during a 4-min interaction task for 145 targets. Based on four raters per target, interrater reliability for a single 30-s excerpt was good (median  $r = .72$ ), and the 30-s excerpts had good validity defined as the correlation between a single excerpt and the sum of the remaining seven excerpts (median item-total correlation = .69). Temporal location of the excerpt within the 4-min interaction did not affect validity. Overall reliability, defined as Cronbach's alpha across all eight excerpts (i.e., all four min), was excellent (median alpha = .90). Estimation of reliability using different numbers of raters and excerpts is discussed. The research provides useful information for researchers as they consider the tradeoffs involved in using excerpts of different durations.

#### D102

**BRINGING CONCORDANCE TO PSYCHOLOGY: SCORE CHANGE PROBABILITIES, STANDARD CHANGE, AND THE CONCORDANCE CORRELATION COEFFICIENT** Kimberly Barchard<sup>1</sup>; <sup>1</sup>University of Nevada, Las Vegas – This paper demonstrates new statistics for evaluating score consistency. In psychology, we usually use reliability coefficients to measure the degree of linear relationship between two sets of scores, ignoring differences in means and standard deviations. In medicine, a more stringent criterion is often used: the extent to which the scores are identically equal. This paper introduces two new statistics, Score Change Probabilities and the Standard Change, and shows their relationship to a statistic used in medical research, the Concordance Correlation Coefficient (Lin, 1989). For each test taker, the Score Change value is the difference between the scores obtained under two measurement conditions (such as the first and second rating). These are arranged into a Score Change Probability Table or Graph to show the probability a score would change by any given amount. The Standard Change is the square root of the average squared Score Change, and represents the average change from one set of scores to the other. Finally, the Concordance Correlation Coefficient ranges from -1 to 1: a value of 1 indicates the two scores are identically equal for every test taker. These three statistics are used to evaluate the consistency of ratings of Emotional Awareness (Lane, 1991). Eighteen raters scored 48 participants on 20 items. Two pairs of raters are described in detail. The first pair was very consistent: Standard Change was 1.53. The second pair was less consistent: Standard Change was 6.25. These calculations demonstrate that these three statistics extend the information given by traditional reliability analyses.

#### D103

**CREATING SHORTER PERSONALITY MEASURES: INCORPORATING ITEM-LEVEL VALIDITY DIAGNOSTICS** Fred Oswald<sup>1</sup>, Richard Lucas<sup>2</sup>, Brent Donnellan<sup>2</sup>; <sup>1</sup>Rice University, <sup>2</sup>Michigan State University – There is great interest in developing shorter versions of existing measures that have both reliability and validity. Reliability is typically judged by a minimum alpha coefficient of .70 whereas validity is judged by the degree of theory-consistent patterns of convergent and discriminant association with other measures. The goal of this research is to exploit the power of computational resources to examine the reliability and validity of short form. First, we identified all possible composites of personality items of the 10-item Big Five personality scales from the IPIP-NEO (i.e., all 1-item scales, all 2-item scales, up to all possible 9-item scales). We then identified which items helped to maximize predictive validity. Interestingly, some items always added validity to a composite, no matter how many items were in the composite (i.e., these items "drove" the criterion-related validity); other items were always redundant with items already in the composite and never incremented validity. We believe that these redundant items are the ones which should be pruned from existing scales to create short forms. Consistent with modern psychometric theory (Little, Lindenberger, Nesselroade, 1999), it was often the case that items that maximized validity had non-overlapping content with other items in the score and therefore lowered the alpha reliabilities of the scales. The present study therefore illustrates the tension between internal consistency and validity and identifies the practical considerations that are relevant when creating short forms.

#### D104

**TO BE OR NOT TO BE? MAKING SENSE OF ITEMS POSED AS NEGATIONS** Lynne Steinberg<sup>1</sup>, Robert E. Wickham<sup>1</sup>; <sup>1</sup>University of Houston – Psychological scales often include reversed-scored items as a way of neutralizing response sets. Typically, such items are phrased as negations (e.g., "I do not feel calm"). People respond differently to assertion statements (e.g., "I feel anxious") than they do to negations, even when the two statements refer to the same trait (e.g., Chang, 1995, Miller & Cleary, 1993, Sinclair & Tetrick, 2000). Previously, we (Steinberg & Knowles, 2005) investigated whether the use of negations changes the meaning of an item and found that negation items have a different meaning compared to assertion items that is not simply a reverse in meaning. The current research investigates the possibility that items posed as negations have limited meaning without the context provided by items presented earlier in the questionnaire. The idea is that items posed as negations lack specificity; in other words, describing oneself as not "something" does not imply a specific referent to being "something." Two studies were conducted that presented assertion or negation questions either earlier or later in an anxiety questionnaire. IRT methods for detecting differential item functioning were used to evaluate differences in item responses between assertions and negations. When negation items were presented early in the questionnaire, significantly less relation of the item response to the underlying construct was observed compared to when the same negation items appeared later. These differences were not found for the assertion items. The findings are discussed in terms of meaning changes for reverse-scored items and implications for item writing and scale development.

#### D105

**PSYCHOLOGICAL RESEARCH AND THE INTERNET: A COMPARISON OF ONLINE AND IN-LAB MILLISECOND-PRECISE TASKS** Brittany Travers<sup>1</sup>, Mark Klinger<sup>1</sup>, Carson Sandy<sup>2</sup>; <sup>1</sup>University of Alabama, <sup>2</sup>University of Texas at Austin – The internet is an increasingly popular tool for data collection in psychological research (e.g., Gosling et al., 2004). However, researchers collecting timing-dependent (both presentation timing and response timing) experiments have been reluctant to use internet data collection due to increased distractions in internet conditions. The purpose of this study was to explore the validity of internet results in non-survey research using a variety of basic cognitive and social psychological phenomena. In-lab and online groups of participants completed six different tasks, including the implicit association task (IAT), a Deese, Roediger, and McDermott false memory task (DRM), an exogenous attention task (EAT), an artificial grammar task (AGT), a working memory capacity task (WMC), and a serial response task (SRT). A between-subjects design was employed to compare the results of the in-lab and online groups on each of the tasks. Variability between the groups was examined in terms of differences in overall task performance and in statistical variance. On all but one task (the AGT), the online and in-lab groups showed similar sized effects on the primary dependent measure (accuracy or reaction time). However, more statistical variability was observed for the online group than the in-lab group in five of the six tasks. The results suggest that timing-dependent online experiments can easily reproduce a wide variety of basic cognitive and social psychological effects. However, because the data showed more variability in responding, larger sample sizes are recommended to increase power that is lost due to the increase in variability.

#### D106

**STATISTICAL MODELS OF STUDYING CULTURE AND ATTRIBUTION** Kaiping Peng<sup>1,2</sup>, Saiwing Yeung<sup>1,2</sup>; <sup>1</sup>University of California, Berkeley, <sup>2</sup>Tsinghua University, China – We investigated causal attribution using two recently developed statistical learning techniques and demonstrated that complex human causal attribution patterns could be computationally decomposed into separate theories and that the individual degree of subjective belief in each theory could be estimated. We hypothesize that underneath human causal attribution for any specific phenomenon are a

shared set of implicit theories that could potentially explain the phenomenon. For each individual the degree of subjective belief for each theory can vary depending on personal knowledge or experience. Different theories are associated with a different set of actors and actors could be shared among theories. In the experiment the subjective belief for each actor that they are responsible for said phenomenon are recorded. The response for each actor from each subject reflects the aggregate of beliefs resulted from all theories. In 2 studies, we collected data from 150 subjects in the US and China using tasks with cover stories of animal behavior and chemical reaction. Subjects were asked to assign strength (Study 1: Likert scale; Study 2: 100-point allocation) according to their subjective probability of each actor being a causal factor. Results were analyzed using Probabilistic Topic Models, which provides inference for the mixture of responses, and Chinese Restaurant Process, a nonparametric discrete-time stochastic process which models the partition of the theoretical human theory space. Analyzing data using the above schemes led to discovery of the causal structures for each human subject. Additional implication for cultural psychology are also discussed.

### D107

#### **BETTER TO COUNT YOUR PRONOUNS THAN TO COUNT YOUR CALORIES: TEXT ANALYSIS OF DIET BLOGS** Cindy K. Chung<sup>1</sup>, James W. Pennebaker<sup>1</sup>;

<sup>1</sup>The University of Texas at Austin – Diet blog communities provide a way for dieters to post records of their weight, and accounts of their struggles, challenges, and progress with each entry. Three research questions aimed to uncover processes underlying self-change: What features of blogs predict weight loss? What changes in blogging predict weight loss? Can we predict dropping out or successful weight loss based on the first two entries? A sample of blogs in a diet community by females that had blogged at least 15 entries within the first 15 weeks of blogging resulted in a total of 186 blogs, representing over 9,200 entries for analysis. We applied computerized text analysis to assess self-focus, emotionality, cognitive processing, keeping food diaries, and perceived social support. Rates of blogging were assessed by entries per week. Social support was assessed through the size of the social network, along with the positivity and negativity of the comments. The results suggested that blogging about personal events was a more effective weight loss strategy than keeping an online food intake diary. The degree to which bloggers had moved past the contemplation phase of self-change, and were actively seeking social support in the blog community were potent predictors of weight loss. Online components of behavioral treatment programs could encourage dieters to browse and comment on other dieters' progress, and to share personal narratives rather than simply focusing on the benefits of food intake diaries, nutrition, and exercise. We discuss what can be learned about online self-help through word counts.

### D108

#### **MANAGING TERROR ONLINE: EVIDENCE THAT EFFECTS OF MORTALITY SALIENCE CAN BE OBTAINED IN AN ONLINE STUDY** Kristopher I. Bradley<sup>1</sup>, Shelia M. Kennison<sup>1</sup>;

<sup>1</sup>Oklahoma State University – Prior research has shown that when participants are reminded of their mortality, they are more likely to complete word fragments with death related words rather than neutral words. Most, if not all, of these studies have been conducted in laboratory settings. The present research investigated the possibility of conducting a Terror Management Theory (TMT) experiment online. In the present research, participants were recruited from a large mid-western university and randomly assigned to either the mortality salience condition (MS) or a control condition. Participants received by email an invitation to participate in a study. The study was available for participation from 10 a.m. to 7 p.m. They were free to complete the experiment at a time and location of their choosing. Participants in the MS condition responded to two essay questions regarding their mortality while participants in the control condition completed two essays regarding dental pain. All participants then completed the word fragment completion task. The results in this online experiment were congruent with previous TMT experiments. Participants in the MS condition were more likely to complete the word fragments with death

related words than the participants in the control condition. The results indicate that the effect of MS can be observed in an online format. The implications and the limitations as well as the future directions are discussed.

## Person Perception/Impression Formation

### D109

#### **PROFESSORS' SELF-PRESENTATIONAL TACTICS IN LECTURES: NAME-DROPPING VERSUS REFERENCING** Tobias Heilmann<sup>1</sup>, Isabelle Ehlers<sup>1</sup>, Michèle Nägeli<sup>1</sup>;

<sup>1</sup>University of Zurich – The goal of the present experiment was to examine the effects of indirect and direct self-presentational tactics (Cialdini & Richardson, 1980) in lectures on perceptions of competence and sympathy. Similar to related research (Cialdini & de Nicholas, 1989; Gurevitch, 1985), we assumed that both, positive and negative effects occur for the indirect, but not for the direct tactic. Name-dropping (Lebherz, Jonas, & Tomljenovic, 2009) is an indirect self-presentational tactic that primarily asserts social closeness between a person who employs the tactic and the individual who is mentioned. In contrast, we define referencing as a direct self-presentational tactic that demonstrates competency and expert knowledge without asserting social closeness. In our name-dropping condition, an alleged professor mentioned research of a colleague during a lecture while highlighting the good acquaintance with this person. In the referencing condition, an alleged professor only referenced research of a colleague during a lecture without highlighting the good acquaintance with this person. In the control condition, the alleged professor did not use any self-presentational tactic, i.e., research was presented without mentioning authors. Results of this study (N = 120) revealed that name-dropping and referencing significantly positively influence students' perceptions of professors' competencies. However, name-dropping led to significantly lower perceptions of sympathy than referencing or without any tactic. These results are in line with some studies that show that indirect self-presentation can lead to both, positive and negative effects. Indirect self-presentational tactics such as name-dropping seem to backfire when they are being perceived too manipulative.

### D110

#### **INCREMENTAL VALIDITY OF META-PERCEPTION: DO PEOPLE KNOW WHEN OTHERS SEE THEM DIFFERENTLY THAN THEY VIEW THEMSELVES?** Jordan Livingston<sup>1</sup>, Katrina Jongman-Sereno<sup>1</sup>, Erika Carlson<sup>1</sup>, Simine Vazire<sup>1</sup>;

<sup>1</sup>Washington University in St. Louis – Researchers have argued that often times, people are not aware of the impressions they make (i.e., meta-accuracy is poor) and that when people achieve meta-accuracy for personality impressions, they do so by simply by assuming that others view them as they view themselves (Kenny & DePaulo, 1993). However, Oltmanns et al. (2005) found that on pathological characteristics, people are aware of the ways in which others view them, as distinct from their own self-views, showing that meta-perceptions (i.e., beliefs about others' impressions) have incremental validity over self-perceptions. The current research extends this finding by examining whether people are aware of the impressions they make on others, as unique from their self-perceptions, on core personality traits (e.g., the Big Five). In three studies, we assessed the incremental validity of meta-perceptions (controlling for self-perceptions) on the Big Five for different types of relationships (e.g., new acquaintances, friends, and family). Results revealed that meta-perceptions have incremental validity over self-perception in predicting others' impressions which suggests that people are aware of the discrepancies between their own self-views and others' perceptions of them on core personality traits. These results have important practical implications for researchers interested in personality or self-knowledge. Specifically, to obtain a clear picture of what a person is like or their level of self-knowledge, researchers should ask people to describe both how they view and how others might describe them.

**D111**

**SOCIAL CATEGORIZATION AND STIGMA: PERCEPTIONS OF RACE AND CRIMINALITY** Julia Scott<sup>1</sup>, Doug Evans<sup>1</sup>; <sup>1</sup>Indiana University, Bloomington – Since Goffman's (1963) groundbreaking work, social stigma has become a crucial component in the social construction of the criminal identity. The pejorative effects of criminal convictions are extensive. Extending past the debilitating nature of the criminal justice process, individuals convicted of a felony often experience a crippling of their social status and identity. Racial and ethnic minorities convicted of criminal offenses struggle with the added social burden of prejudice, discrimination, and stereotyping resulting from the color of their skin. The purpose of this study is to examine how a community sample not stigmatized by criminality perceives convicted individuals. Information was gathered through a survey instrument that measured the feelings, attitudes, and attributional judgments of university students. This research sought to identify which aspects of social interaction with convicted offenders evoke significant emotive response in individuals with little or no experience with the criminal justice process. Findings from this study serve to strengthen the literature which informs offender reintegration policy and programs, and builds upon the dearth of emergent empirical work which addresses the development of successful offender redemption strategies. Analysis of variance (ANOVA) reveals that people who knew someone that had been incarcerated were less likely to stigmatize ex-offenders than those without a connection to an incarcerated person. Furthermore, Asians were most likely to stigmatize ex-offenders, while ex-offenders were least stigmatized by African-Americans. Findings indicate that variables of race (race of respondent and race of the fictional ex-offender) and personally knowing an ex-offender mediated the perceived stigma of ex-offenders.

**D112**

**THE OPEN BOOK QUESTIONNAIRE: ASSESSMENT OF PEOPLE WHO ARE EASY AND HARD TO JUDGE** Sun Park<sup>1</sup>, Krista Hill<sup>1</sup>, Randall Colvin<sup>1</sup>; <sup>1</sup>Northeastern University – Research shows that some people are like an open book; their personalities are easily and accurately judged (i.e., highly judgable) whereas other people are enigmatic and difficult to judge. Accurately judged people tend to score high on self and other rated measures of psychological adjustment (Colvin, 1993a, 1993b). Although this line of research is informative about mental health, the labor-intensive multi-method requirements are so daunting that few researchers have attempted to study judgability. To overcome this limitation, we developed the Open Book Questionnaire, a 20-item self-report measure of judgability (e.g., The person I am is the person others see, My friends all know my life story). The purpose of the current research was to assess the validity of the Open Book. MBA students (N = 125) were rated by (a) self, (b) 4 student peers, and (c) 4 work colleagues on several personality questionnaires. After a five-person group decision task all students rated the performance of self and others. In addition, students completed the Open Book, several performance tasks, and testosterone and cortisol levels were assayed. Cronbach's alpha reliability was .75. Preliminary results revealed a positive correlation between students who were most accurately judged (via self-student, and self-work peer agreement on personality) and their Open Book scores. These and additional results provide evidence for the reliability and validity of the Open Book questionnaire.

**D113**

**ACHIEVING EMPATHIC ACCURACY: DO SCHEMAS HELP?** Karyn Lewis<sup>1</sup>, Blake Locher<sup>1</sup>, Sara Hodges<sup>1</sup>; <sup>1</sup>University of Oregon – Empathic accuracy is the ability to correctly infer another's thoughts and feelings (Ickes, 2001). Myers and Hodges (2009) recently proposed that people may draw upon cognitive schemas in order to determine the thoughts and feelings of others. The current study tested whether general schemas about a salient target group – in this case, new mothers – can boost accuracy in inferring a specific target's thoughts and feelings. A total of 145 participants (49 men, M age=19.2) watched a videotape of one of six targets discussing

her experience as a new mother. Following procedures established by Ickes et al. (1990), participants attempted to infer the thoughts and feelings originally reported by the target. In order to determine the schema consistency of these thoughts and feelings, each of the targets' reported thoughts and feelings were coded for the extent to which they were consistent with those of the "typical" new mother. We used hierarchical linear modeling to account for the nested structure of the data and to explore the variability at the thought/feeling level. Participants were more accurate at inferring schema-consistent thoughts and feelings even when controlling for how easy an inference was to guess generally. Analyses also revealed that individuals low in emotional stability (Big 5 neuroticism) received less of a boost in accuracy when inferring schema-consistent thoughts and feelings. Thus, individuals appear to effectively use schemas to guess other people's thoughts and feelings, but their success at doing so is moderated by individual differences.

**D114**

**THIN SLICING IN GROUPS** Paul Stillman<sup>1</sup>; <sup>1</sup>Ohio State University – Judgments of other people are remarkably accurate even when judges are provided with thin slices of others' behavior. The present research extends thin slice research from a focus on individual targets to examine the accuracy of judgments made about groups, based on thin slices of their behavior. A first study found that non-expert judgments of rock band synchronization and cohesion based on thin slices of their performances were highly correlated with the judgments of experts given longer exposure. A second study examined accuracy of predictions for groups' future behavior. Participants estimated the win percentages of ultimate Frisbee teams based on three ten-second video clips of their practice sessions. Ratings were highly correlated with actual win percentage. Together, the results suggest that when given brief exposure to a group, people are able to both infer traits of the group and their future performance. Furthermore, as participants were able to accurately predict traits pertaining to the rapport of the group in addition to traits pertaining to people, participants appeared to do more than judge and average across individuals to generate their ratings.

**D115**

**THE CASE OF BLACK ENGINEERS & ASIAN ATHLETES: PREFERENCE FOR STEREOTYPE CONFORMERS AND BIAS AGAINST STEREOTYPE VIOLATORS** Melissa A. McManus<sup>1</sup>, Nilanjana Dasgupta<sup>1</sup>; <sup>1</sup>University of Massachusetts, Amherst – The current study measured people's evaluations of individuals who were either stereotypical or counterstereotypical of their racial group. Participants listened to audio clips of Asian, Black, and White individuals making statements about their hobbies and interests. All statements were positively valenced and either conformed to stereotypes of the target's racial group (e.g., an Asian American engineering student), violated stereotypes of the target's racial group (e.g., an Asian American athlete), or were neutral in stereotype content. Each speaker's race was subtly implied by their voice intonation and name. After listening to each statement, participants evaluated the speaker in terms of how much they (a) liked or disliked the individual and (b) wanted to approach or avoid the individual. Results indicated that participants liked Asian Americans who conformed to Asian stereotypes significantly more than those who deviated from Asian stereotypes ( $p < .05$ ) and those who were stereotype neutral ( $p < .01$ ). Similarly, participants liked Black Americans who conformed to Black stereotypes over those who deviated from Black stereotypes ( $p = .07$ ). Participants also indicated more willingness to approach and befriend Asian American targets who conformed to Asian stereotypes compared to those who violated the same stereotypes. However, for Black American targets, participants' behavioral intentions did not vary significantly as a function of the stereotypicality of the statement. Together these findings suggest that individuals who conform to positive stereotypes of their racial group tend to be better liked, approached, and befriended than stereotype violators, thus reinforcing the racial status quo.

**D116****ATTITUDES TOWARDS FATHERS AS PRIMARY AND SECONDARY CARE**

**GIVERS** Katharine Wilson<sup>1</sup>, Kareem Johnson<sup>1</sup>, <sup>1</sup>Temple University – Very little research has examined perceptions of fathers in the non-traditional role of primary care giver. Using an online survey, we examined attitudes towards traditional fathers, stay-at-home fathers, single fathers, and fathers with secondary custody. Survey respondents were given brief vignettes depicting the four types of fathers in parental, social, and workplace situations. In a free response section, participants were asked to list adjectives describing traditional fathers, stay-at-home fathers, single fathers, or fathers with secondary custody of their children. Free response adjectives were coded with respect to the Stereotype Content Model (SCM; Fiske et al, 2002). Results showed that traditional fathers were rated the most positively for competence and warmth, corresponding with the SCM's concept of inducing pride. Single fathers and stay-at-home fathers were also rated high in warmth and competence. Fathers with secondary custody of their children were rated most negatively, eliciting significantly lower levels of pride and significantly higher levels of contempt relative to other types of fathers. Analysis of the vignettes found that people high in social dominance orientation (SDO) rated stay-at-home fathers as less competent parents and as less likeable. SDO did not predict lower ratings for other types of fathers in terms of parenting or likeability. No differences were found for evaluations of potential workplace effectiveness across the different types of fathers. Results suggest that attitudes towards fathers who choose to stay at home to care for children are primarily favorable except amongst people who hold strong beliefs about traditional social roles.

**D117****SEEING FRIENDLINESS IN NEGATIVE FEEDBACK**

David S. Lee<sup>1</sup>, Scott J. Moeller<sup>1</sup>, Oscar Ybarra<sup>1</sup>, <sup>1</sup>University of Michigan – When encountering unfamiliar others, humans need to distinguish friend from foe, as connecting with the wrong person can be disastrous. In the present laboratory study, we examined the idea of informativeness as a cue people use to assess others' friendliness. College undergraduates (N=83) were led to believe they would be interacting with another research participant in a "getting acquainted" session. Prior to the presumed interaction, they heard their partner answer various ice-breaker questions (the partner was fictitious; partner responses were prerecorded). In one condition, the partner provided elaborate answers to the ice-breakers; in another condition, the partner provided short responses. Also as part of the procedure (and experimentally independent of the extent of partner informativeness), participants were led to believe that their partner, after listening to the participant's own recorded answers to the same ice-breakers, provided either a positive or negative evaluation of the participant. Although we expected such feedback to influence judged friendliness ratings, our central hypothesis was that people would rate as more friendly a partner who provided more elaborate responses. Results indeed showed that in the more elaborated responses condition, participants rated their partner as friendlier,  $F(1,79)=43.85$ ,  $p<.001$ , and indicated that they wanted to spend more time with him/her,  $F(1,79)=6.48$ ,  $p<.05$ ; these main effects emerged independent of the experimental feedback (positive or negative). Thus, these findings suggest that informativeness emerged as a cue for friendliness of a potential interaction partner even if that partner evaluated the participant negatively.

**D118****PERCEPTIONS OF MOTHERS AND CHILDREN IN VARIOUS WORK-FAMILY**

**SITUATIONS** Jennifer Livengood<sup>1</sup>, Mark Barnett<sup>1</sup>, Tammy Sonnentag<sup>1</sup>, <sup>1</sup>Kansas State University – Stay-at-home mothers tend to be rated as more family-oriented and nurturing than working mothers. However, relatively little is known concerning attitudes toward mothers whose employment status represents a compromise between these two extremes. Prior research has also failed to adequately address whether individuals' attitudes toward mothers with different employment statuses extend to attitudes toward their children and their relationships with their children. The present study addressed these issues. Under-

graduate participants (N = 96) listened to an audiotape of one of three interviews in which a woman described herself as (a) a stay-at-home mother, (b) a working mother who was employed full-time outside the home, or (c) a "middle mother" who chose to take a maternity leave during her child's infancy and then gradually increased her involvement in work outside the home. After listening to an interview, all of the participants watched the same videotape in which the mother interacted with her 4-year-old son during various activities (e.g., completing a puzzle). After watching the videotape, participants completed a series of questionnaires that assessed their attitudes toward the mother, her child, and the mother-child relationship. Participants were found to rate the stay-at-home mother and middle mother more positively than the working mother. This pattern was also found for ratings of the child and the mother-child relationship. Ratings associated with the favored stay-at-home and middle mothers did not differ, suggesting that individuals may value mothers who choose to gradually return to part-time employment after the birth of a child.

**D119****WHO IS WHERE?: SOCIOESPATIAL IDENTITY-LOCATION LINKS ARE STRONGER FOR HIGH-STATUS TARGETS**

Nathaniel J. Ratcliff<sup>1</sup>, Shriver Edwin<sup>1</sup>, Hugenberg Kurt<sup>1</sup>, <sup>1</sup>Miami University – Remembering who-is-where, or sociospatial memory, is an important challenge in effectively navigating the social environment. Past research has found that sociospatial memory, or the binding of a target identity with an episodic memory for location, is better for attractive female targets (Becker, Kenrick, Guerin, & Maner, 2005). The current research investigates whether the perceived power of a target also affects sociospatial memory. Participants completed a Concentration-style matching game, in which they saw 8 pairs of faces arrayed on face-up cards in a 4 × 4 grid. After briefly viewing the faces, the cards were turned face-down. Participants then flipped pairs of cards face-up, attempting to match all of the identities in the array with as few flips as possible (Becker et al., 2005). Some of the targets were depicted in high-status roles (doctor), whereas others were depicted in low-status roles (farmer). Because participants had to remember both the identity and location to successfully make a match, the efficiency with which the targets were matched indicates the strength of sociospatial memory. Supporting the hypothesis that sociospatial memory is better for high-status targets, high-status targets were matched more efficiently (fewer errors) than low-status targets. High-status targets were also more likely to be matched first, indicating that high-status targets attracted initial attention (DeWall & Maner, 2008). This demonstrates that stronger sociospatial (i.e., target-location) links are formed when a target is functionally relevant to the perceiver, such as when that target is high in status or wields power.

**D120****ERROR MANAGEMENT AND THE ATTRIBUTION OF NEGATIVE EMOTIONS: ANGER IS ATTRIBUTED TO PERSONALITY MORE THAN DISGUST**

Andrew Galperin<sup>1</sup>, Martie Haselton<sup>1</sup>, <sup>1</sup>UCLA – The Correspondence Bias (CB), one of the most studied phenomena in social psychology, occurs when observers attribute targets' behaviors to their personality (enduring disposition) more strongly than is logically warranted, usually by underestimating the importance of situational forces acting on the target. The current study is one of the first direct demonstrations that the magnitude of the CB can vary systematically across different domains. An Error Management Theory perspective (Haselton & Buss, 2000) predicts that the CB can be adaptive when the fitness costs of mistakenly ascribing particular personality traits to targets (a false positive) have been lower throughout evolutionary history than the costs of mistakenly failing to detect those traits (a false negative). We tested this hypothesis by comparing the degree to which expressions of anger versus disgust are attributed to personality. We predicted that angry behaviors would be attributed to personality more so than disgusted behaviors, because a failure to detect high dispositional anger in individuals is more costly for future interactions than a failure to detect high dispositional disgust. Undergraduate participants (N=158) read vignettes that showed a ficti-

tious individual reacting to a range of anger- and disgust-inducing situations with an appropriate amount of each respective emotion, and then rated this individual's dispositional anger and disgust. Despite the fact that the individual's actions portrayed him as displaying a moderate and equal amount of both emotions, results showed that participants still rated the individual higher on dispositional anger than on disgust.

#### D121

##### WHEN MORE IS LESS: PREDICTING PSYCHOLOGICAL ADJUSTMENT FOLLOWING MARITAL SEPARATION FROM THIN SLICES OF INFORMATION

Ashley E. Mason<sup>1</sup>, David A. Sbarra<sup>1</sup>; <sup>1</sup>The University of Arizona – Person-perception investigations have revealed that people with whom we are unacquainted (unacquainted judges) are able to accurately infer our personalities and other characteristics. This study applied a person-perception paradigm to the investigation of psychological adjustment (PA) following divorce. Specifically, we examined the degree to which judges and recently divorced individuals (targets) agreed about targets' PA (concurrent validity) and the degree to which judges' perceptions of targets' PA were predictive of targets' subsequent PA (predictive utility). We also examined how the amount of information provided to judges affected these two outcomes. Participants were one hundred and nine (38 men) recently divorced adults who completed two self-report indices of PA. During a laboratory visit, participants completed a stream-of-consciousness (SOC) digital voice recording during which their speech was recorded for four minutes. Eight undergraduates served as judges who listened to either 30-second or 3-minute auditory clips made from these recordings. Ratings made by both the 30-second and the 3-minute judges were significantly related to targets' self-reported PA (self-other agreement). After accounting for PA at T1 and other covariates, the 3-minute ratings of targets' depressive symptoms, and the 30-second judges' ratings of targets' emotional reactivity were predictive of targets' self-reported PA at T2. Increases in information were associated with greater self-other agreement among targets and judges. Increases in information were associated with greater predictive utility of judges' ratings of targets' depression, but were negatively associated with judges' ratings of targets' emotional reactivity, suggesting that more information does not always lead to increased accuracy.

#### D122

##### HALF A MIND: CONSIDERING OTHERS' INTENTIONS DECREASES SENSITIVITY TO THEIR EMOTIONS

Adrianna C. Jenkins<sup>1</sup>, Daniel M. Wegner<sup>1</sup>; <sup>1</sup>Harvard University – People often perceive other minds along two dimensions: agency, the capacity for intention and planning, and experience, the capacity for emotion and sensation (Gray, Gray, & Wegner, 2007). The ability to infer someone's experience facilitates predictions about what that person will do. If a person is afraid, she may run away; if hungry, she may try to steal your sandwich. However, if one already knows what a person intends to do, preoccupation with his or her experiential state may be less useful and potentially distracting. This study tested whether inferring a person's plans and intentions interferes with one's ability to infer his or her emotions. Participants made a series of paired judgments about photographed individuals' intentions and emotions in a 2 (Prime content: Intention, Emotion) x 2 (Target content: Intention, Emotion) response facilitation design. A two-way ANOVA on response times revealed the predicted interaction between Prime and Target content. First considering a person's intention reduced the speed with which participants responded to questions about the person's emotion, whereas first considering a person's emotion had no such effect on participants' consideration of intentions. Results underscore the dissociability of agency and experience as dimensions of mind perception and suggest an asymmetry in their relationship. Focusing on others' emotions is compatible with thinking about their intentions, but focusing on their plans, intentions, and goals may temporarily blind perceivers to their emotions. Gray, H., Gray, K., & Wegner, D. M. (2007). Dimensions of mind perception. *Science*, 315, 619.

#### D123

##### TO APE, OR NOT TO APE? AUTOMATIC COMPLEMENTARITY RESPONSES IN REACTION TO DOMINANT AND SUBMISSIVE MOVEMENTS

Barbara C.N. Müller<sup>1</sup>, Ron Dotsch<sup>1</sup>, Matthijs L. van Leeuwen<sup>1</sup>, Ap Dijksterhuis<sup>1</sup>, Rick B. van Baaren<sup>1</sup>; <sup>1</sup>Behavioural Science Institute, Radboud University Nijmegen, The Netherlands – The mimicry literature suggests that mimicry is almost always the default reaction in human interaction; humans are 'wired' to imitate. (Iacoboni, Woods, Brass, Bekkering, Mazziotta, & Rizzolatti, 2001; Rizzolatti, Fadiga, Gallese, & Fogassi, 1996). In contrast, research on interpersonal circumplex theory has classified interpersonal behaviour along two independent axes (Kiesler, 1983). First, behaviours on the 'affiliation' axis associated with agreeable-quarrelsome behaviours are supposed to be imitated. In contrast, the 'control' axis is associated with dominant-submissive behaviours which are thought to be complemented, i.e., engaging in the opposite type of behaviour of one's interaction partner. Recent studies on both animal and human behaviour suggests that complementarity might be a contextually activated default reaction (de Waal, 1982; Tiedens & Fragale, 2003). The present study examined whether complementarity rather than imitation is an automatic motor response to dominance-related movements in human beings. Participants saw a two-framed sequence of photographs of male or female confederates who were making either a dominant or submissive movement, and were instructed to either make a dominant or a submissive movement themselves, resulting in imitative or complementary movements. Interestingly, results showed that participants showed faster complementarity reactions in response to male confederates, while mimicry reactions were faster in response to female confederates. The current study provides further insights into the underlying processes of automatic nonverbal behaviour. Correlated experiences of observing one set of dominance-related behaviours and executing another set of complementary behaviours could seemingly overrule automatic mimicry responses under certain circumstances.

#### D124

##### PERSONALITY JUDGMENTS FROM A LINEUP

Andrew Beer<sup>1</sup>; <sup>1</sup>University of South Carolina Upstate – The scientific study of accuracy in personality judgment typically involves the utilization of rating scales to make decisions about a target individual. While this method has its merits, it is at times restrictive and is further removed from full ecological validity than one would desire. These studies represent an attempt to develop an alternative methodology for the study of personality judgment. The objective is simple: create a choice task for personality judgment. There are two primary benefits to this endeavor. First, such a method would facilitate previously difficult lines of inquiry in the field of personality judgment, such as mood and cognitive load effects. Second, one could argue that in our daily lives, we make simple comparative choices between people (e.g., in a job interview setting) rather than exhaustive numerical ratings about people whom we encounter, thus a choice task more closely approximates the naturally occurring psychological process. To accomplish these goals, I created a series of photo sets containing pictures of three individuals, each representing a different level (based on self reports) of a specific personality trait. The participant's task was to select high and low scorers on a dimension from the photos. Study 1 demonstrates that people can select targets with extreme scores from a photo lineup better than chance across several personality dimensions. Study 2 shows that this ability has some degree of temporal consistency. Study 3 represents an improvement on the general method via enhanced criteria for stimulus (target) selection, incorporating both self and peer reports.

#### D125

##### RESPECT YOUR (PERFECT) ELDERS!: THE CONTINGENT NATURE OF ELDER RESPECT

Monica J. Harris<sup>1</sup>, Candice Tucker Groves<sup>2</sup>, Sarai Blincoe<sup>1</sup>; <sup>1</sup>University of Kentucky, <sup>2</sup>Western Kentucky University – Past cross-cultural research shows that elderly individuals overwhelmingly view disrespect as the most painful form of mistreatment. Psychological

research on respect suggests that it is vital to relationship satisfaction and group commitment; therefore, elderly individuals who feel disrespected may disengage from society. The present study investigated college undergraduates' reports of the extent and nature of respect they would give in interactions with different elderly prototypes. 173 participants read a brief vignette describing an interaction with a hypothetical Mrs. Brown, whose behavior characterized one of four elder stereotypes (perfect grandparent; self-centered old person; cognitively impaired; physically frail). Participants then rated their likelihood of performing 20 respectful behaviors on Mrs. Brown's behalf and provided an overall rating of their respect for her. The 20 behaviors were combined into five composites (i.e., care, gift, courtesy, advice and linguistic). The perfect grandparent was deemed most respect-worthy overall, and was the most likely to receive care, gift and courtesy respect. When Mrs. Brown was portrayed as physically frail or cognitively impaired she received less respect, but was still significantly more respected than when described as self-centered. No significant differences were found for the likelihood of giving linguistic respect, raising the intriguing issue of whether linguistic respect reflects cultural norms rather than a truly respectful attitude. The present research reveals that in the case of the elderly, respect is contingent on the behaviors of the target as opposed to being socially obligatory.

#### D126

##### **SAVING THE SAVINGS MEASURE: A SIMPLIFIED METHOD FOR ASSESSING STRENGTH OF ASSOCIATIONS** Erica D. Schneid<sup>1</sup>, Donal E. Carlston<sup>1</sup>; <sup>1</sup>Purdue University

This study sought to create a new, simpler self-report method of assessing associative strength as well as further investigate the role of memory in the formation of Spontaneous Trait Inference (STIs) and Spontaneous Trait Transference (STT). After receiving one of three instructional sets, participants (N = 316) were presented with 16 trait-implicative behavior descriptions that were either self-or other-referent, as well as eight neutral items. Approximately half of the participants were given a delay/decay task immediately after presentation. Strength of association was later measured using a novel, single-item, self-report scale. Participants were also asked to report any information they could recall about the incident originally paired with each photo. Results replicated the pattern of results seen in previous research. The self-reported strength of association between a given photo and a trait was significantly stronger for self-referent items (reflecting STIs), followed by other-referent statements (reflecting STTs), with neutral statements showing the least strength of association (reflecting base-lines). These results were impervious to different processing goals and to the delay manipulation. The recall data also suggests that the effect is not memory dependent-- Neither STIs nor STTs depend on participants' ability to recall the original stimulus behaviors. It appears that this new measure obtains the same results as past research with considerable savings of time and effort.

#### D127

##### **PERSON PERCEPTION BY ACTIVE VERSUS PASSIVE PERCEIVERS**

Ashley Waggoner<sup>1</sup>, Eliot Smith<sup>1</sup>, Elizabeth Collins<sup>2</sup>; <sup>1</sup>Indiana University, Bloomington, <sup>2</sup>CIS/ISCTE, Lisbon, Portugal – Person perception research is dominated by studies of passive perceivers who exert no control over the information they receive. In contrast, perceivers in everyday life can often actively choose the type and quantity of information they receive (Smith & Collins, 2009). In this study, active and yoked passive perceivers formed impressions of individuals based on information from their Facebook profiles. Active participants chose which components of a targets' Facebook profile to view, and decided when to stop viewing information and provide their impression. Passive participants were shown the same items chosen by their yoked active perceiver before providing their impression. Perceivers judged the targets on several dimensions: the Big Five personality dimensions, political ideology, and degree of religiosity. They also indicated how confident they were in their judgments, how easy these were to form, and how much they liked the target. Compared to active perceivers, passive perceivers reported greater

confidence ( $p < .02$ ) and ease ( $p < .001$ ) in their judgments. Passive perceivers exhibited greater confidence (though not greater accuracy) with increased information. Active perceivers did not show this effect, placing a boundary condition on past research. Passive perceivers also liked targets more than active perceivers ( $p < .02$ ), a finding that is not explained by valence-dependant sampling by active participants, or by misattribution of fluency or greater sensitivity among passive participants. These provocative findings highlight the need to account for active and interactive processes in person perception rather than continuing to focus on passive perceivers.

#### D128

##### **MENTAL STATE ATTRIBUTION IN MEDICINE: DIFFERENTIAL EFFECTS OF FOCUS ON EXPERIENCE VS. AGENCY** Andrea S. Heberlein<sup>1</sup>, Jordan Ford<sup>1</sup>, Daniel M. Wegner<sup>1</sup>; <sup>1</sup>Harvard University

More empathic doctors are obviously desirable from a patient standpoint. However, the proliferation of "empathy training" curricula in medical schools, numerous anecdotes of declining empathy among physicians, and published reports of empathy decreasing even across clinical training years suggest that there are constraints on physician empathy. The present study explored this apparent tension between how empathic doctors ought to be, and how empathic they are able to be, using attention to the mind of another as a proxy for empathy. We focused on a distinction between two qualities that people attribute to other minds: experience (the capacity to feel sensations and emotions) and agency (the capacity to plan and control one's behavior). Participants read a doctor-patient conversation vignette and were instructed to generate two additional questions the doctor could have asked to get more information about the patient's goals, feelings, or medical history (between subjects). These questions were rated, independently, for agentic and experiential content. After a delay, participants listed 10 things they remembered about the patient. Level of agentic content in participants' questions was correlated with the number of medical details participants spontaneously recalled, whereas experiential content was correlated with the number of biographical details recalled. A second study in which participants played the role of the doctor in a scripted interaction replicated these findings. These results suggest that attending to a patient's feelings and emotions distracts physicians from medically-relevant information, whereas attending to other mental features-- her treatment goals-- does not have the same effect.

#### D129

##### **SEXUAL ACTIVITY REDUCES MEN'S PERCEIVED FACIAL ATTRACTIVENESS AND FRIENDLINESS OF UNKNOWN WOMEN** Annie

Simard<sup>1</sup>, Pascal Thibault<sup>2</sup>, Nancy Smith<sup>1</sup>, Michel Cossette<sup>1</sup>, Marie Lasalle<sup>1</sup>, Ursula Hess<sup>1</sup>, Stuart Brody<sup>3</sup>; <sup>1</sup>University of Quebec at Montreal, <sup>2</sup>McGill University, <sup>3</sup>University of the West of Scotland – People pay great attention to physical attractiveness when it is time to choose a sexual partner, especially for short-term relationships. Hess et al. (2007) found that this propensity is significantly reduced for women if they engaged more frequently in sexual behaviors with their current partner. In order to replicate with men this original study of Hess et al. (2007) on sexual activity and attractiveness, thirty-eight men reported the frequency of five sexual behaviors (oral sex, masturbation, masturbation with a partner, penile-vaginal intercourse and penile-anal intercourse) and rated the facial attractiveness and friendliness of 20 women (10 Gabonese, 10 Quebecois). As regards attractiveness, we found that the frequency of orgasm experienced during all the partnered activities excluding penile-vaginal intercourse correlated negatively and significantly with perceptions of attractiveness. Also, a significant and marginally negative correlation emerged between the perceptions of attractiveness and the frequencies of penile-anal intercourse and of masturbation with a partner. The results also revealed that the frequency of masturbation, of orgasm from masturbation and of penile-anal intercourse correlated significantly and negatively with the perception of friendliness. Thus, men who experienced more frequently orgasm from partnered sexual activities excluding penile-vaginal intercourse and who engaged more frequently in penile-anal intercourse during the last 30 days perceived unknown

women as less facially attractive. Moreover, men who masturbated more frequently and experienced orgasm from it more frequently perceived unknown women as less friendly. Overall, these results from men largely replicated Hess et al (2007) findings with women.

### D130

**SELF-PRESENTATION IN THE MULTIPLE AUDIENCE SITUATION DEPLETES REGULATORY RESOURCE** Yuu Kasagi<sup>1,2</sup>, Ikuo Daibo<sup>1</sup>; <sup>1</sup>Graduate School of Human Sciences of Osaka University, <sup>2</sup>JSPS – Multiple audience problem (e.g., Fleming, 1994) is the difficult self-presentation situation in which someone is faced with two or more “audiences”, simultaneously wanting each audience to form or preserve a different impression of him/her. Generally, people often confront with this problem, but they can't resolve it effectively. According to Vohs et al. (2005), self-presentation under challenging condition or according to counter-normative patterns led to impaired self-regulation later, suggesting that those self-presentations depleted self-regulatory resources. While when self-presentation conformed to familiar, normative, or dispositional patterns, self-regulation was less implicated. So, we hypothesized that participants in multiple audience condition should therefore experience self-regulatory resource depletion. Participants were randomly assigned to the multiple audience condition or the control condition. Then, they spoke in front of the video camera to impress others who would watch this video. After the participants spoke in front of the video camera for 3 sessions, participants engaged in a self-control task of completing 3-digit × 3-digit multiplication problems by hand. Previous studies showed that this task is quite tedious and the desire to stop arises quickly: hence, persistence requires that one override the urge to quit and exert extra effort to continue. As we predicted, the results revealed that participants in multiple audience condition gave up faster than participants in the other conditions. The self-presenting style in the multiple audience situation would have required more self-regulatory resources than in the control condition. So, they might have fewer resources to help them continue working on the multiplication problems.

### D131

**IMPRESSIONS OF OLDER ADULTS** DeAnn R. Collins<sup>1</sup>, Shannon Whitten<sup>1</sup>, Erin Murdoch<sup>1</sup>, Karen Mottarella<sup>1</sup>; <sup>1</sup>University of Central Florida – The purpose of this study was to investigate the factors associated with impressions of older adults. Participants were asked to rate 169 images of older adults based on their initial impression of each image on a six point Likert scale ranging from 1 (highly negative) to 6 (highly positive). The images depicted older adults in various everyday settings. Patterns were explored by identifying the 25 most positively and 25 most negatively rated images. Average ratings for negative images ranged from 1.61 to 2.42, whereas ratings for positive images ranged from 4.95 to 5.64. The resulting data identified two significant patterns: positive images included more than one person and more outdoor settings. The data are summarized as follows: positive images including more than one person 64%, image is outdoors 84%; compared to negative images including more than one person 4%, image is outdoors 40%. A chi-square analysis was conducted on both of the dependent variables to test whether the differences between the positive and negative images were statistically reliable and the results are significant at the  $p < .01$  level. This supports the idea that older adults who appear socially engaged and/or are more physically active are perceived more positively whereas older adults depicted in a more sedentary setting by themselves were more often perceived negatively. The implications of these findings are that in order to be perceived positively, older adults should be portrayed in more physically active and socially engaged roles.

### D132

**PHYSICAL SIMILARITY AND ATTRACTIVENESS SIMILARITY PREDICT SEATING DISTANCE** Sean P. Mackinnon<sup>1</sup>, Christian H. Jordan<sup>1</sup>, Anne E. Wilson<sup>1</sup>; <sup>1</sup>Wilfrid Laurier University – Research has shown a general trend for people to choose friends and romantic partners who are similar in race, socioeconomic status, attractiveness, and physical appearance. The

current study is interested in micro-level behaviors between strangers that might lay the groundwork for this tendency in more established relationships. Prior observational research in our lab revealed a general tendency for students to sit beside physically similar others within a naturalistic classroom setting. The current study expands on these naturalistic studies by examining the phenomenon within a laboratory setting. Specifically, we propose that participants will sit closer to a confederate who physically resembles them. In this study, participants came into the lab one at a time to join a female confederate posing as another participant. Photos of participants were coded for physical similarity to a confederate by independent coders. Attractiveness was also coded. Before a short social interaction with the confederate, participants placed their chair relative to the confederate. The distance between the chairs was measured once the participant left. Results showed that participants sat closer to the confederate as physical similarity to the confederate increased. This finding remained significant even when controlling for sex and race. Interestingly, participants also tended to sit closer to the confederate when they matched her level of attractiveness. Physical similarity and attractiveness similarity each accounted for unique portions of the variance when predicting seating distance in a multiple regression analysis. The implications of these findings for early relationship formation are discussed in the context of prior research.

### D133

**CATEGORY CONTRAST CREATES CONTEXTUALLY-DEPENDENT SHIFTS IN ATTRACTIVENESS** Tyler Davis<sup>1</sup>, Bradley Love<sup>1</sup>; <sup>1</sup>University of Texas at Austin – The beauty-in-averageness (BIA) effect describes the finding whereby faces that are average, in a statistical sense, are judged as more attractive in comparison to less average faces. There are two widely held perspectives on BIA. One perspective derives from evolutionary theory, and suggests that average faces are held as more attractive because averageness provides a cue for mate-value. Another perspective holds that BIA arises because averages are more fluent or ‘easy on the mind.’ In the present study, we dissociate fluency and evolutionary accounts by systematically manipulating how novel artificial categories are contrasted with each other as subjects acquire them. Previous research (Davis & Love, in press) has shown that these manipulations can distort people's perceptions of category averages such that, in certain contexts, statistical averages are processed more fluently, and in other cases extreme (/caricatured) stimuli are processed more fluently. Consistent with our predictions, across subjects, the same stimuli were rated as either more or less attractive depending on how the subjects acquired the categories. Specifically, when a stimulus dimension was contrasted during learning, stimuli that were extreme along this dimension were rated as most attractive, not the averages. Non-contrasted dimensions were not found to influence attractiveness ratings. Our results support a fluency-based perspective of attractiveness, and suggest that perceptions of attractiveness can be shaped by something as culturally sensitive as one's learning history.

### D134

**FAMILY MATTERS: WHO YOU'RE BORN WITH AFFECTS WHO YOU'LL END UP WITH** Elizabeth Osborne<sup>1</sup>, Yexin Jessica Li<sup>1</sup>, Adam Cohen<sup>1</sup>; <sup>1</sup>Arizona State University – People should use every available cue to determine a potential partner's genetic fitness. Existing attractiveness research examines only cues directly from a prospective partner, like waist to hip ratio, or symmetry versus fluctuating asymmetry. In a new theory we call the Kin Inferred Selection Theory we propose that people also evaluate a potential mate's genetic fitness by evaluating the fitness of their relatives. A person does not express all genes. Some may be recessive while others may be expressed later in life. These genes may be expressed in family members. In a first experimental test of our theory, we exposed women to photos of an average male target who was surrounded by attractive, unattractive, or no family members (control). Participants made judgments on various traits of the target now and twenty years from now. We found there was little effect between conditions for all traits for the target now, but twenty years from now targets were expected to be significantly more attractive, healthy, desirable, nicer and

more intelligent if they were surrounded by attractive family members. The difference in attractiveness and health ratings were particularly high between all three conditions, suggesting that these effects are due to evaluations of genetic fitness. This first experiment provides evidence that we base long term mating decisions not only on the characteristics of a mate but also their family members.

### D135

**I'M NOT A SEXIST, BUT... THE IRONIC EFFECT OF DISCLAIMERS ON IMPRESSION FORMATION.** Corey Columb<sup>1</sup>, Joyce Ehrlinger<sup>1</sup>; <sup>1</sup>Florida State University – People sometimes offer disclaimers for potentially problematic statements. For example, before making critical comments about a co-worker who happens to be a minority, one might first say "I'm not a racist, but..." We propose that disclaimers are used to diffuse the possibility of a negative reaction but, instead, lead people to more often assume the very characteristic that the disclaimer disavows. We argue further that the effect of a disclaimer on impression formation depends upon the personal relevance for the perceiver. Participants were asked to read a vignette portraying a conversation in which a man told a potentially sexist joke to a woman. Half of participants read that the man said "First, I should tell you that I am not sexist, but..." before telling the joke while the other half read a version including no disclaimer. The vignettes were identical outside of this manipulation. An ANOVA revealed a main effect whereby participants who read the disclaimer version were more likely to rate the man as sexist than were those who read the control vignette. Further, this main effect was qualified by an interaction between disclaimer condition and gender. Men were unaffected by the presence of a disclaimer when evaluating the target, while women were much more likely to rate the target as sexist when he offered a disclaimer denying sexism. Instead of preventing a negative reaction as intended, disclaimers actually increase the possibility of a negative reaction, but only if the disclaimer is relevant to the person making the perception.

### D136

**DO OUR SELF-VIEWS INFLUENCE THE WAY WE THINK OTHERS SEE US? INFLUENCE OF PRIVATE KNOWLEDGE ON INTERPRETING OTHERS' IMPRESSIONS** Corinne Novell<sup>1</sup>, John Chambers<sup>1</sup>; <sup>1</sup>University of Florida – People fail to understand the impressions they make on others. We suggest that such failures occur in part because people utilize information known only to them when interpreting others' feedback and impressions of them. To examine this question, participants in this study performed a task and some learned how other participants in their session had performed. They then received a neutrally-worded evaluation from a judge—who supposedly viewed their performance and no one else's—and rated the positivity of that evaluation. Participants who were led to believe they had performed better than their fellow co-participants interpreted the judge's evaluation more positively than those who were led to believe they had performed worse (with those provided no information about their fellow co-participants rating the evaluation more neutrally). These effects were limited to impressions of personal traits relevant to the task domain and were mediated by participants' perceptions of their own performance on the task. Overall, these findings suggest that when people construe others' impressions of them, they may not weigh others' actual opinions as much as their own—that is, people may use their self-perceptions to process incoming information more.

### D137

**STARING RIGHT AT YOU: "HEAD ON" DEPICTIONS OF AUTOMOBILES PRIME POWER** Jonathon Schuldt<sup>1</sup>, Sara Konrath<sup>1</sup>, Norbert Schwarz<sup>1</sup>; <sup>1</sup>University of Michigan – Multiple features of the human face, including direct eye gaze, signal power. Research shows that humans readily perceive faces in non-living objects, including the fronts of automobiles, suggesting that merely depicting automobiles as "head on" may be sufficient to prime power. Data from three studies were consistent this conjecture. Content analysis of images appearing on manufacturers' websites (Study 1) revealed that automobiles depicted head on placed

higher on a number of objective power variables (e.g., retail cost, fuel-inefficiency) than non-head on vehicles. Web experiments featuring eight automobiles and over 400 participants (Study 2) revealed that SUVs, but not sedans, were rated as more powerful when depicted head on versus in side profile, suggesting that power primes may be more applicable to targets with additional dominance attributes (e.g., size). A lab experiment employing a person perception task (Study 3) revealed that a businessperson, "Adam", was rated higher on highly context-relevant power traits (e.g., hardworking in the business-professional context), but not domain-general power traits (e.g., dominant), when his SUV was depicted as head on versus in side profile. These findings suggest that head on depictions covary with power attributes in the real world and facilitate the perception of automobiles and their owners as more powerful, although only in applicable contexts.

### D138

**SOCIAL EXPLANATORY STYLE AS AN (UNDER-EXAMINED) ASPECT OF ORDINARY PSYCHOLOGY** Michael Andreychik<sup>1</sup>, Michael Gill<sup>2</sup>; <sup>1</sup>Fairfield University, <sup>2</sup>Lehigh University – The present work is focused on the fundamental lay theories that structure social understanding in everyday encounters as people strive to "make sense of" the social propensities (e.g., patterns of actions and outcomes) of others. We argue that whereas existing approaches have focused primarily on the idea that people's lay theories of social action contain explanatory principles relating human action to unobservable mental states (i.e., work stemming from a Theory of Mind approach), there exist additional, under-examined aspects of lay theories of social action. In particular, we advance the idea that lay theories of social action also contain causal-explanatory principles relating to the nature of person characteristics and the mental states associated with them. The results of three studies provide evidence consistent with the idea that individuals possess Social Explanatory Styles—broad and characteristic tendencies to explain the social propensities of others in terms of terms of either self-existent (e.g., "That's just the way she is! She's always doing that!") or interconnected (e.g., "Anyone who grew up in an environment like that would behave just like her!") person characteristics. Further, our results are also consistent with the idea that these Social Explanatory Styles function as lay theories in the sense that they exert theory-like effects on the processing of social information.

### D139

**CONSIDERING SINGLE PARENTS AS POTENTIAL PARTNERS: THE INFLUENCE OF ATTRACTIVENESS, SEX, AND BODY MASS INDEX** Shane Moulton<sup>1</sup>, Markus Kimmelmeier<sup>1</sup>, Lorie Sicafuse<sup>1</sup>, Valerie Lykes<sup>1</sup>; <sup>1</sup>University of Nevada – The U.S. has one of the highest divorce rates worldwide with almost one in two marriages ending in divorce. More than ever there are single parents, men and women with children, who are looking for new romance. And just like never-married mothers and fathers have experienced all along, previously married mothers and fathers are discovering that other singles would rather not get involved with someone who already has some kids in tow. This research project investigates how "parent status" affects college students' partner selection choices; and how the effect is moderated by target and perceiver factors. Using online-dating-style profiles, we manipulated the parent status and physical attractiveness of male and female targets, and asked heterosexual participants (n = 196) to rate their hypothetical interests in various forms of short- and long-term relationships with the targets. Results showed that target factors (attractiveness and parent status), as well as participant factors (sex and body mass index [BMI]), affect individuals' romantic interests in the opposite sex. Participants desired highly attractive targets over those of average-attractiveness, but this effect was qualified by sex and parent status in that women were more likely than men to express interest in the high-attractiveness targets with children. Moreover, there was strong evidence that high-BMI participants desired average-attractiveness targets with no children more than did those of low-to-average BMI. These results suggest females are more tolerant of parent status than men; and that individuals with high BMI are more lenient regarding attractiveness of a person with no children.

**D140****PHYSICAL ATTRACTIVENESS: FROM INITIAL JUDGMENTS TO KNOWLEDGE OF DYNAMIC PERSONALITY CHARACTERISTICS** Kinsey

Pell<sup>1</sup>, Derrick Wirtz<sup>2</sup>, Steven Barger<sup>1</sup>, Steven Funk<sup>1</sup>; <sup>1</sup>Northern Arizona University, <sup>2</sup>East Carolina University – Judgments of physical attractiveness inherently emphasize physical characteristics such as facial features. However, can knowledge of a target individual's inner attributes – such as personality – affect how physically attractive that target appears? Early research examining this question demonstrated that the same photographed individual was judged more physically attractive when the photograph was accompanied by a positive (versus negative) personality description (Gross & Crofton, 1977). The present study examined how judgments of physical attractiveness were affected by a dynamic representation of a target individual, similar to a brief, everyday encounter. Sixty-three heterosexual female participants were randomly assigned to view a scripted video interview in which a moderately attractive male target's personality was portrayed as either pleasant or unpleasant. Participants rated the target's physical attractiveness before and after the interview, along with a series of distraction measures. Prior to the interview, target physical attractiveness did not differ across conditions. After viewing the interview, participants in the pleasant personality condition rated the target as more physically attractive (compared with their initial rating), while those who viewed the unpleasant personality condition rated the target as less physically attractive (compared with their initial rating). These findings confirm that nonphysical attributes can affect perceived physical attractiveness, consistent with both social cognitive (e.g., Berscheid & Walster, 1974; Nisbett & Wilson, 1977) and evolutionary perspectives (e.g., Kniffin & Wilson, 2004; Langlois, Kalakanis, Rubenstein, Larson, Hallam, & Smoot, 2000).

**D141****THE EFFECT OF AGE UPON ESTIMATION OF AGE** Manuel Voelkle<sup>1</sup>,

Michaela Riediger<sup>1</sup>, Natalie C. Ebner<sup>2</sup>, Ulman Lindenberger<sup>1</sup>; <sup>1</sup>Max Planck Institute for Human Development, <sup>2</sup>Yale University – Perceived age is one of the most prominent characteristics to describe a person (e.g., a suspect) and influences how we interact with somebody. The present study addresses a) the effect of perceiver's age upon the precision of age estimation, b) the role of the target persons' age, and c) the impact of displayed emotions. Pictures from the recently created FACES database (Ebner, Riediger, & Lindenberger, in press) were used as stimuli. The database contains 2052 standardized photographs of 171 men and women aged 20 to 81 years, each displaying angry, fearful, disgusted, happy, sad, and neutral facial expressions. One hundred fifty-four women and men of the same age range rated the age of each of the depicted persons. Across all raters, the age of young faces was slightly overestimated, whereas the age of older faces was considerably underestimated. However, while young individuals were quite accurate in estimating the age of members of their own age group, they tended to largely underestimate older faces. In contrast, older persons significantly overestimated the age of young faces. They also underestimated the age of members of their own age group, however to a lesser degree than did young raters. Furthermore, accuracy of age estimation was affected by posed emotions: Happy (and to a lesser degree neutral) faces tended to make a face look younger, resulting in more accurate estimates of young faces and less accurate estimates of older faces. Results are discussed in the context of own-age-biases and their practical implications.

**D142****DRM AND PERSONALITY: USING FALSE MEMORIES TO STUDY THE IMPLICIT THEORY OF PERSONALITY** Ludmila Nunes<sup>1</sup>, Leonel Garcia-

Marques<sup>1</sup>, Mário Ferreira<sup>1</sup>, Margarida Garrido<sup>2</sup>, Teresa Garcia-Marques<sup>3</sup>; <sup>1</sup>University of Lisbon, Portugal, <sup>2</sup>CIS/ISCTE – Lisbon University Institute, Portugal, <sup>3</sup>ISPA, Portugal – We extended the Deese-Roediger-McDermott paradigm (Roediger & McDermott, 1995) to study impression formation. Our main goal was to explore special characteristics of the associative memory structure underlying impression formation. Traits most com-

monly used in describing person-targets were used to identify four clusters underlying the implicit theory of personality structure (intellectual positive/negative; social positive/negative). Then, we developed lists including semantic neighbours of the traits closest to the clusters' centroid and a-thematic (non-trait) words. Participants were presented with these lists and instructed to form an impression of personality or to simply memorize them. Impression formation relatively to memory participants produced higher levels of true recognition and of false memories of lures corresponding to the same cluster of the list traits. In a following gist test, in which participants were asked to identify both presented words and related ones, we also found a similar pattern of results. In a subsequent study, we manipulated the dimension, valence and presentation order of presented traits. The pattern of results obtained in the first study was replicated; and in the impression formation condition, we obtained a primacy effect moderated by valence, with more false memories from the dimension of the first presented traits when these were positive. Taken together, results suggest that forming impressions imply the activation of a specialized associative memory structure underlying the referred implicit theory of personality (Rosenberg, Nelson, & Vivekanathan, 1968); and that many factors may have different effects depending on the associative memory structure activated by the encoding goal.

**D143****EXPOSURE TO MATING CUES ENHANCES MEMORY RETRIEVAL**

Michael Baker<sup>1</sup>, Jon Maner<sup>1</sup>; <sup>1</sup>Florida State University – Two studies test the relationship between exposure to mating cues and memory processes. In Study 1, men who viewed attractive female faces while listening to a story remembered more details of the story than men who viewed female faces of average attractiveness. Study 2 was designed to establish whether the memory enhancement found in Study 1 was due to a boost in encoding or retrieval (or both). Participants were presented with attractive opposite sex faces prior to encoding or prior to retrieval, while participants in a control condition viewed average faces. Results suggest an enhancement of retrieval but not encoding for both men and women, though the effect is stronger in men. Potential mechanisms and future directions are discussed.

**D144****MOTIVATING THE UNMOTIVATED: IMPROVING THE INTERPERSONAL SENSITIVITY OF PREJUDICED PEOPLE WHEN JUDGING BLACK TARGETS** Susan Andrzejewski<sup>1</sup>, Judith Hall<sup>2</sup>; <sup>1</sup>Franklin & Marshall College,

<sup>2</sup>Northeastern University – Previous research has found an inverse relation between prejudice and decoding such that the more prejudiced individual does worse on decoding interpersonal sensitivity tests involving Black targets. The present study suggests that low motivation may be one factor contributing to this decoding deficit. If high prejudiced persons are withdrawing effort when they are asked to decode a Black target test, then motivating them to want to perform well might improve their performance. Participants were randomly assigned to either a motivated or control condition and to one of two interpersonal sensitivity tests (Black or White targets). For the Black targets test, in a motivation condition (motivated vs. control) X implicit attitudes (low prejudice vs. high prejudice, by median split) ANOVA, there was a significant interaction showing that external motivation increased the accuracy scores of the high prejudiced individuals. On the White targets test, motivation had no effect on accuracy. While previous literature has shown that motivation has no significant effect on accuracy in judging nonverbal cues, the results suggest that when motivation is relatively low to begin with (as hypothesized to be the case for high prejudiced participants when taking the Black targets test), and external motivation is provided, motivation does increase accuracy. This suggests that nonverbal decoding of Black targets by high prejudiced participants is a specific context where external motivation can increase nonverbal accuracy due to the prejudiced participants' withdrawal of effort unless an external motivator is present.

## Personality Processes

### D145

#### ONLY HUMAN: SEEING NEGATIVE TRAITS AS 'HUMAN NATURE' MAKES THEM EASIER TO ACKNOWLEDGE.

Peter Koval<sup>1</sup>, Nick Haslam<sup>1</sup>; <sup>1</sup>The University of Melbourne – People employ an assortment of self-protective mechanisms to defend themselves against negative self-views (Alicke & Sedikides, 2009). Recent research on biases in the attribution of humanness (Haslam, Loughnan, Kashima & Bain, 2008) suggests that believing personal flaws to be part of 'human nature' also serves a self-protective function. We present correlational and experimental evidence supporting this hypothesis. In Study 1, participants (N=80) selected 15 negative traits (flaws) from a set of 60 to describe either themselves or an ingroup. All participants subsequently rated all 60 flaws on self-descriptiveness, desirability, 'human nature' (HN), and several other dimensions. Flaws selected to describe the self were rated higher in HN than those selected to describe the ingroup. HN ratings were the strongest predictor of participants' self-descriptiveness ratings across the 60 flaws. Finally, a multi-level analysis examining the relationship between participants' self-descriptiveness ratings and their idiosyncratic HN ratings of the flaws (controlling for all other participants' mean HN ratings), indicated that people project their personal flaws onto their conception of HN. In Study 2, HN beliefs about flaws were experimentally manipulated and the effect on self-descriptiveness ratings observed. Participants (N=180) were randomly assigned to read a bogus scientific article designed to manipulate their beliefs about a set of flaws. Participants rated flaws as more self-descriptive when told that these flaws were part of HN, compared to non-HN and control conditions. Results of these two studies support the hypothesis that HN beliefs may serve a self-protective function by helping to mitigate personal flaws.

### D146

#### THE NOSTALGIC RECOLLECTIONS OF HIGH AND LOW NARCISSISTS

Claire Hart<sup>1</sup>, Constantine Sedikides<sup>2</sup>, Tim Wildschut<sup>2</sup>, Clay Routledge<sup>3</sup>, Jamie Arndt<sup>4</sup>; <sup>1</sup>Southampton Solent University, <sup>2</sup>University of Southampton, <sup>3</sup>North Dakota State University, <sup>4</sup>University of Missouri – Research on nostalgia has revealed that the content of nostalgic recollections is generally positive and often features close others (friends, family) (Wildschut, Sedikides, Arndt, Routledge, 2006). Is this also true of sub-clinical or normal narcissists who are characteristically self-centred and show little concern for others (Campbell & Foster, 2007)? Two studies have sought to identify whether differences exist in the content of high versus low narcissists' nostalgic and ordinary recollections (Study 1), and, whether nostalgia serves different functions for high versus low narcissists (Study 2). In Study 1, participants' narratives were coded for themes of agency and communion, using the Linguistic Inquiry Word Count (LIWC; Pennebaker, Francis, & Booth, 2001). Significant differences in the content of nostalgic self-descriptions were revealed, which were in line with the high narcissists' basic personality structure (high agency, low communion). Furthermore, in Study 2, when asked to reflect on how a self-selected nostalgic event made them feel, significant differences emerged, such that high narcissists rated the functions of self-regard, optimism, and wisdom significantly higher than low narcissists. No significant differences were found in the function of social bonding between high and low narcissists. Thus, such findings suggest that high narcissists recall more agentic nostalgic recollections than low narcissists and use nostalgia in a different manner. Implications of this will be considered.

### D147

#### ARE AMERICANS VIEWED AS NARCISSISTIC? EVIDENCE FROM AN EXAMINATION OF NATIONAL CHARACTER

Laura E. Buffardi<sup>1</sup>, W. Keith Campbell<sup>1</sup>, Joshua D. Miller<sup>1</sup>; <sup>1</sup>University of Georgia – Previous research using national samples has shown that Americans score somewhat higher on narcissism than those from other nations (Foster, Campbell, & Twenge, 2003). Perceptions of national character, however, might better predict objective cultural measures of personality than mean levels of

self-reported personality (Heine, Buchtel, & Norenzayan, 2008). We thus asked if American perceptions of national character are consistent with the profile of Narcissistic Personality Disorder (NPD) and trait narcissism. In Study 1, we correlated reports of American national character and perceptions of an acquaintance's personality on the Five Factor Model (FFM; McRae & Terracciano, 2006) with FFM profiles of DSM-IV personality disorders from both experts (Lynam & Widiger, 2001) and a meta-analysis (Samuel & Widiger, 2008). In Study 2, we compared within-subject self-reports, acquaintance reports, and perceived American national character reports of narcissism measured using a modified version of the Narcissistic Personality Inventory. Results of Study 1 showed that American perceived national character was strongly correlated with the expert FFM profile of NPD,  $r = .78$ ,  $p < .001$  and the meta-analytic NPD profile,  $r = .82$ ,  $p < .001$ , but acquaintance reports were non-significantly correlated with NPD,  $r_s = .22$ , ns. Results of Study 2 showed that reports of American national character on narcissism ( $M = 29.40$ ) were greater than the acquaintance reports ( $M = 21.07$ ) and self-reports ( $M = 15.74$ ),  $\&\text{circ}\delta = .479$ ,  $F(2, 80) = 43.50$ ,  $p < .001$ . Overall, results suggest that Americans view their culture's character as more narcissistic than individual Americans' personalities.

### D148

#### WHAT MAKES PEOPLE CREATIVE? COGNITIVE CONTROL PERSPECTIVE.

Darya Zabelina<sup>1</sup>, Michael D. Robinson<sup>1</sup>; <sup>1</sup>North Dakota State University – Creative individuals have been described in terms suggestive of greater automatic processing (e.g., defocused attention, looser associations) and greater controlled processing (e.g., greater abilities to focus while working on a creative task). Both views cannot be correct from a static ability-related perspective. On the other hand, both views could be correct if creative individuals are better able to modulate the functioning of their cognitive control system in a context-sensitive manner. The present study ( $N = 50$ ) assessed individual differences in creativity in terms of original responses on the Torrance Test of Creative Thinking (TTCT) and also in terms of creative performance by the Creative Achievement Questionnaire (CAQ). The same participants performed a color-word Stroop task. Creative individuals were neither more nor less capable of overriding cognitive conflicts on incongruent (relative to congruent) Stroop trials. On the other hand, creative individuals displayed more flexible cognitive control, as defined by greater cognitive control modulation from trial to trial. Implications for theories of creativity and its underlying processing basis are discussed.

### D149

#### TRAIT SOCIAL ANXIETY AND SPEECH PERFORMANCE RATING IN SELF AND OBSERVATION SCENES

Takashi Hosokawa<sup>1</sup>; <sup>1</sup>Toyo University, Graduate School of Sociology – The purpose of this study was to examine the interpretive bias of speech performance ratings among high and low social anxious students. The Fear of Negative Evaluation Scale (FNE) was administered to 75 vocational school students, and 18 high and 20 low socially anxious students were selected on the basis of FNE scores. They were asked to recall the scene which he/she gave a speech in public and the scene which they observed others giving a speech. Then they were asked to rate their own and the other's performance of speech on three 7-point scales. The results were as follows: (1) In self-scene recall, high socially anxious students rated their performance lower than did low socially anxious students, but the mean ratings of others' performance was not different between two groups. Thus it seems that a distortion of the self-rating was seen in high socially anxious students in the recall scene. (2) Each of the rating of scene recall was compared with a theoretical midpoint. For high socially anxious students, the rating of the self-scene recall was lower than the midpoint and the rating of the observation scene recall was higher than it. For low socially anxious students, the rating of the observation scene recall was lower than it. Though they might recall any kind of scene, high socially anxious students recalled such a scene. This may be regarded as being influenced by the negative rumination, which was one of the characteristics of the interpretation bias.

**D150****AFRICAN AMERICANS EXHIBIT HIGHER HEALTH OPTIMISTIC BIAS THAN EUROPEAN AMERICANS**

Ross E. O'Hara<sup>1</sup>, Marissa D. Alert<sup>1</sup>, Frederick X. Gibbons<sup>1</sup>; <sup>1</sup>Dartmouth College – Previous research has found that African American adolescents report lower perceived vulnerability than European American adolescents for most health risks, despite being at higher risk for 9 of the 15 leading causes of death. The goal of the current study was to measure racial differences in health optimistic bias and health-risk behavior among a college-aged sample. Participants completed an online questionnaire in which they estimated their own and others' (same age and gender) vulnerability to 13 medical conditions. Health optimistic bias was calculated by subtracting perceived personal vulnerability from perceived others' vulnerability. Participants also reported their health-risk behaviors related to these conditions. African Americans showed stronger optimistic bias than European Americans, who showed no optimistic bias. No gender difference or Race x Gender interaction was detected. A MANOVA that included each medical condition and controlled for health-risk behavior revealed that African Americans were more optimistic than European Americans about their risk for skin cancer, alcohol abuse, and drug abuse. European Americans, however, were more optimistic than African Americans about their risk for diabetes. College-aged African Americans were more optimistic than European Americans about their health, controlling for health-risk behavior. Although African Americans were accurately optimistic about their risk for skin cancer, their optimism about their risk for substance abuse may have been unrealistic, as prevalence rates are roughly equal among races. African Americans did engage in significantly less health-risk behavior than European Americans, justifying some of their optimism; future research should measure health optimistic bias among an at-risk sample.

**D151**

**PERSONALITY AND LONGEVITY ACROSS SEVEN DECADES** Margaret L. Kern<sup>1</sup>, Leslie R. Martin<sup>2</sup>, Howard S. Friedman<sup>1</sup>; <sup>1</sup>University of California, Riverside, <sup>2</sup>La Sierra University – Personality impacts every aspect of life, including its length. The present study examined individual and synergistic personality trait predictors of longevity across seven decades in the Terman Life Cycle Study (begun in 1922). Reliable and valid measures of conscientiousness, agreeableness, and neuroticism were derived based on self-rated traits in young adulthood (1940). We collected death certificates from state agencies to determine longevity, now known for 90% of the original sample. Cox proportional regressions were used to predict all-cause mortality risk from 1940 through 2008 for each trait – individually, simultaneously, and in interaction models – separately for men (N = 692) and women (N = 541). In addition, we conducted tertile comparisons for each trait. Women significantly outlived men. For women, high conscientiousness was protective (rh = .77, 95% CI = .67, .87), and high neuroticism was a risk for earlier mortality (rh = 1.18, CI = 1.03, 1.35). There was a significant interaction between conscientiousness (C) and neuroticism (N), such that women with high-N/low-C were at especially great risk, whereas women with low-N/high-C faced the lowest risk. For men, conscientiousness was protective earlier in life but of diminished relevance late in life. Paradoxically, the men who were conscientious and neurotic (high-C/high-N) were at lower risk. Agreeableness was protective. The findings shed new light on the associations between neuroticism, conscientiousness, and health across the long-term.

**D152****EVIDENCE THAT WEAK SENSE-OF-SELF INDIVIDUALS "BORROW"**

Ronen Cuperman<sup>1</sup>, William Ickes<sup>1</sup>; <sup>1</sup>The University of Texas at Arlington – For over four decades, clinical psychologists have claimed that individuals with a weak sense of self temporarily take on aspects of the personalities of interaction partners who have a stronger sense of self. The present study provided the first empirical test of this claim. After rating themselves on the Big Five dimensions in a departmental pretest at the start of the semester, the participants later interacted for six minutes as strangers

in initial, unstructured dyadic interactions. One member of each dyad had a weak sense of self; the other member had a strong sense of self. Immediately afterward, the participants completed the same Big Five measure, but this time with the instruction to rate themselves as they felt at that exact moment. Consistent with clinical observations, the "weak" dyad members changed their post-interaction personality ratings in the direction of the "strong" members' pre-interaction personality, but not vice versa. A follow-up analysis ruled out the possibility that this difference could be attributed to differential regression to the mean (average) personality profile.

**D153****THE IMPACT OF PERSONALITY, FIT, AND SATISFACTION ON COLLEGE STUDENT WITHDRAWAL: AN SEM APPROACH**

Mark Zorzie<sup>1</sup>, Abigail Billington<sup>1</sup>, Michael Braun<sup>1</sup>; <sup>1</sup>Michigan State University – Despite decades of research on college student attrition, persistence rates have remained relatively consistent. Existing models have found support for the effects of student background characteristics, a student's fit with his or her university, and satisfaction on both withdrawal intentions and decisions to withdraw or persist. The entry characteristic of personality is an oft-neglected element in the discussion of causes of withdrawal. Personality has been theorized to affect student withdrawal, but empirical investigation of this relationship has been limited. The emergence of the Big 5 personality factors provided a framework for such investigation. Drawing on literature from the area of student persistence, we hypothesized that 3 of the Big 5 personality factors (Conscientiousness, Agreeableness, and Emotional Stability) would affect student withdrawal. An individual's personality affects interactions with the collegiate environment and how much one fits with the university. Greater fit should lead to greater satisfaction with the academic environment. The current study uses structural equation modeling to empirically test the role of personality, fit and satisfaction in the withdrawal process in a cohort of undergraduates from ten institutions over four years. Personality is thought to affect fit, which in turn affects satisfaction, ultimately leading to decisions to persist or withdraw. Results demonstrate that these personality factors significantly affect the proposed withdrawal process. Specific factors differentially impact the process depending on the cohort's year in school. Therefore, it is important to recognize the importance of personality characteristics in student withdrawal to help universities identify at-risk students and increase persistence rates.

**D154****THE USUAL SUSPECTS IN THE MIRROR: EFFECTS OF JUST WORLD BELIEFS ARE MODERATED BY GENDER MATCH.**

Miho Shirai<sup>1</sup>; <sup>1</sup>Toyo University – Previous researches in to the just world beliefs suggest that people more or less believe that the world is essentially fair, thus only good people are rewarded and bad people are punished. Accordingly, an innocent victim might be held accountable for their bad fate. However, it is unclear whether the victim would still be held accountable for the incident when the perpetrator comes into play. The present study sought to extend the previous findings by examining the effects of Just World Scale (JWS) scores on the assessments of appropriate punishment for a crime. Two hundred and seventy undergraduate students completed the JWS and read a description of a homicide case which varied the gender of the perpetrator and the victim. Hierarchical multiple regression analysis was run to test a Participant gender x Perpetrator gender x Victim gender x JWS score effects. The analysis revealed a reliable Participant gender x Perpetrator gender interaction. Post hoc tests indicated that when the gender of the participants and the perpetrator matched, higher JWS scores predicted lower punishment (p<.05). However, the exact reverse pattern was observed when the gender of the participants and the perpetrator mismatched; higher JWS scores predicted higher punishment (p<.05). The important role of the gender of the participant, perpetrator, and victim as a moderator of the effects of just world beliefs in the context of punishment for a crime is discussed.

**D155****IMPLICIT PRIMING OF ATTACHMENT REPRESENTATIONS REVISITED: A COMPARISON OF METHODOLOGIES** Dylan Selterman<sup>1</sup>, Markus Maier<sup>1</sup>;

<sup>1</sup>Stony Brook University – Social cognitions occur consciously and outside of conscious awareness. Previous work (e.g. Mikulincer, Birnbaum, Woddis, Nachmias, 2000; Mikulincer, Gillath, Shaver, 2002) has demonstrated a link between conscious reports of attachment style and implicit mental representations assessed by automatic responses to attachment-laden prime words. The purpose of the present study was to replicate this work and further examine the implicit nature of attachment representations. Participants in our design were exposed to threatening or neutral prime words (as presented on a computer screen), which were followed by presentations of target words signifying a primary caregiver (mother/mom) or a neutral person (painter; chef). A lexical decision choice task (word vs. non-word) and pronunciation task (oral response) were used to assess reaction times to the target words. Subjects completed the Experiences in Close Relationships questionnaire (ECR) as a measure of attachment avoidance and anxiety. ANCOVA and regression analyses both indicated a 3-way interaction between (a) type of prime word (threat or neutral), (b) type of target word (mom or neutral person), and (c) attachment insecurity dimensions on the ECR. Replicating previous work, participants who reported high avoidance were slower to react to caregiver targets after the presentation of threat primes using the lexical decision task methodology. However, the pattern of responses found using the word-pronunciation task was in the opposite direction (higher avoidance yielded faster responses), indicating a much more complex picture than previously thought. Implications for theory and research are discussed, with particular focus on associations of mental schemas and "spreading activation."

**D156****PARTNER PERSONALITY AND LONG-TERM HEALTH: COMPENSATORY AND COMPLEMENTARY RELATIONS** Loryana L. Vie<sup>1</sup>, Chandra A. Reynolds<sup>1</sup>, Margaret L. Kern<sup>1</sup>, Howard S. Friedman<sup>1</sup>;

<sup>1</sup>University of California, Riverside – Personality ratings of participants and spouses were derived from 626 couples in the Terman Life Cycle Study in 1940 (mean age = 30 years). We created a composite assessment of physical health in 1986 for those Terman participants who lived to reach old age (N = 341). We here extend the findings of Roberts, Smith, Jackson, and Edmonds (2009) on spouses' compensatory conscientiousness in three important ways. First, we examined self and partner personality ratings in relation to physical health 46 years later to test whether the patterns found by Roberts and colleagues could be replicated for health outcomes measured across the lifespan. We found comparable support for compensatory conscientiousness, i.e., partner's level of conscientiousness above and beyond self-ratings of conscientiousness, as predictive of Terman women's later health (partial  $r = .08$ ) but not of Terman men. Second, we explored cross-partner cross-trait predictions of health. The interaction of self and partner's conscientiousness and neuroticism was related to 1986 health for Terman women (partial  $r = -.13$ ), such that complementary patterns (e.g. high conscientiousness coupled with low neuroticism or vice versa) were predictive of better 1986 physical health. Finally, we considered the role of compensatory extraversion in relation to health. Wives' extraversion predicted better 1986 physical health for Terman men (partial  $r = .11$ ), above and beyond self-ratings of extraversion. Across more than four decades, partners' personality ratings were important predictors of participants' later health.

**D157****LET'S AGREE TO BE FUNNY: AGREEABLENESS, SOCIAL INFLUENCE, AND PERCEPTIONS OF HUMOR** Meara M. Habashi<sup>1</sup>, Thomas D. Mulderink<sup>2</sup>,

William G. Graziano<sup>3</sup>; <sup>1</sup>Iowa Wesleyan College, <sup>2</sup>Illinois State University, <sup>3</sup>Purdue University – Sense of humor is extremely influential in perceptions of others. In fact, people with a sense of humor are rated as more agreeable and extraverted and less neurotic than their peers. Overall, it seems that individuals with a sense of humor are seen in a more positive

light than those without. Research has identified how humorists are perceived, but little research has identified how personality relates to perceptions of humor. The current research examined the relations among personality, social influence, and perceptions of humor. In two studies participants were asked to rate 24 jokes that were both aggressive (i.e., jokes intended to harm) and affiliative (i.e., jokes not intended to harm) and paired with either positive or negative feedback (i.e., rated as funny or not funny by peers). A pilot study (N=160) found that regardless of joke type, participants rated the jokes funnier when paired with positive feedback. These results were qualified by an Agreeableness X Joke Type X Feedback interaction in Study 1 (N=137),  $F(1, 140) = 3.71$ ,  $p = .05$ ,  $\eta^2 = .16$ . Participants were most influenced by peer feedback when the joke format was inconsistent with their personality. For aggressive jokes participants high in Agreeableness were more influenced by feedback,  $F(1, 67) = 5.47$ ,  $p = .02$ , than participants low in Agreeableness. For affiliative jokes, participants low in Agreeableness were more influenced by feedback,  $F(1, 73) = 10.57$ ,  $p < .01$ , than participants high in Agreeableness. Results indicate personality plays an important role in social influence and humor.

**D158****RELIGION AND LOCUS OF CONTROL** Jennifer Jones<sup>1</sup>, Jared B. Kenworthy<sup>1</sup>;

<sup>1</sup>The University of Texas at Arlington – I examined the relationship between one's religiosity and locus of control. I predicted that individuals who were highly religious would exhibit an external locus of control. For study 1, the meta-analysis, I found an average correlation coefficient,  $r = .09$ ,  $p < .05$ , between religiosity and one's locus of control, indicating that as intrinsic religiosity increased so did their level of internal locus of control. Gender was found to be a moderator, such that the relationship between being intrinsically religious and having an internal locus of control was stronger for females than for males. Publication year also moderated the relationship between religiosity and locus of control. The more recent publications showed the reverse relationship, such that intrinsic religiosity was more associated with an external locus of control. This finding is consistent with Twenge, Zhang, and Im's (2004) meta-analysis regarding the increasing rates of individuals who exhibit an external locus of control over time. A follow-up study investigated this relationship while controlling for personality (i.e., The Big Five). Controlling for the Big Five personality traits, intrinsic religiosity predicted an external locus of control, whereas extrinsic religiosity predicted an internal locus of control. Theoretical and practical implications are discussed.

**D159****USING MYSPACE INCREASES THE ENDORSEMENT OF NARCISSISTIC PERSONALITY TRAITS** Elise Freeman<sup>1</sup>, Jean Twenge<sup>1</sup>;

<sup>1</sup>San Diego State University – Millions of people use social networking sites (SNS), but it is not clear how these sites shape personality traits and identity. Undergraduates were randomly assigned to either spend time on their MySpace page or to complete another online task as a control (looking at Google Maps). Those who edited and wrote about their MySpace page subsequently scored significantly higher on the Narcissistic Personality Inventory (NPI) than the control group. The effect was significant for women but not for men. Thus spending time on MySpace caused young women to endorse more narcissistic traits. Consistent with previous research, those with higher NPI scores also reported having more friends and page views and agreed that their pages reflected the image they wished to present. Previous research has shown that narcissism has been rising over the generations, particularly among college women. Thus narcissism may be increasing among women partially due to time spent on SNS, and SNS may play a significant role in shaping identity in a more narcissistic direction.

**D160****THE BIG FIVE PERSONALITY FACTORS AND CHOICE OF NEWS OUTLET**

Shannon Whitten<sup>1</sup>, Jeffery Bedwell<sup>1</sup>, Karen Mottarella<sup>1</sup>, DeAnn Collins<sup>1</sup>, Ashley Harper<sup>1</sup>, Lauren Maleski<sup>1</sup>, Brooke LaJoie<sup>1</sup>, Jeffery Gilliard<sup>1</sup>; <sup>1</sup>University of Central Florida – Programs like The Daily Show and The Colbert Report have gained popularity resulting in debates about the kind of audience this programming attracts as well as the potential social consequences of presenting news in this way. The purpose of the present study was to explore what personality characteristics are correlated with watching or reading categories of news media such as comedy, internet, argumentative discussion, and traditional news. Participants were asked to construct an argument taking a stance on one of three issues. Following this, they were asked to rate how frequently they watched or read 32 different news sources. Immediately afterward, they were administered the Five-Factor Personality Inventory. Results indicate positive correlations between the Openness to Experience scale and frequency of watching a variety of comedy news programs, but no correlations were found with any other category of news media. Pearson Correlations were conducted between Comedy Programs and the Openness Subscale of the Five-Factor Personality Inventory and are listed below and are significant at .01 level. Saturday Night Live: +.124\* The Colbert Report: +.243\*\* The Daily Show: +.246\*\* The Onion: +.158\*\*. The data is correlational, thus it is not possible to determine whether watching comedy facilitates an open attitude or whether those with a high degree of openness seek out and enjoy receiving news from a comedic perspective. However, as the big five personality factors have been shown to have trait-like enduring qualities, it is more likely that the openness to experience personality trait preceded the choice of news outlet.

**D161****A 5-YEAR LONGITUDINAL STUDY OF THE RELATION BETWEEN SECRECY AND SUBJECTIVE WELL-BEING: THE DIFFERENTIAL ROLES OF PROCESS AND TRAIT**

Andreas Wismeijer<sup>1</sup>, Marcel van Assen<sup>1</sup>, Klaas Sijtsma<sup>1</sup>, Ad Vingerhoets<sup>1</sup>; <sup>1</sup>Tilburg University – Secrecy has long been thought to have negative effects on subjective well-being. However, some studies have challenged this view and found a positive relation between keeping a major secret and subjective well-being when the stable tendency (personality trait) to self-conceal was controlled for. Our aim was to replicate this finding using a 5-year longitudinal prospective study, including 1,011 subjects that were assessed at four different points in time. We indeed replicated this finding and conclude that secrecy as a process has a positive influence on subjective well-being when controlling for the personality trait of self-concealment. Further, self-concealment was found to be negatively associated with subjective well-being over time. Finally, we found that keeping a major secret inconsistently mediated the relation between self-concealment and subjective well-being. We discuss implications for clinical practice and future research.

**D162****YOU NEVER THINK ABOUT MY FEELINGS: INTERPERSONAL DOMINANCE AND EMOTION PERCEPTION ABILITIES**

Sara K. Moeller<sup>1</sup>, Michael D. Robinson<sup>1</sup>, Benjamin M. Wilkowski<sup>2</sup>; <sup>1</sup>North Dakota State University, <sup>2</sup>University of Wyoming – Theories related to power have sought to understand how dominance might influence cognitive, emotional, and behavioral processes. Importantly, research has found that individuals high in interpersonal dominance pay less attention to interaction partners and stereotype to a greater extent when forming impressions of others (Operario & Fiske, 2001). However, somewhat surprisingly, no research has focused on understanding dominance as it relates to emotion decoding and labeling abilities. We conducted two studies, one using a facial emotion labeling task (Study 1) and the other using audio and video clips of actors expressing different emotions (Study 2). We hypothesized that individuals high in interpersonal dominance (Wiggins, Trapnell, & Phillips, 1988) would be less accurate at labeling emotion in both tasks. This hypothesis was confirmed in Study 1, particularly when more emotional information was present. Study 2 found additional support for the

hypothesis, as dominant individuals were less accurate in labeling emotions for both the audio and video clips. In both studies, relations between dominance and decoding accuracy were independent of which particular emotion was involved. The findings extend our knowledge of the interpersonal circumplex dimension of dominance-submission to abilities that define the construct of emotional intelligence. The findings also extend our knowledge of the social cognitive correlates of dominance and power, which had previously involved stereotyping but not decoding abilities of the present type. Finally, our findings are suggestive of why one's own feelings often seem ignored when interacting with dominant individuals.

**D163****SHORT-TERM TRAJECTORY OF DEPRESSIVE SYMPTOMS AND THE ROLE OF TEMPERAMENTS AS PREDICTORS**

Yusuke Takahashi<sup>1,2</sup>, Kensuke Okada<sup>1,3</sup>, Takahiro Hoshino<sup>4</sup>; <sup>1</sup>Japan Society for the Promotion of Science, <sup>2</sup>Keio University, <sup>3</sup>Tokyo Institute of Technology, <sup>4</sup>Nagoya University – The main goals of the present study were (a) to establish the different short-term developmental trajectories of depressive symptoms on the basis of self-rating scale and (b) to examine how Gray's temperamental traits: Behavioral Inhibition and Activation Systems (BIS and BAS) contributes to the developmental trajectory courses of depressive symptoms by using a growth mixture modeling (semiparametric group-based approach; Najin, 1999, Jones et al., 2001). Japanese Female students (N = 90, mean age = 19.82, S.D. = 3.44) completed the questionnaire booklet including temperament and depressive symptom items from Times 1 to 4 at weekly intervals. Short-term developmental trajectories of female undergraduates' depressive symptoms were modeled, and by model comparisons, three latent classes were identified: a relatively high level group (20.5%), a mean level group (60.0%), and a relatively low group (19.5%). Follow-up analysis with predictor variables revealed that BIS and BAS predicted class membership probability fairly consistently. Female students with high BIS and low BAS tended to exhibit a relatively high trajectory class of depressive symptoms. Although previous studies have only reported that depressive symptoms was positively correlated with BIS and negatively correlated with BAS, the results in this study additionally showed that depressive symptoms described three different trajectory courses during four weeks, and that BIS and BAS could predict the membership probability for these trajectory courses. These findings may have implications for the effectiveness to identify female students at risk for further evaluation, and for the selection of intervention targets and strategies.

**D164****NARCISSISM, CAUSAL ATTRIBUTION AND AFFECTION TO PAST EVENTS**

Emi Miura<sup>1</sup>, Fujio Yoshida<sup>1</sup>; <sup>1</sup>University of Tsukuba – Narcissism can be classified into oblivious narcissism and hypervigilant narcissism (Gabbard, 1994). Rhodewalt (2001) showed that oblivious narcissists employ social and cognitive strategies to maintain their ideal self-image. One of these strategies involves self-serving bias using causal attribution (Rhodewalt & Morf, 1995, 1998). Targeting both oblivious narcissism and hypervigilant narcissism, the present study examines the relation between causal attribution and affection on positive (and negative) experiences and discusses a strategy for self-evaluation maintenance. In study 1, a measurement of narcissistic personality was developed on the basis of two types of narcissism. A factor analysis of the measurement of narcissistic personality revealed the following six significant factors: "self-glorification", "sensitiveness to evaluation", "the need for attention and admiration", "jealousy", "self-absorption", and "the tendency to experience fantasies about the ideal self". In study 2, the subjects recalled positive and negative experiences, and then completed causal attribution and affection about each event. We conducted a multiple regression analysis for prediction the narcissism factors with attribution and affection. The results showed that for positive experiences "self-glorification" and "the need for attention and admiration" promote inner attribution and positive affection in the form of oblivious narcissism. For negative experiences, "self-glorification", "jealousy" and "the tendency to experi-

ence fantasies about the ideal self" promote external attribution and negative affection. As a form of hypervigilant narcissism, "sensitiveness to evaluation" promotes inner attribution and negative affection and feeling of inferiority and jealousy. Hypervigilant narcissists do not employ aggressive strategies for maintaining their ideal self-image. However they exhibit jealousy toward others.

## Self-Esteem

### D165

#### **DETERMINING SELF-APPRAISAL FOR CURRENT AND PAST SELVES AND IN RELATION TO PEERS FOR CLINICAL ADOLESCENT POPULATIONS**

Alex Peters<sup>1</sup>, Adam Brown<sup>2</sup>, <sup>1</sup>Sarah Lawrence College, <sup>2</sup>Weill Medical College of Cornell University – Previous work on temporal self theory has demonstrated that individuals in western culture are motivated to maintain positive self-regard, and do so by either enhancing or disparaging past-selves, as well as viewing their current self as more favorable to their peers (Wilson & Ross, 2001). However, the extant research on temporal self theory has focused on healthy adults; less is known about the generalizability of this phenomenon to other contexts and populations. Would an enhanced present self emerge among individuals whose current emotional functioning and physical surroundings are such that they serve as cues that the present self is functioning at lower levels than a previous self? Thirty adolescents hospitalized on a psychiatric inpatient unit were assessed on their appraisal of present and past self, as well as their current functioning in relation to their peers. This study hypothesized that psychiatric inpatient adolescents, given their current emotional difficulties and physical surroundings, would view their past self as better than their current self, and worse than their peers. Interestingly, findings revealed that the current self was perceived more positively than their past self. However, individuals viewed their current self as significantly worse than their peers. Critically, this pattern was enhanced for females. Findings suggest that although adolescents suffering from a psychiatric disorder, and in particular females, are more likely to view themselves unfavorably relative to peers, their ability to view the current self as better than the former self may reveal a way in which clinicians can foster resilience in treatment.

### D166

#### **DOES SELF-BOOSTING THOUGHT MAKE THE WORLD SEEM LESS RISKY? AN EXAMINATION OF THE IMPACT OF SELF-AFFIRMATIONS ON RISK PERCEPTION**

Sean E Moore<sup>1</sup>, Shungu-Elaine Mushayandebvu<sup>1</sup>, Crystal L Butler<sup>1</sup>, <sup>1</sup>University of Alberta-Augustana Campus – Prior research has demonstrated that participants who experience a boost in self-affirming thoughts are more open and accepting of threatening information concerning personal health risks (Sherman, Cohen, & Steele, 2000). While this research demonstrates that self-affirmations help reduce defensiveness in response to more proximal, immediate threats, little research has examined how self-affirmations impact people's perceptions of more distal, long-term perceptions of risk. It may be the case that while self-affirmations lower perceptions of threat in the short-term, they may also inadvertently lower people's perceptions of their long-term susceptibility to less salient personal risks. As a result, self-boosting thought may be a cause of optimistic biases in risk perception. To investigate this possibility, we conducted two studies to examine how self-affirmations impact the perception of various lifetime health risks. In both studies, participants completed a commonly used self-affirmation manipulation that involved writing about either important, self-relevant values (affirmed condition) or non self-relevant values (non-affirmed condition). Next, in a presumably unrelated task, participants read over a list of health risks (adapted from Johnson & Tversky, 1983) and rated their subjective worry about the harms (Study 1) or their perceived risk of experiencing the harm relative to the average person (Study 2). Results indicated that self-affirmed participants felt less worry as well as less comparative risk about rare and controllable harms compared to non-

affirmed participants. Implications of these results for self-affirmation theory and the understanding of how ego-boosting thought impacts people's risk perceptions and health coping behaviors are discussed.

### D167

#### **COMPETENCE AND ACCEPTANCE: EXPLORING CONTRIBUTORS TO DAILY SELF-ESTEEM**

Erika Koch<sup>1</sup>, <sup>1</sup>St. Francis Xavier University – According to sociometer theory, self-esteem serves as a gauge of perceived inclusion or exclusion. Empirical support for sociometer theory demonstrates that state self-esteem correlates positively with perceived inclusion, and that state self-esteem drops in response to perceived exclusion. Subsequent laboratory experiments, hypothetical responses, and retrospective accounts all showed that while feelings of competence contributed to state self-esteem, the contribution of feelings of acceptance was stronger. The present research sought to extend this finding by examining daily reports of self-esteem in a naturalistic setting. Over two weeks, participants (N = 97) provided end-of-day reports (N = 683) of the events that most affected their self-esteem. Reports presented via a web site contained single items assessing the importance of the event and ratings of how competent and accepted the event made participants feel. Participants also completed a state version of the Rosenberg Self-Esteem Scale. HLM analyses revealed that contrary to predictions, although both perceived competence and acceptance significantly predicted state self-esteem, the contribution of competence was significantly stronger. Results held when controlling perceived importance of the events and when examining positive versus negative events separately. Between-participant analyses examined several possible moderators: gender, contingencies of self-worth, rejection sensitivity, trait self-esteem, and the need to belong. Gender and the God's love contingency of self-worth emerged as significant moderators. Specifically, women and individuals basing their self-worth on God's love demonstrated a particularly strong acceptance/self-esteem relationship. Results suggest an exception to previous findings indicating a stronger contribution of acceptance (versus competence) to state self-esteem.

### D168

#### **FRAGILE SELF-ESTEEM AS A PREDICTOR OF THOUGHT SUPPRESSION**

Jennifer Borton<sup>1</sup>, Rebecca Ashby<sup>1</sup>, Abigail Crimmins<sup>1</sup>, Jessica Ruddiman<sup>1</sup>; <sup>1</sup>Hamilton College – Previous research has shown that suppressing negative self-referent thoughts makes them hyperaccessible and negatively affects mood and self-esteem (Borton & Casey, 2006). Who might be particularly likely to suppress such thoughts? In the current study, we examined whether individuals with fragile high self-esteem (i.e., those with defensive, unstable, or contingent self-esteem) would be more prone than those with secure high self-esteem to suppress intrusive thoughts following an ego threat. Participants completed an explicit measure of self-esteem, the self-esteem IAT, and a measure of contingent self-esteem. In addition, they completed a modified version of the Rosenberg Self-Esteem Scale twice daily for the five days prior to the study as an assessment of self-esteem stability (higher standard deviations represented lower stability). In the lab, they received false negative feedback on an intelligence test and spoke into a tape recorder about whatever came to mind for five minutes. Finally, they indicated the extent to which they had attempted to suppress test-related thoughts during the speaking task. Results indicated that participants with defensive self-esteem (defined as high explicit paired with low implicit self-esteem), high unstable self-esteem, and contingent self-esteem were more likely to report suppressing test-related thoughts than were those with more secure self-esteem. In sum, the results suggest that individuals with fragile self-esteem are more prone to suppressing negative thoughts about the self than are those with secure self-esteem, and may therefore be more vulnerable to suppression-related anxiety and depression.

**D169****FAMILY BACKGROUND AND SELF-EFFICACY: WHICH BETTER PREDICTS ACADEMIC OUTCOMES?**

Dana A. Weiser<sup>1</sup>, Daniel J. Weigel<sup>1</sup>, Alexandra E. Sigillo<sup>1</sup>; <sup>1</sup>University of Nevada, Reno – A variety of family and personal features have been found to predict students' academic achievement. Self-efficacy is a powerful predictor of grades and school persistence, even more than ability and intelligence. Researchers have also determined family characteristics and practices predict students' academic outcomes. The purpose of the current project is to explore which self-efficacy and family background variables better predict academic achievement. 133 university students in Northern Nevada completed questionnaires assessing academic and general self-efficacy, parental marital status, socioeconomic status, parental education attainment, parental school involvement, parental relationship quality, and parental school aspirations, GPA, and expectations of academic success; Cronbach's alphas ranged from .68 to .95. Two multiple regression analyses were conducted with no evidence of multicollinearity ( $VIF \leq 4.29$ ). Self-efficacy and family variables were first regressed to predict GPA [ $R^2 = .19$ ,  $F(10, 107) = 2.47$ ,  $p < .05$ ] and only academic self-efficacy was found to uniquely contribute variance [ $\beta = .42$ ,  $t(107) = 2.34$ ,  $p < .05$ ]. Self-efficacy and family variables were then used to predict expectations of academic success [ $R^2 = .32$ ,  $F(10, 107) = 5.17$ ,  $p < .001$ ]. Both academic self-efficacy [ $\beta = .30$ ,  $t(107) = 1.84$ ,  $p = .07$ ] and parental involvement [ $\beta = .16$ ,  $t(107) = 1.76$ ,  $p = .08$ ] were found to marginally contribute unique variance. These findings indicate self-efficacy may be a better predictor of academic outcomes compared to family background. This finding is encouraging because efficacy beliefs are more malleable compared to family demographics. Researchers and educators should focus on testing methods to increase efficacy beliefs in order to enhance academic achievement. It may also be important to develop methods to increase parental school involvement.

**D170****SELF-ESTEEM DEVELOPMENT FROM YOUNG ADULTHOOD TO OLD AGE: A COHORT-SEQUENTIAL LONGITUDINAL STUDY**

Ulrich Orth<sup>1</sup>, Kali H. Trzesniewski<sup>2</sup>, Richard W. Robins<sup>3</sup>; <sup>1</sup>University of Basel, <sup>2</sup>University of Western Ontario, <sup>3</sup>University of California, Davis – The authors examined the development of self-esteem from young adulthood to old age. Data came from the Americans' Changing Lives study, which includes four assessments across a 16-year period of a nationally representative sample of 3,617 individuals aged 25 to 104. Latent growth curve analyses indicated that self-esteem follows a quadratic trajectory across the adult life span, increasing during young and middle adulthood, reaching a peak at about age 60, and then declining in old age. No cohort differences in the self-esteem trajectory were found. Women had lower self-esteem than men in young adulthood, but their trajectories converged in old age. Whites and Blacks had similar trajectories in young and middle adulthood, but the self-esteem of Blacks declined more sharply in old age than the self-esteem of Whites. More educated individuals had higher self-esteem than less educated individuals, but their trajectories were similar. Moreover, the results suggested that declines in socioeconomic status (SES) and physical health account for the decline in self-esteem that occurs in old age. Given that SES and physical health might be reciprocally related to self-esteem, an important task for future research is to better understand the dynamic interplay between self-esteem development and important life outcomes across the life span.

**D171****THE EFFECT OF SOCIAL ACCEPT AND SOCIAL INCLUSION ON SELF-ESTEEM**

Inge Brechan<sup>1</sup>; <sup>1</sup>University of Oslo – According to the Sociometer theory the main function of self-esteem is as a meter of social accept (Leary & Baumeister, 2000), thus social accept should be the major and most proximal factor of self-esteem. According to social reward theory (Buss, 1983) people are motivated by two distinct sets of social rewards: Content rewards (e.g., social accept) and process rewards (e.g., social inclusion). Social inclusion may be an antecedent of social accept, as peo-

ple infer others' attitude toward them from others' behavior toward them (Jones & Davis, 1965). In three surveys with student samples ( $n_1 = 185$ ,  $n_2 = 234$ ,  $n_3 = 190$ ) we found from regression analyses that both social accept and social inclusion had a unique contribution to self-esteem, and that the effect of social inclusion was partly mediated through social accept. A Sobel-test indicated that the indirect effect of social inclusion on self-esteem was significant. A t-test showed that women reported lower self-esteem and higher social accept than men. A chi-square test revealed no gender differences in effect sizes. In the second study we added instrumental and emotional social support as explanatory factors and in the third study we included also social attention, but these factors did not contribute to the explanation of self-esteem beyond what could be attributed to social accept and social inclusion. The results support social reward theory, as social inclusion is not merely a more distal factor of self-esteem, but has also a direct contribution beyond what is mediated through social accept.

**D172****WHY NARCISSISTS DON'T DESERVE OUR ADMIRATION: A STUDY OF NARCISSISM AND INTEGRITY IN A COLLEGE SAMPLE**

Amy B. Brunell<sup>1</sup>, Sara Staats<sup>1</sup>, Julie Hupp<sup>1</sup>; <sup>1</sup>The Ohio State University at Newark – Narcissism has been linked to lower morality in the workplace. For example, narcissists make less ethical decisions in hypothetical situations (Antes et al., 2007) and tend to be rated by their supervisors as lacking integrity (Blair et al., 2008). Surprisingly, research has not investigated narcissism in academic contexts. We hypothesized that narcissists would self-report less moral behaviors, more cheating behaviors, and a greater intention to cheat on future academic work. We hypothesized that self-esteem, however, would be positively associated with moral behaviors, including fewer cheating behaviors and less intention to cheat in the future. 114 female and 93 male college students completed a questionnaire packet to assess narcissism and integrity. Participants completed measures of narcissism and self-esteem in addition to measures of immoral behavior and academic cheating behaviors. Regression analyses revealed that narcissists reported a) fewer moral behaviors, b) more classroom cheating behaviors, and c) a greater intention to cheat on academic work in the future. Self-esteem, by contrast, was positively associated with more moral behaviors and less academic cheating behaviors. Self-esteem was not associated with the intention to cheat on academic work in the future. Additional analyses revealed no significant link between narcissism and self-reported GPA. Self-esteem, however, was positively associated with GPA. Taken together, it appears that narcissists are more likely to cheat but not necessarily perform better on their academic work. By contrast, individuals with self-esteem are less likely to cheat but more likely to perform better on their academic work.

**D173****COMMUNAL NARCISSISM**

Jochen Gebauer<sup>1</sup>, Constantine Sedikides<sup>1</sup>, Bas Verplanken<sup>2</sup>, Gregory Maio<sup>3</sup>; <sup>1</sup>University of Southampton, <sup>2</sup>University of Bath, <sup>3</sup>Cardiff University – Normal narcissism is a personality variable that may be best described by a pervasive pattern of grandiosity. Consequentially, normal narcissism has been traditionally assessed by measures of grandiose self-beliefs. Of importance, current measures of narcissism, such as the Narcissistic Personality Inventory (NPI), focus solely on grandiose self-beliefs in the agentic domain. Indeed, narcissists – as assessed by the NPI – score especially high in the agentic domain. For example, narcissists rate themselves as better than average on agentic but not on communal traits. Minimally, then, narcissism is considered an extreme form of agency. Our research, in contrast, demonstrates that people not only report grandiose self-beliefs in the agentic domain ("I am the most capable person") but also in the communal domain ("I am the most understanding person"). Based on this finding, we constructed and validated the Communal Narcissism Inventory (CNI). We showed that agentic narcissists (as assessed by the NPI) and communal narcissists (as assessed by the CNI) employ different strategies in order to satisfy their common narcissistic needs for self-enhancement, grandiosity, admiration, and power. For example, (a) agentic and communal narcissists both

scored high on power motivation, power and achievement values, and individualism, (b) only agentic narcissists perceived themselves as better-than-average on agentic traits, and (c) only communal narcissists perceived themselves as better-than-average on communal traits. Furthermore, we provided additional validation of the CNI by examining relations between communal narcissism and various well-documented correlates of agentic narcissism such as self-construal, aggression, empathy, psychological health, love styles, modesty, and the big 5.

#### D174

##### **PERCEPTIONS OF PARTNER COMMITMENT MODERATES THE RELATION BETWEEN IMPLICIT SELF-ESTEEM AND POSITIVE RESPONSES TO RELATIONSHIP THREAT** Julie Longua<sup>1</sup>, Tracy DeHart<sup>1</sup>; <sup>1</sup>Loyola University Chicago

The current study explores how implicit self-esteem influences reports of verbal and nonverbal behavior during a threatening romantic relationship interaction, and whether these effects are moderated by perceptions of a romantic partner's commitment. The risk regulation model suggests that differences in self-esteem influence how people respond to the risk of rejection (Murray, Derrick, Leder, & Holmes, 2008). This regulation process can happen at an implicit (unconscious) level (DeHart, Pelham, & Murray, 2004), suggesting implicit self-esteem may influence behaviors during relationship threat. In the current study, participants were randomly assigned to either a relationship-threat or control condition. Analyses revealed that, in the relationship-threat condition, perceptions of partner commitment moderated the relation between implicit self-esteem and verbal and nonverbal behaviors. Specifically, participants high (vs. low) in implicit self-esteem reported engaging in more positive verbal and nonverbal behaviors when they perceived their partner as more committed. Participants high and low in implicit self-esteem did not differ in reported positive behaviors when partner commitment was low. Perceptions of partner commitment did not moderate the relation between implicit self-esteem and behavior in the control condition. The findings suggest that implicit self-esteem influences reports of verbal and nonverbal behavior during a threatening relationship interaction. The findings are also consistent with the idea that risk regulation dynamics are specific to relationships where the possibility of rejection is painful enough to activate the risk regulation system. That is, when perceptions of partner commitment are low, relationship threats may not elicit feelings of rejection or activate relationship regulation processes.

#### D175

##### **SOME THINGS ARE BETTER LEFT UNSAID: SELF-ESTEEM DIFFERENCES IN POSITIVE AND NEGATIVE EXPRESSIVITY AND THEIR EFFECTS ON INTERPERSONAL RELATIONSHIPS** Amanda L. Hogle<sup>1</sup>, Joanne V. Wood<sup>1</sup>; <sup>1</sup>University of Waterloo

Self-disclosure and emotional expressivity are good for close relationships. In fact, expressivity is viewed as the key to relationship success, promoting satisfaction (Berscheid & Regan, 2005) and stability (Sprecher, 1987). But is expressivity always good? Having a partner who is expressive but always focuses on the negative could be draining. Individuals with low self-esteem (LSEs) experience higher levels of nearly all negative emotions and suffer more depression and anxiety than do individuals with high self-esteem (HSEs; Leary & MacDonald, 2003). Would LSEs' expressivity be good for their relationships? Evidence suggests that LSEs have less satisfying and stable relationships than HSEs (e.g., Leary & MacDonald, 2003). We tested the hypotheses that LSEs engage in more negative expressivity and less positive expressivity than HSEs, and that this negative expressivity contributes to LSEs' less favorable relationship outcomes. Participants were asked to provide their 10 most recent status updates from the popular social networking website, Facebook. Two independent sets of raters coded each status update for a) the degree of positivity and negativity expressed, and b) the social appeal of the update's author (e.g., interest in spending time with the author, anticipated enjoyment of interacting with the author, etc...). Relative to HSEs, LSEs expressed less positivity and more negativity in their updates and were rated as less socially

appealing. These findings suggest that LSEs express themselves more negatively than HSEs, and that such negativity may alienate their friends.

#### D176

##### **FRAGILE HIGH SELF-ESTEEM AND ROMANTIC RELATIONSHIPS** Jessica

Fulton<sup>1</sup>, Virgil Zeigler-Hill<sup>1</sup>; <sup>1</sup>University of Southern Mississippi – Discrepant high self-esteem is a form of fragile self-esteem characterized by high levels of explicit self-esteem but low levels of implicit self-esteem. Individuals with discrepant high self-esteem are believed to possess positive, yet vulnerable, attitudes toward the self that lead them to exhibit overt grandiosity in an effort to conceal unacknowledged negative attitudes toward the self. This is a pattern consistent with classic views of narcissism (see Bosson et al., 2008, for a review). The present study examined the association between discrepant high self-esteem and romantic relationship processes. We expected that individuals with discrepant high self-esteem would report less investment in their romantic relationships than those with secure high self-esteem (i.e., high levels of both explicit and implicit self-esteem). Data were collected from 432 undergraduate students (140 men and 292 women) concerning their explicit self-esteem, implicit self-esteem, susceptibility to infidelity, and mate retention strategies. Individuals with discrepant high self-esteem reported a higher probability that their partners would cheat on them than individuals with congruent high self-esteem ( $\beta = -.15, p < .01$ ). Despite their suspicions concerning the fidelity of their partners, individuals with discrepant high self-esteem reported using lower levels of all mate retention strategies ( $\beta$ 's  $> .11, p$ 's  $< .05$ ). These results may suggest that individuals with discrepant high self-esteem exhibit an overall disinterest in maintaining their romantic relationships. Discussion will focus on the potential implications of fragile self-esteem for romantic relationships.

#### D177

##### **STRESS AND COPING MEDIATE RELATIONSHIPS BETWEEN TYPES OF SELF-ESTEEM AND ALCOHOL-RELATED PROBLEMS** Angelee G.

Shamaley-Kornatz<sup>1</sup>, Stormy Morales-Monks<sup>1</sup>, Rebecca L. Palacios<sup>2</sup>, Joe Tomaka<sup>1</sup>, Sharon E. Thompson<sup>1</sup>; <sup>1</sup>University of Texas at El Paso, <sup>2</sup>New Mexico State University

Although high global self-esteem conveys personal benefits, a contingent sense of self-esteem can result in negative affect and behavioral outcomes, including alcohol consumption (Luhtanen & Crocker, 2005). Increased stress and maladaptive coping are hypothesized links between contingent self-esteem and negative outcomes (Crocker, 2002), however, these associations have not been examined to date. Accordingly, the present study: (1) Assessed relations between types of self-esteem (global and contingent) and alcohol consumption and related problems, (2) examined associations between self-esteem and stress and coping behaviors, and (3) examined stress and coping as mediators of associations between types of self-esteem and alcohol-related outcomes. Participants completed measures of self-esteem; alcohol consumption and related problems; and stress and coping in a single testing session. Global self-esteem correlated negatively with alcohol-related problems ( $r = -.21^{**}$ ), whereas contingent self-esteem correlated positively with such problems ( $r = .19^{**}$ ). Neither type of self-esteem related to drinking consumption. Global self-esteem correlated negatively with stress ( $r = -.51^{**}$ ), and avoidant forms of coping ( $r = -.11^*$  to  $-.33^{**}$ ), but positively with engaged forms of coping ( $r$ 's =  $.11^*$  to  $.28^{**}$ ). In contrast, contingent self-esteem correlated positively with stress ( $r = .23^{**}$ ), and several forms of avoidant coping ( $r$ 's =  $.14^{**}$  to  $.25^{**}$ ). Stress and coping variables related predictably to alcohol-related problems ( $\beta$ 's =  $.11^*$  to  $.40^{**}$ ) and completely mediated both the negative association between global self-esteem and alcohol-related problems, and the positive association between contingent self-esteem and alcohol-related problems (both NS in hierarchical regression). The results illuminate mechanisms linking the forms of self-esteem to alcohol-related outcomes.

**D178****MINDFUL ACCEPTANCE INCREASES CONGRUENCE BETWEEN IMPLICIT AND EXPLICIT SELF-ESTEEM** Joshua L. Clark<sup>1</sup>, Clara Michelle Cheng<sup>1</sup>,

<sup>1</sup>American University – Implicit and explicit forms of self-esteem are weakly correlated at best (Bosson et al., 2000). Research has further demonstrated that discrepant self-esteem (high explicit/low implicit or high implicit/low explicit self-esteem) tends to be associated with maladaptive traits and behaviors (e.g., Jordan et al., 2003; Zeigler-Hill & Terry, 2007). As an attempt to gain further insight into the relationship between implicit and explicit self-esteem, recent research has begun to identify moderating variables that enhance the correspondence between the two forms of self-esteem. The current study sought to examine mindfulness – defined as being aware of the present moment without judgment of one's experiences – as one such moderator. Mindfulness encourages acceptance of one's thoughts and feelings, including those relevant to positive or negative self-evaluations. We thus expected mindful individuals to exhibit stronger congruence between implicit and explicit self-esteem due to a lower need to consciously censor or modify their explicit self-evaluations. In this study, 86 participants completed the name-letter preference task (an implicit self-esteem measure), the Rosenberg self-esteem scale (an explicit self-esteem measure), and the Five Facet Mindfulness Questionnaire (FFMQ; a measure of mindfulness). Results based on multiple hierarchical regression analyses revealed a significant positive relationship between implicit and explicit self-esteem among participants who scored high on the mindfulness facet of "acceptance without judgment," but not for those who scored low.

**D179****REACTIONS TO INJUSTICE: THE ROLE OF EXPLICIT AND IMPLICIT SELF-ESTEEM** Irene Cheung<sup>1</sup>, Glen Gorman<sup>2</sup>, James M. Olson<sup>1</sup>; <sup>1</sup>University of Western Ontario, <sup>2</sup>Wilfrid Laurier University – Research has shown that individuals' overall self-worth can be evaluated at an explicit and implicit level (e.g., Greenwald & Banaji, 1995), and that different combinations of explicit and implicit self-esteem can lead to different response tendencies: individuals with high explicit and high implicit self-esteem tend to be relatively secure, whereas those with high explicit and low implicit self-esteem tend to be relatively defensive (Jordan et al., 2003). The present research examined whether individuals with varying combinations of explicit and implicit self-esteem respond differently when their just-world beliefs are threatened. Participants read a newspaper article about an 18-year-old Canadian who was assaulted and robbed while traveling. The perpetrators were either caught and punished for the harm (low threat to just-world beliefs) or were never apprehended (high threat). Results revealed a three-way interaction between threat, explicit and implicit self-esteem for recommended punishment of the perpetrators and willingness to help the victim. Specifically, when there was high threat, among participants high in explicit self-esteem, those with high implicit self-esteem recommended harsher punishment for the perpetrators and reported more willingness to help the victim relative to those with low implicit self-esteem. When there was retribution, however, among participants high in explicit self-esteem, those with high implicit self-esteem recommended less severe punishment and reported less willingness to help the victim than those with low implicit self-esteem. This pattern was not observed among participants low in explicit self-esteem. Thus, individuals with varying combinations of explicit and implicit self-esteem seem to have different reactions to justice threats.

Participants high in explicit self-esteem, those with high implicit self-esteem recommended harsher punishment for the perpetrators and reported more willingness to help the victim relative to those with low implicit self-esteem. When there was retribution, however, among participants high in explicit self-esteem, those with high implicit self-esteem recommended less severe punishment and reported less willingness to help the victim than those with low implicit self-esteem. This pattern was not observed among participants low in explicit self-esteem. Thus, individuals with varying combinations of explicit and implicit self-esteem seem to have different reactions to justice threats.

**D180****SWEETS, SEX, OR SELF-ESTEEM? COMPARING THE VALUE OF SELF-ESTEEM BOOSTS WITH OTHER PLEASURABLE REWARDS** Scott

Moeller<sup>1</sup>, Jennifer Crocker<sup>1</sup>, Brad Bushman<sup>1</sup>; <sup>1</sup>University of Michigan – Prior research has highlighted the importance people ascribe to self-esteem. However, little research has examined the subjective value attributed to boosting one's self-esteem, specifically when compared with the value of other pleasurable rewards. College undergraduates (Study 1: N=130; Study 2: N=284) completed a modified version of the STRAP-R question-

naire (Goldstein et al., in press), originally designed to test preference for addictive drugs against other pleasurable rewards. We hypothesized that valuing of self-esteem boosts would exceed valuing of (1) eating one's favorite food, (2) engaging in one's favorite sexual activity, (3) receiving one's paycheck, and (4) seeing one's best friend (items 1-2: both studies; items 3-4: Study 2). We further hypothesized that self-image goals (goals to construct, maintain, and defend desired images) would moderate valuing of these rewards (Study 2), such that people with high self-image goals would especially value self-esteem. Within-subjects ANOVAs (with follow-up Bonferroni-corrected pairwise comparisons) revealed that valuing of self-esteem boosts exceeded valuing of eating one's favorite food or engaging in one's favorite sexual activity [Study 1: omnibus  $F(2,127)=137.77$ ,  $p<.001$ ; Study 2: omnibus  $F(2,271)=143.01$ ,  $p<.001$ ], and receiving one's paycheck or seeing one's best friend [Study 2: omnibus  $F(2,274)=5.43$ ,  $p<.005$ ]. Moreover, self-image goals moderated valuing of these rewards [food, sex, self-esteem:  $F(2,269)=3.20$ ,  $p<.042$ ; money, friend, self-esteem:  $F(2,272)=3.68$ ,  $p<.026$ ], such that self-image goals related to valuing self-esteem ( $\beta=.14$ ,  $p<.019$ ) but not other rewards ( $-.06\leq\beta\leq.03$ ,  $ps>.29$ ). Thus, consistent with our predictions, these findings collectively show that people (especially those high in self-image goals) self-report valuing self-esteem boosts over other pleasurable rewards.

**D181****WHEN NARCISSISM AND CONTINGENT SELF-ESTEEM COLLIDE: THE LINK BETWEEN NARCISSISM, FRIENDSHIP CONTINGENT SELF-ESTEEM, AND FRIENDSHIP JEALOUSY** Sara A. Kruse<sup>1</sup>, M. Janelle Cambron<sup>2</sup>;

<sup>1</sup>University of Alabama, <sup>2</sup>Texas A&M University – Researchers have suggested that people high in narcissism, which reflects an inflated sense of self, actually have an unstable self-esteem and therefore may have contingent self-worth (see Crocker & Park, 2004). However, past research has failed to consistently show a relationship between contingencies of self-worth and narcissism (Zeigler-Hill, Clark, & Pickard, 2008). What may be more important to consider is whether contingent self-worth and narcissism interact to predict negative outcomes. One negative outcome of particular importance is friendship jealousy. Friendship jealousy has been found to be associated with peer victimization and loneliness (Parker, Low, Walker, & Gramm, 2005). In the present study, we examined whether narcissism would interact with one particular domain of contingent self-esteem, basing one's self-esteem on the quality of one's friendships ("friendship contingent self-esteem") to predict friendship jealousy. We hypothesized that whereas individuals high in narcissism may not experience jealousy over their friends, individuals high in narcissism who also base their self-worth on their friendships may experience the greatest friendship jealousy. In the present study, 405 college participants completed measures of global self-esteem, narcissism, friendship contingent self-esteem, and friendship jealousy. After controlling for global self-esteem, friendship contingent self-esteem moderated the relationship between narcissism and friendship jealousy. Specifically, individuals who base their self-esteem strongly on their friendship quality and report greater narcissism reported the greatest friendship jealousy. This finding suggests that narcissism is a risk factor for friendship jealousy, only to the extent that individuals high in narcissism base their self-worth on the quality of their friendships.

**D182****DEFENSIVENESS IN RESPONSE TO FAILURE: WEIGHT DISCRIMINATION AMONG INDIVIDUALS WITH DISCREPANT HIGH SELF-ESTEEM** Jessica

L. Almonte<sup>1</sup>, Kimberly B. Arnold<sup>1</sup>, Shannon P. Lupien<sup>1</sup>, Ariana F. Young<sup>1</sup>, Mark D. Seery<sup>1</sup>; <sup>1</sup>University at Buffalo, The State University of New York – Previous research has shown that individuals with discrepant high self-esteem (i.e., high explicit and low implicit self-esteem) behave more defensively than others when confronted with failure. Evidence further suggests that people with discrepant high self-esteem may engage in ethnic discrimination as a defensive response to self-threat. However, it is unclear how important a target's stigmatized status is for eliciting such discrimination when ethnicity also creates a particularly clear sense of ingroup ver-

sus outgroup, which could encourage discrimination to enhance the ingroup regardless of stigmatized status. We thus extended past research by investigating discrimination based on weight, a stigmatizing characteristic that should connote less cohesive ingroups and outgroups than ethnicity. Participants completed measures of implicit and explicit self-esteem and then received failure feedback on a test of reasoning ability. Next, participants were asked to evaluate the suitability of a fictitious applicant for a student advisor position. The stigmatized status of the applicant was manipulated by digitally altering an image of a woman to appear slim or obese. This slim or obese picture of the applicant was affixed to an otherwise identical application. As predicted, in the obese condition, individuals with discrepant high self-esteem rated the applicant more negatively than other participants did. In contrast, in the slim condition, no differences in ratings emerged as a function of self-esteem. These results suggest that after self-threat, individuals with discrepant high self-esteem derogate stigmatized individuals in particular, and that such discrimination does not depend on the clear ingroup/outgroup distinction connoted by ethnicity.

### D183

#### ATTENTION AND INFORMATION PROCESSING BIASES IN FRAGILE SELF-ESTEEM: A TEST OF THE "EVALUATIVE SET" Whitney L. Heppner<sup>1</sup>;

<sup>1</sup>University of Georgia – Previous research demonstrates that markers of fragility versus security of self-esteem, such as self-esteem contingency, can impact defensive self-esteem maintenance processes, including verbal defensiveness (Kernis, Lakey & Heppner, 2008) and self-serving biases (Heppner & Kernis, 2009). The current study explored possible attention and information processing mechanisms that play a role in fragile versus secure self-esteem and resultant defensive outcomes. Specifically, I tested a three-part model which states that individuals with fragile self-esteem possess an "evaluative set" of (a) orientation toward evaluative information or events, (b) bias toward the interpretation of events as self-esteem relevant, and (c) linking momentary self-esteem to such self-esteem relevant events (e.g., Greenier et al., 1999). To examine this model, first, participants received randomly assigned success or failure feedback on a cognitive functioning task. Next, participants reported their state self-esteem and a single-item measure of how their self-esteem was affected by their performance on the cognitive functioning task. Then, participants completed a lexical decision task (LDT) containing success- and failure-related words. Results revealed support for all three parts of the evaluative set model. Participants higher in self-esteem contingency who failed responded more quickly to failure words relative to success words on the LDT (orientation), and directly reported more self-esteem relevance for their performance on the cognitive functioning task (bias). In addition, participants higher in contingency, regardless of feedback condition, experienced lower state self-esteem following the task (linking). Discussion centers on the importance of attention and information processing variables for future self-esteem research.

### D184

#### FELT SECURITY UNCONSCIOUSLY INFLUENCES DECISION MAKING AFTER THREAT Jennifer Smith<sup>1</sup>, Julie Longua<sup>1</sup>, Tracy DeHart<sup>1</sup>;

<sup>1</sup>Loyola University Chicago – The goal of the current research was to examine how people's attitudes towards significant others influence their evaluation of people with the same first name as their significant others. Previous research has found that people low in felt security demonstrate an implicit preference for their partners only when things were going well in their relationship (DeHart, Pelham, & Murray, 2004). However, people high in felt security demonstrate an implicit preference for their partners regardless of current relationship quality. Study 1 examined the effects of chronic felt security (i.e., trait self-esteem) and Study 2 examined the effects of current felt security (i.e., current relationship quality) on decision making after a threat. Undergraduate students were randomly assigned to either the threat or control condition and then read a description of a job applicant. Some participants read a description about an applicant with the same first name as their romantic partner, and the others read a description about an applicant with a control name. All

participants were then asked to evaluate the job applicant. Multiple regression analyses revealed that in the threat condition, participants with low felt security evaluated a job applicant with the same name as their partner more negatively than participants with high felt security. However, there was no relation between felt security and evaluation of the applicant with the control name. This pattern was not evident in the non-threat condition. These findings provide the first evidence that implicit beliefs about romantic partners influence our evaluations of others.

### D185

#### THE IMPACT OF SELF-ESTEEM AND EGO THREAT ON PERSPECTIVE-TAKING Kristie Vail<sup>1</sup>, Carrie Wyland<sup>1</sup>;

<sup>1</sup>Tulane University – The present study aimed to determine how self-esteem, as well as a threat to self-esteem, influences the ability to perspective-take. Perspective-taking is typically defined as the ability to 'put oneself in someone else's shoes'. For this study, participants first completed measures of contingent self-esteem (i.e. how much one's sense of self-worth is dependant on positive external outcomes, such as success and acceptance) and need to belong. Next, half of the participants received an ego threat (failure feedback) and half received no feedback, after which they completed a perspective taking measure which required them to identify emotions in photographs of faces. Results of the study indicated that participants with higher contingent self-esteem and higher need to belong scores were better able to correctly identify emotions compared to participants with lower scores on either scale. Additionally, the ego threat manipulation intensified this difference, such that those with higher contingent self-esteem and need to belong showed improved performance after an ego threat, while those who scored low on these measures performed worse after threat. These findings have implications for understanding the role of individual differences, as well as situational factors, in perspective taking; namely this suggests that individuals who place more importance on belonging and whose self-esteem is highly contingent may actually be better at understanding others and, further, failure may increase this "other focus" for these individuals.

## Stereotyping/Prejudice

### D186

#### RELATIONSHIP CLOSENESS AND ASSOCIATIVE STIGMA: WHEN ARE PEOPLE MOTIVATED TO DISCLOSE STIGMATIZED RELATIONSHIPS?

David A. Richards<sup>1</sup>, Catherine A. Cottrell<sup>1</sup>;

<sup>1</sup>University of Florida – People in social relationships with stigmatized others may manage associative stigma by distancing themselves from the stigmatized person, or may choose to publicly disclose their associative stigma. What predicts disclosure or concealment of associative stigma? Some such predictors may be internal psychological factors, namely self-verification processes and the self-concept. People self-verify (Swann, 1983, 1987) to align others' perceptions of them with their own self-image by disclosing personal information about the self, including stigmatizing information (Swann, 1996; Swann et al., 2004), particularly when the stigma is central to the self-concept. Regarding associative stigma, stigmatized relationships may be described in terms of self-expansion processes (Aron & Aron, 1986), wherein self-concepts are expanded to encompass and incorporate close others into the self-concept. A person may therefore be more motivated to disclose the existence of a stigmatized (but close) relationship. It was predicted that closer relationships between a stigmatic and a nonstigmatic will be more central to the nonstigmatic's self-concept, and the nonstigmatic may be more motivated to disclose the marked relationship's existence. We artificially manipulated the closeness between a participant and a (stigmatized) confederate, and then created a self-verification threat by providing false feedback on the apparent closeness between the participant and the confederate. The participants were given the opportunity to correct this false feedback by disclosing their actual closeness to the confederate. Results partially supported predictions, and implications are discussed.

**D187**

**LEGALISTIC DIVERSITY MANDATES: DO THEY UNDERMINE EGALITARIAN TENDENCIES?** Ana P. Nunes<sup>1</sup>, Geoffrey Cohen<sup>1</sup>, <sup>1</sup>University of Colorado at Boulder – Since 1964 public institutions have been mandated by the federal government to post legalistic mandates that explicitly state their commitment to averting bias and discrimination in hiring decisions and academic admissions. However, little if any research has examined the effects of such legalistic messages. The present research seeks to fill this gap by examining how legalistic messages consistent with Title VI and VII of the Civil Rights Act of 1964 affect the likelihood of decision-makers' selection of minority vs. majority group members. We expected that such legalistic messages constitute a double-edged sword. Though these messages can deter discrimination among those with racist beliefs, they may ironically undermine the egalitarian interests of those who would have made non-racist decisions in the absence of the mandate. Consistent with this expectation, we found that subjects who selected a minority candidate after being exposed to a legalistic anti-discrimination message were, relative to various control conditions, subsequently less likely to positively evaluate and select another highly qualified minority candidate. No such effects were found for evaluations of White candidates. Consistent with classic theories of self-perception, salient external surveillance and pressures, as potentially embedded in legalistic regulations, can undermine intrinsic motivation, in this case the egalitarian motives of decision-makers. Discussion centers on issues of underlying process, the effects of regulation on self-perception, and the complex practical trade-offs involved in the propagation of legalistic messages and mandates.

**D188**

**"IMAGINARY CONTACT": DEVELOPING AND EVALUATING A NEW PREJUDICE-REDUCTION INTERVENTION FOR SCHOOLS.** Sofia Stathi<sup>1</sup>, Lindsey Cameron<sup>1</sup>, <sup>1</sup>University of Kent – Psychological research has shown that children's attitudes towards different social groups can be improved through prejudice-reduction interventions that are grounded in psychological theories and research findings (e.g. Cameron, Rutland, Brown & Douch, 2006). Our project aimed to develop and evaluate a prejudice-reduction intervention for children, based on the mental simulation of inter-group contact (i.e., imagined contact, Stathi & Crisp, 2008). We tested the technique with a new sample, children (aged 7-9 years), in an applied context (a school) and explored potential mediators such as inter-group anxiety, self - out-group closeness and perceived similarity. Furthermore, we tested ways to increase the effectiveness of the technique via either common-in-group or individual-based contact instructions. In the intervention itself children imagined that they were interacting with a same-age peer belonging to the target out-group (Asian children) in a number of contexts, for example the beach, school playground, a party. The children took part in the intervention three times (once a week for three weeks) and used pictures and photographs of themselves and Asian children to help stimulate their imagination. In order to provide a baseline of children's attitudes towards Asian children, there was a control condition in which children did not receive the intervention. Analysis revealed the effectiveness of the technique; children who experienced the intervention were significantly more positive in their attitudes towards the ethnic out-group. The role of the mediators, along with the theoretical implications and the design of interventions, are discussed.

**D189**

**DECREASING PREJUDICE WITH A LITTLE HELP FROM YOUR FRIENDS: THE IMPACT OF HOMOGENEITY AND DIVERSITY INFORMATION ON ATTITUDES TOWARD AN OUTGROUP** Charlene Christie<sup>1</sup>, Kimberly Joy<sup>1</sup>, Alyssa Tufano<sup>1</sup>, Jaclyn Kinash<sup>1</sup>, <sup>1</sup>SUNY College at Oneonta – The current study examined how a focus on homogeneity or diversity would influence attitudes toward Hispanic immigrants, and how outgroup friendships might impact this relationship. The outgroup homogeneity effect has been shown to have both a detrimental and beneficial impact on

intergroup relations. Ps were exposed to summary information about the outgroup (describing the culture in terms of either homogenous or diverse characteristics), then completed a series of DV measures assessing attitudes toward the issue of Hispanic immigration in the U.S. We also inquired whether Ps had friends, or friends of friends, who were Hispanic immigrants. Results showed a main effect of information, with Ps in the homogeneity group expressing less prejudice than Ps in the diversity group. This pattern was moderated by the friendship variable. A significant information x friendship interaction revealed that people who were friends with immigrants showed fewer prejudicial attitudes when exposed to the homogeneity information, as opposed to the diversity information. While it was unexpected that the diversity-focused group displayed more prejudice than the homogeneity-focused group, the role of friendships in the development of outgroup attitudes is especially compelling. These results illustrate the potential benefits of the outgroup homogeneity effect, in that individuals who are friends with members of an outgroup may perceive other members of that group as less threatening when presented with information that focuses on the homogeneity of the outgroup.

**D190**

**WHAT DOES SPEAKING WITH A FOREIGN ACCENT MEAN?: CONTENT ANALYSIS OF NEWSPAPER ARTICLES** Agata Gluszek<sup>1</sup>, Irene B. Murimi<sup>1</sup>, John F. Dovidio<sup>1</sup>, <sup>1</sup>Yale University – Guided by a theoretical framework on stigma and communication, we content-analyzed newspaper articles in respect to stereotyping, discrimination, negative and positive social evaluation, problems in communication, and accent modification (e.g., Lippi-Green, 1997). We hypothesized that accents would be portrayed as a negative trait interfering with communication and in need of reduction. Two judges coded articles that satisfied a priori defined selection criteria, such as referring to pronunciation and not other meanings of foreign accents (N=103; years 1999-2008). A codebook (11 categories, 28 subcategories) based on articles prior to 1999 was created. The initial interrater reliability was good =78%; all disagreements were discussed, reaching 100% agreement. The results confirmed the hypotheses: 16 percent of articles mentioned stereotyping and 27% discussed discrimination based on accent. Although positive feelings (7%) and positive social evaluation (18%) were mentioned (mostly in the context of accents stereotypically perceived as prestigious), negative feelings (18%) and negative social evaluation (27%) were discussed more often. The listener's perception than an accent impairs communication was mentioned more often (26.2%) than the speaker's perception (16.5%). Accent reduction was discussed in 29% of articles, but only 17% pointed out the difficulty (or impossibility) of eliminating foreign accent, which has been widely supported by research (e.g., Scovel, 2006). In 44% of articles accent served as an identifier and 29% of articles referred to accent strength, reflecting the importance of accents in identifying out-group members. This study offers an initial support to the notion of complex representations of accents in the print media.

**D191**

**THE ROLE OF OPTIMISM IN MAKING ATTRIBUTIONS TO AND PLANS TO CONFRONT GENDER DISCRIMINATION** Gretchen Sechrist<sup>1</sup>, <sup>1</sup>Mansfield University – Three studies examined the role of optimism in women's willingness to make attributions to and confront gender discrimination. Study 1 showed that there was no correlation between optimism and making attributions to discrimination, however there was a significant positive correlation between optimism and women's intention to confront discrimination. In Study 2, results indicated that although discrimination attributions did not differ by level of optimism, women high in optimism were more willing to confront a perpetrator of discrimination than women intermediate or low in optimism. Study 3 demonstrated that, compared to pessimists and intermediate participants, female optimists were more willing to confront discrimination because they take an active approach to dealing with discriminatory feedback and expect to have successful outcomes in confronting their perpetrator. Thus, this research demonstrated that optimism increased women's plans to con-

front gender discrimination, and showed that this relation was not a result of attributions to discrimination or perceptions of discriminatory events. Rather, as shown in Study 3, such differences were due to optimists' strategies for coping with discrimination. Women may suffer from discrimination both as a result of the direct effects of experiencing such negative events as well as because they are unwilling to perceive or report that they are victims. Thus, it is important to identify factors, such as optimism, that increase the likelihood that women will confront the discrimination they experience. In confronting discrimination and holding perpetrators responsible for their actions, perhaps the occurrence and frequency of gender discrimination can be reduced.

**D192**

**THE EFFECTS OF GENDER-ROLE-RELEVANT CHOICES ON PERCEPTIONS OF WOMEN** Lea A. Folsom<sup>1</sup>, Danielle C. Zanotti<sup>1</sup>, Sarah J. Smith<sup>1</sup>, Donald A. Saucier<sup>1</sup>; <sup>1</sup>Kansas State University – Perceptions of women as a social group are complicated by several factors. Sexism may take various forms, from benevolence to hostility (Glick & Fiske, 1996), and from old-fashioned to modern forms (e.g., Swim & Cohen, 1997). Further, perceptions of pregnant women are complicated by the women's degree of adherence to traditional gender roles (Hebl, King, Glick, Singletary, & Kazama, 2007). We sought to better understand how gender-role-relevant behavioral choices made by women may affect the expression of prejudice toward them via the justification-suppression model (Crandall & Eshleman, 2003). In our study, participants read one of 16 vignettes of a target woman in a 2 (pregnancy status) x 2 (smoker status) x 2 (marital status) x 2 (religious involvement) between-groups design. Participants completed dependent measures that included their ratings of warmth toward her, their perceptions of the woman's personality and abilities as a mother, and their desire to interact with her. Participants' levels of sexism (hostile, benevolent, modern, and old-fashioned) and religiosity (extrinsic, intrinsic, quest, and fundamentalism) were also measured. Results converged to indicate that target women's levels of religious involvement served as a suppression factor for negative reactions toward her regardless of her pregnancy status, smoker status, or marital status. Interestingly, religiosity was not a suppression factor for negative perceptions of women. Our results contribute to our understanding of how women are perceived as functions of their behavioral choices and extend the justification-suppression model in its ability to predict and explain perceptions of women.

**D193**

**IMPLICIT AND EXPLICIT ATTITUDES UNDERLYING DISCRIMINATION AT WORK** Elizabeth L. Haines<sup>1</sup>; <sup>1</sup>William Paterson University – Gender and parental bias at work were assessed in terms of implicit and explicit sexism. At time 1, 229 participants (49.5 % White; 74.8 % female) completed an implicit (IAT associating men with competence and women with warmth) and explicit (Ambivalent Sexism Inventory) measure of sexism. At time 2, (allegedly as an unrelated experiment) participants were asked to act as a supervisor in an employee evaluation scenario. Participants were assigned to one of four conditions (gender X parental status). Participants were provided with a job analysis and evaluation scenario and were then asked to evaluate the worker on performance, availability, and employment decisions (layoff, training, promotion). Results indicate that (a) Mothers (vs. all workers) were perceived to be less available, parents (vs. non parents) were perceived as more trainable, and men were perceived as more trainable than women, (b) stronger implicit bias was associated with: a lower likelihood to layoff a father (compared to a mother) and positive performance evaluations of mothers (compared to fathers and non parent workers), (c) explicit sexism was associated with the perceived availability of mothers and non-parent men. These findings are discussed in terms of the different pathways implicit and explicit bias may take in creating discrimination at work.

**D194**

**LOOKING FOR THE ANGRY MAN: EVIDENCE FOR RACIALLY BIASED VISUAL SEARCH** Marte Otten<sup>1</sup>, Mahzarin R. Banaji<sup>1</sup>; <sup>1</sup>Harvard University – In a visual search task, items that are detected more efficiently are assumed to attract greater attention. We used such a task to test the effects of implicit race bias on attention to black and white faces during emotion detection (smiling vs. angry). In Experiment 1 participants searched for an angry face in a display of 4 or 8 faces. We compared search efficiency for black and white target faces by computing search slopes (i.e. the relative increase in response latency as a function of display size). Overall we observed no difference in search slopes for black or white targets. However, an implicit measure of race bias (IAT) predicted search efficiency: the stronger the anti-black race bias, the greater the efficiency in locating black compared to white targets ( $r=.32$ ). In Experiment 2 we tested whether this effect would also be present when participants searched for happy faces. Here, we found no effect of participants' implicit race bias on black vs. white search efficiency ( $r=.01$ ). The bias-dependent search-asymmetry for black and white targets thus seems to depend on the association between black and anger, and future work will test the generality of this result to a broader range of negative attributes. Taken together, our results suggest that individual differences in racial preference shape the way we attend to the people around us.

**D195**

**SPECIFIC EMOTIONS MEDIATE THE EFFECT OF INTERGROUP CONTACT ON PREJUDICED ATTITUDES: COMPARATIVE EVIDENCE FROM A NATIONAL SAMPLE OF THREE ETHNIC GROUPS.** Ishani Banerji<sup>1</sup>, Charles Seger<sup>1</sup>, Eliot Smith<sup>1</sup>, Diane Mackie<sup>2</sup>; <sup>1</sup>Indiana University, Bloomington, <sup>2</sup>University of California, Santa Barbara – Previous research has provided considerable evidence to suggest that intergroup contact reduces prejudice towards outgroups, with affective mediators playing a key role. (Tropp & Pettigrew, 2005) However, many of these studies have examined only one or two emotions, often anxiety. (e.g., Islam & Hewstone, 1993) Furthermore, most previous studies focus on a single perceiver group (usually Caucasians) and a single target group (often a minority group). Scarcely any studies examine relations between minority groups. (Tropp & Pettigrew, 2005) The current study examined specific positive and negative emotions as mediators of the contact-prejudice relationship using a national survey sample of White, Black, and Asian American respondents (total N=639). Each respondent was randomly assigned one of the other ethnic groups as the target outgroup. Reports of previous contact, positive and negative emotions towards the target group, and attitude towards the target group were analyzed. Consistent with previous research, contact was associated with more positive attitudes towards the target outgroup. Admiration and anger (but not anxiety, pity, disgust, or jealousy) fully mediated the relationship between contact and attitudes. (cf. Baron & Kenny, 1986) The effect of admiration on attitude differed across groups, but other paths in the overall analysis did not statistically vary across the groups. These results suggest that previous research, which has focused only on anxiety as a mediator, may be flawed. The findings are of interest in showing which specific emotions mediate the contact-prejudice relationship, as well as permitting direct comparisons across six pairs of respondent-target groups.

**D196**

**IF SHE CAN DO IT, SO CAN I! CONFRONTATION BEHAVIOR IN RESPONSE TO OTHERS' SUCCESSFUL OR UNSUCCESSFUL CONFRONTATION ATTEMPTS** Alexander M. Czopp<sup>1</sup>; <sup>1</sup>Western Washington University – Although many people report commitment to fighting prejudice and discrimination, when presented with opportunities to confront bias directly most people remain passive (e.g., Swim & Hyers, 1999). Research on the consequences of interpersonal confrontations suggest that despite interpersonal costs, active attempts to address others' can be effective in reducing biased behavior (Czopp et al., 2006). One potential way to increase the likelihood of actual confrontations among would-be confronters is to increase their awareness of the effectiveness of such con-

frontations. Following a social learning approach, female participants interacted with a female confederate who discussed her previous experiences with sexism. The confederate described a successful, unsuccessful, or lack of confrontation in a work setting. Afterwards, participants interacted separately with a male confederate who discussed his traditional beliefs regarding gender roles. All participants provided public (i.e., directly to the confederate) and private ratings of both confederates. The female confederate was consistently rated more favorably than the male confederate and particularly when she was a successful confronter. Furthermore, participants' evaluations of the female confederate did not differ in public versus private. In contrast, participants evaluated the male confederate more negatively in private than in public but only when they had previously heard the female confederate's attempts to confront bias, and the public-private discrepancy was strongest after hearing about the unsuccessful confrontation attempt. The role of awareness of descriptive norms and social costs/benefits are discussed.

#### D197

**EMPATHY THE CAUSE AND THE CURE: THE ROLE OF EMPATHY IN RACIAL PAIN TREATMENT BIAS** Brian Drwecki<sup>1</sup>, Colleen Moore<sup>1</sup>; <sup>1</sup>University of Wisconsin-Madison – Recent findings suggest that across numerous hospitals, doctors' offices, and clinics, racial analgesic prescription biases exist where African Americans are prescribed less pain medication than European Americans. Our work tests the hypothesis that empathy is both the cause of and the solution to racial analgesic prescription bias. Across two experiments participants (university undergraduates) viewed four videos of real patients suffering from acute pain, made analgesic prescriptions, and provided responses indicative of emotional empathy and perceived patient pain. Experiment 1 examined the extent that empathy and perceived patient pain statistically mediated racial bias in pain treatment. Experiment 2 introduced perspective taking instructions as a way to induce empathy and in turn reduce racial analgesic bias. Results from experiment 1 indicated that patient race had direct effects on empathy and pain treatment with participants feeling less empathy and prescribing less pain medication for African American patients. A mediation analysis confirmed that empathy was mediating the effect of race on pain prescriptions. Results from experiment 2 indicated that the perspective taking manipulation eliminated racial pain treatment bias. Follow-up analyses provide some evidence that the perspective taking manipulation was acting through empathy and perceived patient pain. These data suggest that racial analgesic bias is not unavoidable, taking the perspective of one's patient may provide the tool that healthcare providers need to eliminate racial bias from pain treatment. While these results are promising, extending this paradigm to real healthcare professionals in real world medical settings is needed.

#### D198

**PREFERENCES FOR GENDER STEREOTYPES IN THE FACE OF SUCCESS** Justin Chase<sup>1</sup>, Scott Eidelman<sup>2</sup>; <sup>1</sup>University of Maine, <sup>2</sup>University of Arkansas – A number of studies demonstrate how stereotypes lead members of stereotyped groups to underperform (e.g., Steele & Aronson). But what if success occurs in spite of this obstacle? Because performers prefer to meet higher standards and to augment success (e.g., Eidelman & Biernat, 2007; Quattrone & Jones, 1978) we predicted that performers would feel better succeeding in the presence of stereotypes. Women took an anagram test that, following performance, was framed in one of three ways. In the male stereotype condition, participants were told that success required reasoning skills and men tended to outperformed women. In the female stereotype condition, participants were told that success required verbal skills and women tended to outperform men. In the no stereotype condition, participants were told that men and women performed equally well. After completing their test, participants were given bogus ideographic feedback indicating that they were successful. They then completed a questionnaire that measured self-esteem. Consistent with predictions, women had higher self-esteem when they succeeded on a test on which men tend to outperform women (the male stereotype condition) compared to the control condition and when women were

said to outperform men. Women also had marginally higher self-esteem when they succeeded in the female stereotype condition compared to the control condition. These findings suggest that performers prefer success in the presence of stereotypes, irrespective of the direction that the stereotypes take.

#### D199

**INCREASING WOMEN'S ASPIRATIONS AND ACHIEVEMENT IN SCIENCE: THE EFFECT OF ROLE MODELS ON IMPLICIT COGNITIONS** Julie E. Phelan<sup>1</sup>, Laurie A. Rudman<sup>1</sup>; <sup>1</sup>Rutgers University – Reducing the gender gap in high-level science achievement is important not only for fostering gender equality but also for reversing the decline in America's scientific prowess. The present research utilized a sample of 534 high school science students in 27 classes to examine factors that decrease women's identification with and enthusiasm for science. Specifically, this longitudinal research examined: 1) the role of students' implicit beliefs about science (gender stereotyping, identification and attitudes) in their science related achievement and aspirations and 2) whether identification with a female role model serves as an effective intervention strategy that can ultimately enhance women's science performance and career aspirations. At the beginning of the school year, students completed implicit and explicit measures assessing gender-science stereotypes, science attitudes, and science identification. At the end of the school year, these measures were repeated, and information about students' science aspirations and achievement was collected. In addition, students' identification with their (male or female) teacher was assessed to examine the influence of identifying with a science role model on students' beliefs. As expected, both male and female students showed robust levels of implicit gender-science stereotypes, which resulted in more positive attitudes towards science and greater identification with science for male than female students. In addition, students' implicit science attitudes and identification were associated with wanting to pursue a science career and their final grade. Of importance, results indicated that identifying with a female science teacher reduced women's implicit science stereotyping, which ultimately increased their science achievement and aspirations.

#### D200

**RELIGIOUS PREJUDICE AS A RELIGIOUS WORLDVIEW THREAT** Joanna Goplen<sup>1</sup>, E. Ashby Plant<sup>1</sup>; <sup>1</sup>Florida State University – By providing people with a moral code, knowledge about the world, and a sense of meaning in life, religion can strongly impact people's worldviews. Although religion has many positive implications, it is also associated with intergroup tension and conflict. We argue that people vary in the degree to which religion influences their worldview and that this individual difference may have important implications for understanding religious prejudice. For people with strong religious worldviews (RWV), religious outgroups may threaten their foundational beliefs and approach to the world, which may heighten outgroup antipathy and avoidance. To examine these ideas, we developed and validated a measure of RWV and then assessed the role of RWV in religious prejudice. We found that RWV was related to more negative attitudes toward religious outgroups. We then manipulated whether Christian participants anticipated interacting with an Atheist, Christian, or control (no religion) confederate and participants reported their feelings about the upcoming interaction. The Atheists were liked the least by all of our Christian participants. However, desire to avoid interacting with the Atheist depended on the participants' level of RWV but not on a more general measure of religiosity. Consistent with a desire to protect their worldview, people with a strong RWV were more eager to avoid interacting with the Atheist than people with a weak RWV. RWV did not affect the desire to avoid interacting in the other conditions. The implications of these findings for the maintenance of interfaith prejudice and aggression are discussed.

**D201**

**MORE THAN JUST A CROSS TO BEAR: THE EFFECTS OF STEREOTYPE THREAT ON CHRISTIANS** Mark Wojda<sup>1</sup>, Jessi L. Smith<sup>1</sup>, Lauren Hawthorne<sup>1</sup>; <sup>1</sup>Montana State University – In two studies, we tested how people higher and lower in religious identification responded to two negative Christian stereotypes: intolerance and unscientific thinking. Christianity as a "stigma" provides unique insight into the stereotype threat (ST) experience, because unlike race or sexuality, religiosity is on a continuum and relatively hidden. In study 1 (n = 54) participants higher and lower in Christianity were randomly assigned to a Christian ST or neutral condition and then completed a difficult science test. The expected interaction emerged, (F (3, 54) = 3.99, p = .05), such that performance was suppressed for people higher in Christianity under ST, whereas people lower in Christianity were relatively unaffected. It was assumed the stereotype was "threatening" even though religion is a concealable stigma. To better test this, Study 2 (n = 59) examined how a Christian's ST experience is altered by revealing their religiosity. Under ST, participants randomly assigned to revealed or concealed conditions read an ambiguous story about an African-American named "Donald" and made several judgments about him. Results showed the expected interaction for mean number of positive judgments, F (3, 57) = 4.72, p < .05 such that people higher in Christianity rated Donald more positively when their Christian status was concealed versus revealed. This suggests that revealing their stigma status under ST resulted in subtle prejudice. Results from both studies yield support for negative effects of ST among highly identified Christians. Implications for advancing ST theory and the study of religious stereotyping and prejudice are discussed.

**D202**

**DOES ENGAGING IN THE CONTROL OF INTERGROUP RESPONSES ENHANCE EGALITARIAN MOTIVATIONS?** Jennifer K. Brooke<sup>1</sup>, David M. Amodio<sup>1</sup>; <sup>1</sup>New York University – After exerting self-control to respond without prejudice, does one have more or less motivation to be non-prejudiced? We hypothesized that effort put into regulating a prejudiced response serves to engage a goal to respond without prejudice in future situations. However, some past research suggests that engaging in prejudice regulation may be cognitively depleting and may sap motivation to regulate intergroup responses in subsequent situations. To test these competing hypotheses, participants completed a self-control task that was either related to racial prejudice (stereotype inhibition) or unrelated to racial issues. Next, in what participants believed was a separate study, we assessed their persistence on a task that was purported to reduced their implicit prejudices. In this task, borrowed from Dastgupta and Greenwald (2001), participants saw pictures of famous, positive Black people (e.g., Bill Cosby) and negative White people (e.g. Timothy McVeigh). Participants were told that as they spent more time studying these pictures, their degree of implicit prejudice would be reduced. Results indicated that participants who engaged in the control of stereotyping spent more time studying the Black figures than those who engaged in control that was unrelated to race. These results suggest that the engagement in the control of intergroup responses serves to enhance one's motivation toward egalitarian goals.

**D203**

**INFLUENCES ON THE EXPRESSION OF CULTURAL-LEVEL AND PERSONAL BELIEFS ABOUT LITTLE PEOPLE** Jeremy D. Heider<sup>1</sup>, John E. Edlund<sup>2</sup>, Cory R. Scherer<sup>3</sup>, James F. Johnson<sup>4</sup>, Joshua A. Staley<sup>1</sup>, Lindsey M. Bray<sup>1</sup>; <sup>1</sup>Stephen F. Austin State University, <sup>2</sup>Rochester Institute of Technology, <sup>3</sup>Penn State University-Schuylkill, <sup>4</sup>University of Oklahoma – Heider, Scherer, and Edlund (2009, February) used an adjective checklist method to show cultural-level beliefs about little people (i.e., individuals with dwarfism) are primarily negative, whereas personal beliefs are primarily positive. The current study extended this work by examining three possible mechanisms to account for the difference in valence: personal experience with little people, socially desirable responding, and believing one's personal beliefs are more unique than they actually are (i.e., false uniqueness). 79

undergraduates selected adjectives to reflect traits constituting either cultural or personal beliefs about little people. They also indicated whether they had personal experience with little people, completed a measure of social desirability, and estimated the uniqueness of the traits they selected. A stepwise regression using condition (cultural or personal beliefs), experience with little people, social desirability, and perceived uniqueness to predict the overall favorability of selected traits revealed condition significantly predicted favorability, R-square = .29, p < .001; personal beliefs were more positive than cultural beliefs ( $\beta$  = .54). Personal experience with little people accounted for additional variance,  $\beta$  = .04, p < .05; participants with personal experience selected more favorable traits ( $\beta$  = .21). Social desirability and perceived uniqueness were not significant predictors, though their coefficients were in the expected directions (.08 and -.15, respectively). Two conclusions seem warranted by the present data: (a) personal beliefs about little people do not necessarily align with the negative cultural stereotypes about them; and (b) personal experience with little people is an important determinant of belief favorability.

**D204**

**WHO YOU ARE MATTERS: HOW HANDICAPPING IMPACTS PERFORMANCE FOR POSITIVELY AND NEGATIVELY STEREOTYPED TARGETS** Patricia N. Gilbert<sup>1</sup>, David M. Marx<sup>2</sup>; <sup>1</sup>Tulane University, <sup>2</sup>San Diego State University – Stereotype-relevant testing situations often have consequential performance implications depending on one's social self (Marx & Stapel, 2006). For instance, negatively stereotyped individuals (e.g., women in math) underperform in such situations due to concerns about confirming a group-relevant stereotype (Steele & Aronson, 1995). Given this, research has begun to explore methods to alleviate threat. One such method is to provide a handicap (i.e., a handy excuse for underperformance) for targets prior to an exam (Brown & Josephs, 1999). However, it is unclear whether the type of handicap (public or private) has a differential effect in stereotype-relevant situations and whether these handicaps are beneficial for both positively and negatively stereotyped targets' performance. Accordingly we conducted an experiment in which participants were assigned to a Public (denied an opportunity to practice), Private (completed a handicapping questionnaire), or Control (no handicap) condition. After the handicap manipulation participants took a math exam under stereotype threat. Results showed that men performed better than women in the Control condition. Furthermore, the performance gap between men and women increased in the Private condition. However, in the Public condition men and women performed equally well. These findings suggest that public handicaps may have made women less concerned about confirming the negative stereotype while the same handicap may have made men more concerned about "living up" to the positive stereotype. These findings demonstrate that public and private handicaps have different implications for performance depending on whether one is positively or negatively stereotyped. Thus, who you are matters in stereotype-relevant situations.

**D205**

**AFFILIATION WITH TARGETS OF PREJUDICE AFFECTS EVALUATIONS OF RACISM AND SEXISM** Laura Spice<sup>1</sup>, Kristen Malone<sup>1</sup>, Marie Danh<sup>1</sup>, Peggy Zizzo<sup>1</sup>, Kathryn A. Morris<sup>1</sup>; <sup>1</sup>Butler University – Research shows that people generally respond more negatively to racism than to sexism (Fiske & Stevens, 1993). One factor that may reverse this trend is affiliation with the target of prejudice. That is, people may perceive sexism more negatively than racism when they are particularly identified with the target of sexism (and vice versa). The 2008 presidential election presented a unique opportunity to investigate this hypothesis. Prior to the election, 294 Ps were asked to imagine a scenario in which a classmate made a derogatory racist remark about presidential candidate Obama or a derogatory sexist remark about vice presidential candidate Palin. They then rated their affective, cognitive, and behavioral reactions to the scenario and reported their voting intentions. Consistent with previous findings, overall, Ps responded more negatively to the racist remark than to the sexist remark. However, this main effect was qualified by Ps' vot-

ing intentions: Ps who intended to vote for the republican ticket reported more negative affective (e.g., more anger), cognitive (e.g., develop a negative view of the person who said it), and behavioral (e.g., ask the person not to say things like that) reactions to the sexist remark than to the racist remark. Ps who intended to vote for the democratic ticket, on the other hand reported more negative affective, cognitive, and behavioral reactions to the racist remark than to the sexist remark. These findings suggest that people's subjective reactions to racism and sexism can be affected by their affiliation with the target of prejudice.

## D206

**CROSSED CATEGORIZATION, EVALUATION, AND FACE RECOGNITION** Nate Way<sup>1</sup>, Devin Ray<sup>1</sup>, David Hamilton<sup>1</sup>; <sup>1</sup>University of California, Santa Barbara – We investigated the relationship between evaluative intergroup bias and errors in intergroup face recognition after crossed categorization (the combination of two social categorizations in defining a target of perception). Although evaluative intergroup bias and errors in face recognition often operate in parallel, we draw on two previously unconnected literatures to predict a dissociation between these two processes after crossed categorization. We tested this hypothesis by assessing participants' evaluations of and recognition of targets who shared two ingroups with participants, targets who shared only one ingroup with participants, and targets who shared neither ingroup. Consistent with predictions, targets' shared and unshared group memberships combined additively to affect evaluation, but targets who shared two ingroup memberships were recognized better than all other category combinations. These results document the relationship between evaluation and errors in face recognition after crossed categorization and indicate that evaluation and errors in face recognition do not necessarily respond to the same antecedents in the same way.

## D207

**AGEISM V. RACISM: AN EXPERIMENTAL EXAMINATION OF STEREOTYPES ABOUT BLACK OLDER ADULTS** Josephine A. Menkin<sup>1</sup>, Meghan G. Bean<sup>1</sup>, Jennifer A. Richeson<sup>1</sup>; <sup>1</sup>Northwestern University – Research suggests that Black Americans are associated with crime and threat while older adults are perceived as warm but forgetful. The present work examines how these conflicting stereotypes affect perceptions of older Black adults. We hypothesize that race moderates the application of the prevailing age-based stereotype that older adults are forgetful. In an online study, non-Black participants read a scenario about either a young or old, Black or White female target who leaves a store without paying for a hat; when confronted by the store manager, the target claims she forgot she was wearing the item. Participants rated how believable the woman's story was as well as how angry the manager should feel as a result of the incident. Supporting our hypothesis, participants who read a scenario featuring an older target felt the excuse was more believable than did participants who read about a younger target. There was also an effect of race, however, such that Black targets were seen as less believable than White targets. Additionally, participants thought the store manager would feel less angry toward older targets compared to young targets but would be angrier at the older Black target than the older White target. These results suggest that age and race stereotypes both impact how older Black individuals are perceived. Interestingly, however, it appears that the stereotype of warmth and forgetfulness associated with older adults is applied more readily to older White adults than to older Black adults.

## D208

**NOT MY PROBLEM: DIFFUSING RESPONSIBILITY FOR CONFRONTING PREJUDICE** Marie Danh<sup>1</sup>, Alex Lindsey<sup>2</sup>, Peggy Zizzo<sup>1</sup>, Kristen Malone<sup>1</sup>, Laura Spice<sup>1</sup>, Leslie Ashburn-Nardo<sup>2</sup>, Stephanie A. Goodwin<sup>3</sup>, Kathryn A. Morris<sup>1</sup>; <sup>1</sup>Butler University, <sup>2</sup>Indiana University-Purdue University Indianapolis, <sup>3</sup>Purdue University – Confrontation is effective in reducing prejudice (Czopp, Monteith, & Mark, 2006), yet people often fail to take action when they witness it (e.g., Swim & Hyers, 1999). The Confronting Prejudiced Responses Model (Ashburn-Nardo, Morris, & Goodwin, 2008) out-

lines obstacles people must overcome to confront prejudice; among them is taking responsibility for responding to prejudice. We hypothesize that when people witness prejudice, they may diffuse responsibility for confronting it to other bystanders. We predict people are especially likely to diffuse responsibility for confronting prejudice to targets of prejudice (i.e., African Americans or women) or authority figures (e.g., student leaders). To test this hypothesis, 330 Ps read scenarios in which a student made a racist vs. sexist remark in the presence vs. absence of a target person and in the presence vs. absence of an authority figure. Ps indicated how they would respond in the scenario. Responses from the 258 Ps who reported their reactions were coded for internal reactions (e.g., "I'd assume somebody else would do something") and external reactions (e.g., "I'd tell him that's not cool"). Both internal and external reactions were consistent with CPR Model predictions. Ps were more likely to diffuse responsibility when a target was present. In addition, Ps reported fewer external responses when a target or authority figure was present. Together, these results suggest that Ps diffuse responsibility for confronting prejudice to targets and authority figures. Thus, one reason people may refrain from confronting prejudice is that they assume someone else is responsible for confronting.

## D209

**INTERRACIAL HOOKUPS: THE EFFECTS OF RACE AND GENDER ON THE PERCEPTIONS OF SEXUAL CONSENT** OrShaundra Benson<sup>1</sup>, Midge Wilson<sup>1</sup>; <sup>1</sup>DePaul University – Research on sexual consent has been sporadic. Very little research has looked at how sexual consent is perceived or understood across different interracial contexts. Based on prior research on sexual consent, sexual script theory, and prejudice, an online research study was conducted to assess how participant gender and couple's racial composition can influence attributions of sexual consent. Participants were randomly assigned to one of four sexual scenarios in which consent granted to sexual intercourse was ambiguous. The four conditions were manipulated so that the initiator was either a Black or White male and the recipient was either a Black or White female. A 2 x 2 x 2 between subjects analysis showed that in sexual scenarios in which consent is ambiguous, participants' standards of consent were higher for same-race couples than for interracial couples. Overall, men viewed the scenarios as being more unambiguous and consensual than women regardless of the couple's racial composition. In addition, men more than women thought that "assumptive" sex is more appropriate with Black women; however, neither felt that it was appropriate for White women. Contrary to expectations, women more than men viewed the recipient as "playing hard to get" and being more accountable for defining sexual boundaries. These findings are discussed in terms of understanding how sexual consent is perceived across different interracial contexts and the role that stereotypes play in these perceptions.

## D210

**EXPLORING THE ROOTS OF DEHUMANIZATION: THE ROLE OF ANIMAL-HUMAN SIMILARITY** Kimberly Costello<sup>1</sup>, Gordon Hodson<sup>1</sup>; <sup>1</sup>Brock University – Little is known about the origins of dehumanization or the mechanisms through which dehumanization impacts outgroup prejudice. We address these issues by measuring and manipulating animal-human similarity perceptions in a human intergroup context. Perceptions of animal-human similarity were experimentally induced through editorials highlighting similarities between humans and other animals or emphasizing the human-animal divide. Emphasizing animals as similar to humans (versus humans as similar to animals, or the human-animal divide) resulted in greater immigrant humanization (even among highly prejudiced people). This humanization process facilitated more re-categorization (i.e., inclusive intergroup representations between immigrants and Canadians) and increased immigrant empathy, both of which predicted less prejudicial attitudes toward immigrants. Implications for research, theory, and interventions for dehumanization and prejudice are considered.

**D211****THE IMPORTANCE OF POSITIVE GROUP INFORMATION IN REDUCING BIAS**

Muniba Saleem<sup>1</sup>, Craig Anderson<sup>1</sup>, <sup>1</sup>Iowa State University – Although there has been a plethora of research on media stereotypes, stereotypes within a new form of media, video games, have not been studied as much. Previous work (Saleem, 2008) has demonstrated the effects of negative video game stereotypes on implicit attitudes. The main goal of this study was to test the effects of positive and negative video game stereotypes on implicit and explicit attitudes. It was hypothesized that compared to a game with no stereotypes about the group of interest, a positive stereotypic game may lower bias, while a negative stereotypic game may increase bias against the targeted group. Participants were randomly assigned to play one of the three games and were given an IAT immediately after game play. The results supported the main hypothesis. Other results revealed influences of overall media stereotypes, sources of information about groups, direct contact with the stereotyped group, and past negative explicit attitudes on current implicit and explicit attitudes. Given the prominence of negative media stereotypes about most groups and the lack of positive representation, these results become especially significant. Specifically, these findings reveal the importance of positive media stereotypes in reducing negative bias, especially in the absence of direct contact with the targeted group.

**D212****EVALUATIVE SETTINGS AND PERFORMANCE: THE IMPACT OF SOCIAL COMPARISON AND PERFORMANCE CONTROLLABILITY ON ATTENTIONAL FOCUSING.**

Alice Normand<sup>1</sup>, Jean-Claude Croizet<sup>1</sup>, <sup>1</sup>University of Poitiers – Social evaluative settings are known to disturb the cognitive performance of low status group members (e.g., African Americans, low SES members). The present work investigates how threatening social comparisons affect attention focusing. Muller and Butera (2007) revealed that upward social comparison can lead to a focusing effect of attention resulting in peripheral information neglect. Yet, other studies demonstrated that performance decrements under upward comparison occurred only when performance was considered as weakly controllable (Johnson & Stapel, 2007). In this study, we hypothesized that upward social comparison reduces attentional focus only when performance on the dimension of comparison is perceived as weakly controllable. Eighty-two participants performed a spatial cueing task alone or were forced to compare their performance with a confederate coactor's one. Participants' performance was always inferior to coactor's performance. Task instructions were manipulated: Participants were told that the task was either linked to intelligence (i.e., not controllable) or to malleable visual capacities. As predicted, the focusing effect appeared only when participants were in upward comparison and believed the task was linked with intelligence (i.e., performance was weakly controllable). Conversely, when the task was presented as being linked with visual capacities (i.e., performance was controllable), upward comparison did not increase attentional focusing anymore. The current study highlights some of the cognitive mechanisms disturbed in threatening situations in attentional terms. The deleterious effect of social evaluative settings implicating the comparison of intellectual capacities will be discussed.

**D213****THE EFFECT OF IDENTITY SALIENCE ON THE RELATION BETWEEN PERSONALITY AND PREJUDICE.**

Robin Bergh<sup>1</sup>, Nazar Akrami<sup>1</sup>, <sup>1</sup>Uppsala University – Based on self-categorization theory it has been suggested that shared views of group members regarding right-wing authoritarianism (RWA) and/or prejudice can wash out the well-documented relation between these constructs. This has been investigated by manipulating salience of different identities. However, previous research has generated inconclusive support for this reasoning. Although it has been hypothesized that weak correlations between RWA and prejudice can result from changes of variance on both constructs, the effect on RWA scores has never been empirically demonstrated. Some studies have placed RWA (or social dominance orientation - SDO) before the manipu-

lation and the prejudice measure(s) after it whereas one study has placed both RWA and prejudice after the manipulation. Consequently, the specific effect of the manipulation on RWA (or SDO) is unknown. In this experimental study (N = 122) we addressed this question by adopting a pre- and a post-manipulation measurement of RWA and SDO under conditions of personal identity, national identity or control (no identity manipulation). Extending previous research, we also introduced basic personality factors from the Big-Five model (Agreeableness and Openness to Experience) as further predictive variables. The results revealed no differences in correlation strength across identity conditions, neither for the pre- nor post-manipulation measurement of RWA, SDO, Agreeableness or Openness to Experience. Importantly, lacking differences between correlations based on pre- and post-manipulation measurement, in combination with lacking differences across conditions, indicated that neither prejudice nor predictive variables were affected by identity salience. Thus, we found no support for the hypothesis from self-categorization theory.

**D214****DO EMOTIONS OF GROUP SYMPATHY AND GUILT CHANGE PRIVILEGED GROUPS' VIEWS OF RACISM AND AGEISM?**

Mary Inman<sup>1</sup>, <sup>1</sup>Hope College – Does feeling guilty about one's group privilege change his/her views of this inequality and other inequalities? Two studies manipulated feelings of ingroup pride and guilt and outgroup sympathy. Extending Harth et al. (2008), we predicted that guilt and sympathy (but not pride) would widen young Caucasians' views of racism and ageism. The method was similar across studies, except Study 1 focused on racism and Study 2 focused on ageism. At pre-test, all participants indicated the extent to which several acts against Blacks reflected racism and several acts against older people reflected ageism. Sixty-three (Study 1, 65 in Study 2) young Caucasians then came to the lab several weeks later. They read fake news stories that manipulated the group-focus and legitimacy of racial (or age) inequality in employment. These manipulations created feelings of group pride, guilt, or sympathy. We assessed their emotions (possible mediators), perceptions that the hiring situation reflected discrimination, attitudes and behavioral intentions to compensate the unhired, and post-test perceptions of ageism and racism. Results were generally consistent across studies. Guilt and sympathy enhanced (pride hindered) behavioral compensation and perceptions that the hiring reflected discrimination. Feeling sympathy for the outgroup about one form of discrimination was related to perceiving other forms of inequality as discrimination (e.g., feeling sympathy for Blacks led participants to see negative events to older people as ageism). However, Study 1 participants failed to say that other anti-Black behaviors reflected racism. Results suggest the utility and limitations in using emotional appeals to change perceptions.

**D215****STEREOTYPE THREAT EFFECTS ON AFRICAN AMERICANS' IMPLICIT SELF-CONCEPTS**

May Ling Halim<sup>1</sup>, Joshua Aronson<sup>1</sup>, David M. Amodio<sup>1</sup>, <sup>1</sup>New York University – The detrimental effect of stereotype threat on African Americans' test performance is well-documented, yet little is known about the effect of stereotype threat on African Americans' academic self-concepts. Prior correlational research has suggested that stereotype threat is linked to the clarity of the academic self-concept. The present research addressed this issue experimentally. African American and White participants completed a difficult reading comprehension exam under conditions of stereotype threat or no threat. In the stereotype threat condition, participants were told that the exam provided a genuine test of their verbal abilities and limitations. In the no threat condition, participants were told that the exam explored the problem solving process. After taking the exam, participants completed a reaction time task in which they categorized whether positive ("intellectual") and negative ("brainless") academic-related words described themselves ("me" or "not me"). Response latencies to positive versus negative words provided an implicit measure of the accessibility of their academic self-concept evaluation. Results for exam performance replicated past research, such that

African Americans performed worse in the stereotype threat compared to the no threat condition, whereas Whites' performance did not differ by condition. Furthermore, following exam completion, African Americans in the stereotype threat condition categorized negative academic-related words more quickly than African Americans in the no threat condition, whereas Whites did not show this effect. These findings suggest that stereotype threat affects the implicit activation of the academic self-concept of African American students, such that it increases the accessibility of negative academic attributes.

#### D216

**HOW CHRISTIAN BELIEFS RELATE TO LESS PREJUDICED ATTITUDES TOWARD HOMOSEXUALS** Thomas E. Ford<sup>1</sup>, Sara Soyars<sup>1</sup>, Andrew Johnson<sup>1</sup>, Sarah M. Jennings<sup>1</sup>; <sup>1</sup>Western Carolina University – Ford, VanVale, Brignall and Macaluso (2009) demonstrated that, when controlling for the effects of right wing authoritarianism, acceptance of orthodox Christian beliefs was associated with less negative attitudes toward homosexuals. The present study extends those findings by demonstrating that the relationship between endorsement of Christian beliefs and attitudes toward homosexuals is mediated by motivation to respond without prejudice specifically derived from one's Christian faith. In a correlational study, 18 male and 46 female heterosexual participants completed the Altemyer's (1996) Right-Wing Authoritarian Scale (RWA), Fullerton and Hunsberger's (1982) Christian Orthodoxy Scale (CO) assessing the extent to which people endorse central tenets of Christianity, Bassett et al.'s (2003) Modified Motivation to Control Prejudice Scale measuring the extent to which one's desire to respond without prejudice toward homosexuals is derived uniquely from one's convictions as a Christian and Larsen, Reed and Hofaman's (1980) Heterosexuals' Attitudes toward Homosexuals Scale (HATH). We separated items on the HATH into those that reference homosexuals and those that reference homosexuality. When RWA and CO were entered simultaneously into a regression analysis, CO related positively to scores on the homosexual referent scale ( $\beta = .2, t = 1.97, p = .05$ ) but not to scores on the homosexuality referent scale ( $\beta = .04, ns$ ). Furthermore, scores on the Modified Motivation to Control Prejudice Scale mediated the relationship between CO and attitudes toward homosexuals. Together, these findings identify orthodox Christian beliefs as a basis for an internal standard of non-prejudiced conduct toward homosexuals.

#### D217

**ECOLOGICAL PRIMING AND A LOW-TECH IAT: DO CHURCHES BREED PREJUDICE?** Jordan LaBouff<sup>1</sup>, Megan K. Johnson<sup>1</sup>, Wade C. Rowatt<sup>1</sup>; <sup>1</sup>Baylor University – The constructs of religiousness and spirituality demonstrate some paradoxical relationships with related constructs. Religiousness appears to be related to both positive and negative outcomes (e.g., charitable donations, prejudice.) Several recent studies (e.g., Preston & Ritter, 2009; Wenger, 2003) have attempted to elucidate these relationships by manipulating levels of religiousness through priming methods. These methods, however, often suffer from a lack of ecological validity. Expanding on research by Berger, Meredith, & Wheeler (2008), the present study attempted to manipulate religiousness and related constructs by placing 277 undergraduate students in either a religious context (i.e., protestant sanctuary) or a control context (i.e., a university classroom.) Implicit prejudice towards gay men and lesbians was assessed utilizing a low-tech Implicit Association Test (IAT) methodology (Lemm, et al., 2008). The implicit measure of sexual prejudice demonstrated associations with political conservatism, explicit sexual prejudice, religious fundamentalism and authoritarianism. Religious importance, self-reported spirituality, and intrinsic religiousness also explained unique variability in the implicit measure whereas the quest religious orientation was negatively associated with prejudice. Examination of within-subjects effects of religious or control context demonstrated that explicit measures of prejudice towards outgroups (e.g., gay men and lesbians, non-Christian religions, atheists, rival universities,

etc.) were higher across both face-to-face contexts. Implications for priming methodologies and implicit attitude measurement techniques are discussed.

#### D218

**SOCIALIZED MEDICINE VS. UNIVERSAL HEALTHCARE: SUPPORT AMONGST THE POLITICALLY ACTIVE BY POLITICAL ORIENTATION, ATTRIBUTIONS, AND EMOTIONS TOWARDS PROGRAM RECIPIENTS.** Geoffrey Wetherell<sup>1</sup>, Melody Sadler<sup>2</sup>; <sup>1</sup>De Paul University, <sup>2</sup>San Diego State University – Although a majority of Americans desire "government guaranteed" healthcare, support for it seems to diverge when it is called "socialized medicine", with 70% of democrats in favor of the idea, and 70% of republicans unsupportive of it (<http://www.physorg.com/news122214361.html>). Research suggests that more conservative people may perceive beneficiaries of "socialized medicine" (as opposed to "universal healthcare") as violating individualism more, as possessing more responsibility for poor circumstances than liberals, and may react to them with more anger than sympathy. This could decrease support for "socialized medicine" as opposed to "universal healthcare." To assess whether politically active individuals react to policy titles, and whether policy titles elicit perceptions of value violations, attributions of responsibility, and emotional reactions, conservative and liberal meet-up groups were surveyed. Although the association between political orientation and support did not depend on policy title, there was evidence of mediation by attributions of responsibility and emotional reactions in a different fashion than predicted. Political orientation predicted emotional reactions and attributions of responsibility simultaneously, and emotional reactions influenced support through attributions of responsibility. More conservative individuals reacted with more anger than sympathy, attributed more responsibility to public healthcare recipients, and were less supportive of public healthcare than liberals. Results suggest that the emotional reactions of politically active people may not influence support directly, but through attributions of responsibility. Therefore, attempting to influence both emotional reactions, as well as attributions of responsibility, may be an effective way to garner policy support from politically active people.

#### D219

**THE DEVELOPMENT OF INTERNAL AND EXTERNAL MOTIVATION TO RESPOND WITHOUT PREJUDICE** Lindsay B. Sharp<sup>1</sup>, Patricia G. Devine<sup>1</sup>; <sup>1</sup>University of Wisconsin-Madison – A shortcoming of the literature on internal and external motivations to overcome prejudice is that it has not explored how or why these motivations develop. Building on developmental models for how children make decisions about what is right and wrong (Smetana et al., 1993), we created an interview to assess whether children of different ages thought racial discrimination violated social conventions or moral rules. The interview involved 5-6 and 8-9 year olds responding to items assessing the seriousness, generalizability, contingency on rules and authority, and deserved punishment for race-based exclusion. We found that older children were more likely to think that race-based exclusion violated moral principles whereas younger children were more likely to think it violated social conventions. These findings suggest external motivation is evident as early as 5 years of age, with internal motivation coming online around age 7. This developmental trend is consistent with other research documenting decreases in racial bias around age 7 (Bigler & Liben, 1993) and self-presentation strategies as early as age 6 (Rutland et al., 2005). It is also consistent with the process of internalization proposed in self-determination theory (Deci & Ryan, 2000), which proposes that a person may come to identify with a set of external standards and then assimilate those standards into his/her personal beliefs. Future work should further integrate research on cognitive-moral development and racial bias to explore the development of motivations to respond without prejudice, with an emphasis on how to promote the transition from external to internal regulation.

**D220****WHEN IMPLICITLY AND EXPLICITLY MEASURED RACIAL ATTITUDES ALIGN: THE ROLE OF HONEST REPORTING**

Joy E. Phillips<sup>1</sup>, Michael A. Olson<sup>1</sup>; <sup>1</sup>University of Tennessee – Previous research has shown that individuals' explicitly measured attitudes often do not align with their implicitly measured attitudes, particularly with regard to race (Devine, Plant, Amodio, Harmon-Jones, & Vance, 2002). In other domains, however, urging participants to report opinions truthfully has produced greater consistency between implicitly and explicitly measured attitudes (Olson, Fazio, & Herman, 2007). We investigated whether honest reporting can reduce some of the discrepancy between implicitly and explicitly measured racial attitudes. In the current study, half of the 42 participants received instructions to report their attitudes toward African-Americans as honestly and accurately as possible, while the other half did not. Following this, all participants completed measures related to their attitudes toward African-American, including an Implicit Association Test (IAT), the Modern Racism Scale (MRS), and a feeling thermometer. Results indicated that when they were in the Honest condition, participants' MRS scores and their preferences for Whites over Blacks (as indicated by the feeling thermometer) were significantly associated with their IAT scores (with some correlations as high as .77). For those in the Control condition, there was no significant association between any of the explicit measures and the IAT, indicating that measures of participants' attitudes were still quite divergent. Further analysis indicated that there were no differences between the means of the Honest and Control conditions. That is, participants who were told to be honest did not merely report higher/lower prejudice; they appeared to adjust their explicit responses to be more similar to their implicitly measured attitudes.

**D221****DOES REDUCING INTERGROUP BIAS LEAD TO GROUP-BASED STEREOTYPING?**

Kunio Ishii<sup>1</sup>, Makoto Numazaki<sup>1</sup>; <sup>1</sup>Tokyo Metropolitan University – It has been well demonstrated that recategorization that brings groups together reduces intergroup bias. Brown & Hewstone (2005) suggested that if intergroup differentiation is not maintained and subgroups don't have functional complementarity, recategorization might not reduce intergroup bias. But intergroup differentiation and functional complementarity might lead to group-based role stereotyping. Present studies tested whether recategorization that brings men and women together after differentiating them would lead not only to favoritism toward opposite sex, but also to gender role stereotyping. In two studies we manipulated participants' representation of both differentiation and recategorization between men and women by using word classification tasks. In the first step, to manipulate differentiation, participants in differentiation condition repeatedly classified names of men and women into different categories, while participants in non-differentiation condition did not. In the second step, to manipulate recategorization, participants in recategorization condition repeatedly classified names of men and women into same category, while participants in non-recategorization condition did not. After these manipulations, we measured explicit gender attitude and stereotyping of male and female participants (study 1), or implicit gender attitude and stereotyping of male participants (study 2). In study 1, participants in the differentiation-recategorization condition rated opposite sex more favorably than other conditions ( $F(3, 62)=3.42, p<.05$ ). In study 2, male participants in the differentiation-recategorization condition exhibited stronger implicit stereotyping toward women than other conditions ( $F(1, 94)=4.05, p<.05$ ). These results suggest that reducing intergroup bias sometimes leads to group-based stereotyping.

**D222****THE EFFECTS OF PRIMING OF A THREATENING OUT-GROUP ON MEN'S BENEVOLENT SEXISM AND GENDER-RELATED SELF-STEREOTYPING**

Makoto Numazaki<sup>1</sup>, Kumiko Takabayashi<sup>2</sup>, Kunio Ishii<sup>1</sup>, Kaori Sasaki<sup>1</sup>, Yoichi Amano<sup>1</sup>; <sup>1</sup>Tokyo Metropolitan University, <sup>2</sup>Hitotsubashi University – System justification theory proposes that prejudice and stereotyping serve to maintain the status quo and bolster the legitimacy of the existing system. We examined the effects of priming of a threatening out-group on men's benevolent sexism and gender-related self-stereotyping. We hypothesized that male participants primed with a threatening out-group would show higher benevolent sexism and strengthen gender-related self-stereotyping. In Study 1, Japanese male undergraduates were instructed to write what they knew about North Korea (one of the most threatening countries for Japanese) or EU. Then, participants read a profile of either a housewife or a career woman and rated the target on several dimensions. After these ratings, they completed Benevolent Sexism (BS) Scale. Consistent with the hypotheses, first, participants primed with North Korea rated the housewife more favorably than those primed with EU. Second, participants primed with North Korea showed higher BS only when they rated the housewife. In Study 2, after the out-group priming used in Study 1, Japanese male undergraduates, who had completed BS scale in advance, rated themselves on 10 positive masculine traits, 10 negative masculine traits, 10 positive feminine traits, and 10 negative feminine traits. Results showed that participants with high BS in the threatening out-group priming condition rated themselves as more masculine, but only on negative traits. These results suggest that threats to the existing system would increase not only men's benevolent sexism but also gender-related self-stereotyping.

**D223****IDENTITY INCONGRUENCE AND BLACK AMERICAN PSYCHOLOGICAL WELL-BEING**

Kendrick Brown<sup>1</sup>, Nkayo Drepaul<sup>1</sup>, Jade Johnson<sup>1</sup>, Carolyn Klingensmith<sup>1</sup>, Hannah Johnson<sup>1</sup>; <sup>1</sup>Macalester College – In recent years, diversity within the U.S. Black community has increased due to immigration from African and Caribbean countries and greater willingness to claim a multiracial identity. Due to this increasing diversity, incongruence between self-selected ethnicity and ethnic categorization by others may occur. This study investigates the psychological consequences for individuals who experience ethnic identity incongruence. Participants included 105 self-identified U.S. Black college students. The experiment led participants to believe that they would be interacting with a partner who they would meet later in the experiment. This "partner" provided a first impression of the participant's ethnicity that was either the same as or different from the participant's self-selected ethnicity. After receiving their "partner's" response, participants completed a questionnaire containing the psychological well-being dependent measures assessing positive and negative affect, state self-esteem, depression, and perceived stress. Results indicated significant interaction between participants' self-selected ethnicity and the identity congruence manipulation. Africans, Caribbeans, and African Americans reported decreased negative affect when experiencing identity incongruence compared to Biracial individuals reported increased negative affect. Also, Africans, Caribbeans, and African Americans showed little change in state self-esteem when experiencing incongruence compared to the congruence condition. Conversely, Biracial individuals displayed lower state self-esteem in the incongruence compared to congruence condition. Lastly, Biracial individuals reported significantly higher depression in the incongruence versus congruence condition, while African, Caribbean, and African American persons did not show any appreciable mean difference between the conditions. Discussion of these results focuses on the impact of ethnic identity incongruence for Black Americans.

**D224****HOW TO IMPEDE JUSTIFICATION IN THE DISCRIMINATION CONTEXT?**

Stephanie Delroisse<sup>1</sup>, Ginette Herman<sup>1</sup>, Vincent Yzerbyt<sup>1</sup>; <sup>1</sup>Catholic University of Louvain – Past research has shown that individuals justify their unfavorable behavior toward outgroups in non-racial terms (Crandall & Eshleman, 2003; Dovidio & Gaertner, 1998): they dismiss outgroup applicants arguing for their lack of qualifications (Esses, Dietz, & Bhardwaj, 2006; Mullen & Dovidio, 1992), but, when qualifications are held constant across ingroup and outgroup applicants, they use superfluous information (i.e., hobby) as a justification (Delroisse, Herman, Yzerbyt, in prep). The present study focused on the process assumed to inhibit the use of superfluous information as justification. We present either hobbies without any comment ("Hobbies" condition) or hobbies explicitly described as irrelevant ("Irrelevant hobbies" condition) or as equally useful ("Hobbies equally useful" condition) to determine whether the applicants fit with the job profile. Moreover, a control condition (no information about hobbies) was presented. We assumed that the participants in the hobby condition would hire more ingroup applicants than outgroup ones, compared to the other three conditions, because they should use the superfluous information as justification. Results confirm our hypothesis and are interpreted in the light of justification processes: favoritism toward the ingroup exists only when decision makers are able to justify their choice with a factor other than ethnic origin. This study goes beyond previous studies by showing how to impede justification processes when ingroup members possess superfluous information.

**D225****GRANDPA IS NOT SLOW BUT KIND: THE EFFECTS OF REPLACEMENT THOUGHT STRATEGY ON STEREOTYPE SUPPRESSION** Yoshika

Tado'oka<sup>1</sup>, Koji Murata<sup>1</sup>; <sup>1</sup>Hitotsubashi University – This research examined the effective replacement thought strategy for preventing the rebound effect (i.e. increased stereotype accessibility after stereotype suppression). Past research has shown that using the counterstereotype (i.e. the elderly is competent) as a replacement thought could not be successful in diminishing the rebound effect, because the counterstereotypes were difficult to generate. A model of stereotype content indicates that stereotypes consist of two dimensions: competence and warmth. Therefore, in this research, we hypothesized that on suppressing the one dimension of stereotypes (i.e. incompetence) the other dimension (i.e. warmth) could be an effective and practical replacement thought. Specifically, we tested that participants who suppressed the incompetence-related aspects of elderly stereotypes didn't experience the rebound effect if they used warmth-related aspects of the elderly as replacement thoughts. Experiment 1 confirmed the rebound effect after suppressing incompetence-related aspects of the elderly, and experiment 2 examined the effect of replacement thought strategy using the other dimension. Participants imagined an elderly man working at a store, and described his short narrative essay in 5 minutes. Half of them were instructed to suppress his incompetence-related aspects in the description, while others were instructed to focus on his warmth-related aspects. After the filler task, participants read a text about a target individual, and rated him/her on competence. As predicted, participants who thought the warmth-related aspects experienced the rebound effect significantly less than those who suppressed the incompetence-related aspects. We discussed the validity of using the other dimension of stereotypes to prevent the rebound effect.

**D226****PERCEIVING MULTIPLE CATEGORIES LEADS TO FUNCTIONAL FLEXIBILITY IN STEREOTYPE CONSTRUCTION** Angela Maitner<sup>1</sup>, Richard Crisp<sup>2</sup>; <sup>1</sup>American University of Sharjah, <sup>2</sup>University of Kent – Research on

impression formation has generally regarded stereotypes as stable and invariant cognitive structures that endure across time and context or as contextually-sensitive and malleable, with emergent properties depending upon situational constraints. We argue that perceiving multiple identities in an unrelated individual before thinking about a group can

functionally influence whether people generate stereotypes that reflect more long-standing, context independent structures, or more situationally-reflexive, context-dependent construals. In 3 studies, participants generated multiple possible categorizations for an elderly individual or simply thought about what that individual was like, before listing (Study 1) or selecting (Studies 2 and 3) traits to describe the group 'students' either in contrast to or simply in reference to another group. Quantitative and qualitative analyses of stereotype content show that individuals who are asked to think about multiple bases for categorizing an individual are subsequently able to retrieve context-independent stereotypes or construct context-dependent stereotypes about students, depending on which is more functional to the group judgment. Individuals who are not asked to think about multiple bases for categorizing others construct context-dependent stereotypes in all cases. We argue that thinking about multiple bases for categorizing others elicits "functional flexibility" in impression formation that has important generalized effects for perceptions of and expectations about other individuals and groups.

**D227****RECOGNIZING PERSONAL EXPERIENCES OF DISCRIMINATION: IMPACT OF ESSENTIALIST BELIEFS OF GROUP DIFFERENCES AND SOCIAL STRUCTURE.**

Nobuko Asai<sup>1</sup>, Minoru Karasawa<sup>2</sup>, Tomohiro Kumagai<sup>1</sup>, Nobuyoshi Kawashima<sup>1,3</sup>; <sup>1</sup>Tohoku University, <sup>2</sup>Nagoya University, <sup>3</sup>The Japan Society for the Promotion of Science – Members of socially disadvantaged groups are often discriminated simply because of their group membership. Nevertheless, they frequently fail to recognize such negative experiences as discrimination. The present study aimed to test two hypotheses: (1) The essentialist belief of inter-group difference and (2) the immutability belief of social structure would inhibit the recognition of personal experience of discrimination. We conducted a survey in Tokyo and obtained answers from 445 respondents (response rate = .37). We analyzed data from 209 female respondents (mean age = 53.36; age range = 20-84) for the present purpose. Consistent with our hypotheses, respondents who considered gender difference as determined by biological essence were more hesitant to report the experience of "gender discrimination". This essentialist belief appeared to justify and/or rationalize the gender inequality. Furthermore, among the respondents who did not essentialize the gender difference, stronger beliefs in immutability of social structure were associated with lower level of likelihood of acknowledging discrimination. When disadvantaged group member believed that the gender inequality was not biologically determined but socially constructed, the immutability belief of social structure would strengthen the perceived stability of discrimination and the negative impact of recognizing discrimination. Thus, they avoid recognizing themselves as targets of negative discrimination to protect mental health. In sum, our study indicates that the beliefs about inter-group difference and social structure play crucial roles in recognizing personal discrimination and consequences of it. Implications of theories about coping strategies for discrimination are discussed.

**D228****DOES THE EXPERIENCE OF DISCRIMINATION ACTIVATE THOUGHTS ABOUT ALCOHOL?** Katarzyna Banas<sup>1</sup>, Laura Smart Richman<sup>2</sup>; <sup>1</sup>VU University Amsterdam, <sup>2</sup>Duke University – Although African Americans

drink less alcohol than Caucasians, their rates of problematic drinking are relatively high. Research findings suggest that discrimination may be contributing to this paradox, since experiencing discrimination is associated with more alcohol use, and more substance use in general. However, the exact mechanisms by which discrimination increases drinking have not been found. In three studies, we tested whether recalling, watching, or experiencing discrimination primes minority members for thoughts about alcohol. We measured mental accessibility of alcohol-related concepts using an adapted Stroop task and a Lexical Decision Task. The results suggest that discrimination does have a priming effect on alcohol-related thoughts. However, the effect was moderated by

aspects of racial/ethnic identity: private regard, public regard, and ethnic behaviors, indicating that a strong racial identity may protect African Americans from the negative effects of discrimination.

#### D229

**REFLEXIVE REJECTION: UNCONSCIOUS DEHUMANIZATION AND IMPLICIT THREAT COMPOUND TO MOTIVATE SOCIAL DISTANCING** Orly Weltfreid<sup>1</sup>, Andres G. Martinez<sup>2</sup>, Paul K. Piff<sup>2</sup>, Rodolfo Mendoza-Denton<sup>2</sup>, Stephen P. Hinshaw<sup>2</sup>; <sup>1</sup>University of California, Los Angeles, <sup>2</sup>University of California, Berkeley – Nonstigmatized individuals, despite professing egalitarianism, frequently socially exclude stigmatized outgroup members. Recent research has illuminated this incongruity by showing that implicit (or unconscious and automatic) processes can evoke discrimination. Whereas most studies emphasize the effects of a single implicit attitude, we demonstrate how a confluence of implicit attitudes can motivate behavior. In the present study (N = 76), we focused on implicit attitudes toward an extreme outgroup (persons with a mental illness label). Results attest to the compounding effects of automatic processes: unconscious dehumanization and implicit perceptions of threat interactively combined to predict motivations for social distance. Hierarchical linear regression analysis showed that these interacting implicit attitudes had unique explanatory power, above and beyond explicit measures. We discuss the implications of these results for theories of attitudes and intergroup relations. Finally, we address how these results can inform stigma reduction interventions.

#### D230

**DOES PERCEPTION OF A COMMON GOAL INCREASE THE TENDENCY TO STEREOTYPE?** Jason Emory<sup>1</sup>, Yarrow Dunham<sup>1</sup>; <sup>1</sup>University of California, Merced – Previous research investigated how different properties of social groups influence the degree to which those groups are stereotyped. For example, groups thought of as entitative, i.e. as cohering into a single unified whole, are more strongly stereotyped (e.g. Spencer-Rodgers, Hamilton, and Sherman 2007). Expanding this investigation to other group-related properties, we previously used rating studies to show that explicit stereotype endorsement is most influenced by perceptions of group member similarity and perceptions of group members sharing a common goal (Emory & Dunham, 2009, SPSP). The current study employs an experimental design to explore the less intuitive finding that perception of common goals increases stereotyping. 116 undergraduates participated in this experiment. Each participant read descriptions of several fictional yet familiar real groups and one description of a completely novel group, in which level of common goal (common goal or no common goal) varied as a between participants factor. Participants rated how strongly new information learned about a single member of one of these groups generalized to other members of the same group. We predicted that descriptions of groups emphasizing shared goals would lead to greater stereotyping. This prediction was confirmed, but only for novel groups. Stereotyping of real groups such as sports teams were not affected by the common goal manipulation. This may be because stereotypes of real groups are already quite entrenched such that our relatively subtle manipulation was insufficient to affect judgments. Future work will extend these findings to implicit stereotyping and to a wider range of social groups.

#### D231

**AN APPLE A DAY KEEPS THE THREAT AWAY: OVERALL HEALTH MODERATES PERFORMANCE IN EVALUATIVE TESTING SITUATIONS** Allyce H. Monroe<sup>1</sup>, David M. Marx<sup>1</sup>; <sup>1</sup>San Diego State University – Considerable research has focused on stereotype threat and its effects on minority students' academic performance. One issue that has not yet been addressed is whether other antecedent risk factors, such as poor overall health, may increase minority students' susceptibility to stereotype threat. Accordingly, the present research provides an investigation of how overall health (i.e., one's general level of physical well-being) interacts with stereotype threat. Given that poor health interferes with one's ability to cope with stressful situations (Spencer-Rogers & Collins, 2006),

we argue that overall health may moderate the effects of stereotype threat, such that minority students with poor overall health will be less resilient and able to cope with the threat of negative stereotypes. We conducted an experiment in which Latino and White participants were placed into an evaluative testing situation and then completed a verbal exam. After the exam participants completed a survey that was ostensibly part of a University initiative on student health and lifestyle. Results showed that, in general, Latino participants underperformed compared to White participants. More important, certain health factors, poor dietary habits and frequent illness, moderated participants' performance. Not surprisingly, all participants performed worse when they were frequently ill. However, poor dietary habits magnified the performance gap between Latino and White participants, such that Latino participants with poor dietary habits performed even worse than their White counterparts. Our findings suggest that certain, perhaps controllable lifestyle choices may further undermine Latino students' ability to cope with evaluative testing situations.

#### D232

**STEREOTYPES AND HARSH IMMIGRATION POLICY ENFORCEMENT** Hyo Yeon Kim<sup>1</sup>, Christine Reyna<sup>2</sup>; <sup>1</sup>Arizona State University, <sup>2</sup>DePaul University – In contemporary American society, people have strong, polarized attitudes toward immigration. An example of such radical anti-immigration attitudes is the Minuteman Project—a group of non-government civilians who patrol the Mexican border. Some minutemen illegally carry weapons with them, and have used overly aggressive tactics while patrolling the border. Anti-immigration laws and attitudes can have severe consequences for both legal and undocumented immigrants. People commonly say they oppose immigration for economic reasons; however, there is evidence that people's attitudes toward immigration vary based on the immigrant group. We wanted to ask if stereotypes play a role in driving immigration attitudes. By administering online questionnaires to introductory psychology students, we examined the associations between 47 stereotypes and 5 immigrant groups. We further investigated the correlation between these traits and how much support people showed for enforcement of harsh immigration policies. Many stereotypes associated with each immigrant group were significantly correlated to harsh policy enforcements, while others were not. Many of the significant stereotypes overlapped across different immigrant groups. We found positive stereotypes like "friendly" to be significantly correlated with opposition to harsh policy enforcement; however, negative stereotypes like "revengeful" were positively correlated with the enforcement of harsh policies. Some stereotypes benefited immigrant groups by framing them positively, while others did not. This issue becomes a problem because some of the negative stereotypes positively correlated to harsh policy enforcement are not controllable. Such stereotypes include "short" and "raised in poverty." Future research could investigate whether the attributional context of stereotypes drives immigration attitudes.

#### D233

**DEATH CAN BE SURPRISING: MORTALITY SALIENCE AND ATTENTIONAL CONTROL INFLUENCE STARTLE REACTIONS TO OUTGROUP AND INGROUP MEMBERS** Dragos Petrescu<sup>1</sup>, Kees van den Bos<sup>1</sup>, Floris Klumpers<sup>2</sup>, Leon Kenemans<sup>2</sup>; <sup>1</sup>Department of Social and Organizational Psychology, Utrecht University, The Netherlands., <sup>2</sup>Department of Experimental Psychology and Psychopharmacology, Utrecht University, The Netherlands. – This study investigated the influence of mortality salience (MS) and attentional control on ingroup favoritism and outgroup derogation, at a basic biological level. University students (N = 39) filled in a questionnaire measure of attentional control and subsequently were led to contemplate their mortality, or a control topic. Their eye-blink responses to a startle probe were measured while they viewed pictures of outgroup members (Arab people) and pictures of ingroup members (Dutch people). As expected, MS led to stronger eye-blink responses toward Arab people, and decreased eye-blink responses toward Dutch people, but

only for low attentional control participants. This result suggests that the biases that MS promotes are already present at a physiological level, and therefore may not be dependent on consciousness. However, the reflexive processes involved in the startle may still be modulated by effortful, top down processes involved in attentional control.

#### D234

**ACCOUNTABILITY, PREJUDICE, AND JUROR DECISION-MAKING: WHEN CAREFUL TRIAL PROCESSING HEIGHTENS RACIAL BIAS** Michael Leippe<sup>1</sup>, Donna Eisenstadt<sup>2</sup>; <sup>1</sup>John Jay College of Criminal Justice, CUNY, <sup>2</sup>Illinois State University – Racial bias can increase convictions of Black defendants (Mitchell et al., 2005), or lower convictions when jurors are concerned with being egalitarian (Foley & Pigott, 2002). Increasing accountability may increase the former, negative bias. Accountable individuals are more likely to consult their beliefs. If jurors believe Blacks are more likely to commit a crime, this should influence their evidence evaluation (Jones & Kaplan, 2003). Also, individuals are less likely to suppress prejudice when self-accountable. Forty-seven non-Black students read a computer-presented robbery-murder trial transcript that included photographs of trial participants. The defendant was either Black or White. Low-accountability participants were instructed to “consider the case carefully.” High-accountability participants were told the study involved a real trial with known verdict and actual guilt, and was a Justice Department-commissioned study of reasoning ability. Participants cast verdicts and rated (11-point scale) their verdict certainty. The conviction rate was lower when the defendant was Black (vs. White; 25.0% vs. 87.5%) under low accountability, but higher when the defendant was Black (100.0% vs. 55.6%) under high accountability. Simple effects analysis of guilt-certainty (verdict coded -1 and +1 multiplied by certainty) revealed, when the defendant was Black (vs. White), guilt-certainty was significantly lower under low accountability ( $M_s = -2.50, 6.88$ ) and significantly higher under high accountability ( $M_s = 7.00, 1.67$ ). Low accountability was associated with “reverse discrimination,” perhaps due to egalitarian self-image concerns. Yet negative racial bias emerged when mock-jurors were accountable. As found in persuasion (cf. Petty & Wegner, 1998), careful message processing can increase bias.

#### D235

**WHEN THE STIGMATIZED EXPERIENCE ANXIETY: THE INFLUENCE OF ETHNICITY SALIENCE AND IMPLICIT SELF-STEREOTYPING ON ANXIETY** Stefanie Paredes<sup>1</sup>, Luis Rivera<sup>1</sup>; <sup>1</sup>California State University, San Bernardino – Research shows mixed evidence for stigmatized individuals’ experiences of anxiety, with some data demonstrating disproportionately heightened anxiety, whereas other data show null effects. To address these divergent findings, we developed and tested a hypothesis at the intersection of clinical cognitive models of anxiety and self-concept theories. Specifically, we posit that stigmatized individuals who negatively self-stereotype possess a perceptual mechanism for detecting potential environmental threats; when this information processing bias is activated, the consequence is heightened anxiety. In an initial test of this hypothesis, we experimentally manipulated the salience of Latino and White participants’ ethnic identity by asking them to complete a brief demographic section that included their ethnicity (participants in the control condition did not complete this procedure). Then, we administered two Implicit Association Tests to assess participants’ association between the self and (a) general Latino stereotypes (e.g., lazy, poor) and (b) a specific Latino stereotype, unintelligence, followed by measures of trait and state anxiety. Results showed that when their ethnicity is made salient, Latino participants experience heightened anxiety if they implicitly self-stereotype, relative to all comparable groups including Latino participants in the control condition and White participants in general. Furthermore, these results were not explained by trait anxiety, as suggested by extant theories. By providing support for a social cognitive perspective of anxiety, we suggest that this research has implications for the mental health disparities of stigmatized individuals.

#### D236

**BELIEFS ABOUT GENDER AND SEXUAL BEHAVIOR AND ATTITUDES TOWARD GAY MEN** T. Andrew Caswell<sup>1</sup>, Jennifer Bosson<sup>1</sup>; <sup>1</sup>University of South Florida – Research on sexual prejudice suggests that heterosexual males high in sexual prejudice tend to have negative affective reactions to gender non-conforming gay men and to depictions of male homosexual sex acts. At the same time, qualitative research suggests a link between perceptions of status, power, and masculinity and male sexual behavior. The purpose of the current research was to assess the relative influence of sex role behavior independent of gender role behavior on sexual prejudice. Two hundred forty-three participants (134 women) read vignettes about a gay man who varied in both sexual behavior (active/penetrative, passive/receptive) and in gender role behavior (feminine, neutral, masculine). A multiple regression analysis found a four-way interaction of sexual prejudice x participant gender x gender role x sex role on disgust (controlling for anger). A simple slopes analysis found that for male participants, sexual prejudice predicted disgust in response to targets whose sexual behavior was consistent with their gender role behavior. Males high in sexual prejudice responded to the feminine/passive, masculine/active, and neutral/active targets with greater disgust than males low in sexual prejudice. However, sexual prejudice did not predict disgust responses to TARGETS whose sexual behavior was inconsistent with their gender role behavior (feminine/active, neutral/passive, and masculine/passive targets). These results suggest that, whereas sexual prejudice predicts disgust reactions to gender-role-consistent gay men, men who exhibit gender-role-inconsistent sexual behavior elicit just as much disgust among low and high homophobic men.

#### D237

**MEANINGFUL NEGATION AS A TOOL TO MODIFY AUTOMATIC RACIAL ATTITUDES** India Johnson<sup>1</sup>, Richard Petty<sup>1</sup>; <sup>1</sup>The Ohio State University – The Meta-Cognitive Model (MCM) of attitudes holds that an attitude object can be associated with both positive and negative evaluations, and that people can “tag” their evaluative associations as true or false, or with varying degrees of confidence. Importantly, a stereotype – a specific belief – can also be held with varying degrees of confidence, and reducing the confidence with which a stereotype is held, through negation for instance, should potentially reduce the automatic activation of racial prejudice. The present research examines whether meaningful negation training – training individuals to think “That’s wrong!” when presented with stereotype-consistent information – can successfully reduce the automatic activation of racial prejudice. Participants were randomly assigned to one of two training conditions: to either meaningfully negate stereotype-consistent information or to meaningfully negate stereotype-inconsistent information. Participants completed an evaluative priming measure of racial prejudice before and after training. As predicted, participants who engaged in meaningful negation of stereotype-consistent information significantly reduced their levels of automatic racial prejudice relative to those who negated stereotype-inconsistent information. Furthermore, this effect was moderated by participant’s motive to control for prejudice reactions (MCPR), such that those participants’ who were high in MCPR demonstrated the greatest observed changes in racial prejudice from time 1 to time 2, relative to those participants’ low in MCPR. Contrary to recent research suggesting that negation training is an ineffective means to reduce automatic racial prejudice, the present research suggests that negation can indeed be a useful tool when the negation is meaningful.

#### D238

**THE ROLE OF STEREOTYPE ENDORSEMENT IN ATTRIBUTING OUTCOMES TO DISCRIMINATION** Jessica Cundiff<sup>1</sup>, Theresa Vescio<sup>1</sup>; <sup>1</sup>The Pennsylvania State University – Because cultural stereotypes attribute the responsibility for group differences to stereotypic traits of group members, endorsement of those stereotypes may consequently lead to fewer attributions to discrimination. To examine this possibility, participants who either strongly endorsed or rejected gender stereotypes evaluated possible

causes of the underrepresentation of women in leadership positions and male-dominated occupations. Consistent with hypotheses, stereotype endorsers were more likely than stereotype rejecters to explain the underrepresentation of women in leadership positions and male-dominated occupations in terms of dispositional differences between women and men and less likely to attribute such outcomes to discrimination. These results suggest that people who strongly endorse stereotypes use those stereotypes to minimize perceptions of discrimination and maintain the view that existing social arrangements are fair, just, and legitimate.

### D239

**CONVERGENT AND DISCRIMINANT VALIDITY OF THE ISLAMOPHOBIA SCALE THROUGH THE MULTITRAIT MULTIMETHOD APPROACH** Chelsea A. Reid<sup>1</sup>, Sherman A. Lee<sup>2</sup>, Stephen D. Short<sup>3</sup>, Ruth Yeh<sup>2</sup>, Jeffrey A. Gibbons<sup>2</sup>; <sup>1</sup>Virginia Commonwealth University, <sup>2</sup>Christopher Newport University, <sup>3</sup>University of Kansas – Following 9/11, fearful perceptions of Muslims have increased among Westerners (Scheufele, Nisbet, & Ostman, 2005), warranting the creation of an Islamophobia scale (Lee, Gibbons, Thompson, & Timani, 2009), which includes affective-behavioral (I-AB) and cognitive (I-CG) subscales that focus on avoidance and fear of Muslims, respectively. The current study examines the validity of the Islamophobia subscales through the multitrait multimethod approach. Questionnaires assessing Islamophobia, right-wing authoritarianism, trait forgiveness, and fears were administered to 68 undergraduates and 68 informants. Results were evaluated according to Campbell and Fiske's (1959) criteria. Neither convergent nor divergent validity were found for I-AB, whereas I-CG showed support for convergent validity and partial support for divergent validity. Specifically, participants' and informants' I-CG ratings were significantly related (validity value), and the validity value was higher than correlations between participant I-CG and variables that had neither a trait nor a method in common. Additionally, requirements that the validity value should be higher than between participant I-CG and other traits of the same method and that interrelationship patterns should be similar were met to a degree. Thus, the beliefs of participants who associated Muslims with fear were confirmed by their informants. The current study provides support for the validity of I-CG and provides an alternative method to measure fearful beliefs of Muslims. The research is consistent with previous findings that self and informant reports show substantial agreement, but, as with I-AB, may be imperfect due to informants' inability to observe all sides of individuals' personalities (McCrae, Stone, Fagan, & Costa, 1998).

### D240

**STEREOTYPE THREAT AND THE INTELLECTUAL PERFORMANCE OF U.S. SOUTHERNERS: THE MODERATING ROLE OF GROUP IDENTIFICATION** Cassie A. Eno<sup>1</sup>, Jason K. Clark<sup>2</sup>, Rosanna E. Guadagno<sup>1</sup>; <sup>1</sup>University of Alabama, <sup>2</sup>University of Iowa – Past research on stereotype threat has found that stereotype activation can inhibit the performance of individuals from many stigmatized groups (see Steele, Spencer, & Aronson, 2002). In particular, recent work has shown that the intellectual performance of U.S. Southerners is impaired when saliency of negative stereotypes (i.e., "Southerners are unintelligent") is relatively high as opposed to low (Eno, Clark, & Guadagno, 2009). The current investigation sought to extend these findings by examining how individual differences in identification as a Southerner may be associated with susceptibility to stereotype threat. Consistent with past research on gender identification and female math performance (Schmader, 2002), we predicted that the effects of stereotype threat should be more pronounced for individuals who are relatively high rather than low in Southern identification. In the present study, southeastern U.S. college students answered difficult quantitative and verbal questions. Prior to this test, half of the participants were given questions designed to activate stereotypes of Southerners and assess their level of identification as a Southerner (i.e., identity-salient condition). The remaining participants did not receive any identity-related materials before the test (i.e., control condition). Consistent

with effects of stereotype threat, test performance was lower for participants in the identity-salient condition compared to the control condition. More importantly, additional analyses revealed that higher levels of Southern identification predicted significantly lower performance for participants in the identity-salient condition. These findings support the hypothesis that increased identification as a Southerner is linked to greater susceptibility to the performance-inhibiting effects of stereotype threat.

### D241

**THE NEW ANTI-SEMITISM ISRAEL MODEL** Florette Cohen<sup>1</sup>, Lee Jussim<sup>2</sup>, Kent Harber<sup>3</sup>, Gautam Bhasin<sup>4</sup>; <sup>1</sup>CUNY College of Staten Island, <sup>2</sup>Rutgers New Brunswick, <sup>3</sup>Rutgers Newark, <sup>4</sup>Columbia Teacher's College – The current line of research examines the psychological underpinnings of prejudice and ethnic discord in the context of the Israeli-Palestinian conflict based on the New Anti-Semitism-Israel model. The NASI was designed based on a juxtaposition of terror management theory (TMT; Greenberg et al., 1986) and modern prejudice theory (Sears & Kinder, 1971). Specifically, it demonstrates that uniquely human fears of death serve to perpetuate expressions of anti-Semitism (a-s) and anti-Israeli sentiment. Because anti-Semitism is often stigmatized opposing Israel may be a safe way to express it. As such the current line of research employed a mortality salience X bogus pipeline manipulation (Devine et al., 1991), in which some participants were led to believe that their underlying attitudes were transparent, and others are led to believe that their underlying attitudes were private. Three studies demonstrated that 1) participants expressed significantly greater levels of anti-Semitism and lower levels of pro-Israeli sentiment when reminded of their own deaths and when told that they would be caught in the act of lying; 2) Anti-Semitism partially mediated the effects of mortality salience X a bogus pipeline manipulation on opposition to Israel; 3) mortality salience increased the perceived size of Israel, but not of other countries; and 4) mortality salience increased opposition to Israeli oppression more than it increased opposition to Russian or Indian oppression. Collectively, results suggest that Jews constitute a unique cultural threat to many people's worldviews, that anti-Semitism causes hostility to Israel, and that hostility to Israel may feed back to increase anti-Semitism.

### D242

**BEHAVIORAL FORECASTING IN AN INTERGROUP CONTEXT: REACTIONS TO OUTGROUP RACISM AND PERCEPTIONS OF THE TARGET** Francine Karmali<sup>1</sup>, Kerry Kawakami<sup>1</sup>; <sup>1</sup>York University – The current research aimed to explore predicted and actual reactions to outgroup racism. In particular, two studies examined how nonblacks responded to a white confederate after he made a racist comment and a black confederate who was the target of the racist act. In accordance with affective forecasting procedures, participants in both studies were randomly assigned to the role of "forecaster" (predicted their reactions), and "experiencers" (actually experienced the racism). Results of Study 1 revealed that predicted behavioral reactions to the outgroup racism were significantly more negative than actual reactions. Furthermore, despite the innocuous behavior of the black target experiencers' perceptions of his behavior were more negative than forecasters on both implicit and explicit measures. In Study 2, again, predicted behavioral reactions to the outgroup racism were significantly more negative than actual reactions. However, when the black target's behaviour was made less ambiguously positive, differences in reactions to the racism between experiencers and forecasters were reduced. These studies not only demonstrated differences between forecasters and experience in their reactions to outgroup racism, but also differences in how participants in these two roles differed in perceptions of the target of the outgroup racism. The implications of these findings for theorizing on prejudice as well as affective and behavioral forecasting are discussed.

**D243****BEYOND SEXUAL PREJUDICE: EXPLORING PREJUDICES AGAINST BISEXUALS LENDS CLARITY TO PREJUDICES AGAINST GAY MEN AND LESBIAN WOMEN** Angela Pirlott<sup>1</sup>, Steven Neuberg<sup>1</sup>, <sup>1</sup>Arizona State University

– How do heterosexuals view bisexuals? Research studying sexual prejudice has focused on gay males and, to a lesser extent, lesbians; however, understanding heterosexuals' views of male and female bisexuals might illuminate processes underlying sexual prejudice more generally. In contrast to views of sexual prejudice that focus on issues of outgroup status or deviance, we adopt an approach that considers the particular threats that male and female individuals of different sexual preferences afford heterosexual perceivers. Heterosexual undergraduates rated the extent to which heterosexual, homosexual, and bisexual males and females elicited a range of emotions and beliefs about the threats and opportunities they pose (e.g., judgments about sexual disease transmission, socialization inclinations). Although, in general, participants responded more negatively to non-heterosexuals, this general tendency masked theoretically meaningful differences in how perceiver sex, target sex, and target sexual orientation interacted to determine specific threat perceptions and emotional reactions. As one of many examples, whereas heterosexual men felt more negatively toward gay men than bisexual men, heterosexual women felt much more negatively toward bisexual men than toward gay men; this female reaction appears driven by beliefs of the enhanced sexual disease threat that bisexual men pose to them specifically (because such women are highly unlikely to have sex with a gay man). Findings such as these reveal multiple, qualitatively distinct prejudices toward different sexual minorities, and suggest that these prejudices result from the different profiles of particular threats believed to be posed by sexual minorities toward heterosexual men and women.

**D244****VIRTUAL PREJUDICE: EXPERIMENTAL EVIDENCE FOR THE MEDIATING ROLE OF AFFECT** Daniel Wigboldus<sup>1</sup>, Ron Dotsch<sup>1</sup>, Joris van den Munckhof<sup>1</sup>, <sup>1</sup>Radboud University Nijmegen

– Research by Dotsch and Wigboldus (2008) has shown that prejudiced implicit associations are related to both physiological and automatic behavioural responses. Their participants were immersed in a virtual environment in which they encountered virtual persons (avatars) with either White Dutch or Moroccan facial features. Their White Dutch participants showed an increase in skin conductance level and maintained more distance when approaching Moroccan avatars compared to White Dutch avatars. Participants' implicit negative associations with Moroccans moderated both effects. Importantly, evidence was found that the relation between implicit prejudice and distance effects was mediated by skin conductance level effects. In the Dotsch and Wigboldus (2008) study all variables were measured. As a result, only correlational evidence was obtained for their hypothesis. In the current research, instead of measuring basic affective responses, we aimed to manipulate them. When approaching an avatar in a virtual environment (with either White Dutch or Moroccan facial features), for 17 ms a negatively valenced picture was presented to participants, or not. In this way we aimed to experimentally induce, in an unobtrusive way, negative affect when approaching an avatar. In line with the predictions by Dotsch and Wigboldus (2008), highly prejudiced participants approaching these avatars kept most distance to Moroccan avatars when negative affect was induced. The current results provide further evidence for the idea that negative affect mediates the effect of implicit prejudice on aversive uncontrolled behavioural reactions towards others.

**D245****NEGATIVE EFFECTS OF THE EXPOSURE TO BENEVOLENT SEXISM ON WOMEN'S TASK PERFORMANCE** Takehiro Yamamoto<sup>1</sup>, Ken-ichi Ohbuchi<sup>1</sup>, <sup>1</sup>Tohoku University

– Grounded in the theory of ambivalent sexism (Glick & Fiske, 1996), sexism consists of two facets, namely hostile sexism and benevolent sexism. Hostile sexism is an overtly negative and

restrictive prejudice against women. In contrast, benevolent sexism is a subjectively positive orientation of protection, idealization, and affection directed toward women. However, benevolent sexism can be harmful for women as well as hostile one. Benevolent sexism serves to activate women's incompetence and weakness. Thus, women who were exposed to benevolent sexism lose confidence in their abilities and performance. In the present study, we experimentally attempted to examine if the exposure to benevolent sexism expressing consideration for women would lower their performance at a cognitive task (Participants were asked to pick up all the vowels in the sentence within 120 seconds). Participants in this study were 58 female volunteers, recruited on the campus of the Tohoku University, Japan (M=19.13 years old). Participants were randomly assigned to one of three conditions (sexism: benevolent, hostile, control). The results showed that female participants in the benevolent sexism conditions were lower in their performance (M=51.93) than those in the hostile sexism condition (M=55.57) and control condition (M=54.75). Further, we found that the negative effect of benevolent sexism was moderated by the trait self-efficacy, that is, only participants low in the trait self efficacy lowered their performance when they were exposed to benevolent sexism. These findings suggest that the benevolent treatment may cause harmful consequences to members of stigmatized groups who are vulnerable in their self-efficacy.

**D246****CORRELATES OF HETEROSEXUAL PREJUDICE AGAINST TRANS PERSONS IN THE UNITED STATES** Cris Youssef<sup>1</sup>, Chuck Tate<sup>2</sup>, <sup>1</sup>California State University, Bakersfield, <sup>2</sup>San Francisco State University

– This study examined the correlates of negative attitudes toward trans persons in the U.S. Heterosexual participants (N = 153) completed the Genderism and Transphobia Scale (Hill & Willoughby, 2005), the Beliefs about Gender Scale (Tee & Hegarty, 2006), which measures the belief in the existence of only two sexes, the Beliefs about Transsexuality Scale (Tee & Hegarty, 2006), which measures the belief that gender is biologically based, the Social Dominance Orientation Scale (Pratto, Sidanius, Stallworth, & Malle, 1994), and a self-report of religiosity, which was determined on a 7-point Likert scale. Results showed that essentialist beliefs were significant predictors of anti-trans attitudes at similar levels for both heterosexual women ( $\beta = .348$ ) and men ( $\beta = .317$ ). However, the relationships of other predictors of anti-trans attitudes were different for heterosexual women and men. Specifically, belief in two sexes was more strongly correlated with anti-trans attitudes for heterosexual men ( $\beta = .512$ ) as compared to heterosexual women ( $\beta = .263$ ). Additionally, social dominance orientation and religiosity were predictors for only heterosexual women; that is, the higher the levels of social dominance orientation or religiosity, the stronger the negative attitudes. These results conceptually replicate previous research on Canadian (Hill & Willoughby, 2005), and U.K. samples (Tee & Hegarty, 2006). Importantly, these results also demonstrate that prejudice against trans persons is predicted by different variables for heterosexual men and women. Differences in heterosexual gender socialization may be an explanation for these effects.

**D247****DOES HAVING A CHOICE MATTER? PSYCHOLOGICAL AND SOCIAL CORRELATES OF HIV STATUS DISCLOSURE AMONG THOSE WITH AND WITHOUT VISIBLE SYMPTOMS** Sarah Stutterheim<sup>1</sup>, Arjan E.R. Bos<sup>1</sup>, John B. Pryor<sup>2</sup>, Herman P. Schaalma<sup>1</sup>, <sup>1</sup>Maastricht University, <sup>2</sup>Illinois State University

– Recent research has explored the psychological and social implications of disclosing versus concealing a stigmatized condition. It has also looked at whether having a concealable stigma is more detrimental than having a visible stigma. In this study, we investigated a number of psychological and social correlates of concealable versus visible stigmas while considering the potentially differential impact of the kind of disclosure employed. Using data from a cross-sectional survey administered to 667 people living with HIV (PLWH) in the Netherlands, we compared PLWH with visible symptoms (involuntary public disclosure) to PLWH without symptoms who either disclosed (voluntary public disclosure) or concealed (no public disclosure) their status in public

social settings. These groups were compared on a number of psychological and social variables, namely disclosure concerns, perceived HIV-related stigma, social support, psychological distress and self esteem. The results showed that PLWH with visible symptoms experienced more psychological distress and lower self esteem than both groups without visible symptoms. They also experienced less social support than those who had no visible symptoms and nonetheless choose to publicly disclose. Among those without visible symptoms, PLWH who disclosed in public settings had less disclosure concerns and experienced less perceived stigma than those who did not publicly disclose. In short, this study provides support for the contention that visible stigmas are psychologically and socially more detrimental than concealable ones. It also supports the contention that the kind of disclosure employed can influence social and psychological variables such as perceived HIV-related stigma and disclosure concerns.

#### D248

**"LATE, ATTITUDE, LAZY, COMPLAIN": A QUASI-EXPERIMENT EXPLORING THE APPLICATION OF THE STEREOTYPE CONTENT MODEL TO WORKPLACE AGEISM.** Scott P. King<sup>1</sup>, Nathaniel D. Krumdick<sup>2</sup>, Sam E. Cole<sup>2</sup>, <sup>1</sup>Mather LifeWays Institute on Aging, <sup>2</sup>Loyola University Chicago – Several lines of research have converged on the finding that interpersonal and intergroup perceptions are universally based on the fundamental dimensions of warmth and competence, with warmth being the primary and more immediate dimension of the two. Elderly adults tend to be seen as high in warmth but low in competence, or, as Cuddy and Fiske put it: "doddering but dear." Younger adults' perceptions of older adults has been the focus of much research in ageism, with older adults' perceptions of younger adults less so. The current study examines the content of age-based stereotypes in a multigenerational workplace sample, and seeks to answer the questions 1) Are older workers viewed as high in warmth but low in competence? 2) Is warmth or competence the primary dimension workers are judged on? 3) Who holds more age-based negative cognitions, older workers or younger workers? Employees of long-term care organizations were asked to provide the first five words that come to mind when thinking of workers (a) age 30 and younger, and (b) age 50 and older. Answers were coded as either warmth- or competence-related, and with positive or negative valence. Results showed 1) Older workers are viewed as high in both warmth and competence across all ages of workers, and younger workers viewed older workers similarly to themselves; 2) Competence is the primary judgment dimension across all ages; 3) Older workers evaluate younger workers significantly worse in both warmth and competence than themselves, and worse than vice versa.

#### D249

**IMPACT OF RACIAL DISCRIMINATION ON SEXUAL AND SUBSTANCE USE BEHAVIORS AMONG AFRICAN AMERICANS ADOLESCENTS: IS RACIAL SOCIALIZATION A PROTECTIVE FACTOR?** Michelle Stock<sup>1</sup>, Frederick Gibbons<sup>2</sup>, <sup>1</sup>The George Washington University, <sup>2</sup>Dartmouth College – The present study examined racial socialization as a protective factor against the negative effects of racial discrimination on risky sexual and substance use behaviors among 649 African American adolescents. It also examined potential gender differences. Multiple regression analyses revealed that higher levels of perceived racial discrimination predicted greater: number of sexual partners, frequency of unprotected sex, and substance use ( $Bs = .19, .23, .17$ , respectively,  $ps < .001$ ). Significant 2-way interactions (Racial Socialization x Discrimination) revealed that the highest levels of risk behaviors were among adolescents reporting high levels of racial discrimination and low levels of racial socialization, whereas high levels of racial socialization were protective against high levels of discrimination ( $Bs = -.10, .27, -.12$ ,  $ps < .05$ ). Gender x Discrimination interactions revealed that males with high levels of perceived discrimination reported the highest numbers of sexual partners and frequency of unprotected sex ( $Bs = -.16, -.27$ ,  $ps < .02$ ). Significant 3-way interactions (Racial Socialization x Discrimination X Gender) indicated the protective impact of racial socialization was stronger for males

against unprotected sex and substance use, whereas racial socialization was more protective against number of partners for females ( $Bs = -.13, .19, -.14$ ,  $ps < .05$ ). This study is one of the first to demonstrate that racial discrimination is associated with risky sexual behaviors and that this relation is stronger among males. These findings demonstrate the need to examine gender differences in the potential of racial socialization to reduce the impact of discrimination experiences on risky health behaviors.

#### D250

**REFINING SELF-AFFIRMATION INTERVENTIONS: GROUP AND SELF-AFFIRMATION IMPROVE PERFORMANCE FOR ACADEMICALLY AT-RISK MINORITY STUDENTS** Natalie Golaszewski<sup>1</sup>, Rachel Sumner<sup>2</sup>, Courtney Beams<sup>2</sup>, Nancy H. Apfel<sup>2</sup>, Jonathan Cook<sup>1</sup>, Geoffrey Cohen<sup>1</sup>, Julio Garcia<sup>1</sup>, Valerie Purdie-Vaughns<sup>2</sup>, <sup>1</sup>University of Colorado, Boulder, <sup>2</sup>Columbia University – Research finds that stereotype threat contributes to the academic underperformance of historically marginalized students. Recent research has found that affirmations of self-integrity—in which people write about an important aspect of identity—can counteract such threat and thus improve performance. We sought to determine the effects of focusing the affirmation topic on students' individual identity (e.g. an important personal value) vs. group identity (racial group). Because a group affirmation more directly addresses the threat posed by the negative stereotype about their group than a standard affirmation, the former was expected to be especially effective in buffering minority students. The conducted experiment took the form of a 2 (participant race: black vs. white) X 3 (experimental condition: no affirmation control vs. standard affirmation vs. group affirmation) factorial design. After the experimental manipulations, participants completed three standardized tests similar in format to the GRE. For blacks in the control condition, a downward trend in performance across the three tests emerged. By contrast, for blacks in both the self and group affirmation condition, this downward trend was interrupted such that by the third test, blacks in both self and group affirmation condition performed as well as whites. Importantly, the group affirmation was as effective as the self-affirmation in boosting performance for black participants. No significant effects of condition for whites were found. Theoretical implications for self-affirmation theory and practical implications for the role of group identity in educational settings are presented.

#### D251

**THE EFFECT OF REVERSE STEREOTYPE PRESENTATION ON PERFORMANCE** Nicole Arbuckle<sup>1</sup>, Jack Bauer<sup>1</sup>, <sup>1</sup>University of Dayton – This study investigated the effect of reverse stereotype presentation on women's performance under stereotype threat. Current research illustrates that identifying with a positive self-concept can eliminate underperformance and that a stereotype threat need not be socially valid to be believable. Thus it was expected that participants who read a reverse stereotype threat statement indicating that women are good at math would not show threat effects compared to participants who read a statement that did not mention gender. 120 female college students took a 20-item math test adapted from the Graduate Record Examination. Before the test they were randomly assigned to four conditions and read that their scores would be compared to national scores, with each experimental group reading a scientific-sounding statement about women's performance in math: threat (ST, women perform worse than men), reverse threat (RST, women perform better than men), a multiple social identities statement (MSI, women are bad at math, but college students are good at math), and control (CT, no information about gender). Results revealed that women in the RST group attempted significantly fewer items than women in the CT group, while there was no difference between the RST, ST and MSI groups. In other words, even reading a positive statement seemed to deplete women's motivation to complete math problems—as much as reading a negative statement.

**D252**

**GENDER BIAS IN PERCEPTIONS OF PRESCRIPTIVE STEREOTYPES OF MANAGER** Joel T. Nadler<sup>1</sup>, Meghan R. Lowery<sup>1</sup>, Marybeth Hentrich<sup>1</sup>, <sup>1</sup>Southern Illinois University Carbondale (SIUC) – Role congruity theory (Eagly & Karau, 2002) states women are less likely to be promoted due to violations of prescriptive stereotypes. Prescriptive stereotypes describe how a group should act (women should be communal) and descriptive stereotypes describe how a group does act (men are agentic). Manager positions are seen as agentic (masculine). Thus, candidates are more likely to be chosen for management if they are seen as agentic. Women need to act agentically to be considered equally for promotion, but then violate the prescriptive stereotypes of how women should behave. This study examined differences in the appraisal of men and women employees. Participants completed Glick & Fiske's (1996) hostile and benevolent sexism scales and then read an employee performance review. Gender was manipulated in the packets. Participants then rated the employee on overall performance, creativity, customer service, dependability, agency, and communality. Hostile sexism was a significant covariate in all of the analyses. Male employees were seen as more agentic ( $F(1, 286) = 3.89, p = .05$ ) compared to women. This same trend (though not significant at a .05 level) was seen in both ratings of creativity ( $t(1, 265) = 3.57, p = .06$ ) and dependability ( $t(1, 266) = 3.13, p = .07$ ). There was no significant difference in overall performance or communal ratings between men and women employees. Men who were described identically to women were seen as more agentic. The implications and potential impact on women's promotion rates as well as future research will be discussed.

**D253**

**RACE AND THE REHABILITATION OF PEOPLE WHO HAVE COMMITTED CRIMES** Cynthia Levine<sup>1</sup>, Aneeta Rattan<sup>1</sup>, Jennifer Eberhardt<sup>1</sup>, Carol Dweck<sup>1</sup>; <sup>1</sup>Stanford University – Past research has shown that people strongly associate Black Americans and crime (Correll, Park, Judd, & Wittenbrink, 2002; Eberhardt, Goff, Purdie, Davies, 2004). The present research asks whether people are not only more likely to attribute the trait of criminality to Black Americans but also to see this trait as stable and unchangeable among Black but not among White Americans. Participants were primed with stereotypically Black or White names and then responded to a number of questions relating to their views about punishment, rehabilitation, and what rights and benefits former prisoners ought to receive. The results show that compared to when primed with White names, participants primed with Black names, thought that it was less possible to rehabilitate those who have committed crimes and that the primary purpose of imprisonment was punishment rather than rehabilitation. Furthermore, they agreed more with restricting rights and benefits such as the right to vote, access to public housing, and others. Thus, strongly associating crime with Black Americans may lead people to view criminality as more of a fixed trait and, as a result, to impose stricter punishments on those who have committed crimes.

**D254**

**LAY THEORIES INFLUENCE PERCEPTIONS OF PERPETRATORS OF BENEVOLENT PREJUDICE** Cherie Werhun<sup>1</sup>, <sup>1</sup>University of Winnipeg, Canada – As blatant prejudice becomes increasingly socially undesirable (McConahay, 1986), contemporary prejudice manifests in behaviours that are covert, ambiguous, and even seemingly benevolent (Werhun & Penner, accepted). For example, when motivated by negative stereotypes, Werhun and colleagues found that dominant group members (Caucasian Canadians) who endorse entity lay theories (Chiu, Hong & Dweck, 1997) were highly motivated to "help" subordinate group team members (Aboriginal Canadians) by assigning easier tasks, extra training, and/or supervision. Arguing that this patronizing behavior is motivated by paternalistic ideologies (Jackman, 1994), the authors suggested that dominant group members often endorse and condone benevolent prejudice in others, as well. To test this new hypothesis, in a 2 (Stereotype: Prime vs. No Prime) x 2 (Theory: Entity vs. Incremental) x 2 (Race: Aboriginal vs. Caucasian) x 2 (Patronizing Bias: Pro vs. Anti) between-

subjects design, Caucasian participants primed or not primed with negative Aboriginal stereotypes and an entity or incremental lay theory, provided their impressions of a potential team member who had earlier evaluated an Aboriginal or Caucasian Canadian candidate. As expected, when primed with negative Aboriginal stereotypes, entity participants were significantly more likely to a) agree with and trust the team member's evaluation, b) believe the evaluation to reflect the candidate's true ability, and c) want the team member on his or her team when the team member exhibited a patronizing rather than anti-patronizing bias toward the Aboriginal candidate. Providing new evidence for how Benevolent Prejudice is propagated in social environments, both theoretical and real-world implications are discussed.

**D255**

**WHITE DOES NOT EQUAL POOR? THE INFLUENCE OF SOCIAL CLASS ON RACIAL CATEGORIZATION** Jonathan Kunstman<sup>1</sup>, E. Ashby Plant<sup>1</sup>; <sup>1</sup>Florida State University – The current work examined the influence of social class on responses to low SES White people. As one of the remaining socially accepted prejudices, derogation of low SES White people exists throughout society from "White Trash" parties on college campuses to prime-time television shows like "My Big Redneck Wedding." Despite this derogation, low SES White people are also frequently overlooked and ignored by large portions of the population (Lott, 2002). Paradoxically, low SES Whites seem to be simultaneously reviled and forgotten. The present work tested whether these paradoxical responses to low SES White people extend to basic psychological processes like racial categorization and memory. Participants completed a computer program that presented a series of pictures of White and Black people in traditionally high (e.g., doctor) or low (e.g., janitor) SES roles. Pictures of White and Black basketball players were also included as a counter-stereotypic White control. Participants were asked to categorize the individuals in these pictures as White or Black as fast as possible. Following a short delay, participants then recalled what percentage of the pictures from the program featured Black and White targets from the various social groups. Consistent with hypotheses and the paradoxical responses described above, participants were slowest to categorize and had the poorest memory for low SES White targets compared to all other targets. They seemed to both see the low SES Whites as less White and forget they had even seen them. The implications of these responses to low SES White people are discussed.

**D256**

**GOOD THINGS HAPPEN TO RACE-LESS PEOPLE: WHITES MAKE MORE ATTRIBUTIONS OF RACIAL DISADVANTAGE THAN PRIVILEGE** Laura R. Ramsey<sup>1</sup>, Diana E. Betz<sup>1</sup>, Denise Sekaquaptewa<sup>1</sup>; <sup>1</sup>University of Michigan – Research on perceptions of racism has focused almost exclusively on negative events. However, this focus overemphasizes race-based disadvantage and underemphasizes race-based privilege in one's perceptions of racism. Recognition of White privilege has been studied at a societal level (i.e., whether it exists in general), but research has not assessed when racial privilege is invoked in attributions for events at an interpersonal level (e.g., when a person receives a promotion). This study examined perceptions of race-related disadvantage and privilege in specific interpersonal situations by measuring race-related attributions for both positive and negative events featuring both Black and White actors. For 20 different scenarios, 71 White participants indicated the extent to which various factors, including race, played a role. The scenarios varied according to two within-subjects variables: event valence (positive or negative) and race of the actor (Black or White). Results indicated a significant interaction between event valence and actor race,  $F(1, 70) = 32.73, p < .001$ . For scenarios featuring Black actors, racial attributions were made more often for negative than positive events; comparatively, for scenarios featuring White actors, racial attributions were made less often for negative events but at similar levels for positive events. In other words, while race attributions were made for negative events significantly more when they featured Black (compared to White) actors, there was no difference according to actor race for positive events. Thus, these

results indicate that race-based disadvantage aimed at Blacks is recognized in interpersonal situations more than race-based privilege aimed at Whites.

### D257

#### **ESSENTIALISM, ENTITATIVITY, AND STEREOTYPING: THE SOCIAL COGNITIVE RAMIFICATIONS OF EITHER/OR THINKING** Tara C.

Dennehy<sup>1</sup>, Elizabeth Schametzki<sup>1</sup>, Avi Ben-Zeev<sup>1</sup>; <sup>1</sup>San Francisco State University – There is an intimate relationship between basic categorization processes and stereotyping. Recent theorizing (Prentice & Miller, 2007) highlights the importance of the interplay between psychological essentialism and entitativity, or a group's perceived similarity/coherence, on perceptual and motivational factors in stereotyping. Psychological essentialism (Medin & Ortony, 1989), refers to people's tendencies to attribute the perceived surface structural similarity of a group (entitativity) to an underlying causal characteristic; an inferred essence. In a study on essentialist beliefs, Haslam, Rothschild, and Ernst (2000) showed a dissociation between judging category membership based on natural/biological factors, discreteness, stability, immutability, and necessity, versus judging category membership based on uniformity, exclusivity, inherence, and inductive potential. We argue that in contrast to (a) Haslam, et al. (2000), discreteness and naturalness are orthogonal, and (b) Prentice and Miller (2007), that it is perceived discreteness and not naturalness that may predict consequential stereotyping and prejudice. In Study 1, we replicated Haslam et al.'s (2000) study but found that discreteness loaded with reification/entitativity items in a principal components analysis rather than naturalness items. In Study 2 we showed that females who endorsed a higher level of discreteness (but not naturalness) were more susceptible to stereotype threat effects on a test that purported to measure their logical mathematical abilities. We discuss the implications of what might be an either/or fallacy in basic categorization judgments to social psychological work.

### D258

#### **INTERSECTIONAL INVISIBILITY: THE DISTINCTIVE DISADVANTAGES OF CONTENDING WITH MULTIPLE SUBORDINATE IDENTITIES** Ezgi N.

Akcinar<sup>1</sup>, Sarah Hailey<sup>1</sup>, Ruth Dittmann<sup>1</sup>, Richard Eibach<sup>2</sup>, Valerie Purdie-Vaughns<sup>3</sup>; <sup>1</sup>Yale University, <sup>2</sup>University of Waterloo, <sup>3</sup>Columbia University – The present research examines the consequences of possessing intersecting subordinate identities (e.g. being both a racial and a sexual minority). We propose that people with intersecting subordinate identities (e.g. Black women, gay women, Black gay people) suffer from a unique form of discrimination: they are overlooked or "invisible" in social representations of their overarching identity groups (e.g. Black Americans, women, gay people). This bias should manifest itself in others' evaluations of the characteristics of these overarching identity groups and in media representations of the overarching identity groups. In Study 1, we presented participants with graphs depicting characteristics (e.g. Quality of Life Index scores) of intersectional (e.g. Black women) and non-intersectional (e.g. Black men) groups who shared the same overarching identity (e.g. Black Americans). Participants then rated characteristics of the group as a whole (e.g. Quality of Life scores for Black Americans). We found that participants weighted information about non-intersectional members more heavily than information about intersectional members in the evaluations of the group as a whole. In Study 2, we coded identity characteristics (e.g. race and gender) of individuals depicted on the covers of TIME Magazine since 1969. Results revealed that people with intersectional identities (e.g. minority women) were significantly underrepresented relative to population proportions and relative to those with non-intersectional identities (e.g. minority men). We discuss evidence that people with intersecting subordinate identities are perceived to be non-prototypical members of their overarching identity groups and that perceived non-prototypicality produces the documented patterns of intersectional invisibility in social representations.

### D259

#### **RELIGIOUS AUTHORITARIANISM: APPLICATIONS IN THE PREDICTION OF HOSTILE AND BENEVOLENT FORMS OF SEXISM** Nathaniel D. Krumdick<sup>1</sup>,

Sam E. Cole<sup>1</sup>, Scott P. King<sup>2</sup>; <sup>1</sup>Loyola University Chicago, <sup>2</sup>Mather LifeWays Institute on Aging – A considerable body of research suggests that right-wing authoritarianism is associated with a number of prejudicial attitudes and behaviors. However, authoritarianism is traditionally defined in a manner that encompasses a variety of social domains (e.g., politics, family, religion, etc.). The current research examined whether a domain specific form of authoritarianism (namely, religious authoritarianism) operates independently from more generally defined right-wing authoritarianism in the prediction of prejudicial attitudes. Of particular interest were hostile and benevolent forms of sexism. Authoritative religious institutions often denounce hostility and aggression, while simultaneously promoting a traditional view of gender roles that can foster sexist attitudes. Consequently, religious authoritarianism may inhibit sexist attitudes that are overtly hostile, but not necessarily those that are subtly benevolent in nature. Alternatively, more broadly defined forms of authoritarianism are often associated with prejudices that are equally broadly defined. Thus, in contrast to religious authoritarianism, conventional right-wing authoritarianism might be expected to relate to both hostile and benevolent forms of sexism. Participants completed a series of questionnaires including the Religious Authoritarianism Scale, Right-Wing Authoritarianism Scale, and Ambivalent Sexism Inventory. Structural equation modeling was used to simultaneously examine the relationships between religious authoritarianism, right-wing authoritarianism, hostile sexism, and benevolent sexism. Results supported the initial hypothesis, revealing that religious and right-wing authoritarianism functioned as independent predictors of sexism. Specifically, right-wing authoritarianism was positively associated with both hostile and benevolent sexism. Alternatively, religious authoritarianism was negatively associated with hostile sexism, but not significantly associated with benevolent sexism.

### D260

#### **VICTIM-BASED RACIAL PROPAGANDA: TARGETING THE AMBIVALENT**

Shannon M. Rauch<sup>1</sup>, Molly Van Deursen<sup>2</sup>, Kevin P. McIntyre<sup>3</sup>; <sup>1</sup>Providence College, <sup>2</sup>Saint Louis University, <sup>3</sup>Trinity University – Extremist propaganda tends to put forth one of two arguments: that Whites comprise a superior racial group or that Whites are a victimized, oppressed group. We predict that victim-based messages are especially powerful persuasion tools, particularly when targeted towards Whites with ambivalent racial attitudes. Seeing oneself as the true victim may serve to lessen ambivalence by justifying negative attitudes or dampening positive attitudes. White participants (N = 67) took part in an internet study in which they completed a measure of structural racial ambivalence and then read one of three essays: one claiming that Whites are a superior racial group, one presenting Whites as the most oppressed group in America, or a control. Participants rated the message and the writer, and completed an implicit affect measure and the Pro- and Anti-Black scales (Katz & Hass, 1988). Participants with positive attitudes towards Blacks and ambivalent participants approved of the messages and the writer significantly less than participants with negative attitudes towards Blacks. However, a pattern emerged such that non-prejudiced participants disapproved of both the superiority message and the victim message, prejudiced participants approved of both messages, and ambivalent participants approved of the victim message but not the superiority message. Non-prejudiced and ambivalent participants who read the victim-based message also expressed lowered positive implicit affect compared to prejudiced participants. Finally, whereas there was no effect of condition on anti-black attitudes, participants who read the victim message tended to have lower pro-black attitudes, suggesting that such messages may work by challenging positive attitudes.

**D261**

**FEMALE LEADER ROLE MODELS: INJURIOUS OR INSPIRING?** Crystal Hoyt<sup>1</sup>, Stefanie Simon<sup>2</sup>, Audrey Innella<sup>1</sup>; <sup>1</sup>University of Richmond, <sup>2</sup>University of California, Santa Barbara – As members of a non-dominant social group, women are underrepresented in top positions in the public sphere. Female leaders who have successfully attained these top positions may serve as inspiring role models for other women. The present research examines the impact of female role models on women's leadership self-perceptions and aspirations. Across two laboratory studies, this research investigates whether female leaders will serve as injurious or inspiring role models by examining their impact on women during a leadership task. In Experiment 1, women were presented with role models (4 conditions: high-level women, high-level men, both high-level women and men, or control) before serving as leaders of ostensible three-person groups. This study established the self-deflating impact of elite female leaders on participants' self-perceptions. The results from Experiment 1 revealed that women exposed to the high-level female leaders reported that they performed worse, that the task was harder, and that they had greater feelings of inferiority compared to those in the other conditions. Experiment 2 further demonstrated the injurious effects elite female leaders have on participants' leadership aspirations. Adding a new condition wherein some women were exposed to mid-level female leaders, Experiment 2 also demonstrated the beneficial impact of mid-level role models on women's leadership aspirations. Moreover, these positive responses were associated with increases in gender counter-stereotypic associations. Our results suggest that outstanding role models can have counterintuitive harmful effects on women's responses to leadership situations, whereas mid-level leaders can be more beneficial for women, in part because they provide counter-stereotypic information.

**Traits****D262**

**THE DISTINCTIVENESS OF EXTRAVERSION AND CONSCIENTIOUSNESS: A TEST OF THE SUBCOMPONENT-STATE FUNCTION THEORY** Kira McCabe<sup>1</sup>, William Fleeson<sup>2</sup>; <sup>1</sup>University of Groningen, <sup>2</sup>Wake Forest University – The purpose of this research is to determine whether state extraversion and state conscientiousness can be explained by momentary goal pursuit in everyday life. In our subcomponent-state function theory, we propose that the purpose of personality traits is to facilitate pursuit of specific goals. Certain goals determine state extraversion (e.g., to have fun), and other goals determine state conscientiousness (e.g., to get tasks done). In Study 1, participants (N = 44) answered questions about their goal pursuit and personality states five times a day for ten days. Findings showed that the hypothesized extraversion goals predicted 45% of the variance in state extraversion, while the hypothesized conscientiousness goals predicted 49% of the variance in state conscientiousness. The bivariate goal-state relationships showed that most goals predicted their hypothesized state, but had little or no relationship with the non-hypothesized state. In Study 2, participants (N = 84) were assigned a goal to pursue during the study. After 45 minutes, they returned to complete questionnaires of goal pursuit and personality states. The findings showed a significant interaction for the goal and state,  $F(1, 82) = 183.67, p < .001$ . Participants who tried to connect with people had significantly higher state extraversion than participants who tried to get tasks done. Participants who tried to get tasks done had significantly higher state conscientiousness than participants who tried to connect with people. These results show that goals determine the personality states people enact in their everyday lives.

**D263**

**I BELIEVE I CAN FLY: PERSONALITY PREDICTORS OF ENGAGEMENT IN FANTASY NARRATIVES** Leschia McElhaney<sup>1</sup>, Russell J. Webster<sup>1</sup>, Scott Fluke<sup>1</sup>, Donald A. Saucier<sup>1</sup>; <sup>1</sup>Kansas State University – Human beings seemingly have an insatiable hunger for fantasy (e.g., the supernatural), and billions of dollars are made from its industry (e.g., Harry Potter). Research has intriguingly shown that belief and engagement in fantasy (e.g., visualizing oneself flying) have been associated with managing anxiety, including the fear of death in terror management studies. Yet, we posit that individuals subjectively experience fantasy at different levels of intensity. The current study investigated whether three personality traits—fantasy proneness (deep involvement in fantasy/make-believe since childhood), absorption (openness to absorbing and self-altering experiences), and empathetic fantasy (the tendency to imaginatively transpose oneself into fictional situations)—are related to more vivid images and greater engagement during a flying fantasy. In total, 78 undergraduates completed a visualization task in which participants either visualized oneself flying or visualized the setting sun through a guided narrative. During the task, participants rated the vividness of their mental imagery; afterwards, participants completed a visualization engagement scale and measures of fantasy proneness, absorption, and empathetic fantasy. Results showed that across both visualization tasks, fantasy proneness was uniquely and positively related to vivid imagery, whereas absorption and empathetic fantasy were uniquely and positively related to engagement. It appears that individuals higher in absorption or empathetic fantasy were more immersed in the visualization tasks, but did not experience more vivid mental imagery. Ultimately, such individuals may have more intense visualizations, but it remains untested whether this greater immersion offers more ameliorative benefits in anxiety-provoking situations.

**D264**

**CROSS YOUR FINGERS: THE EFFECTS OF PESSIMISM AND LOCUS OF CONTROL ON BELIEF IN SUPERSTITION** Scott Fluke<sup>1</sup>, Russell J. Webster<sup>1</sup>, Leschia McElhaney<sup>1</sup>, Donald A. Saucier<sup>1</sup>; <sup>1</sup>Kansas State University – Many people on occasion are superstitious (e.g., crossing one's fingers for "good luck"); that is, people believe that an unrelated action, object, or ritual will result in a more desirable outcome. Superstitions likely provide a sense of control (as superstitions are believed to sway outcomes) thereby lowering anxiety; yet, superstitions might become maladaptive when supplanting more productive behaviors (e.g., bringing a rabbit's foot to a test instead of studying). We posit that certain individual differences are related to superstitious beliefs. We reason that individuals higher in external locus of control (ELOC) or pessimism should more greatly endorse superstitious beliefs because such individuals would likely endorse beliefs that help them regain a sense of control over the external world. In total, 135 undergraduates completed measures of pessimism, locus of control, and a newly-developed belief in superstition scale composed of three factors: superstitions to avoid bad luck, superstitions to bring good luck, and whether it was generally worth trying to change your luck. Regression results showed pessimism was uniquely and positively related to avoidance of bad luck, whereas ELOC uniquely predicted both avoiding bad luck and bringing good luck; neither pessimism nor locus of control predicted whether it was worth to change your luck. Results suggest then that ELOC and pessimism are related to different types of superstitions. Because superstitions really only affect the internal assessment of the expected outcome (vs. directly affecting the outcome), future research should assess whether superstitions gainfully manage anxiety whether or not the desired outcome is achieved.

**D265**

**THE DEVELOPMENT OF BIG-FIVE DOMAINS AND FACETS FROM LATE CHILDHOOD THROUGH MIDDLE AGE** Christopher Soto<sup>1</sup>, Oliver John<sup>2</sup>, Samuel Gosling<sup>3</sup>, Jeff Potter<sup>4</sup>; <sup>1</sup>Colby College, <sup>2</sup>University of California, Berkeley, <sup>3</sup>University of Texas at Austin, <sup>4</sup>Cambridge, Massachusetts – Data from a very large cross-sectional sample (N = 1,267,218) of children, adolescents, and adults (ages 10 to 65) were used to test hypotheses about the normative development of the Big Five personality domains – Extraversion, Agreeableness, Conscientiousness, Neuroticism, and Openness to Experience – and several more-specific facet traits within these broad domains. The results supported several conclusions. First, adult developmental trends were in the direction of greater psychosocial maturity, including gains on Agreeableness and Conscientiousness, and declines on Neuroticism. Second, mean-level increases and decreases were often especially pronounced during late childhood and adolescence, and were sometimes in different directions than the adult trends. For example, among females, levels of Neuroticism increased substantially from late childhood into adolescence, then declined gradually across adulthood. Finally, the related but distinguishable facet traits within each broad Big Five domain often showed quite different developmental trends. For example, within the Extraversion domain, mean levels of energy and enthusiasm declined substantially from late childhood through adolescence, whereas levels of assertiveness did not. These findings highlight the need for further research that examines personality development (a) during childhood and adolescence, and (b) at the level of Big-Five facet traits.

**D266**

**MOTIVES, ABILITIES, AND PERCEPTIONS UNDERLYING VARIATION IN BIG FIVE TRAITS** Molly Hensler<sup>1</sup>, Dustin Wood<sup>1</sup>; <sup>1</sup>Wake Forest University – Although considerable attention has been given to how personality traits relate to variation in behavior, it is not well understood what causes variation in personality traits. As suggested by others (Mischel & Shoda, 1995; Wood, 2007), individual differences in patterns of behavior indicated by trait measures may originate from differences in what people find desirable or undesirable (motives), what people are capable or incapable of doing (abilities), and how people construe their social environments (perceptions); we refer to these collectively as "MAP variables." We compiled an inventory of 400 MAP variables, extracted from two previous qualitative studies, which were then related to scores on the Big Five Inventory for over 300 participants. We expected that each Big Five trait would share some MAP antecedents, but also have some relatively unique antecedents. In line with our predictions, using extraversion as an example, we found that extraversion and agreeableness were both associated with heightened motivation to comfort others, elevated confidence in one's abilities, and high expectations for positive outcomes in social interactions. Extraversion was also associated with MAP antecedents that were relatively unassociated with other traits, for example, a heightened motivation to seek attention. As expected, the results suggest that there are many distinct motivations, perceptions, and competencies that underlie variation in personality traits, that some MAP variables are associated mainly with a single trait, and that other MAP variables may be antecedents of multiple traits simultaneously. The results provide insight into the origins of variation in personality traits.

**D267**

**AFFILIATIVE MEETS AFFILIATIVE: EFFECTS ON COMPLIANCE AND TRUST** Gaëtan Cousin<sup>1</sup>, Marianne Schmid Mast<sup>1</sup>; <sup>1</sup>University of Neuchâtel, Switzerland – There is evidence that in social interactions, affiliative individuals are more sensitive than dominant individuals to affiliativeness in others (Battistich, 1980). The aim of this research was to test whether affiliativeness as a personality characteristic affects the outcome of a social interaction depending on the affiliativeness of the interaction partner. We predicted that the more affiliative a person, the more positive the interaction outcome with an affiliative interaction partner as compared to a non affiliative one. Participants (60 students) watched video-

taped excerpts (2 min each) of 4 physicians (2 women and 2 men) exhibiting an affiliative interaction style and 4 physicians (2 women and 2 men) showing a non affiliative interaction style, and reported after each physician their satisfaction with him or her, their trust in him or her, and how well they thought that they would follow the treatment recommendations of the physician (compliance). The personality trait of affiliativeness was obtained by a factor analysis based on the facets of the dimensions of neuroticism, extraversion, and agreeableness of the NEO-PI-R (Costa & McCrae, 2007). For men, results confirmed the moderating effect of affiliativeness on the link between the physicians' affiliative interaction style and the interaction outcomes of compliance and trust, but not for satisfaction. However, for women no moderating effect emerged. The more affiliative a man, the more he adheres to the treatment recommendations of the affiliative as compared to the non affiliative physician and the more trust he has in the former.

**D268**

**BIRDS OF A FEATHER: THE INFLUENCE OF BIRTH ORDER ON FRIENDSHIPS AMONG GIFTED STUDENTS** Laura A. Boettcher<sup>1</sup>, Gayle T. Dow<sup>1</sup>; <sup>1</sup>Christopher Newport University – Previous researchers investigating the influence of birth order on personality suggest common traits exist within oldest, middle, & youngest born individuals (Sulloway, 1997). The goal of the current study was to investigate this influence of birth order status on the selection of close friends among gifted students. A demographics survey was completed by approx. 60 high school rising seniors from a gifted arts summer program with questions regarding participants' birth order as well as who they considered to be a best friend for at least one year. A Chi square test of the participants' birth order and their best friends' birth order revealed a significant relationship. We found that birds of a feather flock together, such that oldest born children tended to be friends with other oldest born and middle born children tended to be friends with other middle born. Implications, limitations and future directions will be discussed.

**D269**

**PREDICTING REAL-WORLD USER CHARACTERISTICS FROM VIRTUAL-WORLD AVATARS: HOW TRULY ANONYMOUS IS THE NET?** Michael Dudley<sup>1</sup>; <sup>1</sup>Southern Illinois University Edwardsville – The overarching goal of this exploratory study was to attempt to identify the extent to which real-world (RW) personality and behavioral characteristics of Second Life users could be predicted from just the appearance and behaviors of their virtual-world (VW) avatars. The underlying assumption of this study was that the personality and behavioral characteristics of the user in the RW would be reflected in the personality and behavioral characteristics of their VW avatar. Thirty-four participants independently assessed both the demographic and personality characteristics of nine Second Life avatars, created specifically as part of this study. These independent ratings were then compared to the same characteristics as supplied by the avatar creator. Consistent with prior research, results indicated a high degree of correlation between the demographics of the RW users and their VW avatars. Using the Big 5 personality factors, a surprisingly high correlation for personality characteristics was also obtained for some avatars (up to  $r > .90$ ). Exploratory analyses were conducted to determine a possible moderating variable between those avatars with high ( $r_s > .70$ ) and low ( $r_s < .30$ ) RW correlations, including a possible mediating role of RW user adherence to traditional gender roles. Implications for these findings regarding how truly anonymous one's online avatar may be are discussed.

**D270**

**REBOUND EFFECTS OF RETRIEVAL-INDUCED FORGETTING** Marcelle Fernandes<sup>1</sup>, Jo Saunders<sup>1</sup>; <sup>1</sup>Swansea University – Previous research has suggested that the intentional suppression of stereotypes can result in that stereotype rebounding both cognitively and behaviourally. Two experiments provide an initial investigation into whether retrieval-induced forgetting (RIF), whereby the attempt to retrieve a target memory results in the forgetting of related but unretrieved memories, can

also have a behavioural rebound effect. Sixty participants read neutral and positive traits (Experiment 1), and neutral and negative traits (Experiment 2), describing a target individual and then either completed relevant or non-relevant retrieval practice. Participants then free recalled all of the traits concerning the target before being asked to sit and wait for the target outside the laboratory where there were eight seats. The dependent variables were the proportion of items reported and the choice of seat. Results for both experiments show a significant RIF effect indicating that selective retrieval practice significantly impaired the participant's ability to recall competing positive or negative traits on a later recall test. A significant behavioural rebound effect was found whereby the RIF of positive traits led a choice of seat closer to the target and RIF of negative traits led to a choice of seat further away from the target as compared to participants who never demonstrated RIF. Thus, the current findings suggest that RIF may also lead to rebounding, where what is not producible on an explicit recall task can be produced on an indirect measure of memory, extending this effect to include positive as well as negative information

#### D271

**CONSTRUCT VALIDITY FOR A SELF-REPORT MEASURE OF DISTRIBUTIONS OF TRAIT BEHAVIOR** Patrick Gallagher<sup>1</sup>, Rick Hoyle<sup>1</sup>, William Fleeson<sup>2</sup>; <sup>1</sup>Duke University, <sup>2</sup>Wake Forest University – The most common and straightforward way to measure people's standing on personality traits is to ask them to choose a number on a scale that best describes them. These single-number scores, though powerfully predictive, neglect other potentially important aspects of trait behavior. Fleeson (2001) proposed that the most comprehensive measure of personality traits is the distribution of trait-relevant behaviors over time. Recent findings have shown that parameters of these distributions are stable, meaningful individual differences. The behavioral distribution questionnaire (BDQ) was designed to assess behavioral distributions through self-report. Previous studies have shown that participants can be accurate in retrospectively and prospectively describing their actual behavioral distributions using the BDQ. In the current studies, participants completed the BDQ and other measures, and parameters derived from the self-reported distributions were compared to scores on other construct to establish predictive and convergent validity. Parameters of BDQ distributions of Big-Five traits were related to several constructs in expected patterns. Means were related to other Big-Five measures ( $r$ s ranged from .34 to .64,  $ps < .01$ ). Means of extraversion and emotional stability were related to positive affect ( $r = .32$ ,  $p < .01$ ) and negative affect ( $r$ s = -.26 to -.49,  $ps < .05$ ) respectively. Other parameters of BDQ distributions were related to other constructs; for example, standard deviations of Big-Five distributions were related to self-concept clarity ( $r$ s = -.31 to -.42,  $ps < .01$ ). These findings contribute to establishing the validity and potential usefulness of the BDQ as an alternative measure of personality traits.

#### D272

**HIGHER ORDER FACTORS OF THE BIG FIVE AND BOTH EXTERNALIZING AND INTERNALIZING BEHAVIORS IN ADOLESCENCE** Dave Miranda<sup>1</sup>, Patrick Gaudreau<sup>1</sup>, Julien Morizot<sup>2</sup>; <sup>1</sup>University of Ottawa, <sup>2</sup>Université de Montréal – Recent studies identified relations between two higher order factors of the Five Factor Model of personality traits (Stability and Plasticity) and externalizing behaviors in adolescence, such as vandalism, drug use, and aggression (e.g., DeYoung, Peterson, Séguin, & Tremblay, 2008). However, less is known about the links between these two higher order factors and a broader range of comorbidity (externalizing and internalizing behaviors) across normal populations of female and male adolescents. Consequently, this study hypothesized relations between self-reports of Stability (Neuroticism inverted, Agreeableness, and Conscientiousness) and Plasticity (Extraversion and Openness), and both externalizing (vandalism, theft, aggression, drug use) and internalizing (depression, anxiety, irritability, cognitions) behaviors in a community sample of female and male adolescents. The sample was composed of 269 regular high school students (age:  $M = 15.63$ ,  $SD = .81$  years; 129

girls, 140 boys) attending a Montreal (Canada) public high school. Overall, results from structural equation modeling with latent variables supported the fit of the model across adolescent girls ( $CFI = .94$ ;  $RMSEA = .05$ ) and boys ( $CFI = .96$ ;  $RMSEA = .05$ ). Higher levels of Stability were related to lesser of both externalizing (girls  $B = -.76$ ; boys  $B = -.98$ ) and internalizing behaviors (girls  $B = -.49$ ; boys  $B = -.92$ ). Higher levels of Plasticity were related to more of both externalizing (girls  $B = .82$ ; boys  $B = .82$ ) and internalizing behaviors (girls  $B = .33$ ; boys  $B = .70$ ). Therefore, Stability and Plasticity metraits may account for a broad spectrum of psychopathological comorbidity in adolescence.

#### D273

**IF IT WALKS LIKE A DUCK AND TALKS LIKE A DUCK: REPLICATION AND CONSTRUCT VALIDATION OF PROVERB-BASED PERSONALITY DIMENSIONS** Heather A. Haas<sup>1</sup>, Steven V. Rouse<sup>2</sup>; <sup>1</sup>LaGrange College, <sup>2</sup>Pepperdine University – Many studies of the personality domain have involved lexical analyses. Proverbs, although not single-word items, also appear to be personality-relevant in that they encode injunctions to behave in particular ways and to believe particular things. Although there is one exploratory study of the personality-relevance of English-language proverbs in the literature, the proverbs in that study were presented along with an explanation of the meaning of the proverbs. Thus, although several proverb-based dimensions emerged in that study, it is unclear whether those dimensions might have been, at least in part, a result of the "explanations" rather than due to the proverbial content itself. In this study, 213 college participants' responses to a more pure proverb endorsement task revealed five proverb-based dimensions, four of which replicated proverb-dimensions previously reported (i.e., Machiavellianism, Restraint, Achievement Striving, and the tendency to Enjoy Life). These dimensions were also clearly personality-relevant, although they did not match isomorphically with the Big Five. Correlations with domain and facet level scores on the NEO PI-R showed that Machiavellianism is related to low Openness and Agreeableness, Restraint to high Conscientiousness and low Extroversion, the Enjoys Life dimension to low Neuroticism and Conscientiousness and high Extroversion, and Achievement Striving to high Extroversion and Conscientiousness. Correlations with scales from the MPQ-BF provided further construct validation for these dimensions. Thus, although proverb-based analyses result in a factor structure that carves nature at a different set of joints, this research confirms that the proverb domain does encode important personality dimensions recognized by the folk.

#### D274

**STABILITY AND CHANGE OF INDIVIDUAL DIFFERENCES: A MODEL FOR SHORT-TERM LONGITUDINAL DATA** Ivana Anusic<sup>1</sup>, Richard E. Lucas<sup>1</sup>; <sup>1</sup>Michigan State University – Stability of individual differences is an important avenue of study for personality psychologists. Stability of constructs gives us insight into their nature, causes, and importance for the everyday functioning of individuals. One prominent model for examining stability and change of individual differences is Kenny and Zautra's (1995; 2001) STARTS model. This model posits that variance of individual differences may be partitioned into a stable trait (ST) component which is perfectly stable, an autoregressive trait (ART) component which changes systematically over time, and a state (S) component which is specific to a single measurement occasion. Although the STARTS model accurately describes patterns of stability and change we observe in the data over longer time periods, it has been greatly underutilized in psychological research. One likely reason for this is that the STARTS model requires repeated assessments over several years, which is often not plausible for studies that employ undergraduate student participants. Thus, we developed two alternative models that can be used with shorter-term longitudinal datasets and applied them to a dataset of personality, life satisfaction, and affective symptoms, assessed weekly over a period of two months. Our results indicated that personality can be adequately described by the model which assumes that individual differences are mostly trait-like. In contrast, life satisfaction and affective symptoms show change even over short time periods and thus their

model must include the autoregressive component. The findings are discussed in the context of short-term longitudinal studies of individual differences and the research questions they may answer.

#### D275

##### **INFLUENCES OF PERCEIVED DEPRIVATION ON STUDENT PERCEPTIONS OF TEACHER SUPPORT** Jennifer Hicks<sup>1</sup>, Debbie Boman<sup>1</sup>, Reba Criswell<sup>1</sup>;

<sup>1</sup>Southeastern Oklahoma State University – Prior research studies investigating the link between the Big Five Personality factors and academic outcomes have primarily indicated that conscientiousness serves as a useful predictor for achievement. Results of some studies have also suggested that socioeconomic deprivation negatively predicts achievement. However, previous studies have considered objective indicators of deprivation exclusively. The purpose of the present study was to investigate the impact of perceived deprivation on conscientiousness and achievement-striving among college students. Perceived deprivation negatively predicted overall conscientiousness, but was not correlated with dutifulness or achievement-striving facet scores on the Conscientiousness domain of the NEO PI-R. However, perceived deprivation of teacher support was significantly linked with scores on three of the five Conscientiousness facets (i.e., achievement striving, competence, and self-discipline). Results supported prior studies indicating a link between conscientiousness and socioeconomic deprivation. Findings are discussed in relation to teacher characteristics that may assist students in developing and strengthening achievement-related behaviors.

## Well-Being

#### D276

##### **LINKS BETWEEN SUPPORT, WELL-BEING, AND BEHAVIOR** Michelle Herrera<sup>1</sup>, Rebeca Aragón<sup>1</sup>, Gertraud Stadler<sup>1</sup>, Niall Bolger<sup>1</sup>;

<sup>1</sup>Columbia University – Perceived support is associated with positive outcomes, e.g., better health. One possible pathway between perceived support and health is health behavior (Berkman, Glass, Brissette, & Seeman, 2000). This poster investigates the relationship between perceived support (in general and specific for exercise and diet), well-being, and health behavior. In Study I, a sample of 259 women (ages 30-50) each completed a questionnaire about general perceived support, specific perceived support for regular exercise and healthy eating, and physical and psychological well-being. Participants also completed a 7-day diary about their physical activity and diet. Health behavior-specific perceived support was not related to physical or psychological well-being ( $r = 0.13$  and  $0.12$ ,  $p > .05$ ) and diet (all  $r_s \leq 0.12$ ,  $p > .05$ ), but was correlated with exercise ( $r = 0.21$ ,  $p < .05$ ). General perceived support was correlated with both physical and psychological well-being ( $r = 0.22$  and  $0.42$ ,  $p < .05$ ), was not related to diet (all  $r_s \leq 0.12$ ,  $p > .05$ ), yet was correlated with exercise ( $r = 0.21$ ,  $p < .05$ ). None of the health behaviors were mediating the link between support and well-being. In-depth interviews were conducted in Study II to better understand the links between support, health behavior, and well-being. Participants reported that others facilitated exercise and healthy eating by creating an environment that made healthy choices easier (e.g., no sweets at home) but neither provider nor receiver labeled this as support. Support receivers and providers experienced direct support attempts at encouraging health behavior as counterproductive.

#### D277

##### **EGOTISTICALLY RESOURCEFUL SOCIAL CAPITALISTS: THE WELL-BEING BENEFITS OF BRIDGING SOCIAL ACTORS AND BUILDING NETWORK CONNECTIONS** Lalin Anik<sup>1</sup>, Michael I. Norton<sup>1</sup>;

<sup>1</sup>Harvard Business School – With the aim of bridging the gap between social structure and the value of social relationships, we investigated people's personal motivations to create social connections. We showed that some people get more utility out of making connections than others and we call these connectors "social capitalists." With the increase of social networking website, there is the hype of individuals to introduce themselves to others as well as creating opportunities to connect their friends. This, we

hypothesized, is strongly related to well-being and life satisfaction. In five separate studies, we explored people's tendencies to connect people to see whether these connections impacted their well-being and preferences for future connections. In Study 1, we looked at whether people's perceptions of how well they connected people in their lives associated with their well-being and whether the depth of their social circles affected this relationship. In Study 2, we investigated whether this utility was specific to connecting just anything or people only in the light of a distinction between actual performance and perceived performance in social circles. In Study 3, we explored how people's network structure impacted their connections with others and whether this had an effect on their well-being. In Study 4, we looked at whether the outcome of the connection (whether it was successful or not) was important and finally, we manipulated people's formation of connections.

#### D278

##### **MONEY CAN BUY HAPPINESS (AT LEAST SOMETIMES): THE EFFECT OF MATERIAL VS. EXPERIENTIAL PURCHASES ON HAPPINESS** Sarah

Estow<sup>1</sup>, Eva Kung Lawrence<sup>1</sup>;

<sup>1</sup>Guilford College, Greensboro, NC – With the current economic downturn, there has been increased interest in identifying how people should best spend their money. Aside from basic necessities, what kinds of purchases should we make to maximize our satisfaction? Two-hundred sixty-four (131 female, 124 male, 9 no response) participants were asked to imagine a future purchase of more than \$100 and rate on a 9-point Likert-type scale how happy the purchase would make them and how well-spent the money would be. Participants were randomly assigned to imagine either a material or experiential purchase, and one that was either for themselves or for another person. Results indicate that neither purchase recipient nor participant gender predicted how happy a purchase would make participants nor how well-spent they thought the money would be. However, both dependent variables were affected by the type of purchase participants were asked to imagine. Participants reported that an experiential purchase would make them happier ( $M = 7.61$ ,  $SD = 2.00$ ) than a material purchase, ( $M = 7.11$ ,  $SD = 1.84$ ),  $F(1, 247) = 4.66$ ,  $p = .032$ . Participants also reported that an experiential purchase would be money better spent ( $M = 7.14$ ,  $SD = 1.73$ ) than a material purchase, ( $M = 6.42$ ,  $SD = 2.10$ ),  $F(1, 247) = 7.50$ ,  $p = .007$ . Overall, these results imply that when people reduce their discretionary spending as many of us are currently doing, they should focus first on material purchases as experiential purchases provide greater "bang for their buck" satisfaction-wise.

#### D279

##### **AN INVESTMENT MODEL ANALYSIS OF COMMITMENT AND WELL-BEING IN GRADUATE SCHOOL** Lindsey M. Rodriguez<sup>1</sup>, Amy L. Bush<sup>1</sup>, Ahmet

Uysal<sup>1</sup>, Helen Lin<sup>1</sup>, C. Raymond Knee<sup>1</sup>, Kristen Petty<sup>1</sup>;

<sup>1</sup>University of Houston – Although graduate students are integral to the successful education, research, and future progress of higher academic institutions, many students report experiencing significant stress and depression during graduate school. In fact, more than 50 percent of those who enter graduate school never complete their advanced degree. The current study employed the investment model (Rusbult, Martz, & Agnew, 1998) to predict variability in student commitment and psychological well-being. Graduate students ( $N = 397$ ) in doctoral psychology programs across North America completed an online survey. Structural equation modeling revealed support for the hypothesized model. Specifically, feeling more satisfied with and invested in graduate school predicted more commitment to one's program. Independently, perceiving higher quality alternatives to graduate school predicted less commitment to one's program. Greater commitment, in turn, predicted better psychological well-being, which was captured by indicators of mental health, anxiety, life satisfaction, and perceived stress. Findings remained after controlling for year in school and frequency of meetings with one's advisor. These findings highlight several areas in which steps can be taken to increase graduate student well-being.

**D280**

**THE INFLUENCE OF MOOD ON THE RELATION BETWEEN PROACTIVE COPING AND REHABILITATION OUTCOMES** Joana K. Q. Katter<sup>1</sup>, Esther Greenglass<sup>1</sup>, <sup>1</sup>York University, Toronto – Orthopaedic joint replacement is an increasingly common surgical procedure aimed at reducing pain and improving physical functioning. It has recently been recognized that psychological and cognitive factors can greatly influence an individual's post-surgical recovery, above and beyond the effects of preoperative function and surgical trauma. Individuals' coping style, the way in which they typically deal with problems they encounter, may be a particularly relevant consideration in predicting psychological well-being following joint replacement. Engaging in proactive coping, a coping style that is goal-oriented and involves approaching stressors as challenges rather than threats, may be particularly beneficial. In the present study, the relation between proactive coping, mood, state of mind, and psychological and functional outcomes was examined in a sample of 228 older adults undergoing rehabilitation following joint replacement surgery. It was hypothesized that proactive coping would be associated with improved psychological and functional outcomes following rehabilitation. Further, it was hypothesized that this relation would be mediated by the experience of positive mood and positive state of mind. Support for the proposed mediation model was found, where proactive coping style was associated with increased vigor and positive state of mind, which were in turn associated with improved functional and psychological outcomes. Theoretical and empirical implications of the findings are discussed, particularly with regard to the transactional theory of stress and coping.

**D281**

**THE ROLE OF TRUST IN PHYSICIAN, COPING STYLES AND DEPRESSIVE SYMPTOMS AMONG WOMEN LIVING WITH BREAST CANCER.** Sheena Aislinn Taha<sup>1</sup>, Kimberly Matheson<sup>1</sup>, Hymie Anisman<sup>1</sup>, <sup>1</sup>Carleton University – Dealing with a tumultuous and potentially life-threatening event, such as breast cancer, requires the support of friends and family, and the use of effective coping styles in order to limit adverse psychological repercussions. In the present study we assessed the influence of several factors that might influence psychological well being, including coping methods and a woman's relation with her oncologist (her main source of hope for survival). An on-line survey assessed support, unsupport, coping styles, and trust in physician, in women undergoing treatment for breast cancer (n = 40), women in remission (n = 74) and women who have never had a cancer experience (n = 146). Trust was greatest in women in treatment; however, these women also reported the most depressive symptoms. In addition, as trust increased, so did the potential for blame associated with adverse events related to treatment. Women in treatment were more likely to use avoidant coping than those in the other groups, whereas women in remission used emotion-focused coping least often. The endorsement of these coping styles was associated with heightened depressive symptoms, whereas the use of problem-focused coping was related to lower depressive symptoms. Neither satisfaction with social support, nor trust in the physician interacted with coping styles. Experiences of unsupport, however, moderated the relation between depressive symptoms and both emotion-focused and avoidant coping. These findings suggest that trust in one's treating physician, the use of emotion-focused and avoidant coping styles, as well as experiences of unsupport, may be important considerations regarding women's well-being.

**D282**

**NOT EVERYTHING HAPPENS TO ANYBODY: SUBJECTIVE WELL-BEING AS A PREDICTOR OF LIFE EVENTS** Maike Luhmann<sup>1</sup>, Michael Eid<sup>1</sup>, Richard E. Lucas<sup>2</sup>, Ed Diener<sup>3</sup>, <sup>1</sup>Freie Universität Berlin, <sup>2</sup>Michigan State University, <sup>3</sup>University of Illinois at Urbana-Champaign – Some researchers have proposed that life events are partly endogenous, i.e., influenced by individual characteristics such as neuroticism and extraversion (e.g., Headley & Wearing, 1989). Our study is the first to examine subjective well-being as

an additional predictor of life events. We analyzed longitudinal, representative data from the German Socio-Economic Panel (N = 20,921), the British Household Panel (N = 11,422), and the Household, Income and Labour Dynamics in Australia panel (N = 11,313) with logistic and Poisson regression methods. Across all samples, baseline subjective well-being was a significant predictor of (1) the total number of later positive and negative life events and (2) the occurrence of specific life events such as unemployment, marital separation, or relocations, controlling for sex, age, and the big five personality variables. These findings replenish recent research on the positive consequences of happiness and provide further support for the notion of endogenous life events.

**D283**

**EXPLORING THE RELATION BETWEEN OPTIMISM, EMOTIONAL SUPPORT, AND PROACTIVE COPING** Melina Condren<sup>1</sup>, Esther Greenglass<sup>1</sup>, <sup>1</sup>York University – Proactive coping is a forward-looking, goal-oriented coping strategy that has often been associated with psychological and physical health. By identifying both internal and external resources that lead to increased proactive coping, we can gain a better understanding of how to encourage the use of this positive coping strategy. The present study examines optimism and emotional support as predictors of proactive coping over a two-month period in 68 first-year university students. A series of regression analyses was performed to examine predictors of difference scores between Time 1 and Time 2. Findings suggest that optimism leads to increased emotional support and not the reverse, and that emotional support leads to increased proactive coping and not the reverse. Support was not found for a causal relation between optimism and proactive coping. When emotional support from different sources was examined, optimism led to increased support from friends and a significant other, but not from family. In addition, support from family and a significant other led to increased proactive coping, but proactive coping led to increased support from friends. Taken together, these findings suggest that emotional support leads to increased proactive coping, and that proactive coping strategies can be used to increase the support received from certain social networks. In addition, individuals may be able to increase the support they receive from certain members of their social networks by adopting an optimistic attitude. Theoretical implications of these findings are discussed.

**D284**

**PROACTIVE COPING AS A PREDICTOR OF COLLEGE ADJUSTMENT** Deletha Hardin<sup>1</sup>, Betty Witcher<sup>2</sup>, <sup>1</sup>The University of Tampa, <sup>2</sup>Peace College – Research on coping typically focuses on problem- and emotion-focused coping. These involve finding solutions to present predicaments or managing emotions. These styles are a reaction to stressors and not a preparation for stressors. However, when individuals use proactive coping (Greenglass, Schwarzer, & Taubert, 1999), they prepare, both behaviorally and emotionally. It involves restructuring situations as challenges rather than problems. Coping research typically focuses on work environments. Research is lacking examining how individuals adjust and respond in another very challenging situation—the first semester of college. This research hypothesizes a positive relationship between proactive coping and college adjustment. First year students at two private institutions completed questionnaires in the fall semester. Students (N = 175) completed the Proactive Coping Inventory (PCI; Greenglass et al., 1999), and the College Adjustment Test (CAT; Pennebaker, Colder, & Sharp, 1990) which includes negative affect, optimism, and homesickness subscales. Regression analyses revealed that the more individuals utilized proactive coping, the better their overall college adjustment and the greater their degree of optimism. In addition, more proactive coping predicted less negative affect and homesickness. The following academic year, 301 students completed the PCI and CAT. Results replicated the majority of findings in the previous study, except that proactive coping did not predict homesickness. Proactive coping appears to be important in adjusting to college. Additionally, adjustment predicts academic per-

formance (Hardin & Witcher, 2007). Therefore, proactive coping research should examine whether it can be modeled or taught in order to assist transition into college and eventually work environments.

#### D285

##### **A LENS MODEL OF SELF-INFORMANT AGREEMENT IN LIFE SATISFACTION JUDGMENTS**

Leann Schneider<sup>1</sup>, Ulrich Schimmack<sup>1</sup>; <sup>1</sup>University of Toronto Mississauga – Accurate knowledge about oneself and others is important to set attainable goals and to avoid negative events in the future. Numerous studies have examined accuracy and biases in perceptions of personality traits (e.g., Funder, Kolar, & Blackman, 1995), however, the accuracy of judgments of well-being (life-satisfaction, positive affect, & negative affect) has not been examined as thoroughly. Past studies have found moderate convergence between self and informant ratings of well-being, indicating that well-being measures are at least somewhat valid (Schneider & Schimmack, 2009). The main purpose of this study is to extend this finding by revealing the sources of agreement and disagreement in life satisfaction judgments. A modification of Brunswik's (1959) lens model was used, with the shared variance in self and informant ratings of domain satisfaction acting as cues for self and informant ratings of global life satisfaction. Results showed (a) significant self-informant agreement for global life satisfaction and domain satisfaction, (b) significantly higher convergence for domain satisfaction judgments compared to global life satisfaction judgments, (c) discriminant validity of domain satisfaction judgments, (d) top-down effects of a general satisfaction disposition on domain satisfaction, and (e) self-informant agreement was fully explained by bottom-up effects of family satisfaction, health satisfaction, and academic satisfaction on self and informant judgments of life satisfaction. Implications for the assessment of well-being are discussed.

#### D286

##### **THE PAST, PRESENT, AND FUTURE OF SUBJECTIVE WELL-BEING: TEMPORAL SELF-COMPARISONS FOR LIFE SATISFACTION, POSITIVE AFFECT, AND NEGATIVE AFFECT, AND ASSOCIATIONS WITH POSITIVE FUNCTIONING**

Michael A. Busseri<sup>1</sup>, Becky L. Choma<sup>2</sup>, Stan W. Sadava<sup>1</sup>; <sup>1</sup>Brock University, <sup>2</sup>Wifrid Laurier University – Subjective well-being (SWB) comprises life satisfaction, positive affect, and negative affect (Diener, 1984). Whereas SWB research typically addresses present well-being, comparatively little is known concerning how people evaluate their well-being through subjective time. Temporal self-comparisons convey valuable information not reflected in evaluations of one's present life: Past life satisfaction is typically judged less positively than present, and present life satisfaction is usually rated less positively than the anticipated future; and emerging research suggests that flatter – rather than ascending – subjective trajectories for life satisfaction are associated with positive functioning, consonant with self-consistency (vs. self-enhancement) theories (Keyes, 2000). Expanding on previous research, we examined all three SWB components and tested associations with indicators of functioning. Undergraduates (n = 462, 80% female, Mage = 18 years) rated their past, present, and anticipated future life satisfaction, positive affect, and negative affect, as well as measures of mental, physical, and interpersonal functioning (e.g., depression, physical symptoms, social support). Results demonstrated that ascending subjective trajectories were normative for life satisfaction, positive affect, and negative affect (reverse-scored); these normative ascending subjective trajectories did not differ in shape or slope across SWB components. Within-individuals, steeper ascending trajectories were positively associated among SWB components and flatter, rather than steeper, subjective trajectories were associated with positive mental, physical, and interpersonal functioning. Thus, subjective trajectories for all three SWB components showed coherence and, as predicted by self-consistency theories, positive functioning was associated with the self-theory that one's SWB is relatively stable over time, rather than improving.

#### D287

##### **LACK OF PERCEIVED MEANING IN LIFE AS AN EXISTENTIAL-SPIRITUAL RISK FACTOR FOR ALCOHOL ABUSE: MODERATING EFFECTS OF GENDER**

Phillip Ianni<sup>1</sup>, Kenneth E. Hart<sup>1</sup>, Stephen Hibbard<sup>1</sup>, Michelle Carroll<sup>2</sup>, Aleks Milosevic<sup>1</sup>, Tobi Wilson<sup>1</sup>; <sup>1</sup>University of Windsor, Windsor, Ontario, Canada, <sup>2</sup>McMaster University, Hamilton, Ontario, Canada – Logotherapy (Frankl, 1963) assumes the human need for a sense of purpose and meaning in life (MIL) is more basic than the needs for power or pleasure. This holistic model of human nature also posits the motivation for MIL reflects a universal yearning that has existential-spiritual roots. When this yearning is frustrated, an 'existential vacuum' is thought to occur (i.e. meaninglessness), potentially increasing a person's vulnerability to excessive use of alcohol. In part, susceptibility occurs because intoxication can temporarily dampen 'psycho-spiritual' distress generated by the failure to satisfy the need for meaning. Research linking MIL to alcohol consumption in non-clinical samples has lacked methodological and statistical rigor. In the current study, we: (1) examined males and females separately; (2) used multivariate statistics; (3) controlled for likely confounds. 560 college students completed a 3-item index of meaninglessness ( $\alpha = .66$ ); the AUDIT measure of alcohol abuse; and covariates such as depression (BDI) and social desirability (SD). In females (n = 462) MIL failed to predict residual variance in AUDIT scores after controlling for age, BDI, and SD. Among the 93 males, the R<sup>2</sup> change for MIL was .047 (F = 5.3, p < .05). The Beta was positive. These data are consistent with Logotherapy and provide qualified support for a psycho-spiritual-existential model of alcohol abuse. Relative to females, males may be more prone to heavy drinking as a form of emotion-focused coping for dealing with the unique kind of suffering that occurs when one's life seems empty and lacking in meaning.

#### D288

##### **ON PASSION FOR A CAUSE: WHO CONTRIBUTES TO SOCIETY AND WHY**

Ariane C. St-Louis<sup>1</sup>, Marc-André K. Lafrenière<sup>1</sup>, Robert J. Vallerand<sup>1</sup>; <sup>1</sup>Université du Québec à Montréal – Some people invest an important amount of time and energy in a cause that they love. Their cause somehow even becomes a part of their own identity. Passion has two facets (Vallerand et al., 2003). Individuals can be harmoniously passionate so that they feel free to engage in the activity, which in turn brings positive outcomes in their lives. But they can also be obsessively passionate. In that case, they experience an uncontrollable urge to part take in the activity and some negative consequences derive from this type of passion. In Study 1, we tested a model proposing that intrinsic versus extrinsic values (Kasser & Ryan, 1993) influence the type of passion people develop toward their cause, which in turn predicts their psychological well-being. Participants were 98 men and women who were nominated "Personality of the week" by the La Presse newspaper for contributing to society. Results from Structural Equation Modeling supported the model. Study 2 replicated the previous model with 86 international humanitarian workers. These findings lead to a number of theoretical and applied implications.

#### D289

##### **WRITING ABOUT THE PERCEIVED BENEFITS AND MEANING OF TRAUMATIC LIFE EVENTS: EXAMINING EFFECTS ON POSTTRAUMATIC GROWTH AND PSYCHOLOGICAL WELL-BEING**

Anjali Mishra<sup>1</sup>, Robert Emmons<sup>1</sup>; <sup>1</sup>University of California, Davis – The goal of this study was to examine the effect of gratitude and meaning in life on posttraumatic growth (PTG). PTG is the positive psychological change experienced as a result of the struggle with challenging life circumstances such as trauma, adversity, or loss (Linley & Joseph, 2004; Park & Fenster, 2004; Tedeschi and Calhoun, 1996). It is generally preceded by major challenges to identity and the crumbling of central assumptions related to life meaning (Davis, Wohl, & Verberg, 2007). Both gratitude and meaning in life have been shown to enhance psychological well-being (Emmons & McCullough, 2003; King, Hicks, Krull, & Gaiso, 2006; Steger, Frazier, Oishi, & Kaler, 2006). There is also accumulating evidence for the psy-

chological and physical health benefits of writing about traumatic events (King & Miner, 2000; Pennebaker, 1993). However, there is minimal research examining the contribution of gratitude and meaning in life to posttraumatic growth. Across 3 consecutive days, 211 college students completed a daily online survey including mood measures and a 20 minute writing exercise. The four writing groups were assigned as follows: posttraumatic gratitude group (n=53); posttraumatic meaning group (n=56); trauma-fact group (n=54); and neutral writing group (n=48). The 3-day daily online portion of the study was preceded by a pre-test online survey, followed by a similar post-test and one month follow-up survey. The meaning and gratitude writing groups reported greater psychological well-being, compared to the trauma-fact and neutral groups. Moreover, individuals in the gratitude group reported greater posttraumatic growth compared to the meaning group.

#### D290

**DETERMINANTS AND CONSEQUENCES OF NEGATIVE GAMBLING OUTCOME EXPECTANCIES: DSM SEVERITY, PERCEIVED MODERATION INEFFICACY & READINESS TO CHANGE** Kenneth E Hart<sup>1</sup>, G. Ron Frisch<sup>1</sup>, Tyler Carey<sup>1</sup>; <sup>1</sup>University of Windsor – The present study extended, to the area of gambling, alcohol-related research that has demonstrated the expectation of aversive drinking consequences is a predictor of motivational readiness to cut back or quit drinking in non-clinical samples. We also sought to identify psychosocial and addiction-related factors that might contribute to increased strength of negative gambling outcome expectancies. Using an online questionnaire methodology, we obtained results from a community sample of 71 mostly male adult gamblers (age = 44.3) who were not yet in the 'action' stage of change (ie., 'precontemplators' or 'contemplators'). Using DSM criteria of disordered gambling, 12.7% were considered "at-risk" gamblers; 22.5% were "problem" gamblers and 49.3% were "pathological" gamblers. In an effort to improve on prior assessment of negative expectancies, we developed a psychometrically sound scale that asked respondents to judge the future likelihood of experiencing a wide range of relatively 'serious' adverse consequences of wagering that are both proximal and distal to (continued future) wagering. Given that the 12-item Readiness to Change Questionnaire (RTCQ) contains no items to tap the "preparation" stage of change, we added 4 such items. Thus, our 16-item RTCQ included the entire range of stages as specified by the Transtheoretical model of change. Results showed perceived inability to gamble responsibly (moderation inefficacy) and DSM-defined problem severity each predicted stronger negative gambling outcome expectancies. The later variable, in turn, predicted greater motivation to change as assessed by a gambling-specific version of the 16-item Readiness to Change inventory. Results have implications for theory, research & intervention.

#### D291

**DISTINCTIVE CHARACTERISTICS BETWEEN HEDONIC WELL-BEING AND EUDAIMONIC WELL-BEING** Haesun Hwang<sup>1</sup>, Eunok Suh<sup>1</sup>; <sup>1</sup>Yonsei University – There are two general perspectives on well-being in current psychology: Hedonic perspective which defines well-being as pleasantness and happiness per se, and eudaimonic perspective which defines well-being as self-realization. These two conceptions are measured by SWB(Subjective Well-Being) and PWB(Psychological Well-Being), respectively. Previous research has shown the similarities of these two conceptions of well-being, but little is known about the differences between the two. Thus the present research aimed to make a distinction between them by particularly focusing on hedonic individuals. Hence, the authors calculated RMH(Relatively More Hedonistic) score by subtracting PWB(Psychological Well-Being) score from ITAS (Intensity and Time Affect Survey) score to distinguish relatively more hedonic people from those who are happy in general. In Study 1, the RMH score correlates particularly strongly with positive affects such as "affection", "love", "fondness", and "caring", which can be considered as positive interpersonal emotions. Informant data also showed the similar pattern that they consider hedonic people as feeling these emotions more often, and that hedonic people are thought to be more likeable as well. These results

suggest that one important nature of hedonic happiness is the rewards from positive interpersonal emotions they may get from interpersonal situations. In Study 2, RMH score correlates strongly with on-line reports of "happiness", "pleasantness", and "meaningfulness". Taking the results from Study 1 and Study 2 together, it is notable that hedonically happy people think their lives are more happy, pleasant, and meaningful, and that it is known by others as well.

#### D292

**UNDERSTANDING MONEY'S LIMITS: PEOPLE'S BELIEFS ABOUT THE INCOME-HAPPINESS CORRELATION** Jeremy Cone<sup>1</sup>, Thomas Gilovich<sup>1</sup>; <sup>1</sup>Cornell University – Although it is often claimed that the correlation between income and happiness is considerably weaker than most people expect, few studies have assessed people's beliefs about the relationship. We report two studies designed to fill that gap by assessing people's beliefs about the relationship between income and happiness in two different ways. In Study 1, participants ranked a set of empirical relationships in terms of strength of correlation and we examined whether they tended to rank the relationship between income and happiness where it actually falls in the set. In Study 2, participants estimated the probability that one individual who has a higher income than another is also the happier of the two. Participants' estimates were then compared to the actual probability based on the relationship between income and happiness reported in the literature. The results indicate that people have a very accurate understanding of the relationship between income and happiness – that contrary to what is often claimed in the literature, people do not expect income to be more associated with happiness than it actually is. We reconcile these findings with other recent studies suggesting that people can overestimate the relationship between income and happiness (e.g., Aknin, Norton, & Dunn, in press) by discussing the role of focalism (Wilson et al, 2000) in people's consideration of the impact of changes in their financial state -- as other studies have explored -- rather than people's assessments of the relationship between income and happiness more generally, as we explored in the current studies.

#### D293

**CALIFORNIA'S BAN ON SAME-SEX MARRIAGE: THE PROPOSITION 8 CAMPAIGN AND ITS EFFECTS ON GAY, LESBIAN, AND BISEXUAL INDIVIDUALS** Adam W. Fingerhut<sup>1</sup>, Natalya C. Maisel<sup>2</sup>, Cristina E. Carter<sup>1</sup>, Christina P. Velasco<sup>1</sup>; <sup>1</sup>Loyola Marymount University, <sup>2</sup>University of California, Los Angeles – Voters and legislators are increasingly weighing in on the rights of lesbian, gay and bisexual (LGB) individuals, creating a unique form of minority stress for these sexual minorities (Rostosky, et al., 2009). One way to cope with this stress is to become more involved in the LGB community and anti-gay political campaigns. Qualitative research suggests that this coping strategy can have positive and negative consequences (Levitt, et al., 2009). The current study builds on this previous research using quantitative methods to examine associations between campaign participation and reactions to anti-gay politics. Specifically, LGB Californians (191 men, 163 women) completed an online questionnaire in the days prior to the November 2008 election in order to assess reactions to Proposition 8, California's anti-gay-marriage campaign, and the role of campaign involvement on individual well-being and relationships with close others. Results indicated that thinking about Proposition 8 and its consequences was almost ubiquitous even though involvement was not. Controlling for demographic factors, higher campaign involvement was related to higher levels of both positive and negative amendment-related affect ( $p < .001$ ), as well as higher levels of perceived conflict and support from both friends and the larger heterosexual community ( $p < .05$ , in all cases). Finally, though campaign involvement was unrelated to perceived conflict in one's romantic relationship, it was positively associated with perceived strengthening of the relationship ( $p < .001$ ). The data suggest that campaign involvement may have conflicting repercussions, serving as a coping device but also as a stressor in itself.

**D294****THE AFFECT-REGULATION MECHANISMS OF ACHIEVING PEACE OF MIND: ATTENTIONAL BIAS TOWARD EMOTIONAL STIMULI**

Yi-Chen Lee<sup>1</sup>, Hsuan-Fu Chao<sup>2</sup>, Ching-Lan Huang<sup>3</sup>, Yi-Cheng Lin<sup>1</sup>; <sup>1</sup>National Taiwan University, <sup>2</sup>Chung Yuan Christian University, <sup>3</sup>National Taiwan University of Science and Technology – Our previous work proposed a new construct to describe the peaceful way of obtaining happiness called peace of mind (POM). Different from the affective component of subjective well-being that emphasizes the importance of hedonic pleasure, the construct of POM is defined as the internal state of peacefulness and harmony. The aim of the present research is to investigate possible affect-regulation mechanisms of people with high POM. An emotional flanker task was designed to explore the attentional bias of people with high and low POM toward different affective stimuli. Unlike extraverts are more susceptible to positive mood inductions, it was expected that people with higher POM are neither vigilant toward positive nor negative stimuli. Our findings showed that people with high POM were not distracted by all the to-be-ignored stimuli, and the low POM group was easily distracted by all the to-be-ignored stimuli. In addition, people with high POM showed more interference by the positive stimuli in comparison with negative stimuli, whereas people with low POM showed similar interference by positive, negative, and even neutral stimuli. The present findings provide evidence of the mood-regulation mechanisms of achieving POM and also imply that the affect regulation mechanisms of achieving POM may be associated with having a greater ability to ignore unrelated negative and neutral stimuli while retaining the ability to process positive information.

**D295****THREE GOOD THINGS, HAPPINESS AND SLEEP**

Cory Scherer<sup>1</sup>, Jess Hartnett<sup>2</sup>; <sup>1</sup>Penn State - Schuylkill, <sup>2</sup>Gannon University – The 'Three Good Things' intervention asks participants to write down three good things that happened to them at the end of the day and explain why the event was good. While this task is frequently used in the positive psychology literature and has been shown to increase happiness and decreased symptoms of depression in participants (see Seligman, Steen, Park, & Peterson, 2005, for review), no clear explanation for the mechanisms behind this mood improvement have been empirically tested. The present studies sought to better understand such mechanisms by exploring 1) the possibility that the task leads to a general increase in subject well being (when compared to a filler task) and 2) that this task leads to better sleep, thus increasing positive mood (Peterson, 2006). In study 1, 80 participants either completed the Three Good Things task or a neutral task. As hypothesized, the three good things task leads to high levels of happiness ( $t(79) = -2.996, p < .001$ ). In study 2, thirty-six participants completed the Three Good Things task every night for twelve nights. An analysis was completed to compare reported sleep quality for participants completing the Three Good Things exercise over the course of twelve days. As hypothesized, paired t-tests found a significant difference ( $t(35) = -3.84, p < .001$ ) in the quality of sleep on the first day of the exercise ( $M = 4.40, SD = 1.21$ ) versus the last day of the exercise ( $M = 5.63, SD = 1.28$ ).

# Poster Session E

Saturday, January 30, 8:00 – 9:30 am, Grande Ballroom

## Assessment

### E1

#### **VALIDATION OF THE MULTI-CONTEXT PROBLEMS CHECKLIST IN A YOUNG ADULT SAMPLE** Michael Boudreaux<sup>1</sup>, Nicholas Stauner<sup>1</sup>, Daniel Ozer<sup>1</sup>; <sup>1</sup>University of California, Riverside

This study examined the psychometric properties of the Multi-Context Problems Checklist (MCPC). The MCPC assesses three broad domains of functioning, tapping into the interpersonal (social, intimate relationships), intrapersonal (thoughts and feelings, attitudes about self), and vocational (work adjustment and environment, performance) problems young adults report experiencing. We administered the scale to 227 young adults and collected data on these participants' personality traits and subjective well-being. The participants endorsed, on average, 30 (SD = 16.4) of 128 items, a 23% endorsement rate. Both frequently and infrequently endorsed items on each subscale were examined. For example, in the "Social" category, 55% of respondents endorsed the problem "being too concerned by what others think," while only 8% reported "being insensitive to social rules and customs." The item content was designed to capture personality-related problems in living and should show relations to personality trait dispositions. Thus, total problems endorsed related strongly and positively to Neuroticism ( $r = .58$ ) and negatively to Extraversion ( $r = -.16$ ), Agreeableness ( $r = -.32$ ), and Conscientiousness ( $r = -.29$ ). Those participants reporting greater problems also reported experiencing negative emotions ( $r = .38$ ) and lower life satisfaction ( $r = -.24$ ). Finally, it was shown that the MCPC predicted these life outcomes, even after controlling for the predictive effects of negative life events. The MCPC proved to have good psychometric properties and warrants attention as a brief psychosocial measure of adaptation.

### E2

#### **DETECTING IMPLICIT PEDOPHILIC PREFERENCES: IMPROVING PREDICTABILITY** Matthijs van Leeuwen<sup>1</sup>, Rick B. van Baaren<sup>1</sup>, Farid Chakhssi<sup>2,3</sup>, Marijke Loonen<sup>1</sup>, Maarten Lippman<sup>1</sup>, Ap Dijksterhuis<sup>1</sup>; <sup>1</sup>Radboud University Nijmegen, <sup>2</sup>Forensic Psychiatric Centre 'de Rooyse Wissel', <sup>3</sup>Maastricht University

Sexual offences are among the crimes that evoke the most public concern, and among these, particularly offences committed by pedophiles. However, assessing pedophilic deviance has been a challenging task. Recently, implicit measures have shown promising results close or equal to many currently used methods like questionnaires or phallometry, but until now the predictive ability of these implicit tasks has not yet risen above the traditional methods. Furthermore, while it has been shown that implicit sexual associations differ between incarcerated pedophiles and incarcerated non-pedophiles, the present research looks at non-incarcerated pedophiles. 20 male self-reported pedophiles and 20 male self-reported heterosexual controls matched on age and education were tested with two implicit measures (Implicit Association Task and the Picture Association Task). Our results show that the combination of two implicit tasks using non-explicit visual stimuli produce the strongest results reported to date in predicting implicit pedophilic preferences (AUC = .97). While replication and further probing into the specificity of implicit measures in detecting sexual preferences is recommendable, these results show promise for potential use in settings where screening of participants' pedophilic associations is desirable.

#### **THE DESIRABILITY, THE MEAN, AND THE STANDARD DEVIATION** Jessica Wortman<sup>1</sup>, Dustin Wood<sup>1</sup>; <sup>1</sup>Wake Forest University

Although personality psychology is the study of individual differences, there has been little focus on whether and why some traits vary more than others. In the

current study, we show that a trait's standard deviation is associated with important properties of the trait, including temporal stability and level of self-other and other-other agreement. We attempt to determine why some traits vary more than others. A sample of students rated their personalities on two occasions and the personalities of others on their dormitory hall. Using this data, we demonstrate that items with very low or high means vary less than others due to ceiling or floor effects. However, after correcting for these effects, differences in variability remain. For instance, a trait's level of variability could be predicted from the level of individual differences in the trait's desirability (i.e., items varied more when they were found desirable by some people and undesirable by others, such as religiosity). In addition, items with higher variability included those that were more visible (e.g., organized, messy). Items with lower variability included those that were mood-related (e.g., cheerful, crabby), abstract (e.g., extraordinary) or that have little variability in social desirability. This study demonstrates that there are differences in how much personality traits vary across people, which has important implications for traits' self-other and other-other agreement and stability. Our findings suggest trait differences in variability are meaningful; although they are partially caused by statistical artifacts, they are also caused by more meaningful differences in the properties of traits.

#### **ASSESSING DEPENDENCY USING SELF-REPORT AND INDIRECT MEANS: EXAMINING THE SIGNIFICANCE OF DISCREPANCIES** Alex Cogswell<sup>1</sup>, Lauren B. Alloy<sup>2</sup>, Andrew Karpinski<sup>2</sup>, David Grant<sup>2</sup>; <sup>1</sup>University at Buffalo, <sup>2</sup>Temple University

Proponents of self-report and projective assessment have approached the assessment of interpersonal dependency quite differently, in ways that are recently becoming more aligned. The present study aimed to address the increasing convergence between the two sides, administering both self-report measures and a newly developed implicit measure of dependency in an attempt to characterize more precisely the relations between these seemingly disparate approaches. The study was successful in validating the implicit measure using criteria proposed by two independent groups. The implicit measure was found to be reliable, orthogonal to two self-report dependency instruments, and predictive of external criteria such as other personality constructs and past depression. This study also provided an examination of dissociations between participants' scores on self-report and implicit measures of dependency, and has implications for the significance of such dissociations. That is, the possibility that dissociations themselves are pathological was not supported, and it was found that dissociations between self-report and implicit dependency scores were associated with different patterns of responding on the Personality Assessment Inventory, a broadband instrument. Finally, the present study offered additional evidence for the relation between dependency and depressive symptomatology, and further identified implicit dependency as contributing unique variance in the prediction of past major depressive episodes.

### E5

#### **EXAMINING CONVERGENT AND DISCRIMINANT VALIDITY BEYOND A GENERAL FACTOR OF EMOTIONAL EXPRESSIVITY** John Humrichouse<sup>1</sup>, David Watson<sup>1</sup>; <sup>1</sup>University of Iowa

Emotional expressivity is the tendency (i.e., trait level) to express one's affective states through nonverbal means. As part of the Couples Assessment Project, 202 newlywed couples completed self- and spouse-ratings of the Berkeley Expressivity Questionnaire (Gross & John, 1995). Newlywed couples achieved significant levels of agreement while demonstrating low levels of similarity and assumed similarity. Self- and spouse-ratings were examined within a Multitrait-multimethod matrix (Campbell & Fiske, 1959) allowing for

simultaneous tests of convergent and discriminant validity at the lower-order level of emotional expressivity. In a recent meta-analysis (Riggio & Riggio, 2002), the relation between emotional expressivity and extraversion was  $r = .39$ ,  $p < .01$  and the relation between emotional expressivity and neuroticism was  $r = -.01$ ; however, emotional expressivity was assessed as a general factor. In the current study, relations between emotional expressivity, the Big 5 and trait affectivity reveal differential relations of positive and negative expressivity, such that positive expressivity is related to extraversion and positive affect and negative expressivity is related to neuroticism and negative affect. Furthermore, hierarchical regressions demonstrate the incremental predictive validity of positive and negative expressivity, beyond positive and negative affect, in predicting extraversion and neuroticism, respectively. Whereas extraversion and neuroticism both have an experiential component, such that extraversion is strongly related to positive affect and neuroticism is strongly related to negative affect, they also both have an expressive component. These analyses highlight the importance of assessing emotional expressivity beyond a general factor.

#### E6

**ELIMINATING EVALUATION FROM SELF-REPORT ASSESSMENT: DEVELOPMENT OF THE BALANCED RESPONSE FORMAT** Erin Horn<sup>1</sup>, Eric Turkheimer<sup>1</sup>, Derek Ford<sup>1</sup>, Erik Pettersson<sup>1</sup>; <sup>1</sup>University of Virginia – Self-report personality inventories are confounded with evaluation. Past efforts to control for this confound have involved attempting to write items with neutral evaluative valence or controlling for evaluation statistically. Although these approaches have met with some success, they present problems of their own. The current investigation introduces a novel way to eliminate evaluation. We constructed items that corresponded to bipolar dimensions with lexically opposite, negatively valenced anchors at the extremes, positively valenced, lexically opposite anchors closer to the center, and a neutral point at the center. A typical trait dimension included pathological representations of a trait at the extremes and normative representations as inner guidelines: I am sometimes suspicious and paranoid with others; I am sometimes skeptical of other's intentions; I am average on this trait; I think people are generally trustworthy; My trust in others sometimes leaves me open to manipulation. The trait dimensions were based on 50 bipolar scales representing the FFM (Goldberg, 1992) and the 77 DSM-IV personality disorder criteria. 370 participants rated themselves on 127 trait dimensions by dragging a slider bar cursor to a location that best represented their trait level. Factor analysis of the ratings demonstrated that five dimensions adequately described the structure of the data and generally corresponded to the Big Five. However, these dimensions differed from those of the Big Five in that they contained negative and positive traits at both poles, and as such were uncorrelated with evaluation. It is concluded that presenting traits on bipolar continua effectively controls for evaluation.

#### E7

**DOES SIMPLE RHETORIC WIN DEMOCRATIC ELECTIONS?: THE OBAMA/MCCAIN CASE.** L. Janelle Gornick<sup>1</sup>, Lucian Gideon Conway, III<sup>1</sup>; <sup>1</sup>University of Montana – Research suggests that the integrative complexity of political rhetoric tends to drop as elections occur, but no research to date directly addresses if this drop in complexity serves to increase electoral success. The present research took samples of political rhetoric from the Obama/McCain election, coded those samples for integrative complexity, and then gave them to participants. Dependent measures focused on the amount of influence a particular paragraph had on participants' voting preferences for the two candidates. Contrary to the simple view that the voting populace unilaterally prefers simplicity, analyses across several studies ( $n = 552$ ) provided a more complex picture of the relationship between rhetoric complexity and voting preference. Overall, McCain was more effective in changing voters' preferences in his favor

when he used complex rhetoric, while the reverse was true for Obama. However, this difference between candidates was most strongly in evidence (and statistically significant) only when the paragraph author addressed foreign (as opposed to domestic) policy: For foreign topics, McCain's complexity was positively correlated with an increased likelihood to vote for him ( $r = .47$ ,  $p < .01$ ), while this same pattern did not occur for Obama ( $r = -.02$ ). These results suggest that complex or simple rhetoric may serve a compensatory function: When candidates are viewed by the populace as having a weakness relevant to complexity on a particular topic area (e.g., McCain being too "simple-minded" on foreign policy), using a level of complexity in opposition to that weakness may change voter perceptions of the candidate.

#### E8

**INFORMATION FRAMING AFFECTS PRO-ENVIRONMENTAL DECISIONS** Hsuan-Fu Chao<sup>1,2</sup>, Jen-Ho Chang<sup>3</sup>, Hsiao-Ling Wang<sup>1</sup>; <sup>1</sup>Chung Yuan Christian University, Chung Li, Taiwan, <sup>2</sup>Research Center for Psychological Science, College of Science, Chung Yuan Christian University, Chung Li, Taiwan, <sup>3</sup>National Taiwan University, Taipei, Taiwan – Energy conservation and carbon emission reduction are vital for human future. Development of new technology is one solution for this issue; however, changes in human attitudes and behaviors are important as well. In this study, we employed information framing using different aspects to examine their persuasive effects on people's intention of conserving energy. The results of our study show that framing information can influence people's intentions. First, people were more willing to turn off the power when their attention was drawn to the electricity consumption charges or the consumption of energy resources than to the emission of carbon dioxide in electricity usage. Second, when the consumption charges were emphasized, people were more reluctant to cut down on the electricity usage when they were not responsible for the consumption charges than when they were. Third, people were more willing to reduce the electricity consumption when it was emphasized that they were contributing to the emission of carbon dioxide. In addition, we show that when the emission of carbon dioxide was emphasized, people with higher altruistic or biospheric value orientations were more likely to reduce electricity consumption. Our results demonstrate the usefulness of information framing in persuading people into energy conservation and carbon emission reduction.

#### E9

**VALUES AND ATTITUDE CHANGE: VALUE ACCESSIBILITY CAN INCREASE A RELATED ATTITUDE'S RESISTANCE TO CHANGE** Kevin Blankenship<sup>1</sup>, Duane Wegener, Renee Murray; <sup>1</sup>Iowa State University, <sup>2</sup>Purdue University, <sup>3</sup>Iowa State University – Attitude theorists have long been interested in attitude strength, a property of attitudes that has implications for how attitudes influence peoples' reactions to the world around them. Strong attitudes have a lasting impact in that they persist over time, resist change when attacked, and influence future thinking and behavior. One structural component of attitude strength, namely accessibility (i.e., the link between an object and its evaluation), may also have implications for attitude strength in inter-attitudinal contexts. Activated evaluations have been shown to increase the accessibility of related attitudes (Judd & Krosnick, 1989). The current research examined whether increasing the accessibility of values (favorable attitudes toward abstract concepts) can increase the strength of specific attitudes related to the values. In Study 1, value accessibility was measured by calculating how quickly participants reported their attitudes toward equality on three semantic differential scales (e.g., bad/good, etc). Afterward, participants read a proposal favoring the elimination of all affirmative action policies on campus, then reported their attitudes toward affirmative action and their willingness to vote against the proposal. Greater accessibility of the value of equality led to more resistant attitudes toward affirmative action and greater willingness to vote against the proposal. A follow-up study manipulated value accessibility and measured counterarguing of the anti-affirmative-action message. This study replicated the resistance

and voting intention results of Study 1. Higher value accessibility also led to greater counterarguing, which mediated value accessibility effects on resistance to the attacking message.

### E10

**RESISTANCE AND SUSCEPTIBILITY TO PERSUASION ACROSS THE IDEOLOGICAL SPECTRUM** Margarita Krochik<sup>1</sup>, Tina H. Schweizer<sup>1</sup>, John T. Jost<sup>1</sup>, Brian A. Nosek<sup>2</sup>; <sup>1</sup>New York University, <sup>2</sup>University of Virginia – The present study examined explicit attitude change in response to implicit and explicit persuasion among liberals and conservatives in order to assess the dynamics of the epistemic motives associated with political ideology. Recent research suggests that liberals and conservatives differ in terms of their meta-cognitions, with liberals exhibiting greater ambivalence and elaboration and conservatives reporting greater certainty, stability, and implicit-explicit attitude correspondence. Drawing on the Associative-Propositional Evaluation model (Gawronski & Bodenhausen, 2006), we predicted that liberals would be more likely than conservatives to be skeptical of their implicit attitudes (i.e., "gut feelings") and to therefore exhibit self-generated attitude change. Participants took part in a study concerning their thoughts and preferences regarding various foods and beverages. They were influenced either explicitly by strong persuasive arguments or implicitly through the use of a modified evaluative conditioning procedure. In line with predictions, conservatives (a) exhibited greater implicit attitude change in response to implicit than explicit persuasion, and (b) adjusted their explicit self-reports to match their implicit preferences. Liberals, on the other hand, exhibited implicit preferences that reacted against both implicit and explicit persuasion attempts, and exhibited no consistent attitude change explicitly. Findings are interpreted in light of the motivated social cognition approach to political ideology as it pertains to reflexive vs. reflective processes of attitude formation, change, and maintenance.

### E11

**WHEN ATTITUDES LEAD TO GROUP DEFENSIVENESS: THE ROLE OF ATTITUDE UNCERTAINTY IN RESPONSE TO INGROUP THREAT** Austin Chapman<sup>1</sup>, Joshua Clarkson<sup>2</sup>, Eliot Smith<sup>1</sup>, Zakary Tormala<sup>3</sup>; <sup>1</sup>Indiana University, <sup>2</sup>University of Florida, <sup>3</sup>Stanford University – Previous research has shown that attitude uncertainty can motivate identification with a group that is relevant to the attitude issue (Chapman, Clarkson, Smith, & Tormala, 2009). Interestingly, this work suggests that - if attitude uncertainty motivates group identification - then attitude uncertainty should indirectly induce group-level consequences. The current research explored whether those who were made to feel uncertain about an attitude would subsequently identify with an attitude-relevant group (i.e., a group that supplies normative information about the attitude) and, consequently, display heightened sensitivity to threat directed at the group. Seventy-three participants were made to feel either certain or uncertain of their attitude toward a new university-wide policy requiring identification cards to access campus buildings. Immediately following the attitude (un)certainly manipulation, participants reported their identification with a group pretested to be either attitudinally relevant (Indiana University students) or irrelevant (environmentally-concerned individuals) prior to responding to different scenarios involving Indiana University students. As in the Chapman et al. work, group identification significantly increased for uncertain individuals presented with the relevant group (relative to other conditions). Furthermore, these individuals demonstrated a significant bias in allocation of financial resources toward the relevant group (Indiana University) and a greater willingness to physically confront a person who verbally derided the group. These findings reveal that heightened uncertainty in an attitude (even one as non-controversial as a bureaucratic university policy) can induce serious (and potentially dangerous) aversive reactions against threats directed at the ingroup.

### E12

**META- AND STRUCTURAL BASES DIFFERENTIALLY PREDICT SELECTIVE PROCESSING** Ya Hui Michelle See<sup>1</sup>, Richard Petty<sup>2</sup>, Leandre Fabrigar<sup>3</sup>; <sup>1</sup>National University of Singapore, <sup>2</sup>Ohio State University, <sup>3</sup>Queen's University – In recent research (See, Petty, & Fabrigar, 2008), individuals' affective or cognitive meta-bases (i.e. subjective perceptions of reliance on affect or cognition in attitudes) were demonstrated to be independent of their structural bases (i.e. objective indicators of the extent to which affect or cognition is closer to overall attitude). Furthermore, meta- and structural bases accounted for unique variances in persuasion. To examine potential differences in how meta- and structural bases influence attitudes, we compared how the two variables predict time spent on reading affective and cognitive information. Participants reported their meta-bases by indicating the extent to which they thought their attitudes were driven by affect and cognition across five objects (See et al., 2008). Structural bases were assessed by examining how well affect and cognition measures actually related to attitudes across the five objects (Huskinson & Haddock, 2004). Participants then received affective and cognitive information about a fictitious animal (Crites, Fabrigar, & Petty, 1994). As expected, meta- and structural bases related in opposite ways to the proportion of time spent reading affective information. Regardless of whether participants received negative or positive information, more affective meta-bases were associated with relatively more time spent on affective than cognitive information. In contrast, more affective structural bases were associated with relatively less time spent on affective than cognitive information. These findings provide initial evidence that meta-bases influence attitude change by impacting the motivation to selectively process information whereas structural bases do so by impacting the ability to efficiently process the selected information.

### E13

**EFFECTIVENESS OF WORD OF MOUTH MARKETING** Clancie M. Maze<sup>1</sup>, Jenna L. Baddeley<sup>1</sup>, James W. Pennebaker<sup>1</sup>; <sup>1</sup>The University of Texas at Austin – Consumers talking about brands is free publicity. It would be valuable for marketers to know the characteristics of the people they are trying to reach with their products. How often do people use brand names in everyday life? What brands do they talk about? Are people's personalities, mental health, and age related to how often people talk about brand names and what kinds of brand names they talk about? Fifty-two participants (15 males, 37 females; 26 currently depressed, 26 controls) wore a recording device, which recorded 12% of ambient sounds, for two to four consecutive days. Transcripts were coded for brand names and brand names were divided into 14 categories. We looked at personality traits, demographics, and depression to find any differences in the frequency and category of mentioned brand names. Participants higher in extraversion talked more about big box stores (i.e. Wal-mart, Best Buy, etc.). Those higher in agreeableness and emotional stability talked more about restaurants. Participants with higher agreeableness scores also talked more about household items, such as cleaning products, and participants higher in emotional stability talked more about toys. The average age was higher for participants that talked about medical brands and household items and lower for participants that talked about restaurants. Depression also played a factor in discussion of brands; those with current depression talked less about big box stores, restaurants, technological brands and financial institutions. This suggests that personality, age, and mental health are related to people's attention to and verbal transmission of brand names.

### E14

**POLITICAL IDEOLOGY DETERMINES PREFERENCES FOR RHETORICAL STYLE** Hulda Thorisdottir<sup>1</sup>; <sup>1</sup>University of Iceland – People who self identify as politically conservative also report having a higher need for closure and less tolerance for ambiguity as compared to self-identified liberals. It is argued that this difference in cognitive preferences is reflected in the typical policies and political stances endorsed by those groups. Conservative political views are typically characterized by cer-

tainty and clarity - both in content and rhetoric - to a larger extent than liberal political views. If true, this should transfer to a preference for a rhetorical style more generally. It was hypothesized that political conservatives would prefer a particular stance or policy more than liberals if written using a rhetorical style characterized by certainty, whereas the reverse would be true for uncertain rhetorical style. Importantly, it was hypothesized that the actual content of the policy could be rendered irrelevant and that support for a policy could be garnered solely based on its style. Two experiments conducted among the general public confirmed the hypothesis. Study 1 (N = 64) shows that when a policy regarding the importance of fighting global warming was stated with certainty and confidence, it appealed to conservatives but when the language expressed less confidence and more uncertainty liberals supported it more. In Study 2 (N = 60) the findings from Study 1 were replicated using the entirely non-political issue of vitamin intake. Combined, these studies show how rhetorical style may be used as a proxy by people of both ideological leanings to determine whether to support a policy or not.

### E15

**THE CRISIS, THE NEED FOR STRUCTURE, AND CONSUMER CHOICE: BACK TO THE PAST** Diederik Stapel<sup>1</sup>, Rob Nelissen<sup>1</sup>, Erik Burgman<sup>1</sup>, Janne van doorn<sup>1</sup>, Maartje Elshout<sup>1</sup>, Suzan Elshout<sup>1</sup>, Roxanne van Giesen<sup>1</sup>, Loretta Groothof<sup>1</sup>, Femke Hilverda<sup>1</sup>, Maartje Meijers<sup>1</sup>, Lieke Nefs<sup>1</sup>, Job van wolferen<sup>1</sup>; <sup>1</sup>Tilburg University, The Netherlands – We live in uncertain times. Major financial institutions are falling down, factories are closing, and many people are losing their jobs. What are the consequences of all this for people's mental lives and the economic choices they make? In four studies, we test the hypothesis that the current economic crisis increases the need for structure and thus the preference for consumer products that (subtly) signal "tradition" and "old times." In study 1, we show that respondents who had read a newspaper article about the current economic crisis scored higher on a need for structure measure (i.e. Thompson et al., 1989) than respondents who read a no-crisis or neutral newspaper article. In Study 2, we show that priming the crisis leads to a higher endorsement of conservative, traditional values (e.g., pro-religion, anti-drugs, anti-feminism) than when the crisis is not activated. In Studies 3 and 4, we investigate the implications of these effects for consumer choice. In Study 3, we show that priming the crisis increases the preference for retro-products over modern-products. Thus, when the crisis is on people's mind, people prefer "Mary Poppins" over "High School Musical" and an old version of Trivial Pursuit over Trivial Pursuit for the Wii. In Study 4, we show that when the crisis is primed, consumers prefer a tea product that is advertised as "traditional" over tea that is advertised as "new." The reverse is true when the crisis is not primed.

### E16

**ME NOW, OTHERS LATER: PERSPECTIVE-FIT EFFECTS ON SUSTAINABILITY** Marijn H. C. Meijers<sup>1</sup>, Diederik A. Stapel<sup>1</sup>; <sup>1</sup>Tilburg Institute for Behavioral Economics Research, Tilburg University – Sustainability is a hot topic: Our planet is heating up and falling apart and we all know we need to take action. Nevertheless, although everybody knows how important it is, not everybody behaves in a sustainable manner. One prevailing idea in the relevant literature is that to increase sustainability behavior people should focus on the long term, on "later". In two studies, we argue and demonstrate that such an abstract long term time perspective (a focus on "later" rather than "now") is only effective when it is combined with a similarly abstract person perspective (a focus on "others" rather than on "me") because then there is a fit between these two perspectives. Research shows that perspective-fit elevates feelings of perceived behavioral success. These feelings of perceived behavioral success are vital to behaving sustainable because only when people feel that their sustainable actions will actually contribute to a sustainable world, they will engage in such actions. The results of our studies indeed clearly suggest that when there is a fit between time and person perspectives (now-me, later-others), feelings of action effectiveness are relatively high and sustainability effects are relatively more likely than when there is

misfit (later-me, now-others). We show these effects on attitude measures and on actual choice behavior (the likelihood that people choose "organic" labeled chocolate over normal chocolate). The effects on attitudes and choice behavior are perfectly mediated by feelings of action effectiveness. Implications on construal level and attitude change theories will be discussed.

### E17

**ON THE WORKINGS AND LIMITS OF SUBLIMINAL ADVERTISING: THE ROLE OF HABITS** Thijs Verwijmeren<sup>1</sup>, Johan Karremans<sup>1</sup>, Wolfgang Stroebe<sup>2</sup>, Daniël Wigboldus<sup>1</sup>; <sup>1</sup>Radboud University Nijmegen, <sup>2</sup>Utrecht University – Recently, the debate concerning the effectiveness of subliminal advertising has been revived. Two lines of research demonstrated that subliminally priming a brand can affect consumer choices, but only when the primed brand is relevant to an active goal of the recipient (Karremans, Stroebe, & Claus, 2006; Bermeitinger, Goetz, John, Neumann, Ecker, & Doerr, 2009). For example, subliminal priming of a brand of beverage positively affects choice for this brand, but only among thirsty participants. Building on this work, in the present research, we further explored when subliminal advertising may or may not be effective. Specifically, we reasoned that subliminal advertising may only be feasible when the primed brand is not a habitual choice for the recipient of the prime. The present study demonstrated that subliminal priming with a brand of beverage positively affected choice for that brand, but as in previous work, only when participants were already thirsty. Most importantly, in line with predictions, this effect was only obtained for participants for whom the primed brand was not their habitual choice of beverage. In contrast, participants for whom the brand is their habitual choice in daily life chose the brand when given the choice, irrespective of being primed or not. These findings extend previous research, gaining insight into the workings and limits of subliminal advertising. Interestingly, these findings may also explain why previous studies failed to obtain effects of subliminal advertising on consumer choices, as many previous studies used brands that are often habitual choices for people (e.g., Coca Cola).

### E18

**PRODUCT EVALUATION: THE ROLES OF REGULATORY FOCUS AND EMOTIONAL LANGUAGE** Graham G Scott<sup>1</sup>, Patrick J O'Donnell<sup>2</sup>, Sara C Sereno<sup>2</sup>; <sup>1</sup>University of Aberdeen, <sup>2</sup>University of Glasgow – This study investigated whether the evaluation of a positive or negative product (here a car), is affected by the valence of the language describing it. E.g., acceleration might be described as 'fierce', implying good, although the word itself has negative valence. We also sought to establish whether promotion- or prevention-focus (Higgins, 1997) in the implied customer interacted with message- and word-valence in determining whether participants recommended the car to the prospective user. A 2 (product: positive, negative) x 2 (language: positive, negative) design was employed: participants read 4 car reviews, rated each product on a series of semantic-differentials and recommend it to a prevention-focused and promotion-focused individual. Prevention-focused recommendations showed main effects of both product and language (both positive > negative). Promotion-focused recommendation showed a product x language interaction: positive products were always recommended higher; language did not impact negative products, positive products reviewed using negative language were recommended higher than those described using positive language. Similar results were reported in semantic-differential ratings for specific aspects of the products; those relating to promotion-focused (e.g., slow-fast) or prevention-focused (e.g., wasteful-efficient) aspects of the cars conformed to the same patterns reported above. It is proposed that when dealing with prevention-focused concerns, individuals take language at face value, processing negative language as another negative aspect of the item at hand. Promotion focus alters processing style so that individuals are more likely to integrate the positive meaning from words in context (e.g., the brutal engine) and this can further heighten their attitude to a product.

**E19****PREDICTING BEHAVIOUR FROM AFFECTIVE VERSUS COGNITIVE ATTITUDES: SITUATIONAL AND STRATEGIC DETERMINANTS** Paschal

Sheeran<sup>1</sup>, Thomas L. Webb<sup>1</sup>; <sup>1</sup>University of Sheffield – Adaptive behavior often requires that action is guided by thoughts rather than feelings. For example, although excessive alcohol consumption may be enjoyable (i.e., characterised by positive affective attitudes), it is also detrimental to health (i.e., negative cognitive attitudes). Previous research has focused on personality factors (e.g., need for cognition) or the type of behavior as determinants of the relative weight attached to cognitive versus affective attitudes in predicting behavior. Two experiments examined whether situational or strategic factors might also influence the predictive validity of these attitude components. In Experiment 1 participants were primed with the goal to think, the goal to feel, or a neutral prime, and subsequently completed measures of affective attitudes, cognitive attitudes, and intentions regarding 22 behaviors. Findings showed that affective attitudes better predicted intentions than did cognitive attitudes in the feel prime and control conditions. However, cognitive attitudes were just as good at predicting intentions as were affective attitudes in the think prime condition. In Experiment 2, participants formed if-then plans (implementation intentions; Gollwitzer, 1999) geared at downgrading the informational value of feelings. We then tested how well affective and cognitive attitudes predicted subsequent behavior. Findings showed that forming implementation intentions enhanced the influence of cognitive attitudes on subsequent frequency of drunkenness and reduced the influence of affective attitudes. Taken together these findings indicate that situations can exert an automatic effect and if-then plans can exert a strategic effect on the weight attached to affective versus cognitive attitudes in predicting behavior.

**E20****EXPLICIT AND IMPLICIT GROUP AND CANDIDATE ATTITUDES IN A REPRESENTATIVE SAMPLE DURING THE 2008 ELECTION** Christopher

Dial<sup>1</sup>, Shanto Iyengar<sup>2</sup>, Kyu Hahn<sup>3</sup>, Mahzarin Banaji<sup>1</sup>; <sup>1</sup>Harvard University, <sup>2</sup>Stanford University, <sup>3</sup>Yonsei University – In October 2008 a nationally representative sample of registered voters (N = 1100; www.polimetrix.com) completed measures of explicit and implicit attitudes toward two pairs of stimuli: social groups (black and white), and highly visible political candidates (Obama and McCain), each a member of these racial groups. Race and candidate tests at Project Implicit's website (implicit.harvard.edu) have drawn over 10 million participants, but suffered from the limitation of an entirely self-selected sample. The present data are the first comparison of a drop-in sample of 643,785 (Nosek, et al., 2009) and the more representative sample from this study. Interestingly, pro-white IAT bias in both samples show similar effect sizes: representative sample  $d = .969$ ; self-selected sample  $d = .868$ . The expected dissociation between explicit and implicit race attitudes was obtained, and analyses revealed three groups particularly prone to underreport white preference: white respondents, those more educated, and Democrats. Positive correlations between group and candidate measures (IAT  $r = .27^{**}$ ; explicit  $r = .33^{**}$ ) showed that stronger preference for the racial group predicted stronger preference for the candidate from that group. Results also revealed far weaker correlation between explicit-implicit racial group attitudes ( $r = .25^{**}$ ) relative to the same participants' correlation between explicit-implicit candidate preference ( $r = .68^{**}$ ). These results (a) give confidence in the generalizability of the data from Project Implicit's website, (b) demonstrate small but significant association between group race bias and candidate preference, and (c) suggest stronger disparity between explicit-implicit attitudes at the group rather than the person level.

**E21****THE EFFECT OF IMPLICIT THEORIES OF JUDGMENT ON ATTITUDES AND EVALUATION** Clifford D. Evans<sup>1</sup>, Amanda B. Diekmann<sup>1</sup>; <sup>1</sup>Miami

University – Extensive research has demonstrated outcome differences between judgments based on feelings and judgments based on reasons (e.g., Gasper & Clore, 2000). However, research examining feelings or reasons as a source of evaluative information has to date relied primarily on contextual manipulation. Insofar as evaluation and judgment are common processes, it is likely that dispositional differences in how evaluations and judgments are made also exist. These differences may manifest themselves as implicit theories of judgment - common-sense assumptions about sources of evaluative information. The purpose of the current research is to examine how implicit theories of judgment moderate sensitivity to implicit and explicit evaluative information, and their relationship to judgment via implicit and explicit attitudes. Participants completed a measure of dispositional endorsement of feelings or reasons-based judgment, and then received opposed-valence subliminal and supraliminal information about a target. Subsequent to the evaluative conditioning task, participants completed measures of implicit evaluation, explicit evaluation, and judgment. Participants who received positive supraliminal information about the target made more positive explicit evaluations and judgments than participants who learned the opposite, across endorsed theories of judgment. However, the endorsed theory of judgment moderated a strong effect of supraliminal information on implicit evaluations. Implicit evaluations were influenced by supraliminal information in directions consistent with explicit evaluation, but only for feelings-based theorists. Implicit and explicit attitudes correlated with each other and with judgment for feelings-based theorists. For reasons-based theorists, implicit and explicit attitudes were uncorrelated and only explicit attitudes correlated with judgment.

**E22****WHY DO PEOPLE EXPRESS AMBIVALENT ATTITUDES? THE INFLUENCE OF EXPOSURE TO CONFLICTING MESSAGES AND THE OPPORTUNITY TO EXPRESS AMBIVALENCE.** Kenji Noguchi<sup>1</sup>; <sup>1</sup>University of Southern

Mississippi – Possessing ambivalent attitudes (i.e., simultaneous positive and negative evaluations of the attitude object) may be uncomfortable, but it can lead to more careful information processing. It is therefore important to study which factors affect the likelihood of experiencing ambivalent attitudes. Two experiments tested the hypothesis that people would be more likely to express ambivalent attitudes after: (1) hearing two sides of an unrelated argument, and (2) having the opportunity to express ambivalence in a previous task. Participants read statements about several attitude objects (e.g., a hotel, a car) that were either one-sided (only positive information about the objects) or two-sided (both positive and negative information). Participants were then asked to evaluate these objects. In one condition, participants could only designate whether they found the objects favorable or unfavorable (i.e., a dichotomous choice). In the other condition, participants were also given the opportunity to express whether they felt ambivalent or indecisive about the objects. After that, in what participants were told was a second, unrelated study, they were asked to indicate their subjective ambivalence (e.g., how much conflict they felt) toward seven new objects (e.g., politicians). The data revealed that those who had the chance to express ambivalent attitudes in the first part of the experiment expressed more ambivalence toward the new attitudinal objects. A second experiment replicated these results using a different manipulation of ambivalence expression. Thus, having an opportunity to make ambivalent judgments is an important factor for expressing ambivalence in other situations.

**E23****HIGHLIGHTING FINANCIAL BENEFITS CAN INFLUENCE THE EFFECTIVENESS OF PRO-ENVIRONMENTAL MESSAGES IN PROMOTING BEHAVIORAL INTENTIONS**

Nadia Bashir<sup>1</sup>, Tina Sarkissian<sup>1</sup>, Penelope Lockwood<sup>1</sup>, Dan Dolderman<sup>1</sup>; <sup>1</sup>University of Toronto – Given the potential environmental threats posed by human activity, it is critical to optimize campaigns aimed at promoting pro-environmental behavior. Relative to traditional campaigns, which encourage personal sacrifices to ensure environmental protection, persuasive messages illustrating the benefits of pro-environmental behavior may achieve greater success. For young adults, who typically value financial success strongly, a message highlighting the personal financial benefits of a pro-environmental stance (e.g., greater employment opportunities) may be particularly appealing. We assessed the impact of such a message on young adults' pro-environmental behavioral intentions. Additionally, we compared young adults born in Canada, and those who were new migrants to Canada. Because new migrants typically strive to succeed financially in their new country, they may be especially motivated by pro-environmental messages that highlight economic benefits. Participants were undergraduate students who either were born in Canada or had migrated to Canada. They first read a pro-environmental message that either highlighted the economic relevance of pro-environmental behaviors, particularly the personal benefits, or illustrated the link between human and environmental health without describing financial benefits. Participants then rated their pro-environmental behavioral intentions. Control participants completed the dependent measure without first reading a message. The economic benefits message significantly boosted the pro-environmental motivation of new migrants but not of individuals born in Canada. Because new migrants may have especially strong goals to succeed financially, they may find messages framed in terms of economic benefits to be particularly persuasive. Pro-environmental messages tailored to fit the goals of various social groups may enhance environmental campaigns.

**E24****ON THE FORMATION OF ATTITUDE CERTAINTY: RELIANCE ON INTERNAL VERSUS EXTERNAL INPUTS**

David Dubois<sup>1</sup>, Derek D. Rucker<sup>1</sup>, Richard E. Petty<sup>2</sup>; <sup>1</sup>Northwestern University, <sup>2</sup>Ohio State University – This work investigates how certainty is affected by external (e.g., information coming from outside oneself, such as source expertise or social consensus) versus internal inputs (e.g., information coming from oneself such as perceived self-knowledge or past behavior). Although prior research suggests any source of certainty might increase individuals' certainty, we propose and find that both personality and situational factors lead individuals to differentially form their certainty on external versus internal inputs. In experiment 1, participants completed a purchasing scenario that contained internal or external inputs, and measured their propensity to self-monitor (Snyder, 1974). While attitudes didn't differ, there was a significant certainty information × self-monitoring interaction ( $p < .01$ ): high self-monitors' certainty was significantly greater after they encountered external information signaling certainty compared to internal information signaling certainty, but the reverse was true for low self-monitors. Experiment 2 manipulated individuals' orientation. Participants completed a self-orientation manipulation designed to momentarily focus individuals on themselves or others (Brewer and Gardner 1996) and were then presented with either internal or external information signaling certainty. Although attitudes didn't differ, individuals with a self orientation were more certain after receiving internal information signaling certainty compared to external information signaling certainty, but the reverse was true for individuals with focusing on others ( $p < .01$ ). A similar pattern was found on behavioral intentions and differences in behavioral intentions were mediated by differences in certainty. Taken together, these findings are the first to shed light on the selective use of certainty-related information and its consequences for behavior.

**E25****EXPLORING THE UNDERLYING PSYCHOLOGICAL PROCESSES OF GAMBLING BEHAVIOUR: INDIVIDUAL AND CONTEXTUAL FACTORS**

Elisabeth Whaley<sup>1</sup>, Alex Kay<sup>1</sup>, Rod C.L. Lindsay<sup>1</sup>, Lee R. Fabrigar<sup>1</sup>, Jamal K. Mansour<sup>1</sup>, Michelle I. Bertrand<sup>1</sup>, Natalie Kalmet<sup>1</sup>; <sup>1</sup>Queen's University – Gambling attitudes and personality factors (e.g., impulsive sensation-seeking; ISS) impact gambling and the development and maintenance of pathological gambling. However, we know very little about the social-cognitive processes responsible for these effects. Our project explored whether attitudes and personality shape people's interpretation of information during gambling, and whether these perceptions are in part responsible for the relationship between attitudes, personality, and gambling. Three studies were conducted using a computerized gambling task. The first study (N=150) consisted of 2 time conditions: timed (i.e., spontaneous) and untimed (i.e., deliberative); and 2 bet conditions: good bets and bad bets (both also had ambiguous filler bets). Participants' attitudes, ISS, and perceptions of bets were assessed. Results indicated that people's attitudes and level of ISS impacted their perceptions and subsequent betting on ambiguous bets, and a contrast effect was seen for these bets such that bets were seen more positively in the bad than the good bet condition. The second study (N=150) replicated the first study, only without assessing perceptions. When participants did not reflect on their perceptions, the time condition had an increased influence and interacted with attitudes and ISS to predict betting. The third study (N=140) further explored responses to ambiguous bets by eliminating the contrast effects of the bet condition seen in the first two studies. As with the first study, attitudes and ISS had a positive relationship with perceptions and consequent betting. Overall, the attitude- and personality-gambling relationship was influenced by people's perceptions of bets.

**E26****THE POSITIVITY AND NEGATIVITY OF AMERICAN ICONICITY: HOW HOT AND COOL RESPONSES TOWARDS AMERICAN ICONIC BRANDS CAN BE MANIPULATED.**

Letty Kwan<sup>1</sup>, Chi Yue Chiu<sup>2</sup>, Angela Ka Yee Leung<sup>3</sup>; <sup>1</sup>University of Illinois, Urbana-Champaign, <sup>2</sup>Nanyang Technological University, <sup>3</sup>Singapore Management University – Previous research on globalization concepts indicated that different globalized icons could elicit either positive or negative affect within an individual. However, affective responses towards globalized icons are complicated and could be affected by an individuals' mindset at their current state. Therefore, in this study, we seek to explore whether individuals could show both positive and negative affect towards the same globalized American iconic brand through priming them into different mindsets of globalization. One way to elicit the two mindsets are by priming them with globalized figures. Specifically in our studies, participants were either given the "Bush", the "Obama" or the "neutral"(baseline) prime. Based on current literature and media portrayal, both Bush and Obama are highly globalized figures; yet carry different representations in globalization. In study 1, 90 Caucasian students in US were randomly assigned to one of the three priming conditions. They were then asked to give affective responses towards 7 previously established globalized American iconic brands and 7 globalized non-iconic brands. In study 2 we recruited 90 Mainland Chinese participants in China using the same methodology for cross-cultural comparison. Results indicated that American participants showed significantly higher positive affect for American iconic brand under the Obama prime than Bush and neutral prime. Study 2 results indicated that under Obama prime, American iconic brand received positive affective ratings; while under Bush prime, American iconic brand received negative affective ratings. Our studies have important implications on individuals' hot and cool responses towards American iconicity, which can be manipulated through priming.

**E27**

**CHANGING BEHAVIORS THROUGH ASKING QUESTIONS: CONTRASTING LOOKING FORWARD VERSUS LOOKING BACK.** Kate Min<sup>1</sup>, Tanya Chartrand<sup>1</sup>, Gavan Fitzsimons<sup>1</sup>; <sup>1</sup>Duke University, The Fuqua School of Business – A growing body of research examines the question-behavior effect, in which simply asking people about their intent to engage in a certain behavior leads to an increase in the probability of their subsequently engaging in that behavior (Sherman, 1980). The current research examines whether the effect of asking questions varies as a function of the time frame asked about – either future intentions or past behavior, and how the valence of the behavior interacts with the time frame. In Experiments 1 and 2, consistent with prior work in this domain, participants who were asked a question about their intent to engage in a positive behavior in the future (e.g., eating a tasty and tempting snack) actually consumed more fattening snacks in a subsequent "taste test," while those asked about their intent to engage in a negative behavior (e.g., fatty food consumption) actually consumed less of the subsequently offered fattening snack. When the question time frame was in the past, however, both the negatively framed (e.g., fatty food) and the positively framed question (e.g., tasty snack) led to increases in actual consumption of a fattening snack. In Experiment 3, we find evidence that these changes in actual behavior in response to valence and question time frame are mediated by participants' automatic evaluations of words related to health and indulgence.

**E28**

**I LIKE IT BECAUSE I SAY THAT I LIKE IT. EVALUATIVE CONDITIONING EFFECTS CAN BE BASED ON STIMULUS-RESPONSE LEARNING** Anne Gast<sup>1</sup>, Klaus Rothermund<sup>2</sup>; <sup>1</sup>Universiteit Gent, <sup>2</sup>Friedrich-Schiller-Universität Jena – Evaluative conditioning (EC) effects are typically assumed to be based on a learned association between a neutral stimulus (CS) and a valent stimulus (US). We demonstrate that this association is not necessary and show that evaluative conditioning effects can also be based on a direct link between the CS and an evaluative response – a CS-ER association. In three experiments participants gave evaluative responses during conditioning to allow an association between the neutral stimulus and an evaluative response. In Experiments 1 and 2, CSs were only combined with forced evaluations but with no USs. Due to this, CS-valence changed in the direction of the forced evaluations both on an explicit and on an implicit measure. As no US was present, this valence change must be due to a CS-ER association. In Experiment 3, CSs were paired with USs and participants were asked to evaluate the pairs during the conditioning phase. The resulting valence change of the CSs (EC effect) was unaffected by a later reevaluation of the USs. This demonstrates that also EC effects found after CS-US pairings which participants had to evaluate are due to CS-ER learning. Therefore, EC effects can be based on two different learning mechanisms: Either on the formation of an association between the neutral and a valent stimulus or on the formation of an association between the neutral stimulus and an evaluative response. It will be discussed how the interplay of these different learning mechanisms can explain seemingly contradicting findings in evaluative conditioning research.

**E29**

**DEPENDENCY OF ILLNESS EVALUATION ON THE SOCIAL COMPARISON CONTEXT: FINDINGS WITH IMPLICIT MEASURES OF AFFECTIVE EVALUATION OF ASTHMA** Sibylle Petersen<sup>1</sup>, Thomas Ritz<sup>2</sup>; <sup>1</sup>University of Hamburg, Germany, <sup>2</sup>Southern Methodist University – Background: The affective dimension of illness representation plays an important role in health self-management. However, little is known about the stability of this affective representation across contexts. We explored the role of social comparison in the affective evaluation of asthma. Methods: Participants included 20 individuals reporting an asthma diagnosis and 33 healthy controls. To measure asthma attitudes, we used three different versions of the Implicit Association Test (IAT), a Single Target IAT (ST-IAT) and two IATs with different social comparison standards for

asthma evaluation: (1) HIV as downward social comparison standard and (2) diabetes as comparison standard on a similar level. Reaction times to pair asthma with positive or negative word stimuli in the three IATs were compared in a repeated measure ANOVA. Furthermore, the relationship between affective evaluation, self-reported asthma specific coping, and negative affect was explored. Results: Individuals with asthma showed a stronger negative evaluation of asthma than healthy individuals in the ST-IAT and in the IAT presenting a comparison standard on a similar level (Diabetes). The negative evaluation in the ST-IAT was related to the self-report of dysfunctional coping strategies. However, in the IAT introducing a downward social comparison with HIV, evaluation of asthma was no longer negative and no longer related to the report of dysfunctional coping strategies. Conclusion: Downward social comparison can buffer against negative affective evaluation of asthma. The context dependency of illness-related attitudes, requires attention in future research and health-management practice.

**E30**

**THE INFLUENCES OF MESSAGE FRAMING, DISPOSITIONAL OPTIMISM, AND ISSUE INVOLVEMENT ON PROMOTING CHOLESTEROL SCREENING** Watch Pengchit<sup>1</sup>, <sup>1</sup>Paul H. White – The current study aimed to examine the role of dispositional optimism—an individual difference regarding favorable general expectancies of future outcomes—as a moderator of the effect of message framing on attitudes and intentions to perform detection behavior. In the 2 X 2 design, participants (N=135) were randomly assigned to either a high or low issue involvement condition and either a gain- or loss-framed message condition encouraging cholesterol screening for early detecting of type 2 diabetes. Optimism was measured as the predictor of the attitudes and intention to obtain the screening. In the high involvement condition, optimism predicted less favorable attitudes toward the screening following a gain-framed message. When the issue involvement was low, optimism predicted less interest in obtaining the screening following a loss-framed message. Although loss framing is usually more persuasive in high involvement circumstances or for detection behaviors, the study found that for individuals with low levels of optimism (i.e., pessimists), gain-framing was more persuasive, possibly because it provides reassurance for pessimists who were more likely to expect unfavorable future outcomes.

**E31**

**FUTURE TIME PERSPECTIVE MODERATES THE RELATIONSHIP BETWEEN SENSATION SEEKING AND THE SAFE SEX ATTITUDES OF ROMANTIC COUPLES** Alma Correa<sup>1</sup>, Amber L. Bush<sup>1</sup>, C. Raymond Knee<sup>1</sup>; <sup>1</sup>University of Houston – Studies have consistently found that college students engage in many high-risk behaviors. Therefore, it is important to understand why certain individuals may put themselves at greater risk than others. Previous studies have found that individuals high in sensation seeking are prone to seek out novel, and often dangerous, experiences. Individuals high in sensation seeking engage in more high-risk behaviors such as excessive drinking and unprotected sex (Kalichman & Rompa, 1995). On the other hand, future time perspective orientation (FTP) has been associated with protective health behaviors such as safe sex as these individuals tend to think about the future when engaging in decision-making (Zimbardo & Boyd, 1999). The current study examined the impact of future time perspective orientation and sensation seeking on condom use attitudes. Dyads (N = 71) involved in a romantic relationship completed a written survey including measures of sexual and nonsexual sensation seeking, FTP, and condom attitudes. Multilevel modeling revealed that participants low in either sexual or nonsexual sensation seeking reported greater self-control to use condoms, but only if they were high in FTP. There were no significant differences between those high and low in sexual or nonsexual sensation seeking when participants were low in FTP. A better understanding of the impact of personality traits on safe sex attitudes and sexual decision-making will contribute to the development of more effective health interventions for college students.

**E32****A META-ANALYSIS ON THE IMPACT OF VIVIDNESS ON PERSUASION**

Rosanna E. Guadagno<sup>1</sup>, Bradley M. Okdie<sup>1</sup>, Brad J. Sagarin<sup>2</sup>, Jamie DeCoster<sup>1</sup>, Kelton v. I. Rhoads<sup>3</sup>; <sup>1</sup>University of Alabama, <sup>2</sup>Northern Illinois University, <sup>3</sup>University of Southern California – The social psychological research on vividness has demonstrated a remarkable lack of consistency regarding the impact of vividness on persuasion (Collins, Taylor, Wood, & Thompson, 1998; Taylor & Thompson, 1982). Guadagno, Rhoads, and Sagarin (2009) hypothesized that this inconsistency was due to ambiguity regarding the vivid object. In two experiments, they demonstrated that figural vividness (i.e., where the persuasion-relevant object is vivid) leads to greater persuasion whereas ground vividness (i.e., where irrelevant objects are vivid) leads to less persuasion. We tested this hypothesis meta-analytically by examining the object(s) made vivid and calculating effect sizes of vivid vs. pallid persuasive communications using figural vividness as a continuous measure. Across all 63 effect sizes, there is a significant effect of vividness on persuasion,  $g^* = 0.175$ ,  $p < .001$ . We next examined whether figural vividness moderates the effect of vividness on persuasion by performing a meta-regression with the continuous measure of figural vividness (ranging from 1 = "totally vivid figure" to 9 = "totally vivid ground") on our effect size measures. We found that the impact of figural vividness interacted with the type of dependent measure. Specifically, figural vividness was a significant predictor of the relationship between vividness and persuasion when attitudes,  $g^* = 0.125$ ,  $p < .001$ , or behavior,  $g^* = 0.472$ ,  $p < .01$ , were assessed but not when beliefs, behavioral intentions, and juror decisions were the dependent measures. Thus, our results support the predictions with an interesting caveat: the type of dependent measure matters.

**E33****WHEN ATTITUDINAL AMBIVALENCE MEETS RESISTANCE TO PERSUASION: THE ROLES OF ATTITUDE CORRECTNESS AND ATTITUDE PERSISTENCE**

John Stutzer<sup>1</sup>, John Petrocelli<sup>1</sup>, <sup>1</sup>Wake Forest University – Strong, as opposed to weak, attitudes are associated with greater attitude behavior consistency, persistence, and stability. Attitude ambivalence (i.e., positive and negative thoughts and feelings toward an attitude object) is often regarded as the antithesis of attitude strength. In fact, research has typically shown ambivalent attitudes to change easily in response to persuasive messages. However, much of this work has employed novel attitude objects. We propose that typical ambivalence (e.g., a smoker's attitude toward cigarettes, attitudes about chocolate or nuclear weapons) is difficult to change. That is, often, people may believe their persistently ambivalent attitudes to be appropriate and correct. In Study 1, we measured ambivalence and manipulated perceived persistence and examined their effects in a traditional persuasion paradigm. In Study 2, we measured persistence and attitude correctness expecting the smallest changes in attitudes to be observed when ambivalent attitudes were perceived to be highly persistent and correct. The low persistence results resemble "amplification of attitude certainty" results of previous research (see Clarkson et al. 2008). Among participants with highly persistent attitudes, attitude change was associated with highly ambivalent attitudes low in perceived attitude correctness, whereas resistance was associated with highly ambivalent attitudes high in perceived attitude correctness. This research specifies some conditions under which ambivalent attitudes are not easily changed.

**E34****THE EFFECT OF A MESSAGE SENDER'S EXPERIENCE ON RECEIVERS' ATTITUDES TOWARD AN OBJECT AND INTENTIONS TO SAMPLE EXPERIENCES WITH THE OBJECT**

Koji Tsuchiya<sup>1</sup>, Tadahiro Motoyoshi<sup>1</sup>, Toshikazu Yoshida<sup>1</sup>, Yoshihisa Kashima<sup>2</sup>; <sup>1</sup>Nagoya University, <sup>2</sup>The University of Melbourne – People often form their attitudes towards an object on the basis of their sampling of experiences with the object. Bringing this insight into social influence processes, Denrell and Le Mens (2007) proposed the interdependent sampling model, postulating that a message sender's attitude may affect others' (receivers') attitudes indirectly by

promoting their subsequent sampling behaviors. Although this model assumed that the sender's positive message about an object can increase the receivers' sampling behavior, this assumption has not been examined to date. We conducted two experiments to examine this assumption while exploring the effect of the sender's experience on receivers' attitude towards the object and intention to sample the object. Participants received an introductory message about a book, which expressed the message sender's positive attitude towards it. However, the basis of the sender's attitude was manipulated in two studies. The sender was said to have written the message on the basis of his own reading (direct experience) or without reading it. The participants then reported their attitudes toward the book, and intentions to sample the book. People who were exposed to the message written by the sender with direct experience had higher intentions to sample the book than those who were exposed to the essay written by the sender without experience in both studies, although there were no differences in attitudes towards the book. These results suggest that the effect of others' attitudes on sampling behavior was more likely to emerge when the sender's attitude is based on direct experience.

**E35****PERSPECTIVE TAKING AFFECTS THE EXPRESSION OF ATTITUDES IN A POLITICAL CONTROVERSY**

Girts Dimdins<sup>1</sup>, Lars Calmfors<sup>1</sup>, Marie Gustafsson<sup>1</sup>, Henry Montgomery<sup>1</sup>, Ulrika Stavlot<sup>1</sup>; <sup>1</sup>Stockholm University – The aim of the study was to examine how perspective taking influences the expression of attitudes about a controversial political issue. As a background for the study, we chose the debate of free competition in wages in Sweden, which previous studies had shown to be a polarizing topic, about which most members of society have an opinion. The participants (N=80) first read a short introduction about the topic. Afterwards, in a between-subjects design, they were asked to formulate the advantages and disadvantages of free trade from a Swedish worker's, a foreign worker's, or a Swedish customer's perspective (a control group thought about pros and cons of their future work). After that, the participants completed a multi-item measure of attitudes towards free trade. The results showed significant differences among the groups in general attitude towards free trade. The group taking the foreign worker's perspective expressed the most positive attitudes towards free trade whereas the group that identified with the Swedish worker's perspective had the most negative attitudes towards free trade. Moreover, specific aspects of free trade were differently evaluated as a result of the perspective taking task. The results show that, within the context of a particular political debate, people have a number of consistent schemata forming a shared reality. Activating a particular schema may significantly alter the expression of debate-related attitudes. Implications for attitude measurement and political persuasion are discussed.

**Emotion****E36****THE UNIQUE RELATIONS BETWEEN EMOTIONAL AWARENESS AND FACETS OF AFFECTIVE INSTABILITY**

Renee Thompson<sup>1,2</sup>, Muge Dizen<sup>1</sup>, Howard Berenbaum<sup>1</sup>; <sup>1</sup>University of Illinois at Urbana-Champaign, <sup>2</sup>Stanford University – Affective instability has been associated with impairment in interpersonal functioning such as in romantic relationships. Although emotional variability and affect intensity are generally considered important facets of affective instability, it is not clear how they are associated with different facets of emotional awareness, which some posit are vital to adaptively using emotional information. The relation between affective instability and two facets of emotional awareness, attention to emotion and clarity of emotion, was examined in two community samples (Ns = 303, 101) and one student sample (N=409). Affective instability was assessed via a structured interview; emotional variability, affect intensity and emotional awareness were assessed with self-report measures. Across the three samples, we found consistent evidence of emotional awareness being associated with affective instability.

Further, different facets of emotional awareness were uniquely associated with different facets of affective instability. Specifically, as hypothesized, emotional variability was inversely associated with clarity of emotion, whereas affect intensity was positively associated with attention to emotion. Further, we found that the associations between emotional awareness and affective instability could not be accounted for by shared variance with gender or neuroticism. Our results provide evidence of emotional awareness being an important and non-redundant correlate of individual differences in affective instability. The findings of this paper underscore that emotional awareness may play a role in emotion regulation—the processes in which individuals influence which emotions they experience, when emotions are experienced, and how emotions are experienced and expressed.

### E37

#### **MIND-BODY DISSONANCE GENERATES COGNITIVE AND CREATIVE SPARKS** Li Huang<sup>1</sup>, Adam D. Galinsky<sup>1</sup>; <sup>1</sup>Northwestern University – We

posit that mind-body dissonance, which we propose occurs when mentally experienced emotions are the opposite valence of facially or bodily displayed ones, generates more creativity and cognitive complexity than mind-body congruence. Our prediction is based on theory suggesting that bodily postures and mental thoughts are not separable or independent sources of emotions, but rather they share a reciprocal relationship. Because of this inseparability and their normal role in validating each other, mind-body dissonance signals unusualness, stripping away directional guidance from normal experiences. As a result, we predicted and tested in three experiments whether mind-body dissonance increases insight, category inclusiveness, and associative ability, and finally cultivates synthesizing of disparate information. Participants who listened to sad music while unobtrusively induced to smile or who listened to happy music while induced to frown performed better on creative insight tasks than participants who experienced only sadness or only happiness. Similarly, recalling a happy memory while frowning or remembering a sad event while smiling led to higher category inclusiveness, greater associative ability, and the expression of more integratively complex ideas. Additionally, associative ability mediated the causal link between mind-body dissonance and integrative complexity. When the mind and body experience different emotions, cognitive activity is stimulated and atypical associations are embraced. We believe that this instinctive desire to overcome conflicting feelings or thoughts endemic to the experience of mind-body dissonance may be the underlying drive to connect, synthesize, and restore "balance" at a higher level of consciousness.

### E38

#### **EXPERIENCED AND ANTICIPATED EMOTIONS IN DECISION-MAKING: HOW YOU FEEL WHEN CONSIDERING A BEHAVIOR INFLUENCES HOW YOU THINK YOU WILL FEEL WITH THE OUTCOME** Stephanie E. Moser<sup>1</sup>,

Leona S. Aiken<sup>1</sup>, Michelle N. Shiota<sup>1</sup>; <sup>1</sup>Arizona State University – Recent years have seen growing interest in the role of emotion in decision-making. Some studies examine the implications of affective associations, the emotions experienced while one considers performing a behavior (e.g., Damasio, 2000; Kiviniemi & Bevens, 2007), whereas others focus on anticipated emotions, the emotions one expects to feel as a result of the behavior (e.g., Sandberg & Conner, 2008; Steptoe et al., 2004). Both are associated with cognitive beliefs of performing a behavior. Affective associations may influence one's anticipated emotions. The present study considered the relationship between these two aspects of emotion, and their role in decisions about cosmetic surgery – a choice involving both potential risks and benefits. In all, 297 undergraduate women contemplating breast augmentation completed questionnaires. In a path model, anticipated regret and anticipated positive emotion each predicted intentions for breast augmentation and preparatory steps women had taken towards breast augmentation (e.g. finding a surgeon). Cognitive beliefs predicted both anticipated emotions; affective associations mediated the relationship between beliefs and anticipated emotions.

### E39

#### **THE INFLUENCE OF REWARDING STIMULI ON FINANCIAL RISK TAKING** Galit Yavne<sup>1</sup>, Craig R. Fox<sup>2</sup>, Brian Knutson<sup>3</sup>, Piotr Winkielman<sup>1</sup>; <sup>1</sup>University of California, San Diego, <sup>2</sup>University of California, Los Angeles, <sup>3</sup>Stanford – It

has been well established that incidental (task irrelevant) emotions influence decisions. However, we lack an understanding of how exactly such emotions enter into the decision process. Previous research has shown that incidental sexual stimuli increase male subjects' acceptance of risky choices. The current study explores whether this effect can be understood in terms of changes in sensitivity of prospective gains and losses. Further, the study explores which stimuli (other than sexual stimuli) causes such an effect, in both genders. In our experiment, subjects were exposed on each trial to different stimuli (3 valence x 3 type categories: Positive, Neutral, Negative; Human, Nature, Object; Human-Positive included sexual stimuli). They then made a gamble choice with varying gains and losses. Positive stimuli, particularly sexual stimuli, were found to bias judgment, causing subjects to accept more gambles than in both neutral and negative conditions. The effect of sexual stimuli was particularly strong for males, causing them to accept significantly more gambles, whereas females showed no change in gambling choice. Furthermore, gender differences appear not only in behavior but also in decision-making strategy, or sensitivity to gains and losses, especially following exposure to sexual stimuli. Males' sensitivity to both loss and gain appear to decrease while females show increased sensitivity to these factors after exposure to sexual stimuli. Our results suggest that incidental positive stimuli influence risk-taking, and in the case of sexual stimuli, this influence results in qualitatively different effects on decision strategy in males and females.

### E40

#### **THE MENTAL TAX ASSOCIATED WITH EMOTION AND COGNITION INTERACTIONS** Justin Storbeck<sup>1</sup>, Gerald Clore<sup>1</sup>; <sup>1</sup>University of Virginia –

Emotion serves to prioritize cognition. Specifically, positive affect promotes verbal cognition, whereas negative affect promotes spatial cognition (Gray, 2001; Storbeck & Clore, 2008). We investigated whether such emotion and cognition interactions influenced the depletion of mental resources. We predicted that when affect promotes the appropriate cognitive process to complete a task (alignment) it conserves mental resources compared to conditions when affect promotes the inappropriate cognitive process (misalignment). For both experiments, positive or negative moods were induced, and then participants completed a verbal or spatial working memory task. This manipulation created the alignment (positive/verbal & negative/spatial) and misalignment (positive/spatial & negative/verbal) conditions. A secondary task was then given, and prior research finds that performance suffers when mental resources have been depleted (Baumeister et al., 2007). In Experiment 1, the secondary task was a creativity task in which participants generated uses for a brick. As predicted, we observed an interaction between mood and working memory task, such that the alignment conditions persisted longer on the task,  $F(1, 100) = 16.00, p < 0.001$ , and generated more uses,  $F(1, 100) = 4.55, p = 0.035$ . The Stroop task served as the secondary task for Exp. 2. Again we observed the same interaction between mood and working memory task, such that the alignment conditions performed better on the Stroop task,  $F(1, 74) = 7.04, p = 0.01$ , and made fewer errors,  $F(1, 73) = 3.60, p = 0.06$ . Thus, emotion and cognition alignment promotes efficient use of mental resources, thus aiding cognitive performance.

### E41

#### **THE AUTONOMIC-CARDIOVASCULAR PROFILES OF EFFORT AND NEGATIVE EMOTION** Lexi Kvasnicka<sup>1</sup>, Clayton J. Hilmert<sup>1</sup>; <sup>1</sup>North Dakota State University –

Identifying the underlying physiology of effort and negative emotion has been difficult because these variables are often confounded with the use of different eliciting tasks (e.g., psychological vs. physical tasks). This experiment was designed to see how effort and negative emotion are associated with cardiovascular and autonomic ner-

vous system functioning during the same task. Two hundred fifty-seven undergraduates rode a stationary bicycle while keeping their heart rate (HR) at 50% maximal for their age (low effort) or 75% maximal (high effort). During the task an experimenter gave feedback designed to elicit high negative emotion or no emotion. Manipulation checks revealed that participants felt more negative emotion in the high relative to no negative emotion conditions ( $p < .05$ ) and that they were putting forth more effort in the high compared to low effort conditions ( $p < .05$ ). Correlations showed that there were a number of differences in physiological profiles depending on condition. For example, when effort was low, HR was negatively associated with parasympathetic activity, indexed by heart rate variability ( $r_s < -.30$ ,  $p_s < .05$ ), however when effort and negative emotion were high HR was positively associated with parasympathetic activity ( $r = .31$ ,  $p < .05$ ). Also, when negative emotion was high and effort was low systolic ( $r = -.24$ ,  $p = .06$ ) and diastolic ( $r = -.32$ ,  $p < .05$ ) blood pressures were associated with sympathetic activity, indexed with pre-ejection period, which was not the case for the other conditions. These results suggest that how much effort is exerted and how much negative emotion is experienced during stress determines the underlying autonomic influence on cardiovascular functioning.

#### E42

**FEELING LIKE YOU LEARNED SOMETHING: UNRELATED EMOTIONS LEAD TO AN ILLUSION OF LEARNING** Jessica L. Alquist<sup>1</sup>, Roy F. Baumeister<sup>1</sup>, Kathleen D. Vohs<sup>3</sup>, Dianne M. Tice<sup>1</sup>, <sup>1</sup>Florida State University, <sup>3</sup>University of Minnesota – The present study demonstrated that experiencing emotion can lead to an illusion of learning. Participants who were asked to write about a time when they felt an emotion (angry, sad, excited, or relaxed) reported that they learned more from an article on George Bernard Shaw than participants who were given a non-emotional writing prompt. This was true even when controlling for how much of the article participants could actually recall. Our hypothesis was based on the theory that one purpose of emotions is to prompt learning in order to inform future behaviors. Implications for educational settings are discussed.

#### E43

**EXERCISE FOR EXTRAVERTS: DO THEY FEEL EVEN BETTER THAN OTHERS AFTERWARDS?** Jeffrey Miller<sup>1</sup>, Zlatan Krizan<sup>1</sup>, <sup>1</sup>Iowa State University – Moderate exercise is one of the best facilitators of positive affect, although not all individuals respond equivalently. Although evidence indicates that extraverts are more likely both to engage in exercise and to experience positive mood, the potential role of extraversion in moderating the effects of exercise on mood and arousal is less clear. To clarify this relation in a real-life setting where duration and intensity of exercise is self-selected, we examined mood and arousal as a function of extraversion among patrons of a recreational facility. Specifically, individuals who just completed or were about to start their workout completed a brief survey assessing their momentary mood and arousal level across multiple measures, including heart rate via a self-administered pulse reading. Finally, respondents rated their extraversion. Consistent with previous work, individuals who just completed their workout reported greater momentary positive affect, increased energy, decreased tiredness, and had higher pulse rates. Similarly, extraversion predicted higher momentary arousal and positive affect. There were no strong effects of either exercise or extraversion on momentary negative affect. Critically, extraverts experienced greater post-exercise arousal level, especially higher positive affect and energy (with no differences in heart rate). Although extraverts tend to be less arousable than introverts and to prefer higher arousal levels, they might have greater responsiveness to exercise relative to their introverted counterparts. However, extroverted individuals also reported engaging in more than one exercise activity (e.g., aerobic exercise and weight training), indicating that their greater emotional boost might be inevitable given higher levels of physical activity.

#### E44

**EXTENDING GROUP EMOTIONS: CROSS-CULTURAL DIFFERENCES ACROSS FOUR GROUP TYPES.** Yufang Sun<sup>1</sup>, Ishani Banerji<sup>1</sup>, Eliot Smith<sup>1</sup>, Diane Mackie<sup>2</sup>, <sup>1</sup>Indiana University, Bloomington, <sup>2</sup>University of California, Santa Barbara – Previous research on group emotions (e.g. Smith, Seger & Mackie, 2007) has focused primarily on American samples and categorical target groups (like political affiliations). The current study sought to expand what is known about group emotions in two ways: explore cross-cultural differences and various target groups. Thus, American and Chinese students (total N = 85) were asked to report their individual emotions and their emotions as members of each of four group types (close groups, task groups, categorical groups, and loose associations). The results indicated significant differences in individual and group emotions. In keeping with previous literature on individual emotions, Americans reported less negative affect, and more positive affect than Chinese participants. In addition, there were significant interaction effects for negative affect, positive affect, and anger across the four group types. American participants reported the greatest negative affect for loose associations, but Chinese participants reported the greatest negative affect for task groups. Similar patterns emerged for both cultural groups for positive affect and anger. Both Americans and Chinese reported the greatest positive affect for close groups and the greatest anger for loose associations. These findings advance the existing literature by examining patterns in group emotions between exemplar independent and interdependent cultural groups. In addition, the study's inclusion of several types of target groups allows for the simultaneous comparison of group emotions across various groups.

#### E45

**AN INVESTIGATION OF INFRAHUMANIZATION IN MENTALIZING** Michael Stevenson<sup>1</sup>, Reginald Adams Jr.<sup>1</sup>, <sup>1</sup>The Pennsylvania State University – Infraculturalization refers to the belief that the human nature (or essence, encompassing such qualities as intelligence, language, and emotionality) of ingroup members is qualitatively different than that of outgroup members. Of particular interest is the topic of emotionality. Past research as shown that participants report associating primary (or non-uniquely human) emotions more with outgroup members and complex (or uniquely human) emotions with ingroup members. A question that remains is how infraculturalization may bias the process of decoding emotional information from facial expressions. In Study 1, White American participants viewed the eye regions of Asian and White faces and were asked to describe, in an open response format, what they thought the person in each photograph was thinking or feeling. Participants attributed a greater proportion of complex mental states to White photographs than Asians, providing evidence for the generalization of infraculturalization to emotion decoding. Study 2 was a replication of Study 1, using Asian participants. This group of Asian participants showed no difference in the attribution of complex mental states to White and Asian photographs. However, unlike the participants in Study 1, this group varied in terms of how long they had lived in the United States. Number of years lived in the U. S. correlated with a difference score of the complexity attributed to Asian and White photographs, such that the longer Asian participants lived in the U.S., the more complexity they attributed to White faces. This finding suggests that infraculturalization is a more malleable effect than previously considered.

#### E46

**BLOOD SPORTS AND SCHADENFREUDE: INGROUP ESTEEM, INGROUP IDENTIFICATION AND REACTIONS TO OUTGROUP MISFORTUNE** David R. Schurtz<sup>1</sup>, David J.Y. Combs<sup>1</sup>, Caitlin A.J. Powell<sup>2</sup>, Richard H. Smith<sup>1</sup>, <sup>1</sup>University of Kentucky, <sup>2</sup>Georgia College & State University – We examined the roles of prior ingroup loss, ingroup esteem, and ingroup identification on schadenfreude in response to sports-related outcomes. In Study 1 participants read about either a rival basketball team losing or a non-rival basketball team losing and gave their affective reactions to this loss. They then completed a measure of ingroup affiliation and ingroup

esteem. As would be expected, participants reported greater schadenfreude when the rival team lost compared to the non-rival. In addition, and contrary to some prior research, this effect was significantly greater for those highly identified with their own team. In Study 2, participants completed measures of both ingroup esteem and ingroup identification. In a second session they read about either their own team losing or a non-rival basketball team losing, then read about an important injury occurring to a member of a rival basketball team, and also gave their affective reactions. Recalling a recent loss had no effect on participants' reactions to the injury; however, higher ingroup esteem and higher ingroup identification were associated with increased schadenfreude. These findings suggest that both ingroup esteem and ingroup identification may play important roles in people's pleased reactions to misfortunes occurring to rival teams, even if the misfortune involves a significant injury.

#### E47

**WHEN DOES SURPRISE INTENSIFY AFFECTIVE REACTIONS?** Dieynaba Ndiaye<sup>1</sup>, Timothy Wilson<sup>1</sup>; <sup>1</sup>University of Virginia – It is a near truism that surprise intensifies affective reactions to events. However, most studies on surprise have confounded how unexpected an event is and how easy it is to explain. We independently manipulated how unexpected a positive event was and how easy it was to explain in order to examine how each of these variables influenced mood. Seventy-two undergraduates played a computer game which was allegedly testing their implicit learning skills. Halfway through the computer game, participants in the expected condition were told that they were doing well; in the unexpected condition, participants were told that they were doing poorly. But at the end of the game, all participants were told that they did very well. In the certain (easy to explain) condition, participants were told that they did well because they used a specific problem solving strategy. In the uncertain (difficult to explain) condition, participants were told that they would not find out which of two problem solving strategies helped them do well. The dependent variable was participants' self-reported mood. The Expectation x Certainty interaction was significant,  $p = .04$ , reflecting the fact that participants were happiest in the uncertain expected condition, and in the certain unexpected condition. Paradoxically participants in the uncertain unexpected condition were no happier than participants in the expected certain condition. In other words, uncertainty or unexpectedness alone intensified positive mood, but both together did not. Perhaps when an event is both uncertain and unexpected, it creates too much uncertainty, which becomes negative.

#### E48

**VALIDATION OF THE SENSITIVITY TO DISGUST MEASURE (SDM)** Ellen Gordon<sup>1</sup>, Rolf Holtz<sup>2</sup>; <sup>1</sup>Ohio University, <sup>2</sup>Troy University – Disgust is a primary emotion in personality and social psychology. However, the currently used disgust measure has serious psychometric weaknesses (Haidt, McCauley, & Rozin, 1994); and it does not assess moral or sex disgust. These concerns limit the range of phenomena to which this scale can be applied. Our current research replicated the factor structure and the reliability of a new disgust measure: The Sensitivity to Disgust Measure (SDM). In addition, the validity of the subscales was examined. Participants ( $M_{age} = 19.43$ ;  $n = 471$ ) completed the SDM and several other measures. Principal components factor analyses extracted five disgust domains that accounted for 57.66% of the variance: body products, animals, death and body envelope violations, sex, and moral transgressions. The alpha coefficient for the total scale is .90; the subscale coefficients range from .78 to .87. Criterion and discriminant-related validity was assessed by correlating the SDM scores with participant scores from several measures: Haidt et al.'s (1994) Disgust Scale, Big-five Short Scale, PANAS, the Contamination Subscale of the Padua Inventory, Food Neophobia Scale, Sexual Attitudes Scale, Fear of Animal Scale, Political Orientation Scale, Body Elimination Attitude Scale, and Fear of Dying Scale. The results offer evidence for the validity of the SDM and its five

subscales. In conclusion, the SDM has improved psychometric properties and measures a broader range of disgust responses in comparison to the current disgust measure.

#### E49

**THE LINK BETWEEN AFFECTIVE STATES AND WILLINGNESS TO ENGAGE IN RISKY SEXUAL BEHAVIOR: THE ROLE OF EMOTIONAL INTELLIGENCE** Elizabeth Pomeroy<sup>1</sup>, Marc Brackett<sup>1</sup>; <sup>1</sup>Yale University – Based on the negative state relief model, it was predicted that negative affect would lead people to be more willing to engage in potentially risky sexual behavior in order to alleviate their negative state. However, it was also expected that emotional intelligence (EI) would moderate this effect. EI was measured with the Mayer-Salovey-Caruso Emotional Intelligence Test (MSCEIT; Mayer et al., 2003), which has four branches: 1) Perceiving emotions, 2) Using emotions to facilitate thinking, 3) Understanding emotions, and 4) Managing emotions. It was predicted that only those with lower scores on the Managing Emotions subscale would be more willing to engage in risky sexual behavior when in a negative affective state. Using a sample of college students ( $N = 58$ ), participants were induced into either a happy, sad, or neutral affective state. Subsequently, their willingness to engage in unprotected sex with a casual partner was assessed. Earlier in the semester, participants had completed the MSCEIT. Regression analyses were conducted, controlling for gender and previous sexual history. As expected, negative affective state was associated with increased willingness to engage in risky sexual behavior, but only for those low in the Managing Emotions subscale (Branch 4). None of the other branches, or the total MSCEIT score, moderated the effect of negative affect on willingness. No effects were found for either the happy or neutral affective states. These findings suggest that negative affect may only lead to risky behaviors for those who are poor at modulating their emotional states.

#### E50

**SHAME AND ANGER ARE ASSOCIATED WITH BEHAVIOURAL AND CORTISOL STRESS-RESPONSES OF EMOTIONAL EATERS** Kate Raspopow<sup>1</sup>, Alfonso Abizaid<sup>1</sup>, Kimberly Matheson<sup>1</sup>, Hymie Anisman<sup>1</sup>; <sup>1</sup>Carleton University – The perceived effectiveness, and endorsement, of coping strategies may differ according to the individual, as well as with the nature of the stressor presented. Furthermore, although generally endorsed to alleviate distress, some coping strategies may be considered maladaptive (compensatory eating). Emotional eating (eating in response to negative arousal), has been associated with emotion-focused and avoidant coping styles. The present investigation assessed whether these coping methods were tied to cortisol changes in response to stressors, and whether emotional eating moderated these effects. In Study 1 participants completed an emotional eating measure, performed a stressor (Trier Social Stress Task; TSST) vs. control task, completed mood and coping effectiveness measures, and had blood samples taken. In Study 2 participants completed an emotional eating measure, performed an anticipation stressor, then mood and food eaten were assessed. Study 1 ( $N=82$ ) indicated that low emotional eaters (EE) perceived problem-focused coping as increasingly effective in response to a stressor (TSST), whereas the reverse was true for high EE. Furthermore, among high EE, feelings of anger and shame were associated with cortisol reactivity. Study 2 ( $N=40$ ) indicated that in anticipation of a stressor, increased food consumption among high EE was related to particular emotional responses, namely shame and anger. A similar outcome was not evident in low EE. It seems that both anticipation and social stressors elicit similar emotional responses among high EE. These data also suggest the possibility that the link between cortisol responses and eating may involve the presence of particular emotional responses among high EE.

**E51****SOCIAL COMPARISON AS A POSSIBLE PSYCHOLOGICAL IMMUNE MECHANISM** Pamela Stager<sup>1</sup>, Tara MacDonald<sup>1</sup>, <sup>1</sup>Queen's University –

People often overestimate the regret they will experience in the future and Gilbert et al. (1998) have proposed that one reason for this is immune neglect, a lack of awareness of one's cognitive mechanisms that alleviate the psychological consequences of negative events. In the current study we propose that social comparison can be used as a psychological immune mechanism. Participants were randomly assigned to work at a task, rigged so all participants failed. Then half of the participants immediately reported their regret over the failure, while the other half reported their regret after a delay. Participants also completed White et al.'s (2006) scale of frequency of comparison (FoC). There was a significant interaction between delay and FoC such that people low on FoC in the no delay condition reported more regret than participants high on FoC in the no delay condition or participants in the delay condition, regardless of their score on FoC. People who reported their regret after a delay had time for the psychological immune system to reduce their regret, regardless of their FoC score. Participants who were given no delay but who scored high on FoC make frequent comparison and so could quickly use these comparisons to reduce their regret. The participants who were given no delay but scored low on FoC could not automatically bring to mind their social comparisons and so were not able to effectively reduce their regret. This study suggests that social comparison is a potential psychological immune mechanism.

**E52****REMEMBRANCE OF THINGS PAST: ENDINGS, REFLECTION ON THE PAST, AND MIXED EMOTIONS** James L. Cazares<sup>1</sup>, Jeff T. Larsen<sup>1</sup>, Hal Ersner-Hershfield<sup>2</sup>, Laura L. Carstensen<sup>2</sup>; <sup>1</sup>Texas Tech University, <sup>2</sup>Stanford University –

The endings of meaningful, enjoyable times (e.g., graduation ceremonies) can elicit mixed emotions of happiness and sadness (Ersner-Hershfield et al., 2008; Larsen et al., 2001), but the underlying mechanisms remain unclear. One possibility is that endings prompt people to reflect on the past, which increases their awareness that a meaningful time in their life is coming to an end. Thus, reflecting on the endings of enjoyable times, in particular, is likely to elicit sadness (Ersner-Hershfield et al., 2008). To the extent that the ending also signals good fortune (e.g., accomplishment), such sadness may not bring with it reduced happiness. Thus, reflection on the past may result in mixed emotions. We investigated this set of possibilities. On either their own graduation day or on a typical day on campus, Stanford students rated the extent to which they felt sad, happy, and other discrete emotions. They also reported what percentage of time during that day they had spent reflecting on the past. Results indicated that graduates experienced more sadness, but no less happiness, than non-graduates. As a result, graduates experienced more mixed emotions. Graduates also reflected on the past more than non-graduates. Mediation analyses indicated that reflection on the past partially mediated the effects of graduation on sadness and on mixed emotions. These results provide evidence that endings of enjoyable times prompt reflection on the past, which, in turn, elicits mixed emotions.

**E53****THE RELATIONS BETWEEN PERSONALITY TRAITS, TRAIT EMOTIONAL INTELLIGENCE AND EMOTION RECOGNITION FOR HAPPINESS AND SADNESS** Peary Brug<sup>1</sup>, Bradley Platt<sup>2</sup>, Keith Aherne<sup>2</sup>, Laurie Batchelder<sup>2</sup>; <sup>1</sup>St Mary's University College, <sup>2</sup>University College London –

The Trait Congruency Hypothesis (TCH; Rusting, 1998, 1999) argues that people are more efficient at processing emotional stimuli that is congruent with their personality traits. Despite this, it still remains unclear whether there is a relation between the five major dimensions of personality and emotion recognition performance (ERP). One explanation for the inconsistencies in the literature is that trait emotional intelligence (tEI) underlies the link between personality traits and ERP, as tEI is an individual's self-perceived ability to process their own and other people's emotions.

To test this hypothesis, the present study measured participants ERP with the newly designed Dynamic Emotional Expression Recognition Task (DEER-T). Specifically, this measures how quickly and accurately participants can identify the emotions of neutral expressions morphing into a full-intensity happy or sad expression. In this study, there were negative correlations between extraversion and response times for happiness and sadness. Moreover, there were negative correlations between extraversion and trait emotional intelligence, and correct identifications for sadness. On the other hand, there were non-significant and weak correlation between neuroticism and DEER-T performance for happiness and sadness. This study contributes further evidence that there is no relation between neuroticism and ERP (Matsumo, et al., 2000), at least for happiness and sadness. The findings are discussed in terms of TCH, with a particular emphasis on whether emotion processing skills underlie the link between personality traits and psychopathology.

**E54****EUROPEAN AMERICAN VERSUS EAST ASIAN DIFFERENCES IN THE REGULATION OF PRIDE: USE OF SUPPRESSION DEPENDS ON CONTEXT** Joshua S. Eng<sup>1</sup>, Oliver P. John<sup>1</sup>; <sup>1</sup>University of California, Berkeley –

A recent study of cultural differences in the regulation of specific emotions (Eng, John, Akutsu, & Gross, 2009) showed that European Americans generally suppress pride less frequently than East-Asian Americans do. Here we propose that this effect depends on context, namely whether the pride experience originates from an individualistic source (e.g., pride in one's personal accomplishments or achievements) or from a collective source (e.g., pride in one's family). We tested this culture-by-context hypothesis in two studies of East-Asian and European Americans (N= 275, 52% Asian; and N=273, 63% Asian), using an emotion-specific version of the Emotion Regulation Questionnaire (Gross & John, 2003). Replicating past research, European Americans indeed suppressed global pride less frequently than East-Asian Americans. However, we also found the predicted interaction of culture and context: whereas European Americans suppressed pride in the individualistic context less frequently, the two cultural groups did not differ in pride suppression in the collectivistic context. Most important, mediation results replicated across the two studies: culture differences in the suppression of individualistic pride fully accounted for differences in global-pride suppression, whereas there were no such mediation effects for the suppression of collectivistic pride. Findings are discussed in terms of differences in the relative value and emphasis that European American (versus East-Asian) culture places on the open expression of one's thoughts and feelings, particularly those that highlight one's positive qualities and successes.

**E55****EXPLORING THE DIMENSIONS OF AFFECTIVE EXPERIENCES WITH THREE-MODE COMPONENT ANALYSIS** Seth Spain<sup>1</sup>, Louis Tay<sup>1</sup>, Ed Diener<sup>1</sup>; <sup>1</sup>University of Illinois, Urbana-Champaign –

Three-mode data refer to data which can be classified by three indices, e.g., participants by variables by measurement occasions. Such data are rich and can be meaningfully used to answer otherwise difficult research questions. Two such questions exist in the study of affect. First, two dimensions of affect are generally accepted, but the proper orientation is debated. The three-mode component model Parafac exploits three-mode variance to obtain rotationally unique solutions (Harshman, 1970). Second, Thayer's (1989) three-dimensional model of affect, where two substantive mood dimensions interact with a third dimension over time has yet to receive a strong test. Tucker's three-mode component model (Tucker, 1966) allows an investigation of Thayer's model. Daily dairies can be used to collect three-mode affect data. We analyzed a 174 participant by 40 variable by 52 measurement occasion array of daily dairy affect data using both Parafac and the Tucker model. Two component solutions adequately fit the data (approximately 87% of original variance accounted for). The Parafac analysis indicated that the rotationally unique dimensions of affect are Positive and Negative Affect, however the dimensions are strongly negatively correlated, consistent with a higher order Pleasant-

Unpleasant dimension (Tellegen, Watson, & Clark, 1999). The Tucker analyses indicate that the person and affect variables interact mainly with the first time component. They interact weakly with each other and the second time component. These results generally support Thayer's three-dimensional model of mood, but suggest that the two mood dimension interact with the third dimension independently of one another.

#### E56

##### **THE ROLE OF EMOTION REGULATION STRATEGIES AND PERSONALITY TRAITS IN THE RECOLLECTION OF AUTOBIOGRAPHICAL MEMORIES**

Ekaterina Denkova<sup>1</sup>, Sanda Dolcos<sup>1,2</sup>, Trisha Chakrabarty<sup>1</sup>, Florin Dolcos<sup>1,3</sup>; <sup>1</sup>Psychiatry, University of Alberta, <sup>2</sup>Psychology, University of Alberta, <sup>3</sup>Centre for Neuroscience, University of Alberta – The available evidence suggests that affective biases in autobiographical memory (AM) - e.g., remembering more negative or positive events - may be linked to variations in the emotion regulation processes. However, it is not well known how individual variations in the habitual engagement of emotion regulation strategies influence the recollection of emotional AM. The present study investigated this issue by assessing the role of two emotion regulation strategies (i.e., reappraisal vs. suppression) in the remembering of positive and negative personal events. Emotional autobiographical events and personality assessments were performed on 51 subjects, using typical AM and personality questionnaires evaluating both general traits (e.g., neuroticism and extraversion) and specific traits linked to emotion regulation. The results showed a positive relationship between the habitual engagement of reappraisal and the percentage and vividness of emotional memories. Additionally, there was also a positive relationship between extraversion and the ability to remember positive memories, and a positive relationship between neuroticism and the ability to remember negative memories. These findings shed light on the role of individual variation in emotion regulation strategies and general personality traits in the affective biases in AM in healthy participants. Moreover, these results also provide insight into understanding affective disorders, such as depression, where there is a negative bias toward remembering negative memories. In current investigation we are also examining the neural correlates on the role of emotion regulation on remembering positive and negative personal memories.

#### E57

##### **THIS FEELS AWFUL - I WANT TO DO IT AGAIN! PREDICTING, EXPERIENCING, AND REMEMBERING A MARATHON**

Kristi M. Lemm<sup>1</sup>, Derrick Wirtz<sup>2</sup>; <sup>1</sup>Western Washington University, <sup>2</sup>East Carolina University – People's limited ability to accurately predict how positive or negative they will feel during future experiences is well documented—as is their inability to accurately remember their affective experiences later on. For example, the experience of vacationers may fall short of pre-trip expectations, yet be replaced with positive post-trip recollections (Wirtz, Kruger, Scollon, & Diener, 2003). The present study examined predicted, momentary, and recalled experience in a physically challenging activity: marathon running. Ten days before a marathon, 17 first-time runners predicted how they would feel physically and emotionally during the race and predicted their future likelihood of running another marathon. Participants were questioned again during the race itself (at miles 16 and 23), one day later, and four weeks later. Results showed participants anticipated feeling more positive physically and emotionally than they reported feeling during the race, particularly at mile 23—the notorious "wall" that confronts runners late in a marathon ( $ps < .05$ ). Yet, just one day later, memories of the marathon were more positive than mid-race reports, and a month later memories were as favorable as original predictions. Interestingly, participants' post-race intentions to run another marathon were correlated with pre-race intentions ( $r = .76$ ), but not with reported physical or emotional experience. These data may elucidate why people run multiple marathons despite the difficult, even painful nature of the experience. People predict (and recall) more positive experiences

than their own reports corroborate, yet discount both past physical and emotional feelings when deciding whether to attempt a future marathon.

#### E58

##### **EMOTIONAL UNDERPINNING OF PARTISANSHIP AND VOTE CHOICE**

Silvia Mari<sup>1</sup>, Martin Rosema<sup>2</sup>; <sup>1</sup>University of Milano-Bicocca, <sup>2</sup>University of Twente – This study examines the impact of emotions on vote choice and the role of partisanship. According to our model, emotional responses toward political parties are key determinants of partisanship, which in turn is the primary determinant of vote choice. We employ a series of items to measure partisanship in terms of two components: partisan self-identity (party identification) and attitudes toward individual parties (party evaluations). Web-survey (Inquisit) data were collected from a sample of students ( $N=171$ ) in Italy, which is a typical example of a multi-party parliamentary system. CFA confirmed the bifactor structure of partisanship. CFA also showed that emotional responses toward each of the five major parties were structured along three dimensions: enthusiasm, anxiety and aversion. For each party, path analyses (LISREL) indicated that enthusiasm and aversion had distinct effects on both components of partisanship, whereas anxiety had no impact. Both partisanship components in turn influenced vote choice with different strength depending on the party, and completely mediated the effects of emotions. These findings are very stable across parties and when considering the effects of the general political orientation. They also suggest that partisanship is best conceptualized in terms of two components (self-identity and attitudes), which both play a pivotal role in linking positively and negatively valenced emotions to vote choice.

#### E59

##### **CULTURAL VARIATION IN EMOTION REGULATION: THE CASE OF ANGER**

Carmel Gabriel<sup>1</sup>, Lauren Berger<sup>1</sup>, Helen Ku<sup>1</sup>, Janice Cheng<sup>1</sup>, Nolan Zane<sup>1</sup>; <sup>1</sup>Asian American Center on Disparities Research, University of California, Davis – Many researchers suggest that the ways in which emotions are recognized and experienced are universal (Ekman & Friesen, 1971; Mesquita & Frijda 1992). However, the ways in which individuals think about, respond to, and handle their emotions, or emotion regulation, vary across cultures (Ekman & Friesen, 1969; Friesen, 1973; Matsumoto, Yoo, & Nakagawa, 2008). Prior research indicates that individuals from East Asian societies maintain a more interdependent view of the self than those from more individualistic, Western societies. Thus, regulating anger, a socially disruptive emotion, may be different for those in Western versus Eastern societies. We hypothesized that East Asians are more likely to regulate their anger in an effort to avoid damaging their interpersonal relationships. The current study examined 68 East Asian Americans and 51 White Americans to see if they regulate their anger differently. Participants were asked to recall anger-eliciting situations and their reactions were assessed. Findings indicate that Asian Americans endorsed significantly more emotion suppression, rumination, positive reappraisal, and acceptance strategies in response to these anger-eliciting situations compared to White Americans. Analyses revealed that the higher levels of rumination, positive reappraisal, and acceptance were mediated by a more interdependent self-construal, whereas higher levels of emotion suppression were mediated by lower acculturation levels compared to White Americans. These findings have important implications for interpersonal and clinical interactions, and for theoretical conceptions of culture and emotions. One implication is that traditional Western psychotherapeutic practices that emphasize the cathartic release of anger may not be as effective with Asian Americans.

#### E60

##### **PARENTS' BELIEFS AND FAMILY CULTURE: HOW VALUATIVE BELIEFS ABOUT EMOTION INFLUENCE CHILDREN'S EMOTIONAL SELF-REPORTED EXPERIENCES**

Paul Dennis<sup>1</sup>, Amy Halberstadt<sup>1</sup>, Rebecca Stelter<sup>1</sup>, Ashley Craig<sup>1</sup>; <sup>1</sup>North Carolina State University – In formulating the Parents' Beliefs About Children's Emotion (PBACE) Questionnaire, Halberstadt et al. (in preparation) identified five broad domains of parents' beliefs,

which they have found to be associated with various emotion socialization processes. One particular domain, regarding parents' valuation of emotions, contains the emotions just are scale, which measures the belief that emotions should not to be evaluated, let alone devaluated; rather, they should be accepted. In light of the *laissez faire* nature of this belief, we predicted that strong beliefs that "emotions just are" would be evident in processes that shed light on family cultures more so than those that involve direct, tangible socialization efforts on the part of the parents. Thus, the aim of the present study was to identify family-cultural markers that could be tested as a function of parents' belief that "emotions just are". In the present study, 63 parents completed the PBACE prior to engaging in a conflict discussion with their 9- and 10-year old children. Three minutes of each dyad's discussion was videotaped and played back to the participants. Separately, they coded each 10-minute segment, identifying which emotion, if any, they were feeling. Parents' self-ratings were significantly related to children's self-ratings, indicating shared perceptions of their interaction. However, this relationship was mediated by parents' belief that "emotions just are". The implications of our findings are discussed in conjunction with concurrent coding projects, which may capture mechanisms behind the influence of parents' belief that "emotions just are" on their children's emotional vocabulary and experiences.

**E61**

**PARENTAL SOCIALIZATION OF EMOTION: ENCOURAGEMENT AND DISCOURAGEMENT IN EMOTION CONVERSATIONS** Fantasy Lozada<sup>1</sup>, Paul Dennis<sup>1</sup>, Rebecca Stelter<sup>1</sup>, Ashley Craig<sup>1</sup>, Amy Halberstadt<sup>1</sup>; <sup>1</sup>North Carolina State University – Parents' beliefs about emotion have been linked to their socialization behaviors during conversation with their children, their masking of emotion, and their emotional expressiveness. This investigation examined the association of parental beliefs assessed by the Parents' Beliefs About Children's Emotions (PBACE) questionnaire and parental socialization behaviors during emotion conversations. Parent-child dyads were invited to the lab to fill out several questionnaires and to play a game that encouraged talk about emotional experiences and situations. These interactions were video-taped, transcribed, and then coded for encouragement and/or discouragement of emotion talk during conversation. Using multi-level modeling, we analyzed four processes—positive and negative encouragement, and positive and negative discouragement—predicting that parents' belief that emotions are bad would be positively related to both positive and negative discouragement and that children's sense of security would be positively related to positive and negative discouragement. After controlling for variation by game-card valence, we found that parents' belief that emotions are bad was negatively related to both positive and negative encouragement, although it was unrelated to discouragement. We also found that children's security was negatively related to parents' discouragement of children's positive emotions.

**E62**

**EMOTIONS IN THE NEUTRAL FACE = PERCEIVED PERSONALITY: THE IMPACT OF PERCEIVED EMOTIONS ON PERSONALITY ATTRIBUTIONS** Marie Lasalle<sup>1</sup>, Sophie Poirier<sup>1</sup>, Annie Simard<sup>1</sup>, Ursula Hess<sup>1</sup>; <sup>1</sup>University of Quebec at Montreal – In order to interact adequately, people are required to judge others' personality based on very subtle clues. Individuals use information about a person's emotional state to infer certain personality traits. Interestingly, people also attribute emotions to a person even when the person is showing a neutral facial expression. The present research assessed the notion that people infer personality traits, such as being warm or being authoritative based on these perceived emotions in the neutral face. For this, two groups of participants were asked to either rate the emotions they perceive or to rate the likelihood that the person has certain personality traits for 40 individuals showing neutral expressions and varying in levels of facial dominance/affiliation. Results showed that perceived happiness positively predicted perceptions of warmth, sociability and nurturing. Perceptions of anger were negatively associated with perceptions of a person's warmth and sociability, and

positively with controlling behavior and dominance. Perceived sadness was a significant positive predictor of affiliation and a negative predictor of confidence and energy. In sum, the present research supports the notions that the emotions we perceive in other's neutral faces entrain perceptions of personality.

**E63**

**THE POLITICS OF PURITY: THE ROLE OF AUTOMATIC PROCESSING IN POLITICAL DIFFERENCES AND MORAL JUDGMENT** Nina Strohminger<sup>1</sup>, Richard Lewis<sup>1</sup>, David Meyer<sup>1</sup>; <sup>1</sup>University of Michigan, Ann Arbor – There is converging evidence that individuals vary in their sensitivity to cues of cleanliness and disgust when forming moral judgments, and that these differences drive individual variation in moral intuitions. Disgust sensitivity is positively correlated with political conservatism (Jones & Fitness, 2008), and predicts opposition to hotbutton issues such as gay marriage and abortion (Inbar et al., 2008). Similarly, political conservatives self-report that purity is more important to their moral decisions than liberals (Graham et al., 2009). Although previous studies have shown a correlation between purity/disgust and political ideology, it is not known whether the effect is causal: primed with purity or disgust, will conservatives be more influenced by this prime? We gave subjects a sentence descrambling task containing dirty, clean, or neutral content before answering moral dilemmas. We found that social liberals were unaffected by these sentences, whereas conservatives experienced a significant decrease in permissiveness for moral violations when compared to clean or neutral content. This is the first experimental demonstration that conservatives incorporate concepts of purity and dirtiness into their judgments more than liberals. This study also addresses a larger question about how deep the differences in conservatives and liberals really runs: although prior data has suggested that these differences only emerge at a very late, cognitive stage of processing (Skitka et al., 2006), our experiment shows that these differences can emerge at an early, unconscious stage of processing. Such findings have important ramifications for the nature of political ideology formation, and point to the origins of individual differences in moral intuitions.

**E64**

**RELATIONSHIP BETWEEN EMOTIONS AND SOCIAL VALUES – FUNCTIONALITY OF EMOTIONS REVISITED** Wing Yee Cheung<sup>1</sup>, Gregory R. Maio<sup>1</sup>; <sup>1</sup>Cardiff University – Traditionally, the processes underlying goal pursuits were assumed to be conscious and deliberate. Current theories have started positing the role of emotions in goal pursuit but rarely look at the specific quality of each emotional state systematically. We argued that it is crucial to consider the context of each emotion and the systemic properties of goals. We primed the salience of a few emotions (shame, guilt, disgust & sadness) and measured the subsequent values importance rating. Experiment 1 found that participants who thought about shame feelings rated openness to change values (e.g., freedom) to be less importance and tradition values (e.g., modest) to be more important. In contrast, participants in the guilt condition gave a higher rating to openness to change values, and lower rating to tradition values. Experiment 2 found that participants who focused on "moral" disgust subsequently assigned higher importance to self-transcendence values (e.g., helpfulness), and lower importance to self-enhancement values (e.g., success). In contrast, participants who focused on "hygienic" disgust subsequently assigned higher importance to conservation values (e.g., family security), and lower importance to openness to change values (e.g., freedom). Experiment 3 found that participants who focused on "death" sadness subsequently assigned higher importance to self-transcendence values, and lower importance to self-enhancement values. These results showed a consistent picture that the context of emotions plays a role in its association to goals, and when an emotion has a promoting effect on one value, it simultaneously has an inhibiting effect on its opposing value.

**E65****IF LIFE IS GOOD, WHY PAY ATTENTION TO CHANGES IN REWARD CONTINGENCIES? HAPPINESS REDUCES REVERSAL LEARNING**

Vera Sacharin<sup>1</sup>, Richard Gonzalez<sup>1</sup>; <sup>1</sup>University of Michigan – Daily life involves dealing with change; the price of gas goes up, the grocery store no longer carries your favorite yogurt, your boss develops a new attitude about your performance. To deal with such events, individuals need to detect changes and adapt their behavior accordingly. We examine the role of emotions in the ability to learn changes in reward contingencies using a reversal learning paradigm. In a reversal learning paradigm, one of two stimuli is associated with a reward. The stimulus that is reinforced changes throughout the task. Differences in appraisals of control and a good and fair world may be particularly relevant for reversal learning. For example, a belief in a good and fair world may reduce and individual's motivation to learn and understand reward-contingencies, because there is no need to understand what is rewarding and what is not when everything is already at its best. Happiness is relatively higher in appraisals of control and a fair world than relief, sadness, and worry. In three experiments, we show that happiness decreases reversal learning. However, other positive or negative emotions (relief, sadness, and worry) do not impair performance. Our results suggest that being happy reduces the ability to adapt to changes in reward contingencies.

**E66****POWER AND EMOTION UNDER A GENDER PERSPECTIVE**

Marianne Schmid Mast<sup>1</sup>, Manuel Bachmann<sup>1</sup>, Petra Schmid<sup>1</sup>, Judith Hall<sup>2</sup>; <sup>1</sup>University of Neuchâtel, Switzerland, <sup>2</sup>Northeastern University – According to approach/inhibition theory of power (Keltner et al., 2003), high power individuals show more approach behavior and low power individuals more inhibition behavior. In addition, high power individuals express and experience more positive and low power individuals more negative emotions. The goal of the present research was to evaluate the relative importance of the approach/inhibition dimension versus the valence dimension in the differential behavior of high and low power individuals and to consider moderation by gender. We used a face-to-face interaction with a virtual human (avatar) in an immersive virtual reality environment. Results demonstrated that high power individuals experienced and expressed more happiness than low power individuals, and this was specific to men. Moreover, high power men experienced and expressed more anger than low power men, whereas for women, this relation was reversed. The approach/inhibition dimension therefore accounts better for the relation between emotion and power. In addition, gender is an important moderator of this relation.

**E67****WARDING OFF THE EVIL EYE: WHEN THE FEAR OF ENVY INCREASES PROSOCIAL BEHAVIOR**

Niels van de Ven<sup>1</sup>, Marcel Zeelenberg<sup>1</sup>, Rik Pieters<sup>1</sup>; <sup>1</sup>Tilburg University – The fear of being (maliciously) envied makes people act more prosocial in an attempt to ward off the potential destructive effects of envy. People in a superior position who were likely to be envied were more likely to help a potentially envious person pick up erasers she accidentally dropped (Experiment 1). Importantly, only if the better off were likely to be maliciously envied did the helping behavior (giving time-consuming advice) increase, not if they were likely to be benignly envied (Experiment 2). Participants who could be envied only helped the potentially envious and not others more, supporting the idea that the better off act more social as an appeasement strategy. The fear of being envied serves a useful group function, as it triggers social behavior that is likely to dampen the potential destructive effects that can result from envy, and simultaneously helps to improve the situation of the worse off.

**E68****POSING EMOTION AND READING EMOTIONAL POSE: HOW AGE AND GENDER MATTER**

Michaela Riediger<sup>1</sup>, Manuel Völkle<sup>1</sup>, Natalie Ebner<sup>2</sup>, Ulman Lindenberger<sup>1</sup>; <sup>1</sup>Max Planck Institute for Human Development, Berlin, <sup>2</sup>Yale University – The ability to recognize emotions in others appears to decline with age. Evidence for this stems mostly from comparing adults of different ages in their ability to decode posed emotional expressions. Understanding emotional pose, however, may be influenced by characteristics of the posing person as well. We therefore investigated the role of age and gender in both the providing and the decoding of emotional pose. The recently created FACES database of facial expressions (Ebner, Riediger, & Lindenberger, in press) was used as source of emotional pose. It contains 2052 pictures of 171 young, middle-aged, and older men and women, each displaying angry, fearful, disgusted, happy, sad, and neutral facial expressions. The database creation involved a standardized procedure for obtaining prototypical emotional poses. Ratings for each of these poses were obtained from 154 young, middle-aged, and older men and women. Age and gender of the person who posed the emotion played a more important role in the emotion-attribution process than those of the person who perceived the emotion. Emotional expressions of young adults and of women were more easily recognized than those of older adults and of men. Two exceptions were emotional poses of anger and neutrality, which were better recognized when displayed by men. Similar but weaker effects were evident for the perceiving persons. Young individuals and women were better in deciphering emotional pose. We discuss implications for understanding age-related differences in emotion recognition and the role stereotypic expectations and socialization of emotional display may play in this respect.

**E69****THE COMPUTATIONAL LOGIC OF GUILT, GRATITUDE, AND ANGER: RECALIBRATING HOW THE MIND MAKES WELFARE TRADEOFFS**

Andrew W. Delton<sup>1</sup>, Leda Cosmides<sup>1</sup>, Daniel Sznycer<sup>1</sup>, Julian Lim<sup>1</sup>, Theresa E. Robertson<sup>1</sup>, Aaron Sell<sup>1</sup>, John Tooby<sup>1</sup>; <sup>1</sup>University of California, Santa Barbara – Do I study for tomorrow's exam or do I console a distraught friend? Social life often requires decisions that affect both one's own welfare and the welfare of others, but how do we decide? Here we investigate the hypothesis that such decisions are regulated by stored variables that index social valuation, called welfare tradeoff ratios (WTR). The magnitude of these variables expresses how much weight one puts on another person's welfare relative to one's own. These variables regulate decisions about when to sacrifice or tradeoff one's own welfare to increase the welfare of another person. Importantly, welfare tradeoff ratios are not static, but are dynamically updated. In particular, the function of many emotions may be, in part, to recalibrate welfare tradeoff ratios: Anger functions to raise another individual's WTR toward the self when it is unexpectedly too low; gratitude to raise one's own WTR toward another when the other provides unexpected benefits; and guilt to raise one's own WTR toward another after undervaluing the other. Using a revealed preference task that involves allocating resources between oneself and specific social others, we show that (1) these decisions are made in surprisingly precise ways, consistent with the existence of welfare tradeoff ratios, and (2) experimentally inducing emotional states causes the predicted recalibration of WTRs. These results are consistent with the hypothesis that social regulatory variables are tightly integrated with emotion systems.

**E70****GREENING BEHAVIOR THROUGH ECO-GUILT**

Robyn Mallett<sup>1</sup>; <sup>1</sup>Loyola University Chicago – Despite widespread support for environmentalism few people prioritize environmental protection. Considering the divide between environmental attitudes and behavior may cause eco-guilt which should motivate eco-friendly behavior. The present research created a reliable and valid measure of eco-guilt and increased the connection between environmental attitudes and behavior by highlighting instances when people fell short of their own or societal standards. Study

1 (n = 277) tested the convergent, discriminant, and predictive validity of personal and group-based eco-guilt scales. Eco-guilt was distinct from measures of moral concern and predicted intentions to repair and protect the environment by changing personal behavior and supporting political action beyond traditionally considered demographic and attitudinal variables. In Study 2, 96 participants responded to five scenarios that measured beliefs regarding how they "should" feel for engaging in environmentally-harmful behavior, then reported eco-guilt and support for a pro-environmental group. To assess whether participants wished to publicly express eco-friendly views, they were offered a button with either a neutral or eco-friendly message. Eco-guilt partially mediated the relation between perceived injunctive norms regarding the extent to which participants believed they should feel bad for harming the environment and two types of eco-friendly behavior: support for a pro-environmental organization and publicly expressing eco-friendly beliefs by taking home an eco-friendly button. Bringing to mind injunctive norms regarding how one should feel about decisions ranging from failing to recycle an aluminum can to buying a car with poor fuel efficiency created eco-guilt which motivated efforts to mend environmentally-harmful ways.

### E71

**IMPLICIT AFFECT MEASUREMENT IN TWO MINUTES ONLY? THE IPANAT** Markus Quirin<sup>1</sup>, Miguel Kazén<sup>1</sup>, Julius Kuhl<sup>1</sup>; <sup>1</sup>University of Osnabrück – An instrument is introduced for the indirect assessment of positive and negative affect, the Implicit Positive and Negative Affect Test (IPANAT; Quirin, Kazén & Kuhl, JPSP, 2009). This test draws upon participant ratings of the extent to which artificial words subjectively convey various emotions. Data are presented that support reliability and validity of the measure. Specifically, factor analyses of IPANAT ratings yielded two independent factors that can be interpreted as implicit positive and negative affect. The corresponding scales show adequate internal consistency, test-retest reliability, stability, and construct validity. More extendedly, we present a study (N=67) that supports criterion-based validity by demonstrating that correlations between implicit and explicit affect are higher under conditions of spontaneous than under conditions of reflective responding to explicit affect scales. The present findings suggest that the IPANAT is a reliable and valid measure with a straightforward application procedure.

### E72

**THE RELATION BETWEEN EVENT PROCESSING AND THE DURATION OF EMOTIONAL EXPERIENCE** Philippe Verduyn<sup>1</sup>, Iven Van Mechelen<sup>1</sup>, Francis Tuerlinckx<sup>1</sup>; <sup>1</sup>University of Leuven – Emotions unfold over time. Consequently, a full understanding of them can be reached only when their time-related aspects are captured adequately. Surprisingly, however, the number of empirical studies focusing on dynamical properties of emotions is scarce. A central time-related characteristic of emotions is the duration of emotional experience. It has been shown that an emotional experience can last for only a couple of seconds up to several hours or even longer. Thus far, this variability has almost exclusively been accounted for by characteristics of the eliciting stimulus whereas almost no attention has been given to actions one may undertake after the emotion has been elicited. In the present study, we will focus on both covert intrapersonal actions (i.e., rumination, reappraisal, and distraction) and overt interpersonal actions (i.e., social sharing). Participants were asked to report the duration of their anger, sadness, joy, and gratitude episodes on a daily basis during five consecutive days. Furthermore, information was collected with regard to their cognitions during the episodes and their social sharing behavior. Discrete-time survival analyses revealed that for each emotion under study (except for gratitude), rumination was related to a prolongation of the episode. In contrast, both reappraisal and distraction appeared to lead to an episode shortening. Finally, social sharing was associated with a prolongation of the duration of the four emotions under study. The implications of these findings for the study of the determinants of emotion duration on the one hand and emotion regulation on the other hand will be discussed.

### E73

**HOW SUFFERING, RESPONSIBILITY-TAKING, AND EXPECTATIONS OF REDRESS EXPLAIN RESPONSES TO APOLOGETIC EMOTIONS** Roger Giner-Sorolla<sup>1</sup>, Sven Zebel<sup>2</sup>; <sup>1</sup>University of Kent, <sup>2</sup>University of Amsterdam – Research on group-based emotions has often assumed that emotions prepare people for action. However, emotions also communicate social meaning. When one group has harmed another unjustly, its members' expressions of emotions such as guilt or sadness communicate two states of mind relevant to apology: suffering and responsibility-taking. Is it enough to see these states of mind to be satisfied with the apology and forgive the person? Or do those inferences only work because they increase pragmatic expectations of reparation from the transgressors? We will report the findings of three studies of non-smokers, two in Britain (N = 171, N = 144) and one in the Netherlands (N = 477). We varied the word a smoker used to describe his reaction to harm from passive smoking: guilty, ashamed, regret, very sad, responsible, or indifferent (apologize in Study 3). These words differed in perceived suffering and responsibility taking, with minor sample differences: feeling "guilty" ("schuldig") involved more suffering and responsibility taking in the Netherlands than in Britain. More importantly, our model was validated across studies. Suffering and responsibility inferences predicted greater satisfaction with the statement, both mediated by expectations of forthcoming behavioural change from the smoker. However, insult and other negative reactions were reduced only by the direct effect of responsibility taking, unmediated by expected action; this makes sense, given the potential of offers of help to cause insult. Overall, then, emotions are important for apologies partly because of the moral statement they make, and partly because they lead to pragmatic expectations.

### E74

**AFFECTIVE MOTIVATIONAL DIRECTION MODEL: ATTENTIONAL BREADTH OF POSITIVE AND NEGATIVE AFFECTS VARYING IN MOTIVATIONAL INTENSITY** Philip Gable<sup>1</sup>, Eddie Harmon-Jones<sup>1</sup>; <sup>1</sup>Texas A&M University – Positive and negative affects high in motivational intensity cause a relative narrowing of attentional focus (Gable & Harmon-Jones, 2008; Easterbrook, 1959). In contrast, positive affects low in motivational intensity cause a relative broadening of attentional focus (Fredrickson & Branigan, 2005; Gable & Harmon-Jones, 2008). The attentional consequences of negative affects low in motivational intensity have not been experimentally investigated. Experiment 1 compared the attentional consequences of negative affect low in motivational intensity (sadness) with a neutral affective state. Results indicated that low-motivation negative affect caused attentional broadening. Experiment 2 found that disgust, a high-motivation negative affect not previously investigated in attentional studies, narrowed attentional focus. Experiment 3 and 4 compared pictures evoking desire, sadness, or neutral affect, and then assessed the relationship of asymmetrical event related brain potentials (ERPs) to local vs. global attentional bias following the affective picture primes. Results revealed that desire pictures caused greater relative left frontal late positive brain potential (LPP) amplitudes, which predicted more local bias following desire pictures. In contrast, sad pictures caused greater relative right frontal LPP amplitudes, which predicted more global bias following sad pictures. In sum, these experiments support the motivational direction model linking high-motivation affective states to more narrowed attention and low-motivation affective states to more broadened attention.

### E75

**THE EXPRESSION OF DETERMINATION: SIMILARITIES BETWEEN ANGER AND APPROACH-RELATED POSITIVE AFFECT** Cindy Harmon-Jones<sup>1</sup>, Eddie Harmon-Jones<sup>1</sup>, Brandon Schmeiche<sup>1</sup>; <sup>1</sup>Texas A&M University – We examined the valence and motivational direction of affect using facial expressions of determination. Determination is a positive, approach-related emotion, whereas anger is a negative, approach-related emotion. Thus, determination and anger share a motivational direction, but are opposite in valence. An implemental mindset has previously been

shown to produce high-approach motivated, positive affect, thus, in Study 1, participants were asked to freely report the strongest emotion they experienced during an implemental mindset. The most common emotion reported was determination. Based on this result, we chose to compare the facial expression of determination to anger. In Study 2, naïve judges were asked to identify photographs of facial expressions intended to express determination, along with photographs intended to express basic emotions (joy, anger, sadness, fear, disgust, neutral). Correct identifications of intended determination expressions were correlated with misidentifications of the expressions as anger, but not with misidentifications as any other emotion. This suggests that determination, a high-approach, positive affect, is perceived as similar to anger. In Study 3, naïve judges were asked to quantify the amount of joy, anger and determination expressed in photographs. The intensity of perceived determination was directly correlated with the intensity of perceived anger (a high-approach, negative affect), and was inversely correlated with the intensity of perceived joy (a low-approach, positive affect). These results demonstrate perceptual similarity between emotions that share a motivational direction, but differ in valence.

#### E76

**FOCALISM AND THE UNDERESTIMATION OF FUTURE EMOTION: WHEN IT'S WORSE THAN IMAGINED** Heather Lench<sup>1</sup>, Martin Safer<sup>2</sup>, Linda Levine<sup>3</sup>; <sup>1</sup>Texas A&M University, <sup>2</sup>Catholic University of America, <sup>3</sup>University of California, Irvine – People typically exaggerate the impact of future events on their emotional reactions. This bias arises in part because of focalism, the tendency to focus on reactions about the target event and to neglect how the surrounding context may mitigate one's emotional reaction. Neglecting context, however, should also lead people to underestimate the intensity of future emotions in certain situations. We examined whether people would underestimate, rather than overestimate, the intensity of their future negative emotional reactions if the emotional experience occurred when the surrounding context focused attention on the emotion-eliciting event. In Study 1, participants underestimated the intensity of their future negative emotions when they reported reactions to a romantic break-up on Valentine's Day (February 14th), but showed the typical overestimation bias if they reported their reactions on February 7th. The relationship between day of reporting and emotional intensity was partially mediated by how frequently they thought about the break-up. In Study 2, participants underestimated the emotional impact of a lost prize when the experimental context forced them to focus on the prize versus when the prize was less evident. Thus, failing to account for the extent to which context would focus attention on the event, a form of focalism, led to underestimation of emotional reactions to a negative event. These studies demonstrate that the well-documented impact bias in affective forecasting, that people overestimate the impact of future events on their emotions, can be reversed if the surrounding cultural or experimental context leads people to focus on the emotion-eliciting event.

#### E77

**HOW YOU MAKE ME FEEL: AFFECTIVE RESPONSES TO COMPARISONS DEPEND ON WHO'S CAUSING THE COMPARISON** Camille Johnson<sup>1</sup>; <sup>1</sup>San Jose State University – Social comparisons can be an effective means for regulating mood. People can look upward for inspiration or downward for reassurance. But, can these mood-regulating effects be harnessed by outside sources, such as managers, teachers or parents? Two studies are presented showing that external factors, specifically the status of the person instigating the comparison, determines how people feel after making a comparison. In Study 1, participants recalled a time when a peer or a family member asked them to make a comparison. Regardless of whether targets were more or less successful, peer-instigated comparisons led to greater confidence whereas comparisons instigated by superiors led to greater guilt and shame. In addition, whereas the negative emotions arising from peer-induced comparisons are associated with withdrawal tendencies, this was not true when the comparisons were induced by a superior. In Study 2, Asian-American (AA) and Anglo-

American (AnA) participants recalled a time when friends or older family members asked them to make an upward or downward comparison. When comparisons were instigated by family members, AA participants felt more shame and less pride compared to AnA participants. In addition, AA participants reported lower self-esteem after comparisons instigated by family members than did AnA participants. No differences were found when peers instigated the comparisons. Overall, these findings indicate that when comparisons are elicited by outside sources, emotional responses are influenced by source status and perceiver's cultural background, suggesting that using social comparisons to regulate the moods of others may not be as simple as selecting targets for exposure.

**HAPPINESS AND POLITICAL ATTITUDE CHANGE: MOOD-AS-INFORMATION AND HEURISTIC PROCESSING** Rick Andrews<sup>1</sup>, Alan Lambert<sup>2</sup>, John Paul Schott<sup>2</sup>; <sup>1</sup>New York University, <sup>2</sup>Washington University in St. Louis – Past research on happiness and attitudes has shown two reliable effects. One, Mood-as-Information, occurs when people use their happy mood as information for judging a target, rating it more positively than they otherwise would. A second effect, Heuristic Processing, occurs when people in a happy mood rely heavily on their heuristics to make judgments. Research was conducted examining these effects in the realm of political attitudes. Subjects were placed in a happy mood (Please think about a time in your life when you were happy and write about it) or a neutral mood via a control condition (Please write about your every day routine). All participants were then presented with a battery of political attitude questions. Results focus on two ideological constructs: a Belief in the Goodness of Human Nature (BGHN) index, and an Authoritarianism-Traditionalism (A-T) index. The present study finds a dissociation of the two happiness effects amongst sub-constructs of ideology. We find evidence that happy mood leads to a Mood-as-Information effect for BGHN, while producing heuristic processing for A-T. Important implications for both the happiness literature and ideology literature are discussed.

#### E80

**ATTENTIONAL BIASES TO CLEAR AND AMBIGUOUS THREAT IN LATERALLY PRESENTED GAZE BY EMOTION CUES ACROSS TIME** Anthony Nelson<sup>1</sup>, Reginald Adams Jr.<sup>1</sup>; <sup>1</sup>The Pennsylvania State University – Multiple social cues in the face can share or clash in their signaling of the basic intentions of others (i.e., approach or avoid). The current research examines attention to social threat cues (angry and fearful facial expressions) with direct and averted eye gaze. Direct gaze and angry expressions both communicate the intent to approach, while averted gaze and fearful expressions both communicate the intent to avoid. Expressive faces with either direct/averted gaze were presented laterally against matched identity, matched gaze faces, for either 500ms (early) or 1000ms (late) durations. Afterward, participants responded to the presence of a target behind one of the two faces. It was hypothesized that there would be an initial attentional bias towards clear threat cues (direct anger, averted fear) at 500ms, with an attentional bias towards ambiguous threat cues (averted anger, direct fear) at 1000ms, as measured by quicker reaction times. The results found an overall gaze by emotion by stimulus duration interaction. Broken down, we found that this was primarily driven by a bias towards ambiguous threat cues at 1000ms. We explain this in terms of an attentional maintenance response to resolve the ambiguity surrounding the stimulus. We address the lack of significant findings at 500ms within the context of chronometric changes in perceptual attunement. Directions for future research, including the examination of individual differences and suggested improvements to attentional protocols, are discussed.

**E81****WHEN DOES SEEING THROUGH YOUR EYES HELP ME? EMOTIONS FUNCTIONALLY ENCOURAGE AND INHIBIT PERSPECTIVE TAKING**

Rebecca Neel<sup>1</sup>, Steven Neuberg<sup>1</sup>, <sup>1</sup>Arizona State University – Taking another's perspective can be an effective, but costly, tool for social information gathering, and thus should be used selectively. One function of emotions is to organize cognitive processing to accomplish active goals; because achieving different goals requires different amounts or kinds of information, one would expect some emotions to facilitate the use of perspective taking whereas others should inhibit it. While goals activated by some emotions (guilt, nurturant love) may require attention to another's thoughts and feelings, others (anger, pride) may have little use for, or even be obstructed by, such costly interpersonal cognition. In the current study, participants wrote about a recent time they interacted with a close other and felt angry, guilty, proud, or loving (control participants wrote about the last time they did their laundry). Because perspective taking should manifest in more self-like attributions for others' behavior (i.e., weighing situation forces more heavily than person forces), participants read scenarios and made person and situation attributions for the protagonists' target behaviors. Consistent with hypotheses, participants feeling nurturant love or guilt made attributions that were more relatively situation-based than did those feeling anger or pride. Moreover, anger and pride more strongly inhibited perspective taking than nurturant love and guilt encouraged it. Alternative predictions based on emotion valence fail to explain our results: Anger and guilt did not differ from pride and nurturant love. This selective engagement of perspective taking highlights the functional interplay among motivations, emotions, and cognitive processes.

**E82****FEELING OTHERS' SOCIAL PAIN: AN FMRI INVESTIGATION OF EMPATHY FOR SOCIAL EXCLUSION**

Carrie Masten<sup>1</sup>, Naomi Eisenberger<sup>1</sup>, <sup>1</sup>University of California, Los Angeles – Recent neuroimaging work has demonstrated an overlap between empathy for physical pain and the neural regions activated during the direct experience of physical pain (Singer, 2006). However, these studies have not examined empathic responses to everyday social interactions. In the current study we examined neural activity during observed social exclusion, and how this activity related to self-reported trait empathy and helping behavior. Sixteen participants were scanned while they observed another individual being ostensibly excluded by others during a virtual ball-tossing game. Participants completed self-reports of trait empathy, and wrote emails to the 'victim' of the exclusion. Outside raters indicated how helpful the emails were using a 5-point scale. Results indicated that observing exclusion (compared to observing inclusion) activated neural regions involved in mentalizing, including the dorsomedial prefrontal cortex. Furthermore, participants who reported greater trait empathy displayed stronger activation in mentalizing regions, and showed stronger 'pain-related' activation (dorsal anterior cingulate cortex, anterior insula) during observed exclusion. Finally, individuals who showed more pain-related neural activity during observed exclusion wrote more helpful emails to the victims of the exclusion, suggesting that neural responses to observed social exclusion can influence observers' helping behaviors. Overall this study suggests that when individuals witness social exclusion in their daily lives, they may actually 'feel the pain' of the victims and thus make efforts to help those involved in these negative social interactions.

**E83****IMAGINING FUTURE EVENTS AND OUTCOMES: THE INFLUENCE OF IMAGERY PERSPECTIVE ON AFFECTIVE FORECASTING**

Karen A. Hines<sup>1</sup>, Lisa K. Libby<sup>1</sup>, <sup>1</sup>Ohio State University – How do people think they will feel in response to future events and outcomes? The present research indicates that it depends on the visual perspective people use to mentally picture those events. We manipulated the visual perspective (own first-person vs. observers' third-person) that students used to picture themselves studying for an upcoming final exam. We then asked them to

make predictions about their future feelings. When it came to the emotions involved in studying itself, first-person participants predicted a greater emotional impact than third-person participants did, but when it came to the emotions they would experience as a result of the exam outcome, third-person participants predicted a greater emotional impact. These findings challenge the common belief that third-person imagery necessarily dampens the emotional impact of a pictured event. These results are consistent with an alternate model in which imagery perspective functions to define an event either in terms of the experience contained within it (first-person) or the meaning it has in relation to other events and self-knowledge (third-person). The model predicts, and the present results show, that third-person imagery has the potential to dampen or enhance the emotional impact of a pictured event, depending on whether the emotion follows from the experience of the event itself or what the event means in relation to other events or self-knowledge. These findings contribute to an understanding of how visual imagery perspective functions in social cognition and have implications for understanding the processes involved in decision-making.

**Evolution****E84****MATE RETENTION BEHAVIORS IN THE NEWLYWED YEAR AND THREE YEARS LATER**

Farnaz Kaighobadi<sup>1</sup>, Todd K. Shackelford<sup>1</sup>, David M. Buss<sup>2</sup>, <sup>1</sup>Florida Atlantic University, <sup>2</sup>University of Texas, Austin – Mate retention behaviors may function to prevent a long-term partner's infidelity or defection from the relationship and to ward off would-be mate poachers. The current research is the first to investigate the performance across time of husbands' and wives' mate retention behaviors. We assessed 49 men and 65 women on their performance of mate retention behaviors once as newlyweds and then again three years into the marriage using the Mate Retention Inventory. Our broad goals in this research were to investigate (1) the cross-time stability of husbands' and wives' mate retention behaviors and (2) sex differences in performance of mate retention behaviors across time. The results indicated that: (1) husbands' and wives' mate retention behaviors as newlyweds correlate with their mate retention behaviors three years later, (2) husbands' and wives' performance of mate retention behaviors decreases after three years of marriage, and that (3) sex differences in performance of particular mate retention tactics as newlyweds persist across time. Across time, husbands more than wives report engaging in resource display and submission and debasement; and wives more than husbands report engaging in appearance enhancement. The discussion addresses limitations of the current research and highlights directions for future research.

**E85****SEX DIFFERENCES IN IMPLICIT MATE PREFERENCE**

Mark Oakes<sup>1</sup>, Kelly Landry<sup>1</sup>, Madeline Caudle<sup>1</sup>, Suzannah Chatlos<sup>1</sup>, <sup>1</sup>Hamilton College – Although men and women agree on the value of many characteristics they seek in long term mates (e.g., kindness, intelligence, and dependability), attractiveness and earning potential are valued differently. According to evolutionary theory, males tend to value attractiveness more than females because beauty and physical health are indicators of reproductive fitness. In contrast, females are more invested in offspring than males and therefore tend to more strongly value earning potential in their mates. Traditional studies use self-reports to gauge mate preferences. However, it may be possible that people's implicit preferences differ from their self-reported preferences due to impression management and/or lack of introspective insight. In addition to self-reported mate value questionnaires, the current study includes an Implicit Association Test (IAT) comparing the associational strength between spouse and attractiveness versus spouse and wealth. Self-reports showed the expected pattern in which males valued attractiveness (relative to wealth) more than females. Although females placed less value on attractiveness than males, they still valued attractiveness significantly more than wealth. Interestingly, IAT results showed a different pattern.

Females found it easier to associate wealth with spouse than attractiveness. Males showed no preference on the IAT, associating wealth and attractiveness with spouse equally. A correlation between the IAT and self-report scores was nonsignificant, suggesting that the IAT may be assessing a different construct from self-report measures. The current study begs the question of whether it is preferable to use self-report or more automatic/implicit methods of measurement when assessing mate preference.

**E86****PREDICTING EVOLUTIONARY-RELEVANT RISK TAKING WITH BIG FIVE PERSONALITY, TIME PERSPECTIVE, AND TEMPORAL DISCOUNTING**

**James R. Daugherty<sup>1</sup>, Gary L. Brase<sup>1</sup>, <sup>1</sup>Kansas State University** – Evolutionary-relevant risk taking involves engaging in behaviors that have immediate benefits, but potential intermediate and long-term costs that would outweigh those immediate benefits. Factors influencing more general measures of risk taking include personality (i.e., Big Five traits), whether one is future- or present-minded (i.e., time perspective), and one's general ability to forego immediate lesser rewards in favor of greater future rewards (i.e., temporal discounting). This study examined the predictive ability of these three factors while examining a recently published scale of evolutionary-relevant risk taking scenarios. Risk taking scores ( $N = 466$ ) assessed with the Domain Specific Risk Taking Scale (DSRTS, Kruger, Wang, & Wike, 2007) were predicted using the Big Five Inventory (John & Srivastava, 1999), Consideration of Future Consequences Scale (Strathman, Gleicher, Boninger, & Edwards, 1994), Zimbardo Time Perspective Inventory (Zimbardo & Boyd, 1999), and the Money-Choice Questionnaire (Kirby & Marakovic, 1996). Using hierarchical regression, the combined time perspective and temporal discounting scales significantly improved the incremental prediction of all five risk taking domains above and beyond sex and Big Five personality. When hierarchical regression models were reversed and sex, time perspective, and temporal discounting scales were entered before Big Five personality, Big Five personality significantly improved the incremental prediction of four risk taking domains. These results suggest, in general, that Big Five personality and the combined time perspective and temporal discounting scales are significant, yet separate predictors of evolutionary-relevant risk taking.

**E87****"DO I STILL LIKE THAT?" COGNITIVE DISSONANCE IN NON-HUMANS**

**Jennifer Vonk<sup>1</sup>, Samantha West<sup>1</sup>, Stephanie Jett<sup>2</sup>, Tamra Beckman<sup>1</sup>, <sup>1</sup>University of Southern Mississippi, <sup>2</sup>University of South Alabama** – We presented seven old-world monkeys, three chimpanzees, six members of the parrot family (Psittacidae) and four American black bears with a cognitive dissonance paradigm modeled after Egan, Santos & Bloom (2007). Subjects were given forced choices between two equally preferred food items and then presented with the unchosen option and a novel, also equally preferred, food item in Experimental trials. In Control trials, subjects were presented with one accessible and one inaccessible option from another triad of equally preferred food items. They were then presented with the previously inaccessible item and a novel member of that triad of equally preferred items. As we predicted, primates as a group, preferred the novel item in experimental but not control trials, indicating that they perceived and resolved cognitive dissonance by de-valuing the unchosen option. Critically they did this only when an option was derogated by virtue of their own free choice. Only monkeys, but not apes, bears, or birds showed this effect when data was analyzed by broad taxonomic category suggesting that this phenomenon might exist within, but not outside of, the primate order.

**E88****INHIBITORY SELF-REGULATION AS A FUNCTION OF THE PRESENCE OF A SUPERNATURAL AGENT**

**Ashley King<sup>1</sup>, David F. Bjorklund<sup>2</sup>, <sup>1</sup>University of Arizona, <sup>2</sup>Florida Atlantic University** – This research examined the differences in inhibitory self-regulation of 4-8 year olds as a function of the suggested presence of a supernatural agent. Previous research implies

that humans are naturally primed to think in terms of supernatural agents and that, given the correct context, both children and adults will readily accept the reality status of novel supernatural entities and alter their behavior accordingly. All children in this study played four games designed to assess their current level of self-regulatory and theory of mind performance. Children in the experimental condition, only, were also introduced to an invisible Princess Alice and were told that she was watching during the games. Following these measures, all children engaged in a resistance-to-temptation task in which they were tempted to cheat by peeking at the correct answer in a game while the experimenter was not watching. Peeking behavior and latency to peek were assessed for differences between conditions to determine whether the suggested presence of a supernatural agent, Princess Alice, affected children's ability to withhold from peeking. I found that although most children do peek, those children exhibiting a well developed theory of mind were more likely to express belief in Princess Alice than were children lacking this cognitive ability. This research provided support that cognitive maturity, rather than immaturity, may be necessary for children to express belief in novel supernatural agents. This study also highlighted the importance of context in which a supernatural agent is introduced as a mediating factor in children's expressed belief.

**E89****BABY FEVER: DOES IT EXIST?**

**Gary L. Brase<sup>1</sup>, Sandra L. Brase<sup>1</sup>, <sup>1</sup>Kansas State University** – The phenomenon of a visceral physical and emotional desire to have a baby (e.g., "baby fever") is well known in popular culture, but has never been studied scientifically. Nevertheless, it is possible to develop multiple theoretical perspectives regarding the existence and causal factors of baby fever. One view is that biological sex drives and maternal feelings are sufficient and therefore a specific desire for having a baby is superfluous. Another view is that baby fever does exist, but as a sociocultural phenomenon not tied to biological or evolutionary forces. A third view is that baby fever could exist as an evolved mechanism for regulating birth timing, proceptive behavior, and general life history trajectories. A series of studies were conducted to explore if baby fever is a measurable construct and what factors might underlie it. Study 1 found that a simple scale measure could elicit ratings of desire frequency and these ratings exhibited significant sex differences. These participants also were readily able to nominate factors eliciting and inhibiting baby fever. Study 2 replicated the sex difference in desire for a baby and found that it was opposite in direction from a general desire for sexual activity. Further, exploratory factor analysis identified underlying dimensions of baby fever. Study 3 extended the findings from the previous studies using a more diverse online population rather than university undergraduates. It does appear that there is a real phenomenon of baby fever and that its underlying structure is multifactorial, favoring a theoretically eclectic explanation.

**E90****HELP ME HELP YOU: THE RELATIONSHIP BETWEEN RECIPROCAL ALTRUISM AND COLLECTIVISM**

**Edward J. Hansen<sup>1</sup>, Lisa McFadden<sup>1</sup>, Brad J. Sagarin<sup>1</sup>, <sup>1</sup>Northern Illinois University** – While evolutionary psychologists debate the existence of altruism, people act in seemingly altruistic ways every day. Based on Trivers' theory of reciprocal altruism (1971), researchers have shown that people will help non-related others if they have an expectation of future reciprocation. Where do these expectations come from? This study examines one possible source of expectations of reciprocation: collectivism, hypothesizing (a) that willingness to help will be related to anticipated reciprocation, and (b) that people with collectivist orientations are more likely to help others and to expect reciprocation in return. 90 undergraduate participants completed a 43-item altruistic behavior scale measuring how likely they would be to perform different altruistic acts and the likelihood of these acts being reciprocated. Collectivism was measured with the INDCOL (Hui & Yee, 1994) and the Horizontal & Vertical Collectivism Scale (Singelis et al., 1995). As predicted, willingness to help and anticipated reciprocation were positively correlated,  $r = .735, p < .01$ . Also as predicted, collectivism

predicted altruism and reciprocity across all three collectivism measures, with horizontal collectivism showing the strongest effects, INDCOL/altruism:  $\beta=.291$ ,  $p<.01$ , INDCOL/reciprocity:  $\beta=.266$ ,  $p<.05$ , vertical collectivism/altruism:  $\beta=.305$ ,  $p<.01$ , vertical collectivism/reciprocity:  $\beta=.314$ ,  $p<.01$ , horizontal collectivism/altruism:  $\beta=.453$ ,  $p<.001$ , horizontal collectivism/reciprocity:  $\beta=.450$ ,  $p<.001$ . Measures of individualism did not significantly predict altruism or reciprocity. Results support the importance of reciprocal altruism in explaining human helping behavior and offer an explanation for greater helping by collectivists: a perceived greater likelihood of future reciprocity.

### E91

**STATUS MEDIATES FEMALES' ATTRACTION TO GOOD MALE STORYTELLERS** John Donahue<sup>1</sup>, Melanie Green<sup>1</sup>; <sup>1</sup>University of North Carolina at Chapel Hill – Effective storytelling could be a positive influence on mate attraction by inducing effects such as excitement or immersion (transportation into a narrative world, Green & Brock, 2000) or by indicating valued traits such as intelligence or social skill. In our previous research (Donahue & Green, 2008) participants were provided with a picture of a potential mate and additional information about their level of storytelling ability. Participants were asked to rate the potential mate's physical attractiveness, attractiveness as a casual date, as a long-term date, and as a friend. Across three studies, men were not more attracted to good female storytellers, whereas women were more attracted to good male storytellers when rating them as long-term dates. The current study used a similar procedure to test a possible mediator of storytelling effects. Participants ( $n = 141$ ) were divided into three conditions: a "good storyteller" condition; a "poor storyteller" condition; and a control condition with no information about storytelling ability. Along with attractiveness ratings, participants rated the person on perceived status. Females preferred good storytellers as a friend, and replicating the earlier studies, as a long-term date. Good storytellers were perceived as having higher status than poor storytellers. Furthermore, the effect of storytelling ability on female's ratings of (long-term) attractiveness was mediated by status. Thus, women might be attracted to good male storytellers because they are perceived as having high status, and may therefore have the ability to provide resources over an extended period of time.

### E92

**TESTING EVOLUTIONARY EXPLANATIONS OF ATTACHMENT** Sooyeon Sung<sup>1</sup>; <sup>1</sup>University of Oregon – Bowlby's attachment theory has made prominent contributions to contemporary social and behavioral science and uniqueness of the theory is partially derived from its taking an evolutionary perspective. In this study, two different theories that explain the adaptive functions of different patterns of attachment and working models of attachment were presented and tested. The Belsky, Steinberg, and Draper model (1991) proposes that environmental conditions influence later reproductive strategies through the quality of parental care and attachment patterns. The authors of this study propose the "learning of social relationship" theory that relationships with parents indirectly serve for fitness by working as a template that transmits information about social environment. In testing aspects of each theory, the relations among family environment, maternal sensitivity, attachment insecurity, age at first sexual intercourse, and dating-relationship quality were examined using the National Longitudinal Survey of Youth 79 Child and Young Adult data and structural equation modeling. The results showed that more favorable early family environment is significantly associated with later onset of sexual behavior and better dating-relationship quality. The relation between family environment and dating-relationship quality was fully mediated by maternal sensitivity, but not mediated by attachment insecurity. In contrast, the relation between family environment and age at first sexual intercourse was partially mediated by attachment insecurity, but not by maternal sensitivity. The implications of the results and future directions were discussed.

### E93

**TWO GUYS, A GIRL, AND AN ADULT DVD: TESTING SPERM COMPETITION HYPOTHESES USING ADULT FILM SALES** Emily J. Miner<sup>1</sup>, William F. McKibbin<sup>1</sup>, Danielle Popp<sup>2</sup>, Todd K. Shackelford<sup>1</sup>; <sup>1</sup>Florida Atlantic University, <sup>2</sup>California State University, Fullerton – Over human evolutionary history, mated men faced the adaptive problem of cuckoldry – unwitting investment of resources in genetically unrelated offspring. Ancestral men therefore may have evolved sensitivity to cues of a partner's sexual infidelity. Men respond to these cues, such as the presence of a rival, in ways that may have increased the likelihood of success for ancestral men in sperm competition – competition between the ejaculates of two or more men to fertilize a woman's egg(s). When choosing between viewing pornographic images that depict two men interacting with one woman and images that depict two women interacting with one man, sperm competition theory has been used to generate the hypothesis that men will prefer the former scenario, which suggests the presence of a rival male. Other theories, such as sexual script theory, can be used to generate the hypothesis that men will prefer the latter scenario because men select pornographic themes which fit their culturally-determined sexual scripts. In the current work, raters coded a random sample of 229 adult DVDs to test the competing hypotheses. Using structural equation modeling, the number of images on a DVD cover depicting two men interacting with one woman predicts DVD popularity (a composite of DVD sales rankings and DVD length), whereas the number of images on a DVD cover depicting two women interacting with one man does not predict DVD popularity. These results are consistent with the sperm competition hypothesis, but refute other hypotheses, notably the sexual scripts hypothesis.

### E94

**DISTINGUISHING VIOLENT FROM NONVIOLENT SEX OFFENDERS AT A GLANCE** Tyler Stillman<sup>1</sup>, Jon Maner<sup>1</sup>, Roy Baumeister<sup>1</sup>; <sup>1</sup>Florida State University – A growing body of evolutionary literature suggests that person perception processes are adaptively tuned. The current investigation tested the hypothesis that people would be able to detect a penchant for violence in other people, based only on a brief glance at their face. Participants rated photos of registered sex offenders after seeing them for 2 seconds each. Estimated likelihood of violence was significantly related to actual violent history, suggesting that violent tendencies can be accurately inferred from a brief look at a person's face. Cues indicative of high masculinity and high male sex hormones (heavy brow, high physical strength, younger age, overall manly appearance) accounted for the accurate judgments. Other cues such as facial emotion and good grooming misled raters. Although there were no sex differences in accuracy, on average women thought targets were more violent than men did. Findings speak to the accuracy and efficiency with which people can detect potential threats to physical well-being.

### E95

**OVULATION AS AN IMPLICIT MATING PRIME: MEN'S RESPONSES TO CUES OF FEMALE FERTILITY** Saul Miller<sup>1</sup>, Jon Maner<sup>1</sup>; <sup>1</sup>Florida State University – Adaptationist models of human mating provide a useful framework for identifying subtle, biologically based mechanisms that influence cross-gender social interaction. In line with this framework, the current studies examined the extent to which cues of female ovulation influence men's mating-related cognition and behavior. Studies 1 and 2 demonstrated that cues of female ovulation – scents of women at the peak of their reproductive fertility – increased men's mating-related thoughts (as indicated by a word-stem completion task) and led men who are sensitive to smells to perceive greater sexual arousal in the ovulating women. Whereas Studies 1 and 2 examined lower-order cognitive processes related to mating, Study 3 examined more "downstream" behavioral processes. In Study 3, men interacted with a female confederate at several points in her cycle. When the female confederate was close to ovulation, men exhibited increased risk-taking tendencies (on a blackjack task) and were more likely to mimic her behavior (touching their

face). These findings suggest that cues of ovulation may shape a range of cognitive and behavioral processes in men aimed at acquiring a mate. Thus, the current research adds to an emerging literature suggesting that human mating is guided, in part, by relatively subtle processes that occur at fundamental levels of biology.

#### E96

**PUNISHERS WON'T BE REWARDED** Yohsuke Ohtsubo<sup>1</sup>, Koji Hayashi<sup>2</sup>, Hidetoshi Yamaji<sup>1</sup>, <sup>1</sup>Kobe University, <sup>2</sup>Fujitsu – Recent evolutionary models of cooperation assume that some forms of punishment for uncooperative members are necessary to sustain large-scale cooperation. According to these models, punishers, who incur personal cost to punish norm violators, would be rewarded by other members' cooperation or enhanced reputation. However, in a recent experiment involving the Prisoner's Dilemma game (PDG) with a punishment option, Dreber et al. (2008) showed that punishment provoked retaliation from the punished partner, and thus punishers had some fitness disadvantage. In Dreber et al.'s study, there was no room for each player's reputation as a punisher to affect the player's payoff. The aim of the present study was to explore the effect of reputation information in Dreber et al.'s experimental setting. Thirty-eight undergraduates engaged in the PDG with the punishment option. Each participant played the game with 20 partners (4 rounds on average with each partner). Prior to the game with each partner, participants were informed of how frequently their new partner had used the punishment option in playing the PDG with past partners. Notice that this information works as reputation information. The result showed that punishers still had some fitness disadvantage: those who had used the punishment option more frequently against the first five partners were less likely to be cooperated by their later partners ( $r = -.44$ ,  $p < .01$ ). The present study, combined with Dreber et al.'s study, poses questions to the validity of the assumption that punishers would not suffer from a fitness disadvantage.

#### E97

**WHO IS THE GOOD JUDGE OF TRUSTWORTHINESS? TRUST, TRUSTWORTHINESS, AND SOCIAL ATTRACTIVENESS** Mizuho Shinada<sup>1</sup>, Toshio Yamagishi<sup>2</sup>, Yang Li<sup>2</sup>, Joanna Shug<sup>2</sup>, Nobuhiro Mifune<sup>1,2</sup>, Hirofumi Hashimoto<sup>1,2</sup>, <sup>1</sup>Japan Society for the Promotion of Science, <sup>2</sup>Hokkaido University – Psychologists have tried for nearly one century to answer the question: "Who is the good judge of personality?" (Adams, 1927). Although there are a number of empirical studies to show what kind of individuals are more successful at judging other's personality than others, most researchers failed to examine the ultimate cause of judgment ability – the adaptive advantages of the detection ability of personality. In this study, we focus on the detection ability of other's trustworthiness and its adaptive advantages. We argue that adaptive advantages of trustworthiness-detection exist only when actors can choose potential exchange partners. For actors who don't trust strangers, the ability to tell trustworthy one from untrustworthy one is useless (since they do not want to choose from alternative partners whom they don't trust). Therefore we predicted that 1) those who trust strangers (as candidates of potential partners) should have trustworthiness-detection skills. Furthermore, we argue that those who want to choose partners can do so only when they have potential partners who want to interact with them – i.e., when they are chosen by the potential alternative partners. Thus, we predicted that 2) socially attractive people should be more accurate in trustworthiness-detection than less attractive people. We conducted two experiments to test these hypotheses. The results supported our hypotheses: our subjects' general trust level was positively correlated with the accuracy of trustworthy-detection (Study 1,  $r = .21$ ,  $p < .05$ ) and the detection accuracy of trustworthiness was also positively correlated with the subjects' social attractiveness (Study 2,  $r = .27$ ,  $p < .05$ ).

#### E98

**STRANGERS IN THE NIGHT: THE EFFECTS OF AMBIENT DARKNESS ON THE DETECTION OF HUMAN AGENCY** Aiyana K Willard<sup>1</sup>, Ara Norenzayan<sup>1</sup>, Will Gervais<sup>1</sup>, <sup>1</sup>University of British Columbia – The theory of hyperactive agency detection predicts that humans should detect human agents more acutely than non-agents. Humans are a potential threat; detecting their presence immediately can reduce chances of harm and would be an evolutionarily adaptive strategy. The minimal cost of reacting mistakenly when no human is present would be offset by the benefits of always reacting when one is present. Under ambiguous circumstances, hyperactive reaction would increase fitness; therefore hyperactivity should increase when feeling uncertain or vulnerable, such as in the dark. Two studies tested this hypothesis. In study 1, participants were asked to identify blurred pictures of either human or nature scenes as "human" or "nonhuman". This was done both in the light and in the dark. Results show that participants were unable to correctly identify the pictures (selecting both "human" and "nonhuman" at chance), but reacted significantly faster when they thought they saw a human over a nonhuman. This effect was exaggerated in the dark. We maintain that darkness creates a sense of urgency for identifying humans. In a second study we tested urgency alone by having participants identify non-blurred pictures of humans or nature scenes in both a time constraint and no time constraint condition. In the time constraint condition we replicated previous results: participants identified humans faster than nonhumans. This effect disappeared in the no time constraint condition. We interpret these results as a bias to react faster to human agents than non-agents in ambiguous situations.

#### E99

**DOES THE RISK OF SPERM COMPETITION PREDICT MEN'S INTEREST IN THEIR PARTNER'S COPULATORY ORGASM?** Vincent Bates<sup>1</sup>, William F. McKibbin<sup>1</sup>, Craig W. LaMunyon<sup>2</sup>, Aaron T. Goetz<sup>3</sup>, Valerie G. Starratt<sup>4</sup>, Todd K. Shackelford<sup>1</sup>, <sup>1</sup>Florida Atlantic University, <sup>2</sup>California State Polytechnic University, Pomona, <sup>3</sup>California State University, Fullerton, <sup>4</sup>Nova Southeastern University – When the sperm of two or more men concurrently occupy the reproductive tract of a woman, the sperm compete to fertilize an egg she may have produced. Copulatory orgasm may be an adaptation that women use to retain preferentially the sperm of a favored man, and this function of female orgasm might be most selectively relevant in the context of sperm competition. If female orgasm has played a selective role in human evolutionary history, then we hypothesize men to have co-evolved an interest in promoting copulatory orgasm in their partner, and we predict this interest to be greatest during periods of greater risk of sperm competition. We further hypothesize that men who are more invested in their current relationship will be especially interested in promoting copulatory orgasm in their partner. We secured self-report data from 225 heterosexual men in a committed relationship. We assessed the risk of sperm competition as the proportion of time the couple had spent apart since their last in-pair copulation and the total amount of time the couple had spent apart since their last in-pair copulation. We assessed men's investment in their current relationship as a composite of their relationship satisfaction and relationship commitment. In support of our predictions, the risk of sperm competition and men's investment in their current relationship did predict men's interest in their partner's copulatory orgasm. The discussion addresses the limitations of the current research and highlights directions for future work.

#### E100

**SOCIAL EXCLUSION: THE IMPACT OF PERCEIVED SIMILARITY AND TESTOSTERONE ON GROUP RELATIONS** Cathy DeSoto<sup>1</sup>, Rory Deol<sup>1</sup>, Derrick McAdams<sup>1</sup>, Robert Hitlan<sup>1</sup>, <sup>1</sup>University of Northern Iowa – The current study analyzed how interactions with others, believed to be either highly similar or dissimilar to oneself, related to testosterone levels. Eighty-two males ( $M_{age} = 19.52$ ) provided saliva samples 20 minutes prior to a group-based chat-room interaction with three other "participants" (confederates). At the end of the interaction period, participants

completed a survey (20 minutes) after which a second sample of saliva was collected. The confederates either included the participant in the discussion, or ignored/downplayed the responses of the participant. Assays of saliva indicated a significant difference between the high and low similarity conditions,  $t = -2.21$ ,  $p < 0.05$ . Of interest, decreases in the levels of testosterone were particularly pronounced when interacting with highly dissimilar, but inclusive others. Such a biological response to out-group inclusion could be adaptive by increasing submissive behavior in a novel environment where group acceptance is likely. It is possible that testosterone drop is a biological substrate that serves to tone down dominance seeking behavior.

### E101

#### **MALE PHYSICAL STRENGTH IS ASSOCIATED WITH FAVORABLE ATTITUDES TOWARDS CASUAL SEX AND SEXUAL SUCCESS** Christina M. Larson<sup>1</sup>, Kelly A. Gildersleeve<sup>1</sup>, Martie Haselton<sup>1</sup>; <sup>1</sup>University of California

Los Angeles – According to sexual strategies theory, individuals evolved the capacity to flexibly pursue different sexual strategies, depending on which strategy is likely to yield the greatest reproductive success. While, on average, men can increase their reproductive success by engaging in casual sex with multiple women, this success is limited by the number of partners a man can obtain. Therefore, the likelihood of a man pursuing an unrestricted, casual mating strategy should vary as a function of his likely success at such a strategy. Several studies have provided evidence that physical strength is an individual difference affecting men's ability to obtain sex partners. The present study sets out to extend the previous research by examining whether stronger men's sexual strategies reflect their likely greater sexual success. In other words, do stronger men have more unrestricted sociosexual motives and desires? To test this prediction, we assessed the physical strength and sociosexuality of male undergraduates ( $N = 59$ ). We obtained measurements of physical strength, self-reports of physical strength, and third party ratings of physical strength. Participants completed the Sociosexuality Orientation Inventory (Simpson & Gangestad, 1991). Self-reports and ratings of physical attractiveness were also obtained. As expected, physical strength was positively associated with sociosexuality. Stronger men were more likely to report favorable attitudes towards casual sex, and a history of engaging in casual sex. Although attractiveness was positively related to both strength and sociosexuality, it did not account for the relationship between the two. These results support the hypothesis that physical strength influences men's sexual strategies.

### E102

#### **WHY IS GOD IMMORTAL? ON THE ATTRACTION OF SPIRITUALITY** Arnaud Wisman<sup>1</sup>; <sup>1</sup>University of Kent, Canterbury

– God has been declared 'death' by many great thinkers and scientists across different generations. However, in spite of ever growing evidence that debunks the core assumptions of religion and spirituality, the vast majority of people are still spiritual. Why is spirituality so essential for most people? Inspired by the Terror Management Theory (Pyszczynski, Solomon, & Greenberg, 2003) I will hypothesize that spirituality functions as a fundamental component of people's defence mechanism against the awareness of death. First, I will show data that suggest that reminders of death motivate individuals to belief in an afterlife. Interestingly this effect was also found among atheist individuals. Second, I will discuss two studies that show that male individuals who were portrayed as spiritual were perceived as more attractive after subliminal reminders of death as compared with a control condition. Moreover, females in the subliminal death condition indicated to be more willing to go out on a short term date with someone who believed in an afterlife after subliminal reminders of mortality. Upon conclusion, I will provocatively hypothesize that spiritual individuals are cultural and genetical more fit.

### E103

#### **GENDER DIFFERENCES IN RESPONSE TO INFIDELITY** Kari Staley<sup>1</sup>, Ajal Patel<sup>1</sup>, Jeremy D. Heider<sup>1</sup>, John E. Edlund<sup>2</sup>, Elizabeth Kelly<sup>1</sup>, Adam J. Williams<sup>1</sup>; <sup>1</sup>Stephen F. Austin State University, <sup>2</sup>Rochester Institute of Technology

– Research in evolutionary psychology (e.g., Buss et al., 1992) suggests most males are more distressed by sexual infidelity, whereas most females are more distressed by emotional infidelity. The current study examined potential personality characteristics of males and females that might influence their degree of sensitivity to sexual and emotional infidelity. 89 psychology undergraduates completed individual difference measures of psychological androgyny, empathic concern, and compassion. Also, sex differences in jealousy reactions were examined using both forced-choice and continuous measures. A sex difference in response to the two different types of infidelity emerged on the forced-choice measure: 63.4% of women reported emotional infidelity would make them more jealous, compared to only 41.7% of men,  $\chi^2(1, N = 87) = 3.39$ ,  $p = .066$ . An analogous sex difference emerged in a repeated measures ANOVA on the continuous ratings, although the interaction in question did not reach conventional levels of significance ( $p > .3$ ). Most importantly, however, all three personality variables correlated with continuous ratings of emotional jealousy in the predicted directions: More masculine participants expressed less emotional jealousy,  $r(88) = -.28$ ,  $p = .009$ ; more empathic participants expressed greater emotional jealousy,  $r(88) = .34$ ,  $p = .001$ ; and more compassionate participants expressed greater emotional jealousy,  $r(88) = .28$ ,  $p = .008$ . These findings suggest individual differences may play an important role in determining whether a given individual (male or female) will be more sensitive to the emotional, rather than sexual, aspects of a partner's infidelity.

### E104

#### **COOPERATIVE COURTSHIP: HELPING FRIENDS RAISE AND RAZE RELATIONSHIP BARRIERS** Joshua Ackerman<sup>1</sup>, Douglas Kenrick<sup>2</sup>; <sup>1</sup>Massachusetts Institute of Technology, <sup>2</sup>Arizona State University

– Do people help each other form romantic relationships? Research on the broader social environment within the context of romantic relationships has traditionally focused on intrasexual competition as a likely outcome. In contrast, we investigated novel patterns of cooperation within courtship interactions. Drawing on theories of parental investment and sexual selection, women were predicted to cooperate primarily in building romantic thresholds and barriers; men were predicted to cooperate primarily in achieving romantic access. In several studies that support these predictions, we find that people consistently perceive cooperation, report cooperative behaviors and make cooperative decisions in romantic situations. People also provide the exact opposite pattern of help to opposite-sex friends from that provided to same-sex friends, suggesting that assistance is flexibly tuned to differences in the romantic selectivity and goals of recipients. This tuning can result in unique and novel forms of helping, as when individuals adopt the role of counterfeit romantic partners. Cooperative courtship is revealed to be a commonly-used set of mating strategies by which people functionally tailor aid to promote both their own and their friends' romantic relationship interests.

### E105

#### **PRACTICE AND THE FACE-IN-THE-CROWD EFFECT** Carson Sandy<sup>1</sup>, Mark Klinger<sup>2</sup>; <sup>1</sup>University of Texas at Austin, <sup>2</sup>University of Alabama

– Some research indicates that people detect angry faces quicker than other types of faces, a phenomenon known as the face in the crowd effect (Hansen & Hansen, 1988). The present study sought to replicate this effect and to examine how practice with searching for happy (instead of angry) faces might affect peoples' reaction times. Participants, either in a control or experimental condition, participated in three search trials: pre-test, practice, and post-test. Practice in the control condition involved searching for a five-petaled flower amongst seven-petaled flowers while practice in the experimental condition involved searching for a happy face amongst angry faces. Pre and post-tests had trials of both

finding an angry face in a matrix of happy faces and finding a happy face in a matrix of angry faces. It was predicted that practice effects for detecting happy faces would be observed. Results revealed that participants in the control condition became faster from pre to post-test at identifying both happy and angry targets. Participants in the experimental condition became faster in the happy target condition but decreased in speed in the angry target condition indicating practice can improve individuals' ability to search for discrepant faces regardless of target type. In addition, practice searching for a particular type of target (happy faces) may interfere with the ability to detect other types of targets (angry faces). Results indicate there is no face-in-a-crowd effect for angry faces. Rather, people are faster at searching for targets for which they are practiced.

### E106

**CHILDHOOD (BUT NOT CURRENT) SOCIOECONOMIC STATUS IS LINKED TO SOCIOSEXUAL ORIENTATION** John S. Kim<sup>1</sup>, Vidas Griskevicius<sup>1</sup>, Jeffrey A. Simpson<sup>1</sup>, <sup>1</sup>University of Minnesota – There are individual differences regarding how one approaches the sexual aspect of mating (Simpson & Gangestad, 1991). On one end of the continuum, there are those with an unrestricted sexual strategy, who are comfortable with sexual behavior in the absence of intimacy and closeness. On the other end, there are those with a restricted sexual strategy, who require a certain level of intimacy and closeness before engaging in sexual behavior. Meanwhile, researchers working from a life-history framework have posited that childhood socioeconomic status, perhaps even more than current socioeconomic status, profoundly influences social development (Belsky, Steinberg, & Draper, 1991). Specifically, lower SES during childhood should be associated with a stressful rearing environment, which then leads that individual towards an orientation characterized by short-term motives. From extant theory, we predicted that childhood relative SES would predict current sociosexual orientation, even after current SES was taken into account. Our analyses (N = 81) supported our hypotheses, as childhood SES predicted current sociosexual orientation ( $p < .01$ ), even with current SES in the model ( $p > .13$ ). That is, people who felt relatively deprived socioeconomically during childhood were more likely to follow a short-term, unrestricted mating strategy. Subsequent analyses indicated that this effect was particularly strong for men, but not women ( $p < .02$ ). We discuss the theoretical implications of these findings, parallel findings with commitment as the dependent variable, and follow-up studies currently in progress.

## Gender

### E107

**DOUBLE STANDARDS AND PERCEPTIONS OF DOUBLE STANDARDS IN ATTITUDES TOWARD THE ROLES OF MEN AND WOMEN** Kathleen Fortune<sup>1</sup>, Gerry Sande<sup>1</sup>, <sup>1</sup>University of Manitoba – This study utilized the "mirror-image" technique to assess double standards in attitudes toward appropriate behaviors and roles for women and men (Sande, 1993). This technique measures attitudes toward the roles, rights, and opportunities of women and men separately using scale items that are identical. For example, one version of the scale contains an item about the importance of educational opportunities for women and the other version contains a parallel item about the importance of education for men. The two versions of the scale were administered with a 4 month time delay which minimized transparency and social desirability concerns and allowed participants to express double standards in two directions, as opposed to unidirectional biases. The items were sorted into 6 domains: education and career, sexual behavior, domestic violence, positive public behavior, negative public behavior, and career versus family priorities. Results indicated that male participants held pro-female double standards in the domains of domestic violence, positive public behavior, and career priorities (for example, they indicated that violence against a female partner should be more severely punished than violence against a male partner). Female participants held pro-female double standards in all domains. Participants were also asked to complete the scale as they believe that the

average male and average female university student would complete them. Results indicated that both male and female participants generally incorrectly believed that the average male student holds pro-male double standards in most domains. Both female and male participants correctly believed that the typical female holds pro-female double standards.

### E108

**THE EFFECTS OF SITUATIONAL AND PERSONALITY VARIABLES THE OBJECTIFICATION OF WOMEN** Marion Wheeler<sup>1</sup>, Tomi-Ann Roberts<sup>2</sup>, Matt Motyl<sup>3</sup>, <sup>1</sup>University of Denver, <sup>2</sup>The Colorado College, <sup>3</sup>University of Virginia – Objectification theory provides a framework for understanding the experience of being a female in a society that objectifies the female body. This theory explains why females tend to experience more shame and anxiety, fewer peak motivational states, and less awareness of internal bodily states. Furthermore, this theory provides one important justification for why women are disproportionately affected by depression, sexual dysfunctions, and eating disorders. To date, most research within the objectification theory tradition has focused on the many deleterious effects objectification has on women. The present study examines factors that may increase objectification of women and what role personality variables may play. We hypothesized that people would objectify women more after reading an objectifying comment. Furthermore, masculinity should positively correlate with objectification whereas empathic emotional attention should negatively correlate with objectification. In the present study, 71 participants completed several personality measures, were randomly assigned to read a story containing an objectifying comment or a non-objectifying comment about a woman playing volleyball, and then completed a measure of objectification. The results confirmed the hypotheses indicating that reading an objectifying comment leads to higher levels of objectification, even among female participants. Furthermore, participants high in masculinity objectified women more than participants low in masculinity. Similarly, participants low in empathic emotional attention objectified women more than those high in empathic emotional attention. This study lays an incipient groundwork for finding ways to reduce the occurrence of objectification inimical to the well-being of women.

### E109

**THE ROLE OF GENDER, PERSONALITY, AND WORK EXPERIENCES IN RISK-TAKING** Meghan Lowery<sup>1</sup>, Joel Nadler<sup>1</sup>, <sup>1</sup>Southern Illinois University Carbondale – Risk-taking is decision making based on the probabilities of an outcome (March & Shapira, 1987). The willingness to take risks can affect many employment-related decisions. Byrnes, Miller, and Schafer (1999) found that gender differences in risk taking were robust. Specifically, men are more likely to take risks compared to women. Interestingly, the gender gap narrowed over time and saw a reduction in older samples. In the current study, we examine gender differences in risk taking adjusting for personality (Big Five), social-economic status (SES), self-efficacy, age, and work experience. Work experience is expected to influence gender difference in risk taking. Participants (N = 305) from a University in the Midwest completed a questionnaire packet containing scales on risk-taking (Blais & Weber, 2006), SES, self-efficacy, Big Five, demographics and work experience. Gender differences were found with men reporting greater likelihood to take risks,  $F(1, 292) = 32.05$ ,  $p < .001$ . Significant co-variables included work experience ( $r = .11$ ) conscientiousness ( $r = -.22$ ), self-efficacy ( $r = .16$ ), agreeableness ( $r = -.16$ ), extroversion ( $r = .15$ ). Age and SES were not related to risk taking. The implications of work experience mediating the relationship between gender and risk-taking has direct impact on gender disparity in the workplace. The nature of gender differences between men and women and how these differences change with work experience is an important piece in examining gender disparity in upper management. The positive relationship between work experience and risk-taking and the decrease in gender differences as samples age will be discussed.

**E110****GENDER SPECIFIC COLOR PREFERENCES OF PRESCHOOL-AGED CHILDREN**

Ashley Amador<sup>1</sup>, Diandra Hilton<sup>1</sup>, Heather Walker<sup>1</sup>, Sarah Miller<sup>1</sup>, Cheryl L. DeLancey<sup>1</sup>, Victor X. Luévano<sup>1</sup>; <sup>1</sup>California State University, Stanislaus – Color is one of the many ways that people and objects are organized into gender categories. Specific colors are used to designate the sex of an infant, sometimes even before birth. Additionally, toys, clothing, and bedroom décor are often marketed to one sex or the other through the use of color. However, still unknown is the extent to which these color associations are based on biologically defined predispositions or socially defined links to gender. The current study used a developmental approach to investigate the color preferences of preschool-aged (3-5) children in order to determine if gender specific color preferences exist in the preschool period and at what age they appear. Twenty-five children colored with nine crayons (red, orange, yellow, blue, green, pink, purple, black, and brown) on a neutral geometric coloring page. The percentages of each color used in each child's picture were assessed on the basis of the color's gender-specificity (masculine, feminine, and neutral). Girls used a statistically higher percentage of feminine colors in their coloring pages than boys,  $F(1, 19) = 7.62, p = .01$ . There was not a significant interaction between age and gender, but as would be expected if color preferences were socially learned, this gender difference was only found at ages 4 and 5 ( $p's < .05$ ). The results of this study may suggest that girls' preferences for feminine colors are socially learned rather than biologically programmed.

**E111****THE ROLE OF BENEVOLENT SEXISM IN THE 2008 ELECTION**

Molly VanDeursen<sup>1</sup>, Shannon Rauch<sup>2</sup>, Eunseong Kim<sup>3</sup>, Hannah Franz<sup>4</sup>, Andrew Luttrell<sup>3</sup>; <sup>1</sup>Saint Louis University, <sup>2</sup>Providence College, <sup>3</sup>Eastern Illinois University, <sup>4</sup>Winthrop University – The theory of ambivalent sexism has traditionally held that benevolent sexists have positive feelings towards women, particularly when they conform to traditional gender roles. The 2008 election may have provided a dilemma for benevolent sexists as a woman could potentially step into a traditionally masculine role. Before the election, online participants ( $N = 140$ ) were given one of two essays describing the vice presidency. One essay described the office in terms of its masculine traits, stressing its potential power. The other described the office in terms of its feminine traits, stressing its supportive and ceremonial roles. Participants then completed measures of feelings of warmth towards candidates, including Palin and Clinton, voting intentions, ratings of each candidate on specific issues, and the Ambivalent Sexism Inventory. Feelings of warmth towards the female candidates were among the strongest predictors of expected voting behavior, although participants indicated that issues were most important. Participants higher in benevolent sexism had colder feelings towards Clinton, but warmer feelings towards Palin, felt Palin reflected their values, and were more likely to vote republican than participants lower in benevolent sexism. Feelings of warmth and attitudes regarding Palin's values mediated the relationship between sexism and voting behavior. Reading a masculine portrayal of the vice-presidency reduced benevolent sexists' certainty about their expected voting behavior, although it did not change the degree of warmth expressed towards Palin or the other candidates. Results suggest that the role of the woman is less important to benevolent sexists than the value system that she represents.

**E112****HELPFUL OR HURTFUL: HOW DO FEMALE ROLE MODELS EFFECT WOMEN IN LEADERSHIP ROLES?**

Audrey Innella<sup>1</sup>, Crystal Hoyt<sup>1</sup>; <sup>1</sup>University of Richmond – Individuals across various domains are seeking role models, mentors, and advisors who will help them attain success. Women, in particular, tend to gravitate towards role models in order to get ahead in non-traditional roles such as science and math. How and why are these individuals of social comparison important? What is it about their qualities that make them outstanding? The present research examines closely the specific qualities possessed by female role models

and the effects these qualities have on women's leadership aspirations. In a laboratory study, female participants were individually exposed to one of three stimuli (stereotypically feminine female role models, stereotypically masculine role models or control) before leading a supposed, 3-person group. The effect of exposure to female role models on women's leadership self-efficacy, leadership aspirations, and general identification with the leadership domain were assessed through measures of self-report after the leadership task. The results of this study revealed that there was a positive impact of both the stereotypically feminine and the stereotypically masculine female role models; in comparison to those in the control condition, women in the role model conditions reported greater levels of leadership efficacy going into the leadership task, post-task leadership confidence, and desire to become a leader in the upcoming task. In addition, women's leadership-related self-perceptions and self-esteem were directly related to their perceptions of their performance on the leadership task. These results suggest that exposing stigmatized individuals, such as women in leadership situations, to individuals of upward social comparison can have a positive effect.

**E113****AMBIENT GENDER CUE VIGILANCE IN CHOOSING COLLEGE MAJORS**

Christina M. Smith<sup>1</sup>, Victoria C. Plaut<sup>1</sup>, Sapna Cheryan<sup>2</sup>, David T. Mitchell<sup>1</sup>; <sup>1</sup>University of Georgia, <sup>2</sup>University of Washington – Choosing a major is arguably the most important decision an undergraduate makes. Previous research suggests that people are disinclined to join a field if they do not feel a sense of belonging (Walton & Cohen, 2007). While sense of belonging matters for everyone, in evaluating belonging, women may be more vigilant to gender cues than men. Research suggests that women avoid joining environments where men are overrepresented (Murphy et al., 2007), and that, beyond numbers, women also pay attention to other ambient gender cues even when no people are present (Cheryan et al, in press). Extending this work, the present research tests whether environmental cues alone in actual, physical college spaces, influence women's desire to join a discipline, and whether these evaluations are linked to gender cues. We tested reactions to pictures of real, but un-labeled educational environments in male-dominated, female-dominated, and gender-neutral majors. Thirty-seven female and 27 male undergraduate students rated the pictures in terms of their desire to be in the environment, their perceptions of social fit, and whether the environment was masculine or feminine. Results revealed significant correlations of perceptions of masculinity/femininity with feelings of fit and desire to be in the environment for women but not for men. Correlations between fit and desirability were significant for both genders. This study suggests that women are more vigilant to environmental gender cues in choosing a college major, which may play a significant role in the under-representation of women in various fields of study.

**E114****WOMEN'S INDIVIDUAL CONTINGENCIES OF SELF-WORTH AND PUBLIC ATTRIBUTIONS TO DISCRIMINATION: THE INFLUENCE OF GENDER IDENTIFICATION**

Lisa Milford<sup>1</sup>, Gretchen Sechrist<sup>2</sup>; <sup>1</sup>Syracuse University, <sup>2</sup>Mansfield University – This research examines the influence of women's level of gender identification (importance of group membership to self-definition) and their individual contingencies of self-worth (domains in which self-esteem is based) on their public attributions to discrimination. Past research has shown that women privately attribute a failure to discrimination, but are unwilling to do so publicly, especially in front of a male. In the current study, we pre-selected women whose self-worth was highly contingent on academics and whose self-worth was not contingent on academics, as well as women who were high vs. low in gender identification. All participants completed a logical reasoning task and received either sexist or non-sexist failure feedback. Participants then made public attributions for their failure. In the sexist feedback condition, women who were high in academic contingencies publicly claimed discrimination as the cause of their failure more than lows. Importantly, women who were high in gender identity and had self-worth contingent on academics publicly attributed their failure more to

discrimination than to their abilities. Women who were low in gender identity but contingent on academics publicly did not minimize the occurrence of discrimination relative to ability; whereas, women whose self-worth was not contingent on academics attributed their failure more to their abilities than to discrimination regardless of their level of gender identification. Future research should further examine factors that will motivate women to publicly claim discrimination.

### E115

#### APPEASING MASCULINITY THREATS THROUGH SELF-SEXUALIZATION. WHEN DO WOMEN DO IT AND HOW DO WE PERCEIVE THEM?

**Kristine A. Schlenker<sup>1</sup>, Theresa K. Vescio<sup>1</sup>; <sup>1</sup>The Pennsylvania State University** – Previous research indicates men often respond to masculinity threats with aggressive behavior towards women (Maass, Cadinu, Guarnieri, & Grasselli, 2003). Little prior research has examined strategies women use to appease masculinity threats and avoid aggression. The goal of this work was to examine one form of appeasement strategy, self-sexualization. In Study 1, we investigated when successful women in masculine domains engage in self-sexualization. We hypothesized that women would engage in self-sexualization when they a) perceived their superior performance had threatened a man's masculinity and b) feared punishment. To examine this prediction, in Study 1 we manipulated perceived threat by varying a man's reactions to losing to a woman. We manipulated fear of punishment by assigning participants to high or low power roles in which they either controlled or were dependent on the man for rewards. In this context, women in the Threat X Low Power condition were predicted to use self-sexualization appeasement strategies. Based on the conditions created by Study 1, we then examined how others perceive women who use self-sexualizing appeasement strategies. In Study 2, participants read vignettes in which a woman outperformed a man in a masculine task (paralleling conditions in Study 1). Participants then rated the female on dimensions of warmth, competence, likeability, trustworthiness, and attractiveness. Results are discussed in light of the Stereotype Content Model (Fiske, Cuddy, Glick, & Xu, 2002), with a focus on the tension women face in masculine domains as a result of attempts to avoid men's aggression while sustaining perceptions of competence.

### E117

#### BEYOND GENDER DIFFERENCES IN MATE PREFERENCES: THE RELATIONSHIP BETWEEN PERSONAL GOALS AND MATE PREFERENCES

**Bobbi Thompson<sup>1</sup>, L. Shay Welsh-Wooten<sup>1</sup>, Angela Synowicki<sup>1</sup>, Carey Ryan<sup>1</sup>; <sup>1</sup>University of Nebraska at Omaha** – Research suggests that men more than women value attractiveness in a mate, whereas women more than men value financial resources in a mate. According to social role theory, this gender difference is a result of the different marital roles that men and women anticipate filling (i.e., provider vs. domestic). Evolutionary theory views gender differences in mate preferences as developing from strategies related to survival and reproductive success. We examined the role of personal goals in mate preferences. College students completed a questionnaire that assessed educational, career, and financial goals; desire for children; and mate preferences. Consistent with findings from evolutionary theory research, men placed more importance on a mate's attractiveness than did women and women placed more importance on a mate's financial resources than did men. However, both genders rated attractiveness as more important than financial resources. In addition, participants who had stronger career goals preferred mates who were physically attractive, whereas participants who had stronger educational and financial goals preferred mates with financial resources. Regression analyses indicated that the effects of the three types of goals and gender were independent. Further, the effects were independent of participants' preferences for mates who were similar to themselves. Neither participants' desire for children nor the number of children planned predicted preferences for attractive or

financially resourceful mates. To the extent that personal goals reflect the roles that people envision for themselves, these results seem particularly consistent with a social role theory perspective.

### E118

#### CONSEQUENCES OF EXPOSURE TO SCIENTIFIC THEORIES OF GENDER SIMILARITY AND DIFFERENCE

**Scott Gould<sup>1</sup>, Kristin Lane<sup>1</sup>; <sup>1</sup>Bard College** – Despite the large degree of overlap between men and women on many traits (Hyde, 2005), far more attention – from both researchers and laypeople – is devoted to gender differences. Prior work has found that reading about a biological (compared to a socio-cultural) explanation for a gender difference increased gender stereotyping (Brescoll & LaFrance, 2004) and impaired women's math performance (Dar-Nimrod & Heine, 2006). The current work extends this prior research into the relatively understudied domain of gender similarities: we tested how theories of both gender differences and similarities affect stereotyping and women's math performance. Fifty-one participants read a fictitious newspaper article about an ostensible ability in plant identification before completing a short math test. As part of a seemingly unrelated study, they then rated the average man and average woman on masculine and feminine traits (Eagly & Diekmann, 2000). The study used a 2 (trait overlap: gender difference or similarity) x 2 (origin: biological or socio-cultural) between-subjects design to test the effects of reading about causal explanations for gender similarities or differences on stereotyping and math performance. Somewhat surprisingly, given prior work, participants endorsed stereotypes most strongly after reading about a biological cause for a gender similarity or a socio-cultural cause for a gender difference. Similarly, women's math performance was lower in these two conditions compared to the others. We discuss possible explanations for these results.

### E119

#### BODY IMAGE AND ATTITUDES REGARDING DATING, SEX, AND SOCIAL SITUATIONS: A MIXED QUANTITATIVE-QUALITATIVE APPROACH

**Alex Natwick<sup>1</sup>, Ioana Mateescu<sup>1</sup>, David Frederick<sup>1</sup>; <sup>1</sup>UCLA** – Many men and women who have negative attitudes about their bodies and physical appearance report a wide array of psychological and health issues. People with poor body image are more likely to exhibit disordered eating patterns and are at greater risk for developing potentially life-threatening eating disorders. Individuals with poor body image are also more likely to report depression, low self-esteem, greater tobacco and alcohol abuse, and engaging in more risky sexual behaviors. A substantial literature has investigated the body image concerns of men and women using quantitative methods and a smaller literature has used qualitative approaches. Little research has simultaneously used both approaches in order to investigate body image concerns, particularly as they relate to issues of interest to social psychologists. We recruited a sample of 630 adults who completed established body image scales (Appearance Evaluation; Cash, 2000) and wrote qualitative responses to questions assessing how their feelings about their body impacted their dating life and their avoidance of certain social situations. Qualitative analyses revealed a strong difference between individuals who report positive vs. negative body image. Individuals with a negative body image reported avoiding a wide range of social situations (e.g., wearing a swimsuit in public, bars) and overall reported that their feelings about their body inhibited them in their dating and sex life. The results highlight the effectiveness of multimethod approaches to understanding the effects of body image on the social experiences of men and women.

### E120

#### SEX-ROLE STEREOTYPING AMONG CHILDREN WITH REGARD TO AGE, GENDER AND OCCUPATION

**Clare Campbell<sup>1</sup>, John Radford<sup>1</sup>, Peary Brug<sup>1</sup>; <sup>1</sup>St. Mary's University College** – Historically, men and women have rarely shared status and power on an equal level within occupational settings (St. Pierre et al, 1992). Often, this has been the result of sexism in society. However, while legislation and the 'sexual revolution' have brought forth dynamic changes with regard to women in the workplace, the sex-

ual stereotypes associated with occupation may still be present. The current study investigated differences in occupational sex-role stereotypes among male and female children across three different school ages. Data was collected from pupils in the United Kingdom in reception year (ages 4-5), year three (ages 7-8) and year six (10-11). Using an experimental design, pupils selected whether a male or female person was more suited for a particular occupation. Analysis indicated that there were significant differences within stereotyping occupations across school years, signifying that stereotyping within occupations appears to develop and change across age. Further analysis signified that males in reception year and year three stereotyped traditional 'female' occupations to a greater degree than females, suggesting that female occupations are considered to be less flexible in regard to gender. However, no overall significant gender differences were reported. Within society there have been positive attempts to reduce sex-role stereotypes that have been associated with occupations to help provide for a gender-fair workplace. However, the results still imply that young school children continue to stereotype to a high degree across a range of traditionally perceived 'male' and 'female' occupations. Implications and limitations of the research are discussed.

### E121

#### **FEARS OF SEEMING FEMININE: MALE ANTIFEMINITY INFLUENCING CAREER ROLE RIGIDITY** Brian Wilkey<sup>1</sup>, Amanda Johnston<sup>1</sup>, Amanda Diekman<sup>1</sup>, Jason Lanter<sup>2</sup>; <sup>1</sup>Miami University, <sup>2</sup>Kurtztown University –

Although women have broadened their gender role to include aspects of the male role, men's roles have remained relatively static (Diekman & Eagly, 2000). Role Congruity Theory (Diekman & Eagly, 2007) suggests that people are motivated to avoid role misalignment for fear of societal sanctions. Thus, men are motivated to avoid roles (e.g., careers) viewed as feminine; acting in a feminine way can jeopardize their manhood in the eyes of society (Vandello et al., 2008). In this research, we examined how individual differences in men's endorsement of masculine role norms influenced their evaluations of men in traditional (e.g., corporate executive) and nontraditional (e.g., social worker) career roles. Male participants rated how focused on status, toughness, and antifemininity (i.e., the desire to not be feminine) a male should be; these scores were used to predict their ratings of positivity and negativity towards men in traditional and nontraditional career roles. Results indicated that men's beliefs about antifemininity positively predicted their evaluations of men in traditional career roles ( $p=.04$ ) and marginally negatively predicted their evaluations of men in nontraditional careers ( $p=.07$ ). Status and toughness did not predict evaluations of traditional or nontraditional careers. These results suggest that beliefs about antifemininity norms influence how males evaluate traditional and nontraditional career role fulfillment by men. Current research is exploring men's emotions and willingness to acquire nontraditional careers after receiving personality feedback indicating they are well-suited for traditionally feminine, as well as masculine, career roles.

### E122

#### **ENACTING COUNTERSTEREOTYPIC BEHAVIOR SHAPES IMPLICIT SELF-CONCEPTS** Lori Malahy<sup>1</sup>, Cheryl Kaiser<sup>1</sup>; <sup>1</sup>University of Washington –

This research examines how counter-stereotypic behavior shapes implicit self-concept. Using the framework of self-perception (Bem, 1967; 1972) counter-stereotypic behavior was predicted to weaken implicit self-concept. Using a paradigm adapted from Bosson and colleagues (2005), participants engaged in either 'hairstyling' (feminine behavior) or 'rope reinforcement' (masculine behavior). In both conditions, participants completed the same action: braiding. It was hypothesized that 1) women in the counter-stereotypic masculine rope reinforcement condition would have weaker implicit female self-concepts than women in the stereotypic feminine hairstyling condition, and 2) men in the counter-stereotypic feminine hairstyling condition would have weaker implicit male self-concepts than men in the stereotypic masculine rope reinforcement condition. Fifty-nine men and 53 women participated in this study at the University of Washington. Men who completed a hairstyling task

(gender counter-stereotypic) had lower implicit male self-concept scores compared to men who completed a rope reinforcement task (gender stereotypic). Women showed no effect of condition. These findings are in line with research showing that men's gender self-concepts are less secure than women's gender self-concept (Vandello et al., 2008). Additionally, the present findings extend the literature on counter-stereotypic behavior by showing how enacting counter-stereotypic behavior implicitly changes how people see themselves in relation to their groups. In doing so, this research provides insight into self-related consequences of engaging in counter-stereotypic behavior.

### E123

#### **OBJECTIFICATION AND MARRIAGE: HUSBANDS' OBJECTIFICATION IS POSITIVELY ASSOCIATED WITH WIVES' SEXUAL SATISFACTION** Andrea

L. Meltzer<sup>1</sup>, James K. McNulty<sup>1</sup>; <sup>1</sup>University of Tennessee – How might sexual objectification affect women in the context of a close relationship? A plethora of research suggests that sexual objectification of women by strangers has a variety of negative psychological consequences for those women (Fredrickson & Roberts, 1997). But given that even robust social psychological effects can differ across relational contexts (Reis, 2008, p. 320; Reis, Collins, & Berscheid, 2000), sexual objectification of women may have different effects in the context of romantic relationships may be more positive. Indeed, a robust literature suggests that women have evolved specific long-term mating preferences that functioned to help them obtain viable partners with whom they could produce and rear the best offspring. Given that women would have most successfully produced and reared offspring with committed mates who desired them sexually, evolution may have also favored women who reacted positively to partners who sexualized, or objectified, them in the context of a committed relationship. We tested this hypothesis in a sample of couples who had been married for two years. Consistent with predictions, husbands who reported greater tendencies to objectify their wives had wives who reported increased levels of sexual satisfaction. These results support the importance of considering the various qualities of the interpersonal relationships in which objectification occurs (e.g., commitment) in order to best understand its psychological consequences.

### E124

#### **DATING 101: THE EFFECT OF SELF-OBJECTIFICATION ON COLLEGE DATING INTERACTIONS** Valerie Earnshaw<sup>1</sup>, Randi Garcia<sup>1</sup>, Diane, M. Quinn<sup>1</sup>; <sup>1</sup>University of Connecticut –

Although state self-objectification is theorized to be both elicited by and impact outcomes related to interpersonal interactions, few studies have examined state self-objectification within an interpersonal context. The current study explored the impact of experiences of state self-objectification within college dating interactions. Fifty mixed-gender dyads interacted for ten minutes while evaluating each other as potential dating partners. After the interaction, they reported the extent to which they self-objectified within the interaction as well as their impressions of their partner. State self-objectification was measured by participants' self-report of the degree to which they felt like a body, rather than a person, during the interaction. Dyadic data analyses were employed to examine how gender and individual differences in state self-objectification interacted within this unstructured, face-to-face interaction to predict participants' impressions of their interaction partners. Experiencing state self-objectification impacted the extent to which some participants liked their partners, desired to date their partners, desired to be friends with their partners, and felt that the interaction went smoothly. Among both male and female participants, greater state self-objectification was related to decreased desire to be friends with their partner and decreased feelings that the interaction went smoothly. Among female participants only, greater state self-objectification was related to decreased desire to date their partner and decreased liking of their partner. These results suggest that experiences of state self-objectification may play an important role in impression formation within college dating interactions, especially among women. Discussion will focus on gender and state self-objectification within interpersonal contexts.

**E125**

**COMPENSATING FOR THREATENED MANLINESS: AN INVESTIGATION OF IDENTITY STRATEGIES** Jessica Cameron<sup>1</sup>, Sapna Cheryan<sup>2</sup>, Zach Katagiri<sup>3</sup>, Benoit Monin<sup>4</sup>; <sup>1</sup>University of California - Berkeley, Haas School of Business, <sup>2</sup>University of Washington, <sup>3</sup>New York University, <sup>4</sup>Stanford University, Graduate School of Business – This research investigates the identity strategies that men use, and those they refrain from using, when their masculinity has been threatened. Results revealed that men compensate for threats to their masculinity by asserting their masculinity to those who doubt it. However, the form this assertion takes depends on which strategies are seen as the best signals of identity. The first study established that asserting masculine attributes/behaviors (e.g., height, number of past sexual relationships) and distancing from feminine consumer products (e.g., a gift certificate to Banana Republic) are considered more effective signals of masculinity than embracing masculine consumer products (e.g., tickets to a sports event), which is seen as less diagnostic of masculinity and easier to fabricate. In the next two studies, males who were either told that their performance on a masculinity test was worse than their male peers (Study 1) or that they were physically weaker than other males (Study 2) expressed a lower preference for stereotypically feminine products, but not for masculine ones. Additionally, threatened men asserted stereotypically masculine attributes and past behaviors, such as height, number of past sexual relationships and aggressiveness. Thus, men who believed they performed poorly on tests of masculinity altered themselves and their preferences to assert their masculinity, but only in the domains that best signal masculinity while circumventing those that do not. These findings provide insight into how men attempt to overcome having a threatened identity by using assertion and distancing strategies and the different ways in which these strategies manifest.

**E126**

**SHE STOOPS TO CONQUER? HOW POSTURE, SELF-OBJECTIFICATION AND STATUS IMPACT WOMEN'S AFFECT AND PERFORMANCE** Tomi-Ann Roberts<sup>1</sup>, Kelsey Patterson<sup>1</sup>; <sup>1</sup>Colorado College – According to a Jamesian view of emotion, physical comportment exerts a strong affective and cognitive influence upon individuals. However, research suggests that women experience different effects of proprioceptive feedback than do men. The present study sought to examine two sociocultural factors that may contribute to the effects of postural feedback in women: self-objectification and power. Eighty female participants completed various cognitive tasks and satisfaction measures while in an upright or slouched posture, sitting in a grandiose throne or child's chair, and wearing a form-fitting tank top or loose sweatshirt. Results showed that when self-objectification was removed from women's awareness (by having them wear a loose sweatshirt), postural positions yielded intuitive effects: women felt better and performed better while upright than while slumped. However, when women wore a shirt that revealed their body, the proprioceptive benefits of upright posture were undermined, and women felt and performed better while slumped. Both the magnitude and valence of different body positions may be influenced by sociocultural factors, suggesting that we must consider context in understanding proprioceptive feedback. The clothing that a woman wears and the extent to which she feels powerful or powerless may enable an upright posture to exert benefits, or these factors may lead a slouched posture to be less disruptive and perhaps even protective. This study suggests that proprioceptive feedback does not exist in a vacuum, but rather must be considered within the context of social experience. Being female in a sexually objectifying culture means that women often stoop to conquer.

**E127**

**POWER AND THE EVALUATION OF AGENTIC WOMEN** Ann E. Hoover<sup>1</sup>; <sup>1</sup>University of South Carolina Upstate – Women who possess stereotypically masculine qualities, such as assertiveness or other agentic traits, face social and economic sanctions from others (Rudman & Fairchild, 2004). Specifically, when women display agentic qualities necessary for

leadership positions, they may be viewed as competent, but also as particularly unlikeable and unworthy of hiring for such leadership positions (i.e., the backlash effect; Rudman, 1998). For women, this represents a major hurdle to gaining access to leadership roles. Consequently, one of the long-term effects of backlash may be a continuance of "gendered power" – with men maintaining greater access to positions of power. If backlash can serve to maintain power, it seems plausible that possession of power (or lack of power) might make backlash more likely. I present research in which male participants evaluated résumés from male and female job candidates applying for a managerial position. Results in each study suggest that lacking power may facilitate backlash. Men assigned to (Study 1) or primed with (Study 2) a low-power role rated the female applicant as less hireable and recommended a lower salary for her, compared to the male applicant. This did not occur in high-power or baseline conditions. A follow-up study suggests that the low-power role may have been threatening to male participants. When low-power male participants self-affirmed before evaluating job candidates, there was no evidence of backlash, suggesting that backlash may partially serve to alleviate threat. Results are discussed in terms of different processes that may produce backlash for high- and low-power men.

## Intergroup Relations

**E128**

**EFFECTS OF PERSPECTIVE-TAKING ON INTERGROUP PERCEPTIONS: THE MODERATING ROLE OF SOCIAL IDENTIFICATION** Mark Tarrant<sup>1</sup>, Raff Calitri<sup>1</sup>; <sup>1</sup>Keele University, UK – Previous studies have demonstrated that taking the perspective of outgroup members can have beneficial effects on intergroup perceptions. Three studies are reported here which show that social identification can moderate these effects. In the first study (N = 359), social identification was found to be negatively correlated with perspective-taking, with strong group identifiers reporting less propensity than low identifiers to adopt the perspective of outgroup members. Using an experimental design, Study 2 (N = 127) demonstrated that perspective-taking led to a more favorable evaluation of the outgroup only amongst participants who were weakly identified with the ingroup. For strongly identified participants, perspective-taking had the opposite effect, leading to a more negative evaluation of the outgroup compared to a no-perspective control. Study 2 also demonstrated that perspective-taking impacted on low identifiers' social mobility intentions: adopting the perspective of an outgroup member led these members to express greater interest in changing their group affiliation. Study 3 (N = 67) found that the negative effects of perspective-taking amongst high identifiers are themselves moderated by the salience of social identity. Specifically, taking the perspective of an outgroup member led to a less negative evaluation of the outgroup amongst high identifiers when the salience of the ingroup identity was reinforced, compared to when a reinforcement was not present. These findings highlight the important role played by social identity concerns in structuring the outcome of perspective-taking.

**E129**

**OUTGROUP MATING THREAT AND PERCEIVED DISEASE VULNERABILITY AMONG MEN** Liga Klavina<sup>1</sup>, Abraham P. Buunk<sup>1</sup>, Justin H. Park<sup>2</sup>, Thomas V. Pollet<sup>1</sup>; <sup>1</sup>University of Groningen, <sup>2</sup>University of Bristol – Throughout human history, outgroup males have posed a range of threats. Some of the intergroup conflict appears to have revolved around access to potential mates. Contextual factors, like high pathogen stress in a community have been shown to intensify intergroup mating competition. Therefore, the negative reactions towards outgroup mating threat should be especially strong among males who perceive themselves as being vulnerable to disease or who are exposed to disease cues. We tested this prediction in two studies. In study 1 (33 males; 88 females), we manipulated outgroup mating threat by presenting outgroup same-sex members as preferred mating partners by ingroup opposite-sex members. We found the predicted effect - male participants who scored high in perceived vulner-

ability to disease showed significantly stronger implicit negative attitudes (assessed with the Implicit Association Test) than males low in perceived disease vulnerability when outgroup mating threat was induced.

### E130

#### THE EFFECTS OF INTRAGROUP AND EXTRAGROUP POWER ON THE WELL-BEING OF GROUP MEMBERS: AN EXPERIMENTAL EXPLORATION

Roxanne M. Aubin<sup>1</sup>, Catherine E. Amiot<sup>1</sup>, Sarah Gobeil<sup>1</sup>; <sup>1</sup>University of Quebec in Montreal – Group life has a deep influence on individual well-being (Haslam, et al., 2009). The study of power is primordial to understanding social interactions (Russell, 1989), including intergroup dynamics. Using a modified minimal group paradigm, this experimental study explored how different forms of social power impact upon group members' individual well-being. While intragroup power refers to the group's control over their own resources (IP), extragroup power (EP) refers to control over the resources of other groups (Jones, 1997). Low and high levels of IP and EP were manipulated independently using vignettes describing a fictitious social group. The participants were 179 college students who received a questionnaire that randomly included one of four vignettes. After imagining themselves as a member of the social group described, participants completed measures of psychological well-being (i.e., positive and negative affect, vitality, anxiety, self-esteem). Main effects of IP and EP on individuals' well-being were hypothesized, and high IP was expected to have a more beneficial effect than high EP (Van Dijke & Poppe, 2006). Controlling for degree of identification (with the fictitious social group), 2 (IP: low/high) X 2 (EP: low/high) ANCOVAs supported the hypothesized main effects of IP and EP for each well-being variable: high IP and high EP led to higher well-being. Follow-up analyses did not find significant differences between the strength of the IP and EP effects. These results were replicated in multiple regressions with self-reported measures of perceived power used as predictors. Implications and future directions will be discussed.

### E131

#### STANDARD = COMPETENCE, DIALECT = WARMTH... REALLY?

Christiane Schoel<sup>1</sup>, Dagmar Stahlberg<sup>1</sup>; <sup>1</sup>University of Mannheim, Germany – Language is an important characteristic of group definition and group identity. Within a language, different varieties such as accents and dialects can be distinguished. During its development a language undergoes a standardization with formal rules and norms receiving social and institutional support. As a consequence, the standard acquires superiority on various dimensions such as social status and aesthetic qualities. For non-standard speakers this entails a devaluation of their group activating the motive to compensate and restore some degree of positive social identity by finding another dimension on which positive differentiation can be achieved. Accordingly, the typical finding is that whereas status and competence are attributed to standard speakers, solidarity and warmth are attributed to non-standard speakers. To investigate whether the latter finding is due to a compensation motive we examined the competence and warmth ratings attributed to standard and southern dialect speakers of German. Respondents were either from Northern or Southern Germany, thus evaluated the southern dialect from an outgroup or an ingroup perspective. Half of the participants gave their ratings on complementary items (i.e., the more the ingroup gets, the less the outgroup gets and vice versa), the other half rated both groups on separate scales. For the standard speakers, we found better evaluations on the competence and for the non-standard speakers on the warmth dimension. More importantly, the warmth ratings were specifically enhanced for German Southerners in the complementary assessment condition arguing for a strong compensation motive of this group.

### E132

#### WHO DONE IT? RACIAL STEREOTYPES ASSOCIATED WITH THE PERPETRATORS OF CERTAIN CRIMES

Sabrina Khan<sup>1</sup>, Danny Osborne<sup>1</sup>, Paul G. Davies<sup>2</sup>, Jennifer L. Eberhardt<sup>3</sup>; <sup>1</sup>UCLA, <sup>2</sup>University of British Columbia, <sup>3</sup>Stanford University – Past research has shown that people have racial stereotypes about criminals. Specifically, people assume that Blacks and other minorities are more likely to be involved in criminal activities than Whites (Dixon, 2008). Though such a finding demonstrates the stigmatized nature of minority racial identities, it is possible that not all criminal stereotypes are of Blacks and minorities. That is, there may be different racial stereotypes associated with different crimes. The current study explored this possibility by having participants at a large university on the West coast evaluate 47 different crimes on the following three dimensions: 1) seriousness of the crime, 2) violence associated with crime, and 3) assumed race of the criminal. A series of one-sample t-tests and dependent samples t-tests confirmed that different racial stereotypes exist for different crimes. For example, drive-by shooters were seen as more likely to be Black than White ( $t(32) = 22.52, p < .01$ ), but serial killers were seen as more likely to be White than Black ( $t(32) = 5.23, p < .01$ ). Subsequent repeated-measures ANOVAs showed that stereotypically White crimes were seen as less violent and less severe than stereotypically Black crimes. This suggests that important distinctions need to be made regarding the racial stereotypes associated with specific crimes. Future research should focus on the origins of these context-specific racial stereotypes. Moreover, scholars should address the possibility that specific crimes prime racial stereotypes that influence important criminal justice outcomes (e.g., eyewitness memory, treatment from police officers, juror decisions, etc.).

### E133

#### DO GROUPS LIE MORE THAN INDIVIDUALS? HONESTY AND DECEPTION AS A FUNCTION OF STRATEGIC SELF-INTEREST

Sun Young Kim-Jun<sup>1</sup>, Taya R. Cohen<sup>1</sup>, Brian Gunia<sup>1</sup>, J. Keith Murnighan<sup>1</sup>; <sup>1</sup>Northwestern University – This research suggests that the greed of groups predisposes them to lie more than individuals when deception is more financially lucrative than honesty. The experiment used the deception game—an interaction in which people send a deceptive or truthful message to earn money—to investigate whether groups lie more than individuals. Participants were randomly assigned to a group (three-on-three) or individual (one-on-one) interaction and were instructed to send either a truthful or deceptive message to their counterpart. If the message was believed, the deceptive message yielded \$6 for the sender and \$5 for the receiver, whereas the truthful message yielded \$5 for the sender and \$6 for the receiver. The response of the receiver (who did not actually exist) was manipulated—participants either did not know whether receivers would believe their message or they learned that receivers had preemptively committed to believing their message. We found a significant Groups-Individuals X Receiver-Response interaction. Groups lied more than individuals when deception was guaranteed to maximize their outcomes, but lied relatively less than individuals when the receiver's response was uncertain and honesty could be used strategically. Not only did groups lie more when they were sure that they would be believed, but they also reported more self-interest. A mediation analysis revealed a significant indirect effect of groups-versus-individuals on lying, with self-interest as the mediator. These findings suggest that groups are more strategic than individuals: they will readily adopt whatever course of action best serves their economic interest, even if it requires deception.

### E134

#### IRONIC EFFECTS OF LEADERSHIP CANDIDATES FROM UNDERREPRESENTED GROUPS: INCREASED SUPPORT FOR THE STATUS QUO

Elizabeth R. Brown<sup>1</sup>, Amanda B. Diekmann<sup>1</sup>; <sup>1</sup>Miami University – In the popular media, the ascent of minority leaders is commonly claimed as evidence of the end of discrimination (e.g., MSN, 2009), potentially reinforcing beliefs that society is fair and just (Jost & Banaji, 1994). However,

no research has examined how exposure to minority leaders influences status quo support. Because women are less represented as leaders (Eagly & Carli, 2007), we predicted that exposure to a female leader would increase both explicit (Experiment 1) and implicit (Experiment 2) preferences for stability. In Experiment 1, participants read about a male or female leadership candidate and then completed a system justification measure (Kay & Jost, 2003). Exposure to a female versus male leader increased system justification,  $F(1,39)=6.09, p=.02$ . In Experiment 2, participants read about a male or female leadership candidate and then completed an IAT assessing evaluative associations with change/stability (Jost, Nosek, & Gosling, 2008). Exposure to a female versus a male leader increased implicit system justification,  $F(1, 58)=4.04, p=.05$ . Findings indicate exposure to a female versus male leader increased explicit and implicit stability preferences. Importantly, endorsement of the candidates was not related to either explicit or implicit system justification, suggesting that it is the mere presence of the underrepresented candidate that is critical. Exposure to a minority leadership candidate could ironically decrease support for social programs aimed at minority advancement because status quo support decreases preferences for social change (Jost & Hunyady, 2005). Furthermore, the presence of minority leaders might lead to the underestimation of barriers to leadership from underrepresented groups.

### E135

#### **SOCIAL IDENTITY COMPLEXITY AND INTERGROUP CONTACT** Karen

Gonsalkorale<sup>1</sup>, <sup>1</sup>University of Sydney – Although contact with outgroup members is becoming increasingly common in many facets of life, such encounters are often awkward and stressful, even for well-intentioned people. Recent theoretical advances suggest that how people think about their own groups may be an important precursor to positive intergroup contact. More specifically, awareness of one's own multiple group memberships may be a key factor. The aim of this study was to test the prediction that individuals who are high in social identity complexity (Roccas & Brewer, 2002)—those who conceptualize "us" as the sum of all their social identities—would be more comfortable in their interactions with outgroup partners. White participants completed a measure of social identity complexity and were randomly assigned to discuss a race-sensitive or race-neutral topic with a White or Asian confederate. Participants' self-reported comfort in the presence of the Asian confederate (but not the White confederate) was predicted by an interaction between social identity complexity and discussion topic. Specifically, in the interracial interactions, greater social identity complexity was associated with higher levels of self-reported comfort only when the discussion topic was race-neutral. These findings suggest that greater social identity complexity may facilitate positive interracial contact in contexts where race is not salient.

### E136

#### **THE ROLE OF COLLECTIVE RESPONSIBILITY IN THE INFRAHUMANIZATION OF OUTGROUP VICTIMS** Daniel Lenzen<sup>1</sup>, Emily Chan<sup>1</sup>, <sup>1</sup>Colorado

College – Infrahumanization is the denial of aspects of the human essence, specifically secondary (uniquely human) emotions, to outgroup members. Castano and Giner-Sorolla (2006) argued that people infrahumanize out-group victims only when they feel in-group collective responsibility for the suffering of the out-group. This study counterargues that in-group responsibility is not a prerequisite for infrahumanization. Extending the Just World Hypothesis (Lerner, 1980), victim derogation should occur regardless of the attribution of responsibility. Therefore, infrahumanization as a form of victim derogation should occur even if the in-group is not seen as responsible for the harm done to the out-group. American participants read a vignette describing a natural disaster with massive fatalities in an out-group (Belgians). We manipulated the attribution of responsibility: (1) In-group responsible (relief supplies from the US improperly manufactured), (2) out-group responsible (Belgian inefficiency in relief efforts), (3) no group responsible (unavoidable occurrence), and (4) control (no vignette). Participants then selected 7-10 emotions that Belgians were most likely to experience, out

of a list of 24 which included 12 primary and 12 secondary emotions, half positive and half negative. Results supported our hypothesis that in-group responsibility was not necessary for infrahumanization. Compared to the control, infrahumanization occurred in the no group responsible and the out-group responsible conditions. Both in-group and out-group responsibility appeared to intensify infrahumanization, compared to the no group responsible condition. However, there were no differences between the in-group and out-group responsibility conditions. Discussion focuses on the role of collective guilt, in-group identity, and intergroup conflict in infrahumanization.

### E137

#### **THE RELATIONSHIP BETWEEN WHITE IDENTITY AND ATTITUDES TOWARD DIVERSITY: A META-ANALYSIS** Matt J. Goren<sup>1</sup>, Victoria C. Plaut<sup>1</sup>, Brittany

Gentile<sup>1</sup>, <sup>1</sup>University of Georgia – Research on how White racial identity strength predicts attitudes toward diversity has shown ambiguous and often contradictory results. For illustrative purposes, we use the broad categories pro-diversity attitudes (e.g., egalitarianism, multiculturalism, or endorsement of affirmative action) and anti-diversity attitudes (e.g., assimilationism, modern racism, or social dominance orientation). Some researchers have found that White identity strength predicts more pro-diversity attitudes (Linnehan, Chrobot-Mason, Konrad, 2006) while others have found that it predicts not only less pro-diversity attitudes (Levin, Sidanius, Rabinowitz, & Federico, 1998), but also more anti-diversity attitudes (Corenblum & Stephan, 2001). Others still have found no relationship (Verkuyten, 2005) or a relationship only when the White in-group is threatened (Lowery, Unzueta, Knowles, & Goff, 2006). In the present study, we try to disambiguate these relationships by conducting a meta-analysis across the entire known White identity literature. The meta-analysis examined correlations between White racial identity and diversity attitudes in over two dozens studies with more than 8,000 participants to yield a more statistically robust estimate of the magnitude of the true relationship between these concepts. Paradoxically, we found that White identity weakly predicted both more anti-diversity attitudes ( $r = 0.179, d = .364$ ) and more pro-diversity attitudes ( $r = 0.059, d = 0.118$ ). We discuss these findings and their generalizability while noting the role of potential moderators, such as prior exposure to diversity and threat to the in-group, and the explanatory power of new theories of identity (e.g., Leach et al., 2008) and identity form (Croll, 2007; Goren & Plaut, under review).

### E138

#### **IMPLICIT AND EXPLICIT RELIGIOUS PREFERENCES** Larisa Heiphetz<sup>1</sup>,

Elizabeth S. Spelke<sup>1</sup>, Mahzarin R. Banaji<sup>1</sup>, <sup>1</sup>Harvard University – Previous work suggests that humans are sensitive to social group differences at an early age. Young children, for example, prefer to befriend those who share their race (Kowalski & Lo, 2001), gender (Martin, Fabes, Evans, & Wyman, 1999), and national origin (Kinzler, Dupoux, & Spelke, 2007). Do such preferences extend to social identities that are less perceptually salient, such as religion? Because religion is a difference in mental states (i.e., beliefs and practices rather than physical form), preferences in this domain may take longer to develop. On the other hand, if children are able to detect group differences in religion, their preferences may reveal the origins of religious prejudice. In Study 1, we presented 5- to 10-year-old children and adults with stories describing Jewish and Christian characters followed by questions about the participants' preferences. Though both children and adults responded at chance to almost all questions, Christian and non-Christian adults showed a strong implicit preference for Christians. In Study 2, adults read two vignettes, one describing a person who believes in God but does not engage in religious practices and the other depicting a person who participates in religious rituals but does not believe in God. Christians responded that the character who believes in God is a better Christian and is more like them, suggesting a privileging of similarity in belief over similarity in practice. We discuss these findings in light of research on intergroup relations and suggest future directions for the study of religious identity and social cognition.

Poster withdrawn.

**E140**

**STATUS-BASED REJECTION SENSITIVITY AND INTERGROUP RELATIONS: THE MODERATING ROLE OF LAY THEORY** Hsin-Ya Liao<sup>1</sup>, Ying-Yi Hong<sup>2</sup>, Melody Chao<sup>3</sup>; <sup>1</sup>San Francisco State University, <sup>2</sup>Nanyang Technological University, Singapore; University of Illinois at Urbana-Champaign, <sup>3</sup>Hong Kong University of Science and Technology – It is believed that members of stigmatized group who are more sensitive to status-based rejection sensitivity (SBRS) experience more negative personal and interpersonal experiences in the majority-dominated social institutions (Mendoza-Denton, Downey, Purdie, Davis, & Pietrzak, 2002). However, there is still little research on the possible individual differences underlying the effect of SBRS and intergroup relations. There is growing evidence to suggest that the effect of intergroup relations is associated with essentialist or malleable view of lay theory (see Hong, Levy, & Chiu, 2001; Levy, Plaks, Hong, Chiu, & Dweck, 2001). Researchers have shown that holding a fixed belief generally is associated with increases in justification of social inequalities as opposed to holding a malleable belief (Verkuyten, 2003). The purpose of the study is to further investigate the moderating role of lay theory on the effect of SBRS and intergroup relations among the stigmatized group. It is expected that holding a fixed view of lay theory tends to have detrimental effects of SBRS on personal and interpersonal experiences, while malleable view of lay theory would attenuate (or buffer) these negative effects. The hypotheses were supported from two intergroup contexts: a) Chinese immigrants in Hong Kong (N =34; stigmatized group) who attended a 4 day high school summer camp with Hong Kong natives (privileged group); and b) 187 Asian American students' social adjustment in a predominately White university.

**E141**

**THE IMPLICATIONS OF BURDENSOMENESS EXPECTANCIES IN AN ANTICIPATED INTER-RACIAL INTERACTION** Celeste Doerr<sup>1</sup>, E. Ashby Plant<sup>1</sup>; <sup>1</sup>Florida State University – The current work examined Black people's interest in engaging in interracial interactions as a function of their expectancies regarding such interactions. Unlike White people, some Black people do not enter interracial interactions with the assumption that their culture is well understood by outgroup members. They may feel instead that it falls on them to educate White people during interactions, which may be unappealing. We refer to such expectations as burdensomeness expectancies. We suspected that for Black people, the burden of having to explain themselves and their culture to White people would have negative implications for their interest in interracial interactions. We both manipulated and measured African-American participants' burdensomeness expectancies for an upcoming interaction with a White person. We then measured desire to avoid the interaction, ratings of a photograph of the ostensible interaction partner, and choice of topics for discussion. Results indicated that pre-existing burdensomeness expectancies and the manipulation influenced participants' intentions. Participants who received the burdensomeness manipulation were more interested in avoiding the interaction than control-group participants. Furthermore, among participants who received the burdensomeness manipulation, pre-existing burdensomeness expectancies predicted choice of conversation topic and partner ratings. Participants who previously reported relatively high burdensomeness expectancies in a mass questionnaire administration planned to discuss race-relevant topics with their White partners, perhaps with the goal of educating their partner, and rated their partners as more "childlike." These findings indicate that both existing levels of burdensomeness expectancies and aspects of the situation interact to influence the course of interracial interactions.

**E142**

**EVIDENCE FOR HYPODESCENT AND RACIAL HIERARCHY IN THE PERCEPTION OF BIRACIAL INDIVIDUALS** Arnold K. Ho<sup>1</sup>, Daniel T. Levin<sup>2</sup>, Jim Sidanius<sup>1</sup>, Mahzarin R. Banaji<sup>1</sup>; <sup>1</sup>Harvard University, <sup>2</sup>Vanderbilt University – Many have argued that the increasing rate of intermarriage between racial minorities and Whites and resulting patterns of biracial identification will lead to the dissolution of the American racial hierarchy (e.g., Alba & Nee, 2003; Lee & Bean, 2004; 2007a; 2007b; Thornton, 2009). However, little empirical evidence exists on perceptions of new racial identities that diverge from older notions of race purity and the "one drop" rule. We tested whether a rule of hypodescent, whereby biracial targets are assigned the status of their subordinate parent group, would govern perceptions of Asian-White and Black-White targets. Participants morphed faces from Asian to White, Black to White, White to Asian, and White to Black. Consistent with a rule of hypodescent, a face needed to be lower in proportion minority to be considered minority than proportion White to be considered White. In addition, the threshold for being considered White was higher for Black-White biracials than for Asian-White biracials, a pattern consistent with the structure of the current racial hierarchy. Finally, an independent racial categorization task confirmed that hypodescent and the current racial hierarchy guide how biracial targets are perceived. Potential distal (e.g., fear of contagion) and proximate (e.g., racism) causes of these phenomena are discussed.

**E143**

**GENERED WORDING AND MAINTENANCE OF THE STATUS QUO: HOW MASCULINELY WORDED JOB ADS AFFECT WOMEN'S PROPENSITY TO APPROACH TRADITIONALLY MALE-DOMINATED OCCUPATIONS** Danielle Gaucher<sup>1</sup>, Justin Friesen<sup>1</sup>, Aaron Kay<sup>1</sup>; <sup>1</sup>University of Waterloo – We present four studies demonstrating that gendered wording in job advertisements may be an underappreciated factor contributing to women's underrepresentation in STEM (Science, Technology, Engineering, and Math) occupations. Using linguistic software, the wording of over 2000 job advertisements was analyzed (Studies 1 and 2). Results indicated that job advertisements for male-dominated areas employed greater masculine than feminine wording than job advertisements within female-dominated areas. We next experimentally tested the consequences of these wording differences, and found that (i) people perceived fewer women within occupations that contained masculine wording (Study 3) and (ii) women found jobs less attractive and ranked them as less appealing when they were masculinely-worded (Study 4). Men showed the opposite pattern, preferring masculinely-worded ads to femininely-worded ones (Study 4). Implications for gender inequality in occupational and educational domains are discussed, and a theoretical model that explains how wording differences affect appeal is proposed.

**E144**

**THE DEHUMANIZATION OF REFUGEES** Stelian Medianu<sup>1</sup>, Victoria M. Esses<sup>1</sup>; <sup>1</sup>University of Western Ontario – Past research has shown that the dehumanization of refugees predicts attitudes and feelings toward refugees, as well as levels of support for refugee policies (Esses, Veenvliet, Hodson, & Mihic, 2008). In the current research, we investigated whether dehumanization also predicts the specific types of helping behaviour that people are willing to endorse for refugees. 100 Canadian undergraduates completed measures of the dehumanization of refugees, and degree of endorsement of three types of help that could be provided for refugees (see Jackson & Esses, 2000). Results revealed that dehumanization predicted lack of willingness to help refugees through empowerment (helping refugees to help themselves), and increased willingness to admonish refugees to change themselves in order to improve their situation; in contrast, dehumanization did not predict willingness to provide direct assistance to refugees. Results are discussed in terms of different models of helping behavior, power relations among groups, and the functions that dehumanization may serve.

**E145**

**FAIRNESS OF THE ACTION AS A CONSEQUENCE OF IDENTIFICATION AND ANTECEDENT OF THE FEELING OF COLLECTIVE GUILT** Nobuhiko Goto<sup>1</sup>, Minoru Karasawa<sup>1</sup>; <sup>1</sup>Nagoya University – The present study examined how justification for an action of one's own group influences the feeling of collective guilt. We argue that under certain circumstances people try to avoid experiencing collective guilt by justifying their in-group's wrongdoing. To test this idea, we conducted a scenario experiment in which participants were led to imagine themselves to be an employee of a company. The scenario explained that a department of their company bought up another company and fired many employees of this company. Identification with the department was manipulated by having participants imagine that either a friend of theirs, or a friend's friend, belonged to the department. After reading the scenario, participants completed measures of collective guilt. Specifically, they rated the extent to which they felt guilty for the company's and for the department's act. They also rated their relationships with the department and with the company using a modified version of the Inclusion of Ingroup in the Self measure (Tropp and Wright, 2001). Finally, they rated their company's action with respect to immorality, legitimacy, procedural justice, and fairness. We predicted and did find that individuals strongly identified with the department and felt less collective guilt in the friend condition than in the friend's friend condition. Furthermore, path analyses revealed that the evaluation of fairness was the only mediator of identification and collective guilt. A motivational perspective is proposed to explain the justification of the in-group's action, and implications for conflict prevention are discussed.

**E146**

**MORAL CRUSADING: THE EFFECTS OF DEHUMANIZING RHETORIC AND CREATURELINESS THREATS ON SUPPORT FOR WAR AND COMPENSATORY MORALITY** Matt Motyl<sup>1</sup>, Tom Pyszczynski<sup>2</sup>; <sup>1</sup>University of Virginia, <sup>2</sup>University of Colorado at Colorado Springs – The present research examines the effect of being dehumanized, from the perspective of terror management theory, and explores how people respond to the threat of being proclaimed an animal. In addition, this research assessed how people defend themselves against the threat created when they support violence while still maintaining the belief that they are moral human beings. Specifically, we hypothesized that when participants are primed with creatureliness and dehumanizing outgroup rhetoric, the participants will display increased intent to engage in moral behaviors as a response to endorsing war. Importantly, however, this relationship should only occur when participants are first asked to complete a measure assessing their support for war, but not when they are first asked to display their intent to engage in a number of moral behaviors (e.g., donating blood). Two hundred thirty-nine participants were randomly assigned to conditions in a 2 (Creatureliness: Human-Animal similarities or differences) x 3 (Iranian rhetoric: Aggressive and Dehumanizing, Aggressive and Humanizing, or Conciliatory and Humanizing) x (order of war support and moral behavior intent assessment) design. The results revealed that support for war predicted higher compensatory moral behavioral intent when participants were primed with creatureliness, dehumanizing rhetoric, and they indicated their support for war prior to indicating their intent to engage in moral behaviors. The fact that this occurred among participants threatened with creatureliness and insulted by dehumanizing Iranian rhetoric supports the hypothesis that compensatory moral striving is something people engage in to affirm their uniquely human moral standing.

**E147**

**EFFECTS OF PERCEIVED INGROUP VICTIMIZATION ON INTERGROUP TRUST** Katie N. Rotella<sup>1</sup>, Jennifer A. Richeson<sup>1</sup>, Joan Y. Chiao<sup>1</sup>; <sup>1</sup>Northwestern University – Trust is an important factor in positive intergroup relations and reconciliation between groups with a history of conflict, but most research has focused on these processes in majority group members. Much social psychological work has found that the introduc-

tion of threat to one's ingroup can lead to intergroup bias in the form of either ingroup favoritism or outgroup derogation. We hypothesize that feeling that one's ingroup has been highly victimized can act as a chronic state of threat and thus alter levels of intergroup trust through preconceived notions of how likely a partner is to reciprocate one's goodwill. Here we examine economic trust by minority group members with religious ingroup and outgroup members. Jewish participants played 24 rounds of an economic trust game each with partners of Jewish, Christian and unknown religious identity. All partners were gender-matched and practiced equal reciprocation rates. Results indicated that male participants who perceived their religious group as highly victimized trusted (i.e., invested more money with) religious ingroup partners significantly more relative to religious outgroup partners. Such a discrepancy did not exist for females or those males who perceived their group as less victimized. Measures of group identification were significantly negatively correlated with reported trust towards the outgroup ( $r = -.56$  and  $-.64$ , for females and males respectively) yet neither measure predicted actual trust behaviors. These findings suggest that perceptions of one's ingroup's level of victimization, rather than group membership or perceptions of the outgroup, influence intergroup trust behaviors. Implications for intergroup relations are discussed.

**E148**

**THE COMPANY YOU KEEP: FEAR OF REJECTION IN INTERGROUP INTERACTION** Matthew Baldwin<sup>1</sup>, Jenessa Shapiro<sup>2</sup>, Sophie Trawalter<sup>3</sup>; <sup>1</sup>University of Kansas, <sup>2</sup>UCLA, <sup>3</sup>UNC Chapel Hill – Intergroup contact is often awkward. Recent research reveals that this is often the case because both interactants believe the other will reject them (Shelton & Richeson, 2005). The present research explores how White participants evaluate Black males as a function of a cue to social rejection— who their friends are. In the first study, White participants evaluated a smiling Black male featured with an ostensible (smiling) Black or White friend. When Black males were paired with a White, compared to Black, friend, participants evaluated them as friendlier and more likely to want to be friends with the participant. Study 2 directly manipulated the role fear of rejection plays in evaluations of friendliness ratings. Participants were randomly assigned to a manipulation of social inclusion before evaluating the same targets from Study 1. In the social inclusion condition, participants wrote about a time when they were accepted. In the control condition they wrote about the previous day. As anticipated, we replicated the patterns from Study 1 in the control condition. However, when participants wrote about a time when they were accepted (i.e., buffering against rejection concerns), the Black males were no longer evaluated differentially as a function of whether they were with a White or Black friend. As a whole, the present findings suggest that intergroup contact is hampered by rejection concerns, and that these concerns may be exacerbated by simple cues, such as the company one keeps.

**E149**

**POLITICAL SOLIDARITY MEETS POLITICAL CONSUMERISM: COMMON FATE, SHARED IDENTITY MEANING AND OPPOSITION TO CORPORATE MISTREATMENT OF SWEATSHOP WORKERS** Emina Subasic<sup>1</sup>, Michael Schmitt<sup>2</sup>, Katherine Reynolds<sup>1</sup>; <sup>1</sup>Australian National University, <sup>2</sup>Simon Fraser University – As consumers, we are often asked to change particular behaviors in order to support a broader challenge to those companies or corporations whose practices, justified in the name of profit and low prices, nevertheless violate some ethical or moral standard. In this context, the key question is when will consumers become willing to boycott certain products and pressure the relevant authorities (e.g. government) to regulate corporations and ensure that the rights of those negatively affected by corporate malpractice (e.g. sweatshop workers) are protected. In line with the Political Solidarity Model of social change (Subasic, Reynolds & Turner, 2008), we demonstrate that this process is not only a function of shared experience of injustice at the hands of the corporation (i.e., common fate), but also the emergence of common cause and shared norms, values and beliefs (i.e. identity meaning) that corporate misbehavior is seen to violate. Common fate (the perception that the

corporation has in some way mistreated both its employees and consumers), increased willingness to act in solidarity with sweatshop workers, but did so through an enhanced sense of common cause between consumers and workers (Experiment 1) and only when corporate behaviour was seen to violate higher-order norms, values and beliefs defining who 'we' are (Experiment 2). Implications of the findings for the relationship between common fate, shared identity and collective action for social change are discussed.

**E150****COLLECTIVISM AS A MODERATOR OF DIRECT AND EXTENDED CROSS-GROUP FRIENDSHIP'S ATTITUDE-IMPROVING EFFECT: A CROSS CULTURAL STUDY COMPARING JAPANESE AND BRITISH**

**Kensuke Kamata<sup>1</sup>, Miles Hewstone<sup>2</sup>, Minoru Karasawa<sup>1</sup>; <sup>1</sup>Nagoya University, Japan, <sup>2</sup>University of Oxford, UK** – Direct (face to face interaction) and extended (listening to an in-group friend about her out-group friend) cross-group friendship has attracted considerable attention mainly because of their powerful out-group attitude-improving effects (Turner, Hewstone, Voci, Paolini & Christ, 2007). Previous studies have shown the in-group norm-following nature of collectivists (e.g., Hornsey, Jetten, McAuliffe & Hogg, 2006), suggesting that extended contact, which provides information through in-group friends, is more influential among high collectivists than among low collectivists. Opposite tendencies should be expected for direct cross-group friendship with the same rationale. Furthermore, unlike westerners, who emphasize category base intragroup relation, Japanese stress network base intragroup relation (Yuki, 2003), implying extended contact works more effectively in Japan than does in western countries. 207 British undergraduates and 207 Japanese undergraduates answered questionnaire, which was composed of the items measuring two types of friendship (direct and extended), out-group (Chinese) attitude, and horizontal collectivism (Singelis, Triandis, Bhawuk & Gelfand's, 1995). Positive correlations between both types of friendships and out-group attitude were found in two countries. Moderated regression (Jaccard, Turrisi & Wan, 1990) showed greater influence of direct friendship among low collectivists in both countries and greater effect of extended friendship among low collectivists as expected, but only in Britain. Extended contact exerted attitude-improving effect regardless of horizontal collectivism in Japan. This study supported external validity of direct and extended cross-group friendship and hinted the potential utility of extended contact in countries with highly collectivistic people and network base intragroup relation.

**E151****ASIAN MEN ON "YELLOW FEVER": EVIDENCE FROM QUALITATIVE AND QUANTITATIVE RESEARCH**

**Vicky Garafola<sup>1</sup>, Colin King<sup>1</sup>, Curtis Yee<sup>1</sup>, David Sears<sup>1</sup>; <sup>1</sup>UCLA** – Asian-American women date and marry outside their own race at disproportionately higher rates than Asian-American men. Much research has been done on the social and psychological factors contributing to this trend, but not on the reaction of Asian-American men. Our research question looks at whether this imbalance causes Asian-American men to dislike outgroup men who date Asian-American women, as predicted from Realistic Group Conflict theory. We approached this in two studies. First, in a focus group study, Asian-American men (N=20) were interviewed about their perspectives on White men who date Asian-American women. Second, in an experimental study (N=40), we tested whether Asian-American male participants socially avoided potential White targets who were dating Asian-American women. The results revealed a divergence in reported attitudes and actual behavior. The online focus group study found that while participants were not against White men who dated Asians, they would often mask their frustration with humor and stereotypes. In our experiment, participants chose between two White potential roommates from brief profiles with photos, with the major difference being the women they dated were either White or Asian. Asian-American men preferred the interracial dating White target, often citing they feel this candidate would more likely be more culturally sensitive. Results show that Asian-American men found White men who interracially date to be less threat-

ening. Even though they knew about stereotypes associated with White men dating, the behavioral data suggest that this does not apply to individuals they encounter.

**E152****PATTERNS AND PREDICTORS OF SELECTIVE EXPOSURE TO GROUP DIFFERENTIATING INFORMATION**

**Jason Popan<sup>1</sup>; <sup>1</sup>The University of Texas at Arlington** – In two experiments, patterns and predictors of selective exposure to group differentiating information were examined. Liberal and conservative participants first read an ostensible news article that served as a manipulation of intergroup distinctiveness. The article depicted the political orientations (liberal and conservative) as being either very similar or very different on a range of political issues. Across two studies, participants demonstrated a tendency to prefer group differentiating information. Because this tendency did not depend on experimental condition, little support for such preferences as a mechanism of intergroup boundary reassertion was found. Instead, the results suggest that intentional encounters with political outgroup sources that are expected to be more extreme and less rational take place out of a desire for personal enjoyment, rather than as a means of intergroup boundary maintenance. Implications of selective exposure to extreme political outgroup sources are discussed in light of potential negative effects on political discourse.

**E153****WHEN PERCEIVED STEREOTYPE-CONSISTENT SIMILARITY LEADS TO RESTRICTIVE IMMIGRATION ATTITUDES: THE ROLE OF NATIONAL IDENTIFICATION**

**Chiara C. Storar<sup>1</sup>, Eva G.T. Green<sup>1</sup>; <sup>1</sup>University of Lausanne, Switzerland** – Despite the multicultural composition of Western societies, immigrants' influence on the job market and their integration in society remain topics of societal debate. To understand the economic and cultural fears related to immigration, it is crucial to study the social psychological processes underlying the demarcation of boundaries between the national in-group and foreign out-groups. The present experimental study (N = 47) examined the extent to which perceived similarity between the national in-group and the immigrants' out-group on stereotypical in-group characteristics leads to restrictive immigration attitudes. We predicted that perceived similarity with immigrants' out-group on work-related characteristics is threatening because it evokes perceptions of intergroup competition. Perceived similarity should be particularly threatening for high national identifiers. That is, people who are committed to and identify with the national group should be especially motivated to maintain clear status boundaries between the in-group and out-groups. A national identification x intergroup similarity interaction was thus hypothesized. Indeed, when work-related similarity (e.g., ambition, efficiency and competence), as opposed to difference, was made salient between the in-group (Swiss) and the immigrant out-group (East European immigrants), national identification predicted more support for restricting immigrant rights and job opportunities, as well as less positive affect towards the immigrant group. Social identity and intergroup threat theories will be drawn upon to interpret these results.

**E154****FOLLOW THE INGROUP: INGROUP NORMS AND THE COMPLEMENTARITY OF DIRECT AND INDIRECT CONTACT**

**Pablo De Tezanos-Pinto<sup>1</sup>, Rupert Brown<sup>1</sup>, Roberto González<sup>2</sup>; <sup>1</sup>University of Sussex, <sup>2</sup>Pontificia Universidad Católica de Chile** – The extended contact hypothesis (Wright et al., 1997) has generated considerable interest as an alternative to direct contact with outgroup members, yet differences in the processes involved in these two types of intergroup contact have received little attention. In Study 1 (N=121; attitudes towards immigrants in the UK) we proposed a model in which direct and indirect contact have different mediators. Even though both variables shared a mediation by intergroup anxiety, direct contact affected attitudes via empathy, while the effect of indirect contact was mainly via ingroup norms about contact. This helps to explain why the effect of indirect contact is of a more cognitive nature

and the effect of direct contact is more affective (Paolini, Hewstone, & Cairns, 2007); Ingroup norms was the main predictor of prejudice, and empathy was the main predictor of affect towards the outgroup. In Study 2 (N=311; attitudes towards Peruvian immigrants in Chile), we added a measure of outgroup stereotypes to strengthen these results. As in Study 1, ingroup norms' effect was stronger on stereotypes, and intergroup anxiety's effect was stronger on affect. Furthermore, in both studies ingroup norms strongly predicted intention for future contact with outgroup members, an effect that was both indirect (suggesting an internalization effect) and direct (suggesting a compliance effect). In sum, these results show that indirect contact –because it can change the perception of ingroup norms– complements the effect of direct contact and can increase the chance of favourable direct contact with outgroup members in the future.

### E155

**IMPROVING INTERGROUP RELATIONSHIPS WITHIN AND OUTSIDE THE CONTACT SITUATION: THE ROLE OF GROUP REPRESENTATIONS AND EMOTIONS OF ANXIETY AND EMPATHY** Dora Capozza<sup>1</sup>, Irene Favara<sup>1</sup>, Elena Trifiletti<sup>1</sup>, Loris Vezzali<sup>2</sup>; <sup>1</sup>University of Padova, <sup>2</sup>University of Modena and Reggio Emilia – In two studies, we tested the basic tenets of the common ingroup identity model (Gaertner & Dovidio, 2000). Our aim was to examine the processes by which contact leads to improved relations with both known and unknown outgroup members. The hypothesis was that group representations would act as mediators in the relationship between: a) contact and emotions felt for outgroup members encountered (Studies 1 and 2); b) contact and evaluation of outgroup members encountered (Study 2). We also hypothesized that the positive effects of contact would generalize to the whole outgroup through the mediation of emotions and evaluation felt for known outgroup members. To test these hypotheses, we carried out two studies in naturalistic contexts. In Study 1, participants were employees (N = 243) of different organizations (hospitals and firms). In Study 2, participants were inhabitants of a small town of central Italy (N = 204). In both studies, respondents completed a questionnaire including measures of: cooperative contact; group representations (in Study 1, only the one-group representation was measured); emotions and evaluation of known and unknown outgroup members. The outgroup was that of immigrants. Findings from both studies supported the hypothesized double mediation pattern. Group representations mediated the relationship between cooperative contact and affect toward known outgroup members, which, in turn, produced more positive evaluations and emotions toward the whole outgroup. The theoretical and practical implications of results will be discussed.

### E156

**OUTGROUP DEHUMANIZATION: TESTING THE MODEL OF THE TWO SENSES OF HUMANNES** Anna Pasin<sup>1</sup>, Dora Capozza<sup>1</sup>, Luca Andrighetto<sup>2</sup>, Emilio Paolo Visentin<sup>1</sup>; <sup>1</sup>University of Padova, <sup>2</sup>University of Milano-Bicocca – Haslam and colleagues (2008) proposed, in addition to an animalistic, a mechanistic form of dehumanization (the outgroup is assimilated to a machine). We performed two studies to test this model; the relationship between Italians and the English was analyzed. The hypothesis was that the English are dehumanized in a mechanistic way. In a pretest, in fact, we found that Italian participants did not associate the typical traits of human nature (warmth, impulsiveness) to the English; moreover, there was no difference in attributions of uniquely human traits. In Study 1, we used two Go/No-gos (Nosek & Banaji, 2001): one for animalistic and one for mechanistic dehumanization. For the animalistic dehumanization, stimuli were: Italian and English names, human (e.g., nurses) and animal (e.g., ape) categories. For mechanistic dehumanization, stimuli were Italian and English names, human and automation (e.g., computer) categories. As expected, regarding mechanistic dehumanization, humanity was more associated with the ingroup than with the outgroup, and automation was more associated with outgroup than ingroup. Regarding animalistic dehumanization, there was no difference between the two groups. In Study 2, we used supraliminal

priming. Primes were: two human faces, one image of robot and one of computer, two neutral ovals. Targets were Italian and English names. We replicated results of Study 1: the ingroup was more associated to humanity than to automation; humanity was more associated to Italians than to the English.

### E157

**ALSO LEFT-WING PEOPLE ASSOCIATE AMERICANS WITH THE IMAGE OF FATHER? A STUDY WITH IMPLICIT MEASURES** Rossella Falvo<sup>1</sup>, Dora Capozza<sup>1</sup>, Elena Trifiletti<sup>1</sup>, Gian Antonio Di Bernardo<sup>1</sup>; <sup>1</sup>University of Padova – The aim of our study was to test the image theory (Herrmann, 1985, 2003) at an implicit level, in the context of Italians/Americans relationship. In two previous studies, examining Italian university students and Italian adults (e.g., Capozza, Trifiletti, Vezzali, & Andrighetto, 2009), it was found that political orientation affected structural perceptions (goal compatibility, relative power, relative status), and explicit images of Americans: left-wing participants perceived Americans as barbarians, while right-wing participants endorsed the images of ally and father. In the present study, we aim at extending previous findings by analyzing the implicit images of the United States in left-wing and right-wing Italian participants (N = 114, university students). The Go/No-go Association Task, adapted from the Nosek and Banaji's (2001) original procedure, was used. The implicit measures of the following images were obtained: ally, barbarian, imperialist, enemy, father. Participants also answered items, measuring the perceived structure of the intergroup relation. Results showed that political orientation influenced structural perceptions. However, at an implicit level, both for right-wing and left-wing participants Americans were represented as a father. Thus, irrespective of the ideological belief system, respondents may have developed automatic associations which can be activated even though they are considered incorrect or undesirable (e.g., Devine, 1989; Strack & Deutsch, 2004). The differential effects of political orientation on explicit and implicit images, as well as implications for behavioral tendencies, are discussed.

### E158

**ACCEPTANCE OF DISCRIMINATION AND WELL-BEING OVER TIME: DIFFERENTIAL CONSEQUENCES OF TYPE OF ACCEPTANCE AND ETHNICITY.** Mindi D. Foster<sup>1</sup>; <sup>1</sup>Wilfrid Laurier University – Studies consistently show that victims of discrimination do not actively combat discrimination, but rather, most often accept the status quo (e.g., Wright, 2001). To understand why victims do not engage in actions that could potentially benefit them it is important to understand the consequences of taking action. Indeed, as learning theory states, if a behavior has positive consequences it will be repeated, but a behavior followed by negative consequences will be avoided (Skinner, 1971). Research has shown that accepting unfair treatment will have more positive interpersonal consequences than taking action (e.g., Kaiser & Miller, 2001, 2003), however less is known about how victims themselves feel after accepting unfair treatment i.e., intrapersonal consequences. This study used a diary methodology to examine how acceptance of daily discrimination would affect measures of well-being over 28 days. Results showed three different types of acceptance: accepting due to fear, accepting due to minimization ("it was no big deal") and dissatisfied acceptance i.e., accepting the treatment despite wanting to do something. Moreover, there were changes in well-being as a function of ethnicity and type of acceptance: ethnic minority women who used dissatisfied acceptance showed increases in happiness, self-esteem and sense of purpose over time. In contrast, white women who used dissatisfied acceptance showed decreases in attentiveness and mastery over time. The differential consequences of dissatisfied acceptance has implications for future action: ethnic minority women who feel good after acceptance may feel little need to take action whereas white women may search for other responses.

**E159****NOW I BELONG TO THEM: EFFECTS OF GROUP CHANGE ON IMPLICIT AND EXPLICIT PREFERENCES TOWARDS ONE'S GROUP**

Jenny Roth<sup>1</sup>, Melanie C. Steffens<sup>1</sup>, Vivian L. Vignoles<sup>2</sup>; <sup>1</sup>Friedrich Schiller University of Jena, <sup>2</sup>University of Sussex – Merely belonging to a group leads to implicit and explicit preferences towards this group. Modern society constrains often force people to change their group membership. Implicit attitudes in general and towards social groups in particular have been claimed to be more stable than explicit attitudes. The present research program, comprising a total of five studies, investigated the malleability of implicit and explicit ingroup preferences. The present experiments investigated whether implicit and explicit ingroup preferences are reduced in people who had to change membership, compared to those who did not change groups. Participants were categorized into artificial groups; half of them had to change their group membership whereas the other half remained in their group. Implicit preferences towards the groups were assessed via an Implicit Association Test and explicit preferences via ratings. Results showed that implicit and explicit preferences towards current ingroups change easily when people do not share a common history with their group members (Experiment 1, N=107). In contrast, given a common group history, people stick more to the former ingroup (Experiment 2, N=175). Unlike models of attitude change the studies suggest that implicit attitudes towards ingroups change rather quickly and that they even may change more quickly than explicit attitudes after group change. The ease of creating an implicit preference towards novel ingroups independently of former group-membership indicates the use of a self heuristic. The reduction of explicit preferences towards the new ingroup after group change could partially be explained by a decline in identification with the new ingroup.

**E160****ARE THINGS GETTING BETTER OR WORSE IN SOUTH AFRICA? THE ANTECEDENTS AND THE CONSEQUENCES OF THE TRAJECTORY OF THREAT IN THE CONTEXT OF DRAMATIC SOCIAL CHANGE**

Emilie Auger<sup>1</sup>, Roxane De la Sablonniere<sup>1</sup>, Donald M. Taylor<sup>2</sup>, Jonathan Crush<sup>3</sup>, David McDonald<sup>3</sup>; <sup>1</sup>University of Montreal, <sup>2</sup>McGill University, <sup>3</sup>Queen's University – Dramatic social changes involve profound transformations that affect the history of a group (Rocher, 1992). Previous research has found that in such context, many group members perceive that the history of their ingroup follows a prototypical group trajectory. A prototypical group trajectory represents one that follows the important events that took place over the history of a group. However, research has also found that within the same in-group there is a significant number of people who perceive that their group's trajectory remained stable, and this, even when threatening social changes occurred (de la Sablonniere, Taylor, Perozzo, & Sadykova, 2009). The goal of our research is to understand why members of the same in-group perceive different group trajectories in terms of threat in the context of dramatic social change in South Africa (N = 3572). To achieve our objective, our research builds on both traditional and recent advances in the field of relative deprivation (Davies, 1962; de la Sablonniere et al., 2009) as well as on Tajfel's work (1978) on social identity. Specifically, we hypothesize that a high level of in-group identification will predict the membership to the prototypical group trajectory. We argue that because group members high in identification are more inclined to make group comparisons, it makes them more aware of the threats that their group faces over time. Results supported our hypothesis. Furthermore, results showed that the different group trajectories influence psychological well-being and intergroup attitudes.

**Norms and Social Influence****E161****BEHAVIORAL MIMICRY, GENDER, AND WELL-BEING**

Liane V. Gillis<sup>1</sup>, Eric A. Morris<sup>1</sup>, Martin J. Bourgeois<sup>1</sup>, Kristin L. Sommer<sup>2</sup>; <sup>1</sup>Florida Gulf Coast University, <sup>2</sup>Baruch College, City University of New York – Previous research has investigated the functions of social influence from the target's perspective, suggesting when one is influenced, there is an increased perception that the fundamental needs for accuracy, belongingness, and self-esteem are being fulfilled (Cialdini & Goldstein, 2004). Bourgeois et al. (2009) examined social influence from the source's perspective and found that successfully persuading another fulfilled these and the additional needs for control and purpose. The present study examined whether the effects of persuasion would generalize to another type of social influence, as seen in the form of behavioral mimicry. We hypothesized that being mimicked (i.e., being a source of influence) would increase a person's perception that the aforementioned needs were being met, and that mimicry would increase liking for the other person. Seventy-nine participants completed a task with a female confederate, who either mimicked their body language or did not. We found a gender by condition interaction in which males reported a greater sense of accuracy when being mimicked. There was also a trend in which males reported a higher sense of purpose and belongingness when being mimicked. Mimicry also tended to increase life-satisfaction and positive mood, and decrease negative mood for males and females. Collectively, the findings reveal that being mimicked by a female confederate enhances satisfaction of some needs and measures of well-being for males but not for females. These gender differences may warrant further research.

**E162****APPROPRIATE JUDGMENT OF INTERPERSONAL BEHAVIOR IN THE GAME SITUATIONS.**

Hiroshi Shimizu<sup>1</sup>; <sup>1</sup>Kwansei Gakuin University – In this study, we attempted to reveal how people would judge appropriateness of interpersonal behaviors. Shimizu and Kosugi (in printing) proposed a hypothesis that people would judge appropriateness of behaviors based on the benefit of their social group as a whole rather than that of individuals. Also, they predicted that this judgment could vary with social relationship between agents. Kelley and Thibaut (1978) suggested that there were two main types of conflict situation. One is the situation where the selections that maximize the benefit of individuals reduce the benefit of group (e.g. PD game: PDG). And another is the situation that there are two selections that maximize the benefit of group though it is unfair (e.g. Battle of sex game: BSG). From those arguments, this study investigated how people would judge appropriateness of selection in both PDG and BSG, by using a scene assuming method. 219 Japanese students at university participated in the study. Participants were asked to assume two scenes (PDG and BSG) where two characters cooperated and performed a college report assignment. Relationships between two characters were manipulated by closeness and hierarchy (close vs. not close, fifty-fifty vs. hierarchical). Then participants judged appropriateness of characters' selections. In the results, participants generally judged the situation with high benefit of group to be appropriate than the other situations. And this tendency was stronger for the fifty-fifty relationship in PDG than in the hierarchical relationship while the effect was reversed in BSG.

**E163****ROMANTIC PARTNER NORMATIVE INFLUENCE ON YOUNG ADULT POSITIVE AND NEGATIVE BELIEFS ABOUT SMOKING**

Paul E. Etcheverry<sup>1</sup>, Nicholas G. Hoffman<sup>1</sup>, Christopher R. Agnew<sup>2</sup>; <sup>1</sup>Southern Illinois University Carbondale, <sup>2</sup>Purdue University – Young adults' beliefs about smoking are predictive of cigarette smoking (Carvajal, et al., 2004). Although romantic partner smoking and approval of smoking is predictive of young adult smoking (Etcheverry & Agnew, 2008), romantic partner influence on smoking beliefs has not been studied. The proposed hypothesis is that romantic partner smoking and approval of smoking is predictive of young adult positive and negative smoking beliefs. Data

was collected in a longitudinal study of young adult smoking. Participants completed a baseline data collection session, indicating positive and negative smoking beliefs. Two weeks after baseline, participants began completing weekly surveys, indicating the number of cigarettes smoked each week. Every four weeks, participants indicated whether their romantic partner smoked and approved or disapproved of the participant smoking. At week 14, participants again reported positive and negative smoking beliefs. Two Structural Equation Models (SEM) were computed predicting week 14 positive and negative smoking beliefs, respectively. For both SEM models, partner smoking and partner approval of smoking for the weeks before week 14 were predictors. Weekly participant smoking and the corresponding baseline smoking beliefs were included as controls. When predicting week 14 positive smoking beliefs, partner approval ( $\beta=.145$ ,  $p<.05$ ) but not partner smoking ( $\beta=.018$ ,  $p=ns$ ) was associated with positive smoking beliefs. In the model predicting negative beliefs, partner approval was non-significant ( $\beta=.118$ ,  $p=ns$ ) but partner smoking was positively associated with week 14 negative smoking beliefs ( $\beta=.132$ ,  $p<.05$ ). These results suggest that romantic partner smoking characteristics are prospectively predictive of young adult beliefs about smoking.

#### E164

##### **GIRLS (AND BOYS) GONE WILD? MISPERCEPTIONS ABOUT OTHERS' COMFORT WITH CHEATING IN ROMANTIC RELATIONSHIPS**

**Kathleen Shaver<sup>1</sup>, Breeanna Caudill<sup>1</sup>, Alexander M. Czopp<sup>1</sup>,<sup>1</sup>Western Washington University** – The current study examined the phenomenon of pluralistic ignorance as it relates to college students' attitudes towards extradyadic sexual behaviors (i.e. infidelity in a romantic relationship). Previous researchers have found pluralistic ignorance to occur with a variety of deviant behaviors, such as drug use and binge drinking (Hines, Saris, & Throckmorton-Belzer, 2002). Pluralistic ignorance may actually contribute to an increase in such behaviors as a result of conforming to false norms (Prentice & Miller, 1993). In this study, 143 participants, 69 of whom were female and 74 of whom were male, rated their own comfort level with engaging in cheating behaviors (e.g. kissing, sexual intercourse). Participants also rated how comfortable they believed the average female and average male to be with those same behaviors. We hypothesized that students would rate their peers as more comfortable with cheating on their partner than they themselves would be. We also hypothesized that both men and women would rate other men as the most comfortable with engaging in cheating behaviors. We found that men believed that other men as well as women were significantly more comfortable with cheating than they themselves were. Women also believed that other women as well as men were significantly more comfortable with cheating than they themselves were. Men were rated by both genders as having the greatest comfort with cheating. False uniqueness and the fundamental attribution error are discussed as possible contributors to the results.

#### E165

##### **AN EGALITARIAN PARADOX: ANTI-DISCRIMINATION NORM AND PERCEIVED INTERGROUP SIMILARITY LEAD TO AN INCREASE IN PREJUDICE AND DISCRIMINATION**

**Fabrice Gabarrot<sup>1</sup>, Juan Manuel Falomir Pichastor<sup>2</sup>, Gabriel Mugny<sup>2</sup>, Clémentine Bry<sup>3</sup>,<sup>1</sup>University of Lausanne, Lausanne, Switzerland,<sup>2</sup>University of Geneva, Geneva, Switzerland,<sup>3</sup>University of Reading, Reading, UK** – One of the greater challenges for social psychology of intergroup relations seems to understand why, despite a generally accepted social norm prescribing tolerance and equality and proscribing prejudice and discrimination (i.e. an anti-discrimination norm), such negative intergroup attitudes and behaviour still persist. The purpose of this communication is to present 3 studies that explore how the interaction between normative principles and intergroup perceptions will affect normative influence (i.e., conformity) in terms of prejudice and discrimination. In particular, it is proposed that, as it proscribes intergroup differentiation, the anti-discrimination norm threatens ingroup's identity and leads to an increase in prejudice and

discrimination. In the first two studies, in-group norms and perceived intergroup similarity were manipulated and in-group identification was measured (Study 2). In the third study, a self-affirmation procedure was introduced in order to alleviate distinctiveness threat. Results consistently showed an interaction between intergroup similarity and in-group norm on intergroup attitudes characterized by high scores of prejudice when in-group norm was anti-discrimination and intergroup similarity was high, and when in-group norm was pro-discrimination and intergroup similarity was moderate to low (Study 1). Further results showed that this interaction was moderated by in-group identification (Study 2). These results are consistent with the idea that this norm induces or augments perceived distinctiveness threat. Furthermore, results showed that alleviating the threat through self-affirmation allows participants to express lower levels of prejudice (Study 3). These results will be discussed in relation with their epistemological implications in the understanding of prejudice, discrimination and social influence.

#### E166

##### **AN EXPLORATION OF THE APPRAISAL FOUNDATIONS OF THE NORMATIVE FULFILLMENT**

**Marisol Villegas<sup>1</sup>, Luis Oceja<sup>1</sup>,<sup>1</sup>Universidad Autónoma de Madrid** – A normative appeal may be not fulfilled because it is not salient; however, not all salient normative appeals are fulfilled. We propose that a salient normative appeal produces a normative-appraisal that, in turn, may influence on the willingness to fulfill it. We propose that normative-appraisal is the product of an assessment based on two dimensions related to the extent to which people perceive that the normative appeal (a) is supported by a formal institution and (b) creates a safe space to build up one's action. According to this two-dimension assessment, one of the following four basic normative-appraisals will be produced: Legitimate Law, Coercive Law, Prescription, and Folkway. We conducted two studies in which participants were presented with a set of 30 normative appeals, and results revealed that 85% of these appeals produced the same basic normative-appraisal in Spain, United States, and Venezuela (Study 1), and that these normative-appraisals predict the willingness to fulfill it (Study 2).

#### E167

##### **POWER, MOOD, AND SYNCHRONIZATION: INTERPERSONAL BEHAVIORAL AND EMOTIONAL CONTAGION OVER TIME**

**Deanna Jackson<sup>1</sup>, Robin R. Vallacher<sup>1</sup>,<sup>1</sup>Florida Atlantic University** – Research on emotional contagion and the chameleon effect have shown that moods and behaviors transmit between people who are interacting, which creates smooth, efficient coordinations. This study is the first to examine the patterns in the aforementioned emotional and behavioral synchronization as they unfold in an interaction. We wanted to test the hypothesis, generated by Nowak and Vallacher's (2005) computer simulations, that changing the strength of coupling between people would increase their synchronization, which would manifest both in convergent and compensatory synchronizations in behavior and mood. Conceptualizing contagion effects as synchronization emphasizes mutual entrainment processes rather than increases in similarities. We manipulated coupling by creating disparate power dyads and equal power dyads, and by inducing a positive or negative mood in one member of the dyad. We measured behavioral synchronization by recording the size of compensatory posture adjustments every 20 seconds. To measure emotional synchronization, participants reported their mood over the course of the interaction while watching a recording of the interaction. As the coupling hypothesis predicted, both disparate power and negative mood manipulations increased the levels of emotional and behavioral synchronization, whereas equal power and positive moods increased an active emotional de-synchronization process over the course of the interaction and decreased behavioral synchronization. These findings support a synchronization conceptualization of emotional contagion and the chameleon effect, and lay the groundwork for future research on the strength and duration of synchronization processes as interpersonal influences.

**E168****THE CONCEPT OF THE "BIOLOGICAL CLOCK" PRESSURES WOMEN TO ACCELERATE IMPORTANT LIFE CHOICES**

Sara Gottlieb<sup>1</sup>, Ruth Dittmann<sup>2</sup>, Tamar Saguy<sup>3</sup>; <sup>1</sup>Macalester College, <sup>2</sup>Yale University, <sup>3</sup>Interdisciplinary Center (IDC) Herzliya – The present research explores the social construct of the "biological clock" as it relates to stress, family planning and life choices among women. Study 1, which involved open-ended responses of both men and women, established that the concept of the biological clock is closely associated with a decline in women's fertility and the societal pressure for women to achieve important developmental milestones such as establishing a career and having children. In Study 2, heterosexual women age 27 to 41 were randomly assigned to either write about their biological clock or about a neutral topic (the television set). Subsequently, they completed an implicit stress measure and a series of questions regarding family and career choices. Results revealed that women who wrote about their biological clock, compared with women in the control condition, displayed significantly more stress and urged other women to focus more on advancing their careers and getting married. Taken together, the results suggest that thoughts about the "biological clock" cause stress for women and are associated with social norms that prescribe accelerating life choices in both the family and career domain. Implications for male-female relations and for how the concept of the "biological clock" is framed in popular discourse, are considered.

**E169****THE EFFECT OF RECIPROCITY IN DETERRING INCONSIDERATE BEHAVIOR**

Satoko Yuo<sup>1</sup>, Toshikazu Yoshida<sup>1</sup>; <sup>1</sup>Nagoya University – The norm of reciprocity implies that people should return favors (Gouldner, 1960). Although reciprocity was found to strongly induce positive behavior (e.g., Goeil et al., 2007), few studies have investigated its effect in preventing negative behavior; nevertheless, it is believed to do so effectively since it seldom causes an antagonistic attitude. This study determines its role in deterring inconsiderate behavior through an experiment conducted on 78 female Japanese students, aimed at examining whether the subjects would behave positively to return a favor done to them. In the experiment, three participants worked out puzzles. To induce inconsiderate behavior, two of them—called "chatterers"—were instructed to discuss aloud while solving a puzzle, while the third, the "quiet person," silently concentrated on it. The quiet person then intimated that their chatting was annoying. The experiment had two conditions: in the Favor condition, the quiet person was instructed to give the chatterers drinks at an intermission, as a favor; in the No Favor condition, she gave nothing. The ANOVA results showed that compared to those in the No Favor condition, those who did the favor felt that the chatterers subsequently lowered their voices considerably and were less of a disturbance. Moreover, they tended to reduce their actual speaking volumes in the Favor condition. These findings suggest that reciprocity is effective in deterring inconsiderate behavior among women who exchange favors frequently and who were sensitive to the norm. Future research should examine whether reciprocity influences men similarly with other types of favors.

**E170****POLITICAL IDEOLOGY AND CONFORMITY: EXTREME CONSERVATIVES ARE BETTER THAN LIBERALS AT RESIST CONFORMITY**

Brad Lytle<sup>1</sup>, Margaret Stevenson<sup>2</sup>, Nicholas Aramovich<sup>1</sup>; <sup>1</sup>University of Illinois at Chicago, <sup>2</sup>University of Evansville – Conservatives are high in rigidity, more dogmatic, and less tolerant of ambiguity (Jost, Glaser, Kruglanski, & Sulloway, 2003). Rigid people ignore new information that contradicts their initial judgments (Furnham & Ribchester, 1995). People often use other group members' judgments as a source of information for revising their initial judgments (Cialdini, 2001). Because conservatives are more rigid than liberals, they should be less likely than liberals to change their opinion under group pressures to conform. Although conservatives are more rigid than liberals, they also value in-groups more than liberals do

(Haidt & Graham, 2007). People who strongly value in-groups should also value trust and group cooperation. Thus, because conservatives value in-group adherence more than liberals, they should be more likely to cooperate with their group and change their opinion in the face of group conformity pressures. In study one, we examined conformity in the context of attitudes about controversial issues. In study two, we examined conformity in context of a jury's deliberation. In both studies participants believed they were interacting with real participants. All the mock group members' opinions and verdicts were the opposite of the participants' preferences. Whether participants switched their initial opinions and verdicts served as our dependant variable, conformity. In both studies, we found that conservatives moved further right of the political spectrum, they became more resistant to conformity. However, for liberals, political extremity did not impact conformity. These results provide a behavioral demonstration of conservative rigidity in two very distinct domains.

**E171****DECISION INFLUENCE FROM SIGNIFICANT OTHERS AND SURGICAL DECISION MAKING IN HIGH RISK PATIENTS**

Christine Rini<sup>1</sup>, Lina Jandorf<sup>1</sup>, Rachel Goldsmith<sup>2</sup>, Sharon Manne<sup>3</sup>, Noam Harpaz<sup>1</sup>, Steven Itzkowitz<sup>1</sup>; <sup>1</sup>Mount Sinai School of Medicine, <sup>2</sup>Reed College, <sup>3</sup>Fox Chase Cancer Center – Patients making major medical decisions often turn to people in their intimate social networks for assistance. Research on social control suggests that significant others influence people's ongoing health decisions (e.g., those related to diet or smoking). However, little is known about how they may influence highly consequential medical decisions made by patients coping with a serious illness. Importantly, these "single-event" medical decisions differ from ongoing health-related decisions in ways that are likely to affect the role of significant others. The present study examined these processes by investigating significant others' influence on the surgical decisions of inflammatory bowel disease (IBD) patients referred for surgery to remove their colon (colectomy) because of medically refractory disease or high risk for colorectal cancer. Patients completed questionnaires assessing their surgical decision, the difficulty of their decision making (decisional conflict), and modes of significant other decision influence that varied along two dimensions: positive versus negative and direct versus indirect. Analyses showed that significant others' use of persuasion/direct communication predicted patients' surgical decision. Furthermore, significant others' assistance with understanding the decision predicted lower decisional conflict. These effects were moderated by patient sex and whether the significant other was a partner or another relation. There was also evidence that negative significant other decision influence increased the likelihood that patients chose surgery, but also led to greater decisional conflict. Findings reveal that significant others can influence patients' decisions and the difficulty of their decision making, and argue for expanded consideration of social/interpersonal aspects of theories of patient decision making.

**E172****SOCIAL CONTAGION OF CORRECT AND INCORRECT INFORMATION IN MEMORY**

Ryan A. Rush<sup>1</sup>, Steven E. Clark<sup>1</sup>; <sup>1</sup>University of California, Riverside – Memories can be contagious such that one person's memory may influence the memory of another person (Loftus & Greene, 1980; Roediger, Meade, & Bergman, 2001). The present study addresses two important questions largely overlooked in the literature on social contagion and memory conformity: 1. How accurate is the information people are exposed to when they discuss an event with another person? 2. To what extent do people incorporate correct versus incorrect information in their own recall following exposure? The present experiment deviates from the social contagion paradigm in that it does not involve a confederate, but rather examines information exchange between participants. Ninety participants (45 pairs) viewed photographs of common household scenes (Roediger et al., 2001). They first recalled the scenes individually, then discussed their recall with their partners, and then recalled individually again. Results showed that initial individual recall was 80%

accurate, and that during discussion participants were exposed to unique items from their partner that were 74% accurate (correct,  $M = 2.68$ ; incorrect,  $M = .93$ ). Participants incorporated more correct ( $M = 1.30$ ) than incorrect ( $M = .22$ ) exposure items into their final individual recall (86% accurate). The study concludes that: 1. the information to which people are exposed when they discuss an event with another person may be largely accurate, although not as accurate as the information in their initial recall, and 2. people are able to distinguish between correct and incorrect exposure information, suggesting that fact may be more contagious than fiction.

### E173

#### CHARACTERIZATIONS OF DESCRIPTIVE AND SUBJECTIVE NORM IN THE THEORY OF PLANNED BEHAVIOR: INDEPENDENT OR COMBINED?

**Allecia Reid<sup>1</sup>, Leona Aiken<sup>1</sup>, <sup>1</sup>Arizona State University** – The theory of planned behavior (TPB; Ajzen, 1991) successfully predicts many health behaviors, including condom use (Albarracín, Johnson, Fishbein, & Muellerleile, 2001). The addition of descriptive norms to the TPB has been recommended (Fishbein, 2000). However, the question of how best to simultaneously account for two normative influences—descriptive and subjective norm—remains. Some retain the two norms as distinct predictors of intention (model 1). Others combine the norms to form a measure of normative pressure (model 2), as implied by Fishbein (2000). We compared these two norm specifications for prediction of condom use among 225 women. Participants rated all TPB constructs. Eight weeks later, they reported their intentions for condom use. Normative pressure was formed by averaging descriptive and subjective norm, which were positively correlated ( $r = .410$ ). Descriptive and subjective norm were correlated with ( $r = .359$  and  $.496$ , respectively) and made independent contributions in predicting intention in model 1. In model 2, normative pressure was similarly correlated with ( $r = .503$ ) and predictive of intention. Variance accounted for in intention was comparable in models 1 and 2 ( $r$ -squared =  $.427$  vs.  $.426$ , respectively). We observed no empirical gain from combining the measures. Different cognitive pathways may mediate the influence of each norm on behavior (Cialdini, 2003); moreover, the two norms may work in opposite directions in particular settings. Combining the two norms loses both the theoretical distinction between them and the empirical examination of their differential prediction of behavior. We recommend against combining them and in favor of retaining the distinctiveness of the norm constructs.

### E174

#### DO THESE NORMS MAKE ME LOOK FAT? CONFORMITY AND BODY TYPE PREFERENCE

**Allison Bair<sup>1</sup>, <sup>1</sup>York University** – Considerable research supports the assertion that body type preference is influenced by social norms. Investigations of participants exposed to manipulated social norms information (Bair & Steele, 2006), as well as examinations of participants from different cultures (Thompson et al., 1996), and different sexual orientations (Bergeron & Senn, 1998), all suggest that beauty ideals are malleable. However, an evolutionary perspective suggests that body type preferences in males originate from a more longstanding preference for physical cues indicating fertility (Buss & Schmitt, 1993). In the current study, we demonstrate that conformity to social norms is an important influence on body preference, by examining both opposite- and same-sex body preferences, and investigating the role that trait conformity has as a potential moderator. 703 University students selected their preferred same- or opposite-sex body from silhouette drawings ranging in size from thin to heavy. Participants were also shown social norms information represented by the purported preferences of other students. In reality, the preferences they saw were experimentally manipulated biases toward either thin bodies, heavy bodies, or a control condition with no social norms information. Participants also completed measures of trait conformity. The results revealed conformity to the manipulated social norms in both same- and opposite-sex body type preferences for male and female participants; however this effect was not

moderated by trait conformity. The findings are examined within both social norms and evolutionary frameworks and implications are discussed.

### E175

#### BEING MANLY MEN: CONVEYING MASCULINITY THROUGH EATING BEHAVIOR

**Lisa Lipschitz<sup>1</sup>, C. Peter Herman<sup>1</sup>, <sup>1</sup>University of Toronto** – Eating small amounts of food can portray femininity, as well as intelligence, morality, and politeness. Males might want to appear masculine and therefore avoid eating small amounts of food, unless they are trying to appear attractive on other dimensions. One hundred and twenty-four males were given false feedback that they scored low (low-M) or high (high-M) on masculinity (masculinity condition) and then given meat pizza to eat or the choice between meat or vegetarian pizza (food condition). Pilot testing equating desirability of meat and vegetarian pizza notwithstanding, men in the choice condition overwhelmingly chose meat pizza. An interaction between masculinity condition and food condition was found, with low-M participants given meat pizza eating a small amount, as did high-Ms given a choice. High-Ms given meat pizza ate a large amount of food, as did low-Ms given a choice. We propose that low-Ms in the meat condition try appear intelligent and polite because they cannot restore their threatened masculinity by freely choosing masculine food. High-Ms in the meat condition are content with their masculinity and therefore eat a lot. Low-Ms given a choice choose a masculine food and want to emphasize their masculinity and therefore eat a large amount. High-Ms given a choice choose a masculine food, but also want to also appear polite and intelligent and therefore eat only a small amount. Depending on the specific circumstances (threatened masculinity, availability of choice) males eat a lot to convey masculinity or eat a small amount to appear attractive on other dimensions.

### E176

#### REACTION TIME DIFFERENCES IN A LEXICAL DECISION TASK FOLLOWING SOCIAL-EXCLUSION.

**David Oberleitner<sup>1</sup>, Rusty B. McIntyre<sup>1</sup>, <sup>1</sup>Wayne State University** – The ramifications of an ostracism event have been widely studied. The effects of exclusion have been shown to include threatened "needs" including belonging, self-esteem, feelings of control, and feelings that one's life has meaning. It has also been established that aggressive responses often follow an exclusionary event. Given the linkage that has been shown between ostracism and aggressive behavioral outcomes, it can be hypothesized that ostracism may prime aggressive thoughts, and that increased accessibility of aggression may be what leads to individuals acting more aggressive following an exclusionary event. The present study tested this hypothesis by inducing an ostracism event in the lab via the Cyberball computer program. Participants were then given a lexical decision style word recognition and categorization task on the computer. Included in the list of words participants had to categorize were words naming a type of weapon (ex: Rifle, Knife). Following this, participants completed a set of questions on the computer, assessing the effect of the Cyberball game on their "fundamental needs" (Zadro, Williams & Richardson, 2004). Results replicated previous findings with participants who were ostracized showing significantly greater threat to belonging, self-esteem, control, and meaningfulness of life. Results further showed that participants identified weapons words faster when in the ostracized condition, without a significant increase in the number of errors made. These results help provide initial evidence of a cognitive link between ostracism and aggression. The ramifications of these results as well as directions for future study will be discussed.

### E177

#### EXAMINING THE PERSUASIVENESS OF THE AUTHORITY HEURISTIC ON EXERCISE

**Tatiana Schember<sup>1</sup>, Gregory Webster<sup>1</sup>, <sup>1</sup>University of Florida** – Although research shows that authority appeals are effective in increasing compliance to a request (Cialdini, 2001), little research has been conducted to test the effectiveness of different authority types against one another. Research also shows that the motivational state of a target can

influence the effectiveness of any given persuasion tactic (Griskevicius et al., 2007). The purpose of this work is to expand on previous research on the persuasiveness of authority appeals – taking a goal-based perspective – and to apply this research to increase health-enhancing behavior such as exercise. Participants completed the study on the Internet. First, participants read a short story designed to elicit one of three motivational states (neutral, affiliation, or status-seeking). Afterwards, participants viewed ads that contained a slogan encouraging exercise and either an expert, high-status, or celebrity authority figure. Participants rated the ads on persuasiveness and reported how much money they spend on gym memberships and how much they planned to spend in the future. As hypothesized, results for reported overall persuasiveness of the ads showed a significant three-way interaction of participant gender, motivational state, and authority type. Money spent on current gym memberships was subtracted from money participants planned to spend on future gym memberships. Results for the difference between current and future gym dollars also showed a marginally significant three-way interaction. The persuasiveness of appeals to exercise depended not only on the type of authority, but also on the motivational state and gender of the target of influence.

**E178**

**TAKING CARE OF BUSINESS--AS LONG AS IT'S EASY: PRIMING BUSINESS IMPACTS PERFORMANCE** Paul A. Story<sup>1</sup>, Ernest H. O'Boyle, Jr.<sup>2</sup>, <sup>1</sup>College of William & Mary, <sup>2</sup>Virginia Commonwealth University – While at work, employees are constantly being monitored and observed. Therefore exposing individuals to objects associated with business may activate these concerns and influence performance. Similar to research on social facilitation we expect these concerns to help on easy tasks but hurt on hard tasks. Across two studies, we exposed participants to business or neutral objects and then had them complete a series of word tasks. In study one, participants performed worse on these tasks while in the presence of business objects compared to neutral ones. The purpose of study two was to determine whether the decreased performance was due to the difficulty of the task rather than the business objects themselves. In addition to exposing participants to business or neutral objects, Study 2 manipulated task difficulty. Results showed that while participants' performance was unaffected by the neutral objects, participants exposed to business objects did better when the task was easy but worse when the task was hard. Future studies are discussed along with theoretical and practical implications concerning the effect of business settings on achievement motivation.

**E179**

**COMPENSATING VICTIMS LEADS TO MORE STATUS CONFERRAL THAN PUNISHING PERPETRATORS** Gabrielle Adams<sup>1</sup>, Elizabeth Mullen<sup>1</sup>, <sup>1</sup>Stanford University – Social psychological research investigating responses to injustice has generally focused more on punishment than on compensation. Additionally, researchers have examined motivations for punishment or the consequences of receiving punishment for the one who is punished, but not the effects of punishing or compensating for the punisher or compensator. In two studies, we demonstrate that individuals are more likely to confer status on (e.g., elect to leadership positions) third-parties who respond to injustice by compensating victims than by punishing perpetrators. In Study 1, participants were more likely to choose an individual to be their group leader who had previously compensated the recipient of an unfair dictator game allocation over someone who either punished the allocator or who did not respond to the injustice. In Study 2, participants were more likely to vote for a political candidate who allocated government funds to compensate victims of the Darfur crisis than one who allocated funds to punish the perpetrators or who did not respond. Participants perceived compensators to be competent and likeable, whereas they perceived punishers to be competent but unlikeable. Liking mediated the effect of injustice response on status conferral. In conclusion, although we need leaders

who are willing to punish norm violators, our results suggest that individuals are more likely to elect individuals who compensate victims than punish perpetrators.

**E180**

**NORM ENFORCEMENT AND CULTURAL CONTEXT: THE VARYING EXCULPATORY FUNCTION OF EXTERNAL ATTRIBUTIONS OF RESPONSIBILITY** William Self<sup>1</sup>, Philip Tetlock<sup>1</sup>, <sup>1</sup>University of California, Berkeley – An experimental study conducted in the United States and Singapore explored the joint effects of severity of consequences of norm violations and strength of external pressure to violate norms on the assignment of blame and punishment. This study sheds new light on a paradox rooted in the uneasy coexistence of three robust empirical findings: East Asians explain behavior in more situational terms than do Westerners; Westerners who advance situational explanations lean toward leniency; judged against modern Western jurisprudential standards, East Asian judicial systems have been more overtly punitive, for instance, in their countenancing of corporal punishment, public executions, penalizing families of offenders, and circumscribing due process rights to challenge accusers and appeal decisions. Both Americans and Singaporeans responded to more severe consequences with escalating levels of internal responsibility attributions and individual punishment, and both made more external responsibility attributions as peer pressure to violate norms grew more overt. The two cultures, however, diverged as group involvement grew stronger: Americans assigned less blame to individuals as external forces grew whereas Singaporeans held firm on individual culpability. Additional mediation tests helped to explain how the experience and target of retributivist anger resulted in different punitive patterns among Americans and Singaporeans. The study demonstrated a caveat against assuming invariance across cultures of mechanisms that intensify or alleviate blame and punishment. Although attribution-of-responsibility processing was strikingly similar in the two cultures studied, external causal attributions conveyed different culturally-derived exculpatory meanings, mitigating blame among Americans while expanding the circle of blame among Singaporeans.

**E181**

**PRACTICING AGAINST WHAT YOU PREACH: SELF, OTHER, AND THE DIFFERENTIAL IMPOSITION OF MORAL STANDARDS** Brian A. M. Clark<sup>1,2</sup>, Eric R. Stone<sup>1</sup>, <sup>1</sup>Wake Forest University, <sup>2</sup>University of Oregon – Previous research on moral hypocrisy has been based on two different working definitions: (a) the motivation to appear moral, but avoid the consequences of behaving morally and (b) the differential evaluation of one's own versus others' moral transgressions. There are also two working theoretical explanations: (a) people deceive themselves into thinking that their immoral behavior is actually moral by suppressing the discrepancy between their behavior and a relevant moral standard and (b) people employ valuable executive resources to suppress negative affect elicited by moral transgressions that violate our moral intuitions. What appears to be missing from this research is the common construal that moral hypocrisy involves the imposition of standards on others that one does not adhere to oneself. Therefore, investigation and theoretical explanation of moral hypocrisy should focus on the processes involved in how people advise others compared to how they decide for themselves. In our study, we adapted an existing paradigm used to study moral hypocrisy, which had college student participants (N = 184) either make decisions for themselves or for another participant (actually a confederate). Surprisingly, we did not find any difference between decisions for self and for other. However, follow-up questions indicated that it is deemed more fair and socially appropriate to choose a "selfish" option for another person than for oneself, which may have contributed to the lack of self-other differences in our study.

**E182****THE ROLE AND INFLUENCE OF SELF-PERCEPTION AND OTHERS ON STUDENT DECISION TO PURSUE HIGHER EDUCATION** Thomas Oliver<sup>1</sup>, Peary Brug<sup>1</sup>, Daniel Handanos<sup>1</sup>; <sup>1</sup>St. Mary's University College

– Previous studies have identified that there are numerous factors that contribute towards an individual's decision regarding education (Marriot, 2007). A review of the literature has shown there to be many reasons are considered when deciding whether or not to apply and attend university, with the majority of studies (e.g., Ball et al., 2002; Zhan et al., 2006) looking at how individual factors influence the decision making process. The current study sought to expand on prior studies by also examining the influence others, family, peers and schools, have on this decision making process. The study involved the completion of a questionnaire by participants who had previously attended university, currently in university and those who had never been. The questionnaire measured various components, previously identified as vital aspects of the decision making process, including concerns over the cost of university attendance, value of higher education, academic self-concept and family background. The results showed that both individual factors (e.g., self-concept) as well as group factors (e.g., family encouragement) played a significant role in predicting whether an individual did or did not attend college. Results show that group as well as individual factors play an important role in the decision process and that families are a key element with regard to the group influences. The findings are further discussed with regards to greater access to university by non-traditional students.

**Other****E183****THE TIME COURSE OF ATTENTION FOR EMOTIONAL INFORMATION: AN EYE-TRACKING STUDY** Mandy Nuszbaum<sup>1</sup>, Andreas Voss<sup>1</sup>, Karl Christoph Klauer<sup>1</sup>; <sup>1</sup>University of Freiburg

– As hypothesized by Kunda (1990), we see what we want to see. However, findings of research in motivated perception are fairly inconsistent (e.g., Juth, Lundqvist, Karlsson, & Öhman, 2005; Öhman, Lundqvist, & Esteves, 2001). Depending on stimulus materials and the actual tasks, a negativity bias or a positivity bias of perception was found in different studies. Analyzing eye movements might offer a better understanding of early perceptual processes. In a "Mood-of-the-Crowd" task, participants had to estimate whether faces showing neutral or valent (i.e. positive or negative in different blocks of the experiments) emotional expressions dominated a crowd of faces. In four studies stimulus material (schematic faces vs. photographic faces) and inspection time (short vs. long) was varied. The time course of attention was explored with an eye-tracking device. Findings suggest that negative faces were attended earlier than positive faces but receive less attention in later stages of the viewing phase, in which attention shifted to positive faces. Preliminary, we conclude that there is an early automatic negativity bias and a later positivity bias.

**E184****AVOIDANCE OF INTIMACY AND INCORPORATING OTHERS INTO THE SELF: THE EFFECTS OF POSITIVE AND NEGATIVE CHARACTERISTICS OF CLOSE OTHERS ON EVALUATIONS OF PERSONAL RESOURCES** Shannon P. Lupien<sup>1</sup>, Kimberly B. Arnold<sup>1</sup>, Jessica L. Almonte<sup>1</sup>, Erin Murphy<sup>1</sup>, Mark D. Seery<sup>1</sup>; <sup>1</sup>University at Buffalo, The State University of New York

– Although close relationships are valuable, not all relationships are optimally beneficial for everyone. Attachment styles play important roles in both developing relationships and deriving benefits from them. Specifically, research has shown that non-avoidants incorporate characteristics of close others into their self-concepts, resulting in reports of increased self-liking when considering friends' positive traits. Conversely, avoidants contrast characteristics, leading to increases in self-liking when considering friends' negative traits. This may indicate that thinking about particular relationships spontaneously induce evaluations of similarities and differences depending on one's tendency to avoid inti-

macy. These spontaneous contrast and assimilation effects may influence how one incorporates another's qualities into the self, thus affecting evaluations of personal resources. The biopsychosocial model of challenge and threat (Blascovich & Tomaka, 1996) holds that cardiovascular responses are sensitive to resource evaluations. Because cardiovascular measures do not depend on participants' conscious attention or prompts to self-reflect, they are well suited to investigate spontaneous evaluations of personal resources while avoidants and non-avoidants consider positive versus negative aspects of their friendships. Results demonstrated that when speaking about a friend's positive characteristics, non-avoidants exhibited cardiovascular responses consistent with high resources, whereas avoidants exhibited cardiovascular responses consistent with low resources. The opposite patterns occurred for negative characteristics. Previously demonstrated effects on self-liking were also replicated. These results provide insight into the processes leading to differential evaluations of personal resources, depending on the tendency to avoid intimacy and the specific friendship aspects that are considered. This has implications for well-being.

**E185****THE EFFECT OF DISTANCE ON FREE RECALL OF PICTURES AND WORDS** Elinor Amit<sup>1</sup>, Yaacov Trope<sup>1</sup>, Daniel Algom<sup>2</sup>; <sup>1</sup>New York University, <sup>2</sup>Tel Aviv University

– How do watching news items on TV versus reading the news items in a newspaper affect one's memory for those items when they concern events that happened in one's own country versus in a foreign country? The broader question the present research investigates is how psychological distance affects episodic memory for pictorial and verbal representation of psychologically proximal and distant objects. As predicted, the results showed better recall of pictorial representations of proximal objects (e.g., a picture of a dollar bill) than distant objects (e.g., the word 'Yen') and of verbal representations of distant objects than near objects. These findings were obtained for various distance dimensions: social, temporal, and spatial. Consistent with functional approaches to episodic memory, we argue that pictures are better suited to represent proximal objects because pictures are concrete representations that are physically similar to the referent objects, and that words are better suited to represent distal objects because words are abstract representations that carry the invariant features of the objects.

**E186****THE LURE OF SUSPENSE: FORECASTING ERRORS IN GAMBLING BEHAVIOR** Cheryl Hahn<sup>1</sup>, Timothy Wilson<sup>1</sup>; <sup>1</sup>University of Virginia

– Based on research examining the pleasure of uncertainty and the hot-cold empathy gap, we hypothesized that people would underestimate the lure of suspense in gambling (Wilson et al., 2005; Lowenstein, 2005). Participants chose between a gamble (50% of winning 5 cents) and a "sure thing" (100% chance of winning 5 cents) on each of 40 trials. Forecasters predicted they would gamble on 20% of the trials when in fact participants gambled on 45% of the trials. We obtained some evidence that this misprediction occurred because people underestimated the pleasure of suspense. In one study we manipulated suspense by varying how long it took to reveal the outcome of the gamble (turning over 1 vs. 7 cards). Participants were especially likely to underestimate how much they would gamble in the suspenseful (7 card) condition, particularly if they were high in dispositional curiosity (Kashdan et al., 2004). In Experiment 2 we manipulated the odds of winning the gamble (50% vs. 75%), with the prediction that suspense would be higher in the 50% than the 75% condition. As hypothesized, there was a tendency for people to predict that they would gamble more when they expected to earn more money (75% odds of winning) but to actually gamble more when the odds were lower (50% odds of winning), particularly among participants with a low attraction toward gambling (Breen & Zuckerman, 1999).

**E187**

**THINKING ABOUT YOUR FAVORITE CELEBRITY: THE INFLUENCE OF PARASOCIAL RELATIONSHIPS ON BODY IMAGE** Ariana F. Young<sup>1</sup>, Shira Gabriel<sup>1</sup>, Gretchen B. Sechrist<sup>1</sup>; <sup>1</sup>University at Buffalo, The State University of New York – Research on the media and body image suggests that exposure to unrealistically thin female celebrities has negative effects on women's body image (see Grabe, Ward, & Hyde, 2008 for review). However, research on self-construal suggests that celebrities with whom one has a parasocial relationship (PSR; one-sided relationship with a media figure) can have positive effects on the self via assimilation of the celebrity's traits onto the self (Derrick, Gabriel, & Tippin, 2008). The present research merged the two lines of research to examine the effects of PSRs with thin female celebrities on body image. In this study, female participants either wrote an essay about their favorite female celebrity (PSR condition) or a non-favorite female celebrity (non-PSR condition), and then completed measures assessing their state body image. Results demonstrated that participants who thought about a thin celebrity with whom they did not have a parasocial relationship suffered losses to their body esteem, replicating the pattern found in most work on the media and body image. However, participants who thought about a thin celebrity with whom they had a parasocial bond actually experienced gains to their body esteem. Thus, this research demonstrates of the moderating role of PSRs on how celebrities influence body image.

**E188**

**THE ROLE OF PASSION IN MAINSTREAM AND RADICAL BEHAVIORS: A LOOK AT THE ENVIRONMENTAL CAUSE** Anne-Sophie Gousse-Lessard<sup>1</sup>, Noémie Carboneau<sup>1</sup>, Robert J. Vallerand<sup>1</sup>; <sup>1</sup>Laboratoire de Recherche sur le Comportement Social, Université du Québec à Montréal (UQÀM) – The Dualistic Model of Passion (Vallerand et al., 2003) proposes that individuals can have two distinct types of passion toward an activity: a harmonious passion (HP) or an obsessive passion (OP). HP is characterized by a volitional engagement in one's activity. Conversely, OP leads individuals to experience an uncontrollable urge to engage in the activity. Initial research has shown that OP leads to less adaptive outcomes than HP (e.g., aggressive behaviors). However, very little research has focused on passion for an activity considered as extremely important such as a cause. In line with the Dualistic Model of Passion, two studies were conducted to test whether similar results would be obtained with respect to HP and OP toward the environmental cause. Participants were people actively engaged in the environmental cause. In Study 1 (n = 106), results from partial correlations (controlling for the other type of passion) revealed that both HP and OP were positively associated with the judgment of acceptability of mainstream behaviors. However, OP (but not HP) was positively associated with the endorsement of radical behaviors. Globally, Study 2 (n = 123) replicated these results by looking at the extent to which participants were willing to engage in mainstream and radical behaviors in two specific real-life situations. By moving from a judgment of acceptability to behavioral intentions, Study 2 provided additional information on the more or less adaptive outcomes of passion. Overall, results underscore the importance of distinguishing HP from OP for an important cause such as the environment.

**E189**

**RESTORING POLITICAL TRUSTWORTHINESS BY APPEARING TO ACT CONTRARY TO SELF-INTEREST.** David JY Combs<sup>1</sup>; <sup>1</sup>University of Kentucky – Politicians sometimes misbehave and lose trustworthiness in the eyes of citizens. If a scandal ridden politician harbors any hopes of restoring trustworthiness, he or she must present some account for their misdeeds. There are many approaches politicians use in hopes of restoring trustworthiness. Sometimes they blame others, plead ignorance, or simply apologize. Prior research by Combs (2009) suggests that appearing to act contrary to self-interest can help build trustworthiness. Though there are many ways one could appear to act contrary to self-interest, one way is to engage in hostage posting (hostage posting generally refers to a self-imposed sanction). Participants read and reacted to

three articles which described an ongoing news story. The first described a sitting governor in very positive terms, the second described the governor being indicted as a result of a scandal, and the third described how the governor accounted for his misdeed. There were four variants of the final article (i.e. hostage post, plead ignorance, blame subordinates, control). Results indicated that the hostage post approach restored lost trustworthiness significantly more than each of the other approaches. Participants in the hostage post condition also reported a restoration in their willingness to consider voting for the scandal ridden politician compared to participants in each of the other conditions.

**E190**

**PREDICTING RAPPORT IN DYADS: MATTERING OVER MIND-READING** John E. Myers<sup>1</sup>, Sara D. Hodges<sup>2</sup>; <sup>1</sup>University of Minnesota, <sup>2</sup>University of Oregon – Which better predicts rapport in a conversation, people's ability to accurately infer another person's specific thoughts, or the overall perception that the conversation is meaningful and important? We sought to answer this question by studying 134 college students (51% female) who participated in previously unacquainted, same-sex dyads. In an intimacy-generating condition, partners first took turns discussing topics designed to generate interpersonal closeness (Aron et al., 1997). Control participants worked on a jigsaw puzzle with partners. All participants then took turns discussing topics similar to those in the intimacy-generating condition. Participants in both conditions watched a video of this final interaction. Following Ickes' paradigm for studying empathic accuracy, participants were asked to report thoughts and feelings they had during this final interaction, and were later asked to infer the thoughts reported by their partners (Ickes et al., 1990). Participants also reported how important their own thoughts and feelings were and how important they thought their partner's thoughts and feelings were. Finally, participants completed questions about rapport with their partner and how the interaction had gone. Analyses revealed that objective measures of empathic accuracy were unrelated to interactants' rapport. Even participants' ability to accurately infer their partners' more important thoughts had no impact on interaction outcomes. However, interactants' perceptions of how important their thoughts were and how important their partner's thoughts were predicted rapport. Thought-by-thought accuracy appears to be less critical than global perceptions of the importance of what is being discussed in terms of predicting rapport.

**E191**

**FUTURE DISCOUNTING IN MONETARY AND SEXUAL DOMAINS** Melissa R. Fales<sup>1</sup>, David A. Frederick<sup>1,2,3,4</sup>, Martie G. Haselton<sup>1,4,5</sup>, Elizabeth G. Pillsworth<sup>3,4,6</sup>; <sup>1</sup>UCLA Department of Psychology, <sup>2</sup>UCLA Center for Society and Genetics, <sup>3</sup>FPR-UCLA Center for Culture, Brain, and Development, <sup>4</sup>UCLA Center for Behavior, Evolution, and Culture, <sup>5</sup>UCLA Department of Communications, <sup>6</sup>UCLA Center for the Study of Women – Life history theorists propose that individuals develop different preferences due to varying developmental and environmental conditions. For example, individual variation in preferences for present versus future financial rewards may be contingent on uncertainty about the future. We propose that future uncertainty should also affect sexual strategies, and hence individuals who prefer immediate financial rewards will also engage in more opportunistic, short-term mating. Because men may be able to translate immediate financial gains into mating opportunities to a greater extent than women can, we further predict that the relationship between financial future discounting and permissive sexuality will be greater among men than among women. In a study of 1124 online participants, we examined the links between present-oriented financial preferences (i.e., preferring smaller, immediate rewards over larger, later rewards), interest in short-term vs. long-term sexual relationships, and number of sex partners. Participants completed established measures of future discounting (e.g., would you prefer 25 dollars now or 38 dollars in three weeks?). Individuals choosing immediate rewards were considered more present-oriented. Participants also completed measures of their sexual history and their attitudes towards casual sex. Consistent

with the predictions, present-oriented individuals reported greater interest in short-term mating, more sex partners, and less interest in long-term mating. As predicted, these associations were stronger among men than women. These findings provide support for a link between future discounting in the monetary and sexual domains. Considering general levels of future discounting is important for potentially determining social behaviors, including one's orientation towards short-term vs. long-term relationships.

### E192

#### WHAT PREDICTS PATIENCE IN A MUSLIM SAMPLE FROM TURKEY?

**Ozanser Ugurlu<sup>1</sup>, <sup>1</sup>Mutluluk Enstitüsü** – A recent study on patience (Schnitker & Emmons, 2007) argues that patience has been an important personal virtue for Jewish, Christian, Islamic, and Eastern (Buddhism, Hinduism, Taoism) perspectives. In the light of diverse religious and psychological perspectives, the researchers developed a valid and reliable measure of patience to explore the relationship between patience and other psychological constructs in the USA. Their 10-item Patience Scale measures a self-evaluation of one's own patience and patient behaviors (F1) as well as the individual's beliefs about the importance of patience (F2). Following the study of Schnitker and Emmons (2007), the purpose of the present study is to explore the association between patience and religious description, hope, gratitude, and optimism in Turkey, predominantly Muslim country. 349 Muslim participants filled out the measures of patience, hope, gratitude, optimism, and how much they feel themselves as religious via internet. Participants' ages ranged from 17 to 52 ( $M=30.05$ ;  $SD = 6.63$ ). Separate linear regression analyses for F1 and F2 were performed. Results showed that inconsistent with the earlier study there was no significant  $R^2$  among F1, whereas consistent with the earlier study there was a significant  $R^2$  for F2. The significant results for F2 indicated that hope ( $\beta=.16$ ,  $t = 2.73$ ,  $p < .01$ ), gratitude ( $\beta=.18$ ,  $t = 3.36$ ,  $p < .01$ ), optimism ( $\beta=.12$ ,  $t = 1.94$ ,  $p = .054$ ), and religious description ( $\beta=.13$ ,  $t = 2.38$ ,  $p < .01$ ) significantly predicted F2 ( $R^2 = .15$ ,  $F(4, 325) = 14.26$ ,  $p < .001$ ). Results are discussed with regard to relevant literature.

### E193

#### PEOPLE OR PROFILES?: SEEKING OUT OR WARDING OFF THE PERSPECTIVES OF OTHERS ON FACEBOOK

**Jordan Carpenter<sup>1</sup>, Melanie Green<sup>1</sup>, Jeff LaFlam<sup>1</sup>, <sup>1</sup>The University of North Carolina at Chapel Hill** – Traditional face-to-face communication requires a complicated, continual process of mutual mind-reading. Although all normal adults have Theory of Mind (an understanding that others have unique perspectives, different from one's own), individuals may differ in their motivation to understand the thoughts and perspectives of others. We have called this individual difference the Need for Social Cognition (NFSC; Carpenter & Green, 2008). Our NFSC scale measures motivations towards Theory of Mind activities along three dimensions: curiosity, engagement, and defensiveness. These dimensions may have different effects on people's use of social networking websites such as Facebook. To examine this question, we created an online survey which included the NFSC scale and questions about Facebook use. Curiosity and defensiveness predicted distinct behavioral and motivational patterns in Facebook usage. For example, those high in curiosity were more likely to use Facebook to find out more information about people they have just met, to browse other people's profiles, and to expect responses to their status updates, suggesting a relationship-seeking strategy integrating Facebook usage with other types of social interaction. Meanwhile, those high in perspective defensiveness used Facebook more often overall, were more likely to have Facebook-only friendships, and were more likely to use Facebook to search for romantic partners, perhaps suggesting that these individuals use Facebook to control the amount of social information they receive. These patterns, which could not be accounted for by extroversion scores, imply two discrete motivations towards Facebook usage: Facebook can be used either as a social or an isolating tool.

### E194

#### TO CONTROL YOU OR TO CONTROL ME? DISENTANGLING THE EFFECTS OF SOCIAL AND PERSONAL POWER

**Nathen B. Lester<sup>1</sup>, Sean M. Laurent<sup>1</sup>, Sara D. Hodges<sup>1</sup>, <sup>1</sup>University of Oregon** – Social power - or having control over others' outcomes - has been the focus of intensive study in past research. Van Dijke and Poppe (2006), however, demonstrated that participants preferred personal power - or control over one's own outcomes - to social power. In the current research, which attempted to further differentiate social power from personal power, 224 participants were first primed with high or low social power, or high personal power. As primes, participants wrote about either a time in their lives when they had power over someone else (high social power), when someone else had power over them (low power), or when they had control over their own actions (high personal power). Following this, participants rated themselves on power-related adjectives and answered power-related questions. Results suggested that people reliably differentiate personal power from social power. For example, low power (e.g., accountability, submissiveness) was strongly and negatively correlated with personal power (e.g., self-direction, freedom), but shared only a weak negative correlation with social power (e.g., dominance, leadership). Correlations between personal and social power varied by priming condition: Social and personal power were positively correlated in the social power condition, but negatively correlated in the personal power condition. This indicates that after priming with social power, social and personal power are not distinct concepts, while after priming with personal power, they are. These findings have important implications for power research, and suggest one possible reason why people seek out social power - to gain control over their own fates.

### E195

#### PERCEIVED DISCREPANCY REGARDING HOOKING UP NORMS

**John J. Grein<sup>1</sup>, Catherine A. Sanderson<sup>1</sup>, <sup>1</sup>Amherst College** – This study examined whether students feel discrepant from campus norms regarding hooking up as well as the long-term consequences of feeling discrepant from others. In the fall, eighty (40 male, 40 female) first year college students reported the number of times they had engaged in various hookup behaviors (i.e., kissing, sexual intercourse), their perceptions of the average students' responses to these items, and a measure of social satisfaction. In the spring, 92.5% of participants (35 male, 39 female) returned and completed the same measures. Findings indicated that across diverse behaviors, women consistently believed that they had engaged in fewer hookups than other women. In contrast, men perceived no self-other discrepancies for hookups involving milder forms of sexual behavior (i.e., kissing, touching), but believed that they had engaged in fewer oral/anal/vaginal sex hookups than other men had. Finally, feeling discrepant from campus hookup norms was associated with experiencing negative consequences: men and women who believed that they had engaged in fewer hookups than others in the fall reported lower levels of social satisfaction in the spring, even when controlling for social satisfaction in the fall and actual self-other hookup discrepancies. This study contributes to prior research on social norms by demonstrating that individuals perceive a discrepancy between their hooking behaviors and others' behaviors, that women perceive larger self-other discrepancies than men, and that feeling discrepant from such norms is associated with diminished social satisfaction for both sexes, even when no actual discrepancy exists.

### E196

#### IMPLICIT THEORIES IN THE CONFLICT CONTEXT: CAN IMPLICIT THEORIES ABOUT NEGOTIATION ABILITY PREDICT AFFECTIVE RESPONSES TO A DIFFICULT NEGOTIATION?

**Alexandra Russell<sup>1</sup>, Carol Dweck<sup>1</sup>, <sup>1</sup>Stanford University** – Previous research (Kray & Haselhuhn, 2007) suggests that incremental implicit theories about negotiation ability predict increased perseverance and success in a dyadic negotiation. Building on these findings, the authors hypothesized that lay theories about negotiation ability would also predict participants' affective

responses to a difficult interpersonal negotiation. To test this hypothesis, participants engaged in a difficult interpersonal negotiation. Following this, measures of attitudes toward the negotiation outcome and feelings toward the negotiation partner were taken. As hypothesized, results showed that implicit theories significantly predicted differences in affective reactions to the negotiation experience. Specifically, equating for negotiation outcome, implicit theories were significantly correlated with levels of irritation, annoyance, and satisfaction regarding the negotiation. Implicit theories also predicted perceptions of the negotiation partner as being warm and competent. An incremental implicit theory was associated with positive affect toward both the partner and the negotiation itself, while an entity theory was associated with more negatively valenced affect. Overall, an incremental implicit theory predicted increased positive feelings and positive regard for the partner and the negotiation experience. These findings suggest that incrementalists might be more inclined to continue difficult negotiations and build on prior successes in long-standing or intractable conflicts.

**E197****THE WAY WE LISTEN MATTERS: NON-COUNTERARGUING LISTENING AS AN INTERVENTION IN THE BIAS-PERCEPTION CONFLICT SPIRAL**

Kathleen A Kennedy<sup>1</sup>, Emily Pronin<sup>1</sup>; <sup>1</sup>Princeton University – The escalation from mere disagreement to conflict is partly driven by imputations of bias to one's opposition (Kennedy & Pronin, 2008). We hypothesize that listening to adversaries in a critical and counterarguing way, rather than with an open ear, is one source of these increased perceptions of bias. We tested this hypothesis by manipulating participants' listening goals in disagreements about university policy (Study 1) and healthcare reform (Study 2) in an attempt to attenuate naturally occurring bias-imputations and provide an intervention for the bias-perception conflict spiral. After providing their position on the issue, participants listened to a recording of another individual's position that was opposite their own. Instructions about how to listen to this target varied. In the control condition, participants were told to respond to the recording as they would naturally. In the counterarguing condition, participants' goal was to critique the recording. In the non-counterarguing condition (our intervention to improve bias-perceptions), the goal was to recreate the opponent's position such that the opponent would feel fairly represented and understood. After listening, participants rated the degree to which they believed their opponent's position was influenced by three objective and three biased sources. The difference between ratings of bias and objectivity varied significantly by condition; participants perceived their opponent more favorably after listening in a non-counterarguing way, while the control and counterarguing conditions did not differ. These improvements in perceptions of adversaries' bias and objectivity are a promising first step toward lessening conflict development by intervening in the bias-perception conflict spiral.

**E198****CONFLICTING OPINIONS: EXAMINING THE EFFECTS OF MULTIPLE THIRD PARTY OPINIONS ON ROMANTIC RELATIONSHIP INITIATION**

Brittany Wright<sup>1,2</sup>, H. Colleen Sinclair<sup>2</sup>; <sup>1</sup>University of Texas at Austin, <sup>2</sup>Mississippi State University – Research has established that social network opinions can influence an individual's romantic relationship quality. The majority of the previous research, however, has focused on examining how one source of opinion can influence one's current romantic relationship state. The present study focused on some gaps in the present literature by experimentally examining the effects of multiple third party opinions during romantic relationship initiation. The main goal of the present study was to examine if one third party's opinion emerged as being more influential than the other when opinions conflicted. Social Exchange theory was also incorporated to potentially explain the differences in source influence. The study employed a virtual dating game paradigm in which participants spoke to two potential romantic partners online and received positive or negative feedback from their friend and parent about one of the partners. The study employed a 2 (Parent Opinion: good match, bad match) x 2 (Friend Opinion: good match, bad

match) x 2 (Interaction Partner: Target, Control – within-subjects) mixed factorial design. Friend opinion emerged as being an influential factor in both the likeability rating of the target interaction partner and the likelihood that the participant would choose the interaction partner that their friend thought was a good match for their final interaction. Parent opinion did not affect likeability or choice until we accounted for how often participants received romantic relationship resources (e.g., advice) from their parent, such that those who depended on their parents more for advice resources were more likely to adopt their parent's perspective.

**E199****SOCIAL ORIENTING IN A COMPLEX SCENE: THE INFLUENCE OF OTHER AUDIENCE MEMBERS' GAZE DURING A LECTURE DELIVERED IN A VIRTUAL ENVIRONMENT**

Cade McCall<sup>1</sup>, Jeremy Bailenson<sup>2</sup>, Jim Blascovich<sup>1</sup>, Masaki Miyahara<sup>1</sup>, Andrew Beall<sup>1</sup>; <sup>1</sup>University of California, Santa Barbara, <sup>2</sup>Stanford University – Gaze is a fundamental component of face-to-face social interaction. Research on social orienting has demonstrated that the mere presentation of an eye or a head pointed toward a given location directs the viewer's attention there. Research has yet to explore, however, the influence of this phenomenon in complex contexts. Along these lines, the current study sought to leverage social orienting to manipulate participants' attention during a lecture presented within an immersive virtual environment. The environment consisted of a conference room with a speaker and a group of other (virtual) attendees. The amount of time the other attendees spent oriented toward the speaker and the frequency of the attendees' orienting movements were manipulated. Participants' own orienting behaviors, memory for the speech, and impressions of the speaker were measured. In line with our hypotheses, participants oriented with the other attendees and stayed fixated on the speaker when the other attendees were oriented toward the speaker. More significantly, participants who experienced a high level of social presence remembered more of the speech when the other attendees spent more time oriented toward the speaker. Together these data suggest that social orienting has powerful effects in complex environments. Furthermore, the paradigm presented here demonstrates the utility of digitally transformed social interactions within virtual environments.

**E200****INTERROGATION THROUGH PRAGMATIC IMPLICATION: COMMUNICATING BENEFICENCE AND PROMISES OF LENIENCY**

Deborah Davis<sup>1</sup>, Jordan Hernandez<sup>1</sup>, William C. Follette<sup>1</sup>, Richard A. Leo<sup>2</sup>; <sup>1</sup>University of Nevada, Reno, <sup>2</sup>University of San Francisco – Interrogators' use of explicit promises of leniency to evoke suspect confessions may result in the suppression of any confession obtained. Hence interrogators are trained to convey such promises through implication. Courts, however, frequently fail to recognize the use of pragmatic implication as effective in communicating promises of help or leniency. We tested the effects of three widely taught interrogation tactics employing implication on perceived beneficence of the interrogator and likely harsh versus lenient outcomes of confession. Subjects read 8 interrogation transcripts varying in the use of three tactics, and then rated the beneficence (helpful intent) of the interrogator and expected results of confession. The "sympathetic detective" tactic consisted of statements of liking and desire to help the suspect. The "set up question" consisted of questions to the suspect regarding whether the guilty party should simply go to jail, or whether there are conditions under which he should get a second chance, maybe get counseling or not go to jail. The "accident theme" consisted of suggestions that perhaps the alleged crime of child molestation occurred by accident, perhaps touching the child while sleeping, thinking of his wife. Each tactic significantly affected perceptions of the extent of the interrogator's choices in whether and with what to charge the suspect, perceptions of the interrogator's liking and helpful intentions (beneficence) toward the suspect, and/or expectations of the likelihood, should the suspect comply and confess, that he would be charged with the most versus least serious versions of the crime, and be convicted if charged.

**E201**

**THE INFLUENCE OF TEAM STRESS APPRAISALS AND COORDINATION ON PERFORMANCE** Tamera R. Schneider<sup>1</sup>, Pamela Dowling<sup>1</sup>, Gaea Payton<sup>1</sup>, Charlene Stokes<sup>2</sup>, Joseph B. Lyons<sup>2</sup>; <sup>1</sup>Wright State University, <sup>2</sup>Wright Patterson AFB – This study examined team stressor appraisals and coordination, and their effects on performance. We expected that challenged teams would coordinate better in a virtual environment, as indexed by online communication, and thus perform better than threatened teams. Data were from 73 5-member teams, working as a crew of a computer-based aerial port. Teams were to prepare incoming aircraft for departure. Performance metrics included the accuracy of the sequence of events needed to depart the incoming aircraft (e.g., disembark passengers, remove cargo, clean and restock aircraft) and the amount of time (sec) taken to carry out the full sequence. Challenged teams appeared to be more accurate and time efficient, but not reliably. However, when teams coordinated well, they were marginally more accurate and reliably more time efficient. The lack of finding for appraisals may be due to losing variability as individual level data were aggregated to the team level. The findings for coordination show that teams who performed well have members who anticipate the needs of their teammates. Although virtual environments add to the complexity of communication in team work units, good team coordination can facilitate some types of performance.

**E202**

**THE JUSTICE-RESTORING EFFECTS OF FORGIVENESS IN INTERPERSONAL AND INTERGROUP CONTEXTS** Michael Wenzel<sup>1</sup>, Tyler Okimoto<sup>2</sup>; <sup>1</sup>Flinders University, Adelaide, Australia, <sup>2</sup>Yale University, U.S.A. – Forgiveness is often assumed to be antithetical to subjective justice, requiring the lowering or sacrificing of justice standards. In our view this notion assumes narrow understandings of justice (as retributive, not restorative) and forgiveness (as a sentiment, not an act). We argue that two symbolic implications of transgressions fuel feelings of injustice in victims: the lowering of the victim's status/power and the questioning of presumably shared values. An act of forgiveness can alleviate either concern; it can give victims moral status and control, and express the expectation or hope that the offender will re-endorse shared values. Forgiveness can restore justice via either of these mechanisms, depending on the victim's (oppositional vs. shared) identity with the offender. In Study 1, participants were instructed to express forgiveness towards a (hypothetical) offender. The forgiveness act significantly repaired victims' feelings of status/power and perceived value consensus with the offender, which independently mediated a positive effect on perceived justice. Using a similar paradigm, Study 2 also manipulated whether the offender was a distant or close other. The forgiveness act again had a positive effect on perceived justice, but this was mediated by status/power for a distant other and by perceived value consensus for a close other. Study 3 used a lab paradigm: after being victimized by an outgroup, the ingroup allegedly decided by vote to send a forgiving or unforgiving message to the outgroup. The forgiveness act led to greater perceived justice, partially mediated by a sense of status/power.

**E203**

**CLASSIFICATION FLUENCY MODERATES THE APPEAL OF CROSS-RACE FACE BLENDS** Jamin Halberstadt<sup>1</sup>, Piotr Winkielman<sup>2</sup>; <sup>1</sup>University of Otago, <sup>2</sup>University of California, San Diego – Cross-race face blends are generally more attractive than the individual faces that compose them, and even more attractive than same-race blends. Although various evolutionary accounts have been offered for their appeal, racial blends may also be attractive by virtue of their cognitive fluency: A racial blend may be a particularly good, easily classified, and therefore attractive example of a face. The same blend, however, may be a relatively poor, difficult to classify, and unattractive example of a specific racial group. Therefore, we hypothesized that cross-race face blends should be less attractive when judgment requires classification in terms of their racial identity. In a test of this hypothesis, participants rated the attractiveness of both same-race and mixed-race blends. Prior to making each rating, half of the

participants classified the face in terms of its racial identity. As expected cross-race blends were more attractive than same-race blends, but the advantage was significantly reduced when faces were categorized prior to rating. The results illustrate that a complete account of the appeal of racial blends must include contextual, high-level cognitive factors that take into account an individual's subjective category structure.

**Personality Processes****E204**

**SCALE DEVELOPMENT AND CONSTRUCT VALIDATION OF A CHIMPANZEE RATING SCALE** Hani Freeman<sup>1</sup>, Samuel D. Gosling<sup>1</sup>, Susan P. Lambeth<sup>2</sup>, Steve Schapiro<sup>2</sup>; <sup>1</sup>University of Texas at Austin, <sup>2</sup>Michale E. Keeling Center for Comparative Medicine and Research – The current study involved the development and evaluation of the reliability and construct validity of a personality rating scale in chimpanzees. The scale is based on a bottom-up approach to scale development and was developed using steps from both Uher (2008a,b) and Gosling (1998). The construct validity was evaluated using a nomological network that specifies predicted relationships between the developed scale and data based on theories from previous studies about age, rearing history, behavior, injuries, minor and major illnesses, blood chemistry, cortisol, and genetics. The scale contained 41 adjectives and was used to rate 160 chimpanzees at the University of Texas MD Anderson Cancer Center Facility in Bastrop, TX. Fifteen people who have worked with the chimpanzees between 6 months to 20 years rated each of the animals. In addition behavioral, epidemiological and biological data were collected on the chimpanzees. Preliminary findings indicate that the scale is reliable for most adjectives. The reliabilities of individual ratings, ICC(3,1), ranged from .17 (depressed) to .80 (dominant), with a mean reliability of .56. The reliabilities of mean ratings, ICC(3,k), ranged from .38 (depressed) to .92 (dominant), with a mean reliability of .76. On-going data analysis will indicate the factor structure and validity of the scale in terms of the variables mentioned above. The results can be used to inform research in primates, animal welfare and wildlife management, and should be used to examine basic issues in animal behavior and human psychology.

**E205**

**THE SOCIAL SIDE OF DRUG USE: LANGUAGE CUES ASSOCIATED WITH DRUG USE** Gabrielle Wirth<sup>1</sup>, Ewa Kacewicz<sup>1</sup>, James Pennebaker<sup>1</sup>; <sup>1</sup>University of Texas at Austin – Substance abuse research has focused primarily on alcohol use. Use of marijuana has been largely neglected because of legality issues. The purpose of this study was to use a naturalistic method to examine how marijuana affects psychological states. Analysis of natural language has been shown to reflect how people are thinking or feeling, thus we examined language use on forums dedicated to smoking marijuana as compared to other comparable forums. The current study examined online posts on the etiquette of marijuana use (n=20), alcohol use (n=20), or carpooling (n=20). Posts were analyzed using LIWC (Linguistic Inquiry and Word Count). Preliminary results suggest that different linguistic variables are associated with different forms of drug use. People writing on alcohol forums seem to be more focused on themselves and others as reflected in higher use of social words (F=6.5; p<.05), such as talk and they, and pronouns (F=8.5; p<.01). Posts on marijuana etiquette appear to be more concrete as gauged by higher article use (i.e. a, an) (F=10.6; p<.01). Posts on carpooling, on the other hand, are the most cognitively complex, using more insight, (i.e. inform, wonder) (F=4.2; p<.05), causal (i.e. solve, thus) (F=10.4; p<.01), and six letter words (F= 19.5; p<.01). These differences in language suggest that people posting to these 3 forums differ in their psychological states. Language can give us a sense of how certain substances influence people's thoughts and perceptions. More broadly, this could have implications in law enforcement, use of medicinal marijuana and public safety in general.

**E206****HIGH NEUROTICISM AND LOW CONSCIENTIOUSNESS ARE ASSOCIATED**

**WITH INTERLEUKIN-6** Angelina Sutin<sup>1</sup>, Antonio Terracciano<sup>1</sup>, Paul Costa<sup>1</sup>; <sup>1</sup>National Institute on Aging, NIH, DHHS – High Neuroticism and low Conscientiousness are frequently implicated in health-risk behaviors, such as smoking and overeating, as well as health outcomes, including mortality. Their associations with physiological markers of morbidity and mortality are less well documented. Using a population-based sample from Sardinia, Italy (N = 4,923), we examined the association between personality and interleukin-6 (IL-6), a pro-inflammatory cytokine often elevated in patients with chronic morbidity and frailty. Consistent with the literature on personality and self-reported health, high Neuroticism and low Conscientiousness were both associated with higher levels of IL-6. The findings remained significant after controlling for smoking, weight, aspirin use, and disease burden. Further, smoking and weight partially mediated the association between impulsivity-related traits and higher IL-6 levels. Identifying critical medical biomarkers associated with personality may help to elucidate the physiological mechanisms responsible for the observed connections between personality traits and physical health.

**E207****SITUATIONAL SIMILARITY AND PERSONALITY TRAITS AS PREDICTORS OF BEHAVIORAL CONSISTENCY**

Ryne Sherman<sup>1</sup>, Christopher Nave<sup>1</sup>, David Funder<sup>1</sup>; <sup>1</sup>University of California, Riverside – This study examines the degree to which situational similarity and personality is associated with behavioral consistency in ecologically representative environments of undergraduate students. On four separate occasions participants provided written descriptions of a situation they had experienced within the past 24 hours. In addition, they described the psychological features of the situation using the recently developed Riverside Situational Q-Sort (RSQ; Wagerman & Funder, 2009) and their behavior using the Riverside Behavioral Q-Sort (RBQ; Funder, Furr, & Colvin, 2000). Results indicate that 1) people demonstrate impressive behavioral consistency across situations ( $r = .40$ ), 2) situational similarity is a strong predictor of behavioral consistency ( $r = .67$ ), and 3) personality characteristics predicted behavioral consistency even when controlling for situational similarity such that persons who, "behave in an ethically consistent manner" ( $r = .21$ ), "favor conservative values" ( $r = .20$ ), and are "calm; relaxed in manner" ( $r = .18$ ) behaved more consistently. Taken together, these results imply that "real world" behavioral consistency is likely caused by multiple sources. These include processes of situation selection (i.e. particular kinds of people selecting themselves into similar situations) and the influence of personality traits that lead to behavioral consistency beyond what is implied by situation similarity.

**E208****WORKERS BEHAVING BADLY: PERSONALITY AT AGE 18 PREDICTS**

**WORKPLACE DEVIANCE AT AGE 32** Kimdy Le<sup>1</sup>, Edward A. Witt<sup>2</sup>, M. Brent Donnellan<sup>2</sup>, Sarah Spilman<sup>3</sup>, Rand D. Conger<sup>3</sup>; <sup>1</sup>Indiana University Purdue University Columbus, <sup>2</sup>Michigan State University, <sup>3</sup>Iowa State University – Workplace deviance includes a variety of behaviors such as absenteeism, theft, and incivility. These actions impose significant costs to organizations in terms of lost capital and reduced morale. A robust finding in the personality literature is that general antisocial behavior is positively associated with Negative Emotionality (the susceptibility to distressing emotions) and negatively associated with Constraint (the ability to exercise self-control). In this poster, we extend this previous research to the prediction of workplace deviance. Data come from the Family Transitions Project (e.g., Conger & Conger, 2002), an ongoing community study based in Iowa (Minimum N = 382, 55% women). Personality was assessed in 1994 using the Multidimensional Personality Questionnaire (Tellegen, 1982) when sample participants were an average age of 18.11 years. Workplace Deviance (e.g., taking property, acting rudely) was measured in 2007 using self-reports on the Bennett and Robinson (2000) measure ( $\alpha = .83$ ) when sample participants were an average age of 31.72

years. Workplace Deviance at Age 32 was correlated with Negative Emotionality ( $r = .20$ ) and Constraint ( $r = -.15$ ) at Age 18. Effects held controlling for gender, even in light of the mean-level differences in Workplace Deviance ( $d = .41$  such that men reported higher scores). However, the personality effects for Negative Emotionality were somewhat stronger for men than women. All in all, broad personality traits statistically predict workplace deviance in a span of over a decade. Moreover, workplace deviance appears to be a specific outcome associated with generalized personality predispositions toward antisocial behavior.

**E209****NARCISSISM AND SELF-DETERMINATION**

Ben Porter<sup>1</sup>, Helen Lee Lin<sup>1</sup>, C. Raymond Knee<sup>1</sup>, Ahmet Uysal<sup>1</sup>; <sup>1</sup>University of Houston – Prior research has shown that narcissism can have both positive and negative effects on well-being. Specifically, entitlement has been linked to lower well-being and grandiosity has been linked to positive well-being (Brown, Budzek, & Tamborski, 2009). The current research seeks to establish the importance of self-determination when studying narcissism. Participants (N=188) completed the 37-item Narcissistic Personality Inventory (NPI) and measures of need satisfaction, authenticity, and well-being. Entitled narcissists should demonstrate lower need satisfaction and authenticity because entitlement shows a discrepancy between how one views oneself and how one is treated by others. Self-admiring narcissists should demonstrate higher need satisfaction and authenticity because self-admiration is more conducive to a coherent (though possibly inflated) sense of self. Consistent with the hypotheses, need satisfaction and authenticity were positively correlated with self-admiration and negatively correlated with entitlement. Furthermore, the relationships between well-being variables and entitlement and self-admiration were mediated by both need satisfaction and authenticity. The results suggest that self-determination theory could be important to consider for the study of narcissism and possibly explain some of the discrepancies associated with narcissistic well-being.

**E210****EFFECTS OF AFFLUENCE LEVEL ON PERCEPTIONS OF CONSCIENTIOUSNESS AND AGREEABLENESS FACETS**

Kevin L. Zabel<sup>1</sup>, Andrew N. Christopher<sup>1</sup>; <sup>1</sup>Albion College – Fiske, Cuddy, Glick, and Xu (2002) proposed a mixed model of stereotype content, in which competence and warmth perceptions are influenced by status and competition, respectively. Based on their similarities with competence and warmth, we evaluated the conscientiousness facets (proactive vs. inhibitive) and agreeableness facets (active vs. interpersonal management tools), and the influence of affluence level on conscientiousness and agreeableness perceptions. College students (N = 251) were randomly assigned to an affluence level condition (affluent or non-affluent), and after reading a vignette, were asked their conscientiousness and agreeableness perceptions of the character. Conscientiousness and agreeableness perceptions were analyzed separately. Our experimental design was a 2 (affluence level: high or low) x 2 (personality facet), with repeated measures on the latter factor. An ANOVA revealed an affluence level by conscientiousness interaction,  $F(1, 247) = 47.44, p < .001, \eta^2 = .16$ , such that participants perceived the affluent character ( $M = 5.27$ ) to be more proactive than the non-affluent character ( $M = 4.77$ ) but perceived the non-affluent character ( $M = 5.67$ ) to be more inhibitive than the affluent character ( $M = 5.34$ ). Regarding agreeableness, an ANOVA revealed solely an affluence level main effect,  $F(1, 246) = 106.81, p < .001, \eta^2 = .30$ , such that the non-affluent character ( $M = 5.11$ ) was perceived as more agreeable than the affluent character ( $M = 4.29$ ). Results support findings regarding affluence level and personality facet associations, and suggest links between the stereotype content model and personality factors (i.e., conscientiousness and agreeableness).

**E211****EMERGING ADULTS' PERCEPTIONS AND DESIRES IN SELF-MOTIVATED, INTENTIONAL PERSONALITY CHANGE** Erik Nofhle<sup>1</sup>, <sup>1</sup>Linfield College –

Clearly, personality changes: a recent meta-analysis of normative personality trait change revealed moderate, mostly positive, amounts of change across the lifespan (Roberts, et al., 2006). Emerging adulthood is a developmental period with one of the largest, most pervasive, pattern of trait changes, and is theoretically the most "volitional" period of life (Arnett, 2000, p. 469), distinguished by active identity pursuits and newfound independence. However, personality change has been typically studied as a passive process – something that happens to a person – stemming from genetic and environmental influences and transactions. What if the sizable personality changes during emerging adulthood result partly from individuals' intentional efforts to improve themselves, characterized by an active, self-guided process rather than a passive one? How do young adults desire to and expect to change? I begin addressing these questions with two samples of college students. Study 1 (N=146) and Study 2 (N=206) assessed individuals' expectations, attributions, and desires for future, intended, personality change, using non-overlapping sets of Big Five adjectives balanced for social desirability. Across both studies, Extraversion-related traits were nominated as the most personally important for individuals to change, followed by Conscientiousness and Emotional Stability-related traits. In addition, Extraversion was expected to increase the most in the near future, followed by Conscientiousness. Finally, Extraversion and Conscientiousness had the greatest discrepancies between current self-ratings and ideal ratings. The findings reveal that young adults are motivated to change on some traits more than others, and suggest intentions to change may result from feeling furthest from one's ideal.

**E212****ARE YOUR NEEDS BEING SATISFIED? HOW INTERPERSONAL STRENGTHS AND PROBLEMS AFFECT INTRAPERSONAL HEALTH AND WELL-BEING.** Alana Greco<sup>1</sup>, Lara Kammrath<sup>1</sup>, <sup>1</sup>Wilfrid Laurier University –

The distribution of a person's interpersonal strengths and weaknesses contains rich information about their behavioral abilities and their behavioral difficulties during various social interactions. Understanding where a person's strengths and problems lie may be useful in predicting important intrapersonal variables. Using our newly developed brief measure of interpersonal functioning, the Good Me Bad Me Questionnaire (GMBM-Q; Greco & Kammrath, 2009), we assessed how a person's overall mean level of strengths and problems and their distribution of strengths and problems differentially predicts global psychological/emotional health and domain specific intrapersonal health. Participants were asked to complete the GMBM-Q, the Basic Psychological Needs Scale (Deci & Ryan, 2000), and Ryff's Well-being Scale (Ryff, 1989). The results indicated that a person's overall interpersonal functioning, in other words having many strengths and few problems, was significantly predictive of their well-being. Furthermore, people's distribution of strengths and problems independently and differentially predicted satisfaction of the basic psychological needs for autonomy, competence, and relatedness.

**E213****DIMENSIONS OF PERSONALITY IN EXPLOSIVE-DETECTOR MILITARY WORKING DOGS** Samuel D. Gosling<sup>1</sup>, David L. Sinn<sup>1</sup>, Stewart J. Hilliard<sup>2</sup>;

<sup>1</sup>University of Texas, Austin, <sup>2</sup>341st Training Squadron, Lackland Air Force Base – Perhaps the most promising domain of canine-personality research is in the area of working dogs. Dogs are called upon to perform a great variety of tasks, ranging from rounding up sheep to assisting the visually impaired, that are of great importance to special economic interests or narrow segments of the population. However, because specially bred and trained working dogs are critical front-line assets in military and law enforcement functions (e.g., suspect apprehension, explosives detection, narcotics interdiction), they also exert have a much more pervasive influence on life in the developed world, especially in this age of

terroristic threat and globe-spanning low-intensity warfare. As in the case of humans, it is becoming clear that some individuals are better suited to some tasks than are others. As the first step in developing models to predict working performance from personality we present a structural analysis of twelve behavioral tests performed on over 465 Military Working Dogs when first acquired during procurement trips in Europe. Factor analyses suggested a four-factor solution. To examine the robustness of the solution, targeted procrustes analyses were performed; these analyses revealed that the solution was almost identical (overall factor congruence = .97) to that found when the dogs were tested again several weeks later prior to training at Lackland Air Force Base, TX. These analyses underscore the viability of measuring personality in working dogs and lay the foundation for developing predictive models of working-dog performance.

**E214****INVESTIGATING THE ASSOCIATION OF ETHNIC IDENTITY, NEUROTICISM, AND THE MODERATING EFFECTS OF COPING STRATEGIES ON REPORTS OF RACIAL DISCRIMINATION** Lenwood Hayman<sup>1</sup>, <sup>1</sup>Wayne State University –

Studies have found racial discrimination to be one of the most significant contributors to chronic stress in Blacks. However, few studies have investigated the role of ethnic identity and neuroticism in how Blacks perceive racial discrimination. Therefore, the purpose of the current study was to explore the influences of individuals' neuroticism and ethnic identity on their perceptions of racial discrimination and how the coping strategies they utilize moderate the resulting stress. It was hypothesized that the more racial discrimination throughout their lifetime individuals experienced, 1) the higher their levels of neuroticism and 2) the lower their ethnic identity. It was also hypothesized that for those individuals reporting frequent usage of a coping strategy, either adaptive or maladaptive, the higher their reports of racism-related stress. Two-hundred ninety-nine Black students, faculty, and staff from a large, urban, Midwestern university responded to an online to questionnaire. Eighty-two percent of the sample was women, with the mean age being 26 years (range = 17-61). Contrary to what was hypothesized, ethnic identity was significantly positively related to the number of lifetime racist events and no significant relationship was observed between neuroticism and number of lifetime racist events. Results also indicate the maladaptive coping strategy of substance use as having a moderating effect on the relationship between lifetime racial discrimination and discrimination-related stress. These findings suggest that past experiences with racial discrimination and how identified individuals are with their ethnicity are more important predictors of perceived racial discrimination than neuroticism and coping strategies.

**E215****"(I CAN'T GET NO) SATISFACTION": EXAMINING THE ROLE OF ACCOMPLISHMENTS AND GUILT IN THE RELATION BETWEEN CONSCIENTIOUSNESS AND LIFE SATISFACTION** Jennifer V. Fayard<sup>1</sup>,

Brent W. Roberts<sup>1</sup>, Richard W. Robins<sup>2</sup>; <sup>1</sup>University of Illinois at Urbana-Champaign, <sup>2</sup>University of California, Davis – Previous research has shown that the Big Five trait domain of conscientiousness is related to emotion, particularly to higher life satisfaction (DeNeve & Cooper, 1998). However, the mechanisms behind this connection have been largely unexplored. One possible explanation for this phenomenon is that conscientious individuals promote positive affect through accomplishments and by engaging in behaviors leading to positive life experiences, and avoid negative affect by avoiding behaviors that would result in negative experiences. This increased positive affect and decreased negative affect should ultimately lead to higher life satisfaction. An alternative explanation is that this relationship may be due to overlap between conscientiousness and extraversion and neuroticism. In a four-year longitudinal study (N = 508), we examined these hypotheses using students' Year 4 cumulative GPAs (accomplishments) and the resulting affect about their GPAs as potential mediators of the association between conscientiousness and life satisfaction. Results confirmed that conscientiousness and life satisfaction. Results confirmed that conscientiousness and life satisfaction.

tiousness at Year 1 predicted life satisfaction at Year 4. Further, these data indicate that Year 4 GPA and guilt about GPA partially mediated the relation between Year 1 conscientiousness and Year 4 life satisfaction. Additionally, we found that extraversion and neuroticism partially, but not fully, accounted for the relationship between conscientiousness and life satisfaction. These results demonstrate that achieving a high GPA and thus experiencing less guilt about GPA could help explain, in part, the relation between conscientiousness and life satisfaction. Also, a genuine relationship may exist between conscientiousness and life satisfaction that is not completely due to overlap with other personality traits.

#### E216

**EXTRINSIC AND INTRINSIC VALUES, FORECASTS, AND EXPERIENCES: AN EXPERIMENTAL APPROACH** Charles Nichols<sup>1</sup>, Kennon Sheldon<sup>1</sup>, <sup>1</sup>University of Missouri – Values and affective forecasts both influence the choices we make. Little research has examined individual differences in affective forecasts and their relation to value differences. An experiment was conducted wherein participants with different values were provided with either a value-congruent or a value incongruent experience, the affective consequences of which they had previously forecasted. Specifically, participants were unexpectedly given the chance to choose an Apple Itune song download, which they were either told to send to themselves or to some other person of their choice. Following this Itune manipulation, hedonic and eudaimonic well-being were assessed. While people in general tended to think that getting something would make them happier than giving something comparable to someone else, there was no significant difference by condition in affect or subjective happiness following the manipulation. Interestingly, giving (but not getting) an Itune significantly boosted participants' scores on a global measure of meaning in life. While relative extrinsic value orientation (REVO; Kasser & Ryan, 1996) did moderate the relationship between condition and forecasts (with more extrinsic participants predicting a larger well-being boost from getting, compared to giving), REVO did not moderate the relationship between condition and the different well-being outcomes. Study results suggest the existence of an affective forecasting error where people systematically overestimate the benefits of receiving relative to giving. Such a bias may be contributing to inefficiency in overall societal well-being maximization.

#### E217

**LESS THAN SATISFIED: EXPLORING THE PURCHASING DECISIONS OF MAXIMIZERS.** Alison L. Purvis<sup>1</sup>, Ryan T. Howell<sup>1</sup>; <sup>1</sup>San Francisco State University – Past research on decision-making has suggested that individuals tend toward a disposition that is characterized by either optimality and deliberation (i.e. maximizers) or sufficiency and action (i.e. satisficers). A recent study reported counterintuitive findings that maximizers are more likely to make spontaneous decisions based on a one-item assessment (Parker, de Bruin, Fischhoff, 2007). The present study was designed to explore any relationship between maximizing and impulsivity within the context of purchasing decisions. The implications for impulsive buying and maximizing tendency on well-being are also examined. Method. A diverse sample (N=140) was recruited using online social networks and a snowball recruitment method. Respondents completed an online survey assessing maximizing tendencies, impulsive buying tendencies, and life satisfaction. Results. Correlational analyses showed no association with self-reported maximizing or impulsive buying; however, both maximizing and impulsive buying tendencies were associated with lower life satisfaction. Strong relationships did emerge between planned buying and life satisfaction as well as self-reported maximizing and experiences of regret following purchases. Conclusion. The present study is the first to explore impulsive buying decisions in maximizers. Although there was no evidence supporting an association between maximizing tendencies and impulsive buying behavior, results suggest maximizers may experience a spike in life satisfaction from pre-buying deliberation followed by a significant life satisfaction drop due to

post-buying regret. Additionally, this study corroborates with past research indicating that self-reported maximizers are less satisfied with life than satisficers.

#### E218

**STRATEGIES TO ENHANCE CREATIVITY: NOVEL IDEA GENERATION AND THE CREATIVE COMBINATION PROCESS** Lian Rameson<sup>1</sup>, Steven Smith<sup>2</sup>, Catherine Mulvenna<sup>1</sup>; <sup>1</sup>UCLA, <sup>2</sup>Texas A&M – The generation of novel ideas is fundamental to the survival of a variety of systems, from social problem solving in everyday life, to the evolution of art and science. Conceptual combination is one of the central processes to novel idea generation. It occurs when two previously known concepts are combined to generate one new concept. The resulting concept can be judged for newness, or 'emergence', by whether it has attributes that are exclusive to it, and not shared with either of the parent concepts. The number of emergent attributes a new concept has can be used as the dependant variable for idea novelty. In an experimental setting, conceptual combinations of two known words, such as 'motorcycle' and 'carpet' are used to form fictional combinations, such as 'motorcycle carpet' for participants to generate definitions for. These definitions are subsequently used to generate lists of attributes, rated for emergence. Previous research has focused on the generative effects of similarity between the two parent words. Here (n=65), we examined the effects that environmental factors have on the creative process, namely generation rate over time (in a 1 hour sitting) and three taught strategies for idea generation. The taught strategies were designed to encourage or discourage idea fixedness. Results showed a significant effect of time and of taught strategy. This suggests it is possible to optimize novel idea generation by manipulating environmental factors. It has implications for individual and group brainstorming, and personal development in creativity.

#### E219

**AUDIENCE-SPECIFIC EXTRAVERSION PROFILES: ULTIMATE SIGNIFICANCE AND PROXIMATE CALIBRATION** Aaron Lukaszewski<sup>1</sup>, James Roney<sup>1</sup>; <sup>1</sup>University of California, Santa Barbara – Recent research in personality psychology has supported the general proposition that personality traits exhibit substantial situational specificity in their intra-individual structure. However, the exact logic of such situational specificity has yet to be elucidated for many aspects of personality. The current research focuses on extraversion, taking an evolutionary psychological approach to identifying the situational dimensions along which individual differences along intraversion-extraversion continua may vary independently. Specifically, it is proposed that individual differences in extraversion should vary somewhat independently with respect to behavioral audiences that have been of distinct adaptive significance across human ancestral environments – specifically, family members, friends, and relatively unfamiliar individuals. In order to evaluate these hypotheses, the current study asked participants (N = 240) to rate a variety of introverted-extraverted behavioral decisions for the extent to which they would describe the behavior they would likely exhibit with respect to each of the focal behavioral audiences (family, friends, and four different unfamiliar audiences). Consistent with predictions, participants were highly consistent in their extraversion scores across the four heterogeneous unfamiliar audiences, while family- and friend-directed extraversion scores, respectively, explained minimal variance in extraversion expressed with respect to any other behavioral audience category (including one another). Furthermore, these audience-specific behavioral profiles were uniquely predicted by other person variables that are theorized to have determined the adaptiveness of an introverted vs. extraverted behavioral strategy across ancestral environments. In sum, these findings preliminarily support the novel proposal that audience-specific behavioral profiles may represent the natural structural units of individual differences in extraversion.

**E220**

**EVALUATING PRESCRIPTIONS FOR OPTIMISM: IDEAL PREDICTIONS ARE OFTEN (BUT NOT ALWAYS) OPTIMISTIC** Sara E. Andrews<sup>1</sup>, David A. Armor<sup>1</sup>, <sup>1</sup>San Diego State University – Is optimism always best? Decades of research has shown optimism to be associated with positive outcomes. However, several additional (and essentially independent) lines of research suggest two common-sense concerns: (1) that people may sometimes be too optimistic, and (2) that while optimism may be advantageous in some situations it may be disadvantageous in others. In the present research, we seek to integrate these considerations. Drawing from recent work on prescribed optimism (Armor, Massey, & Sackett, 2008) participants (N = 115) were randomly assigned to either make prescriptions (i.e., to indicate what predictions would be "best" to make), or to describe what predictions they would actually make, in each of 30 distinct situations. Analyses revealed three principal results: First, participants who were asked to prescribe ideal predictions clearly prescribed optimism. Across situations, these participants indicated that the best predictions would be significantly more optimistic than accurate, and significantly more optimistic than participants in the descriptive condition said they would be in these situations (implying that people are not optimistic enough). Second, there was a significant effect of situation, with participants reliably prescribing (and describing) more optimism in some situations than in others (pessimism was sometimes, though rarely, prescribed). Third, among participants who were asked to describe what predictions they would make, those who claimed to make predictions that were closer to the average prescribed ideals were better adjusted than those who claimed to make predictions that were further from these ideals. Implications of this situationally-sensitive approach to optimism will be discussed.

**Physical Health****E221**

**CONSCIENTIOUSNESS & HEALTH BEHAVIORS: CONSIDERATIONS OF LOWER ORDER FACETS AND OBSERVER RATINGS OF CONSCIENTIOUSNESS** Karen Sixkiller<sup>1</sup>, Yusuke Takahashi<sup>2</sup>, Grant W. Edmonds<sup>1</sup>, Joshua J. Jackson<sup>1</sup>, Tim Bogg<sup>3</sup>, Kate E. Walton<sup>4</sup>, Dustin Wood<sup>5</sup>, Peter Harms<sup>6</sup>, Jennifer Lodi-Smith<sup>7</sup>, Brent W. Roberts<sup>1</sup>; <sup>1</sup>University of Illinois, <sup>2</sup>University of Tokyo, <sup>3</sup>Indiana University, <sup>4</sup>St. John's University, <sup>5</sup>Wake Forest University, <sup>6</sup>University of Nebraska, <sup>7</sup>University of Texas – Although past research has shown strong correlations between conscientiousness and health behaviors, systematic multiple method assessment of this relation is lacking. This set of three studies examined the lower order structure of conscientiousness and its relationship to specific health behaviors (N = 617, 325, 259). Using participants from Illinois statewide, community and student samples and both self and observer reports, the results show differences in the predictive validity of self versus observer reports of conscientiousness when predicting health behaviors. Specifically, observer ratings were superior predictors of health behaviors than self reports. We also tested which facets of conscientiousness were the strongest predictors of health behaviors. Consistent with past research, Impulse Control and Conventionality were robust predictors of risky health behaviors across method. Preventative health behaviors were best predicted by Industriousness and Orderliness.

**E222**

**THE INFLUENCE OF CLOSE OTHERS' EXERCISE HABITS** Xiaomeng Xu<sup>1</sup>, Susan Darlow<sup>1</sup>, Arthur Aron<sup>1</sup>; <sup>1</sup>Stony Brook University – Previous research in the health domain has shown that support for exercise from close others is related to greater adherence to exercise. In the present study, building on social psychological theoretical models we investigated the role in this basic effect of potential mediators and moderators including interpersonal closeness, type of relationships, and context relevant attitudes and motivations. Specifically, we asked undergraduates to report on their own exercise habits, the exercise habits of their best friend and their

romantic partner (if they had one) for a typical week, as well as on the other hypothesized relevant variables. As expected, frequency of own exercise was positively correlated (especially strongly for mild and moderate forms of exercise) with frequency both of partner's and of friend's exercise. Exercise frequency was also positively correlated with frequency of exercising with another person (regardless of whether this person was a friend, partner, or someone else). Intrinsic, introjected, and identified motivation (but not external motivation) were significantly positively correlated with frequency of own exercise. Social support was not significantly correlated with frequency of exercising on one's own, but was significantly related to frequency of exercising with someone else. Felt closeness to the other person was also related to exercise frequency. These findings illustrate the role that social factors such as closeness and type of relationship may have on influencing exercise behavior and bears on our more general understanding of the role of relationship variables in important personal behaviors.

**E223**

**TARGET SEX AND FACIAL EXPRESSIVITY AFFECT OLDER ADULT OBSERVERS' FIRST IMPRESSIONS OF INDIVIDUALS WITH PARKINSON'S DISEASE** Amanda Hemmesch<sup>1</sup>, Linda Tickle-Degnen<sup>2</sup>, Leslie Zebrowitz<sup>1</sup>; <sup>1</sup>Brandeis University, <sup>2</sup>Tufts University – Problems with social relationships are common complaints for individuals with Parkinson's disease (PD). These difficulties may be related to facial masking, a symptom characterized by reduced expressivity in the face. Because gender norms suggest that women should be more socially-oriented and expressive than men, facial masking may be particularly detrimental to women with PD. Fifty-eight older adult observers viewed thin-slice videotapes of 12 individuals (6 women) with PD with lower or higher facial masking. Observers expressed less interest in getting to know women with higher facial masking and also rated them as less likely to provide social support than lower masking women. Facial masking was not associated with observers' ratings of men in these domains, possibly because higher facial masking violates gender norms for expressivity in women but not in men. These results highlight the role of facial expressivity in first impressions and suggest that biased impressions may contribute to social difficulties for individuals with PD, especially women.

**E224**

**COPING WITH CANCER: THE ROLE OF DEATH THOUGHT ACCESSIBILITY IN QUALITY OF LIFE AMONG WOMEN DIAGNOSED WITH BREAST CANCER** Cathy Cox<sup>1</sup>, Stephanie Reid-Armdt<sup>2</sup>, Jamie Armdt<sup>1</sup>; <sup>1</sup>Department of Psychological Sciences, University of Missouri, <sup>2</sup>Department of Health Psychology, University of Missouri – The diagnosis and progression of cancer can be a traumatic event for those affected and may trigger fears associated with pain, suffering, helplessness, and death (e.g., Ferrell et al., 1998). A long tradition of existential theorizing and the more contemporary perspective of terror management theory (Greenberg, Solomon, & Pyszczynski, 1986) suggest that the human struggle with the awareness of death can greatly affect people's physical and psychological well-being. The purpose of the present research was to examine whether being diagnosed with cancer increases concerns about death, and how associated increases in death accessibility influence health-related quality of life. Participants consisted of a community sample of 44 females who were diagnosed with either a cancerous or a non-cancerous breast mass. Participants completed a word-stem completion task measuring the accessibility of death-related thoughts (Greenberg et al., 1994), as well as the Functional Assessment of Cancer Therapy-Breast scale (FACT-B; Brady et al., 1997), which assesses quality of life across four domains: physical, emotional, social, and functional well-being. Consistent with past research, the results revealed that women diagnosed with cancer reported impaired physical, emotional, and functional well-being. Interestingly, they also evidenced greater death thought accessibility compared to those in the non-cancerous control condition. This heightened death thought accessibility was associated with lower well-being, and the effect of cancer diagnosis on well-being was mediated by death

thought accessibility. Implications of this research for coping with cancer diagnoses and the terror management health model (Goldenberg & Arndt, 2009) will be discussed.

### E225

**PSYCHOSOCIAL CONTRIBUTORS TO LATER LIFE HEALTH OPTIMISM AND PESSIMISM** Joelle Ruthig<sup>1</sup>, Bridget Hanson<sup>1</sup>, Heather Pedersen<sup>1</sup>, Alyssa Weber<sup>1</sup>, Judy Chipperfield<sup>2</sup>; <sup>1</sup>University of North Dakota, <sup>2</sup>University of Manitoba – Emerging research yields valuable information by comparing older adults' subjective health appraisals to an objective health (OH) indicator (e.g., physician's assessment). According to this "health congruence" comparison (Chipperfield, 1993), "health optimists" appraise their health as good despite poor OH, whereas "health pessimists" appraise their health as poor despite good OH. Health optimism benefits well-being, functional health, and survival. Health pessimism is maladaptive to well-being, functioning, and reliance on formal health care services. We extend limited research on contributors to health optimism and pessimism by examining psychosocial predictors (depression, dispositional optimism, social support, and life event stress) of health optimism among 297 older adults (60+) in poor OH and of health pessimism among 192 older adults in good OH. Controlling for age, gender, and income, OLS regression results showed significant predictors of health optimism were dispositional optimism ( $\beta = .16$ ), social support ( $\beta = .14$ ), and depression ( $\beta = -.26$ ). Significant predictors of health pessimism were dispositional optimism ( $\beta = -.19$ ) and life event stress ( $\beta = .16$ ). Using structural equation modeling (SEM), we examined health optimism and pessimism's associations with functional ability, health care management, healthy behaviors, and health control, accounting for the aforementioned psychosocial predictors. SEM results revealed significant positive paths from health optimism to functional ability ( $\beta = .43$ ), healthy behaviors ( $\beta = .38$ ), and health control ( $\beta = .15$ ); and negative paths from health pessimism to functional ability ( $\beta = -.33$ ) and health care management ( $\beta = -.20$ ). Findings indicate health optimism and pessimism have different psychosocial contributors and health correlates, highlighting the validity of the health congruence approach to later life health and well-being.

### E226

**PEERS AND PARENTS: MEDIATORS OF A DISCRIMINATION-TO-RISK RELATIONSHIP** Megan E. Roberts<sup>1</sup>, Meg Gerrard<sup>1,2</sup>, Frederick X. Gibbons<sup>1</sup>; <sup>1</sup>Dartmouth College, <sup>2</sup>Norris Cotton Cancer Center, Dartmouth Medical School – Considerable research has demonstrated the negative effects of early racial discrimination on subsequent developmental outcomes, such as poor mental health and behavioral problems. However, very few studies have focused on the association between racial discrimination and subsequent risky sexual behavior. In order to explore this relation, the present study used data from the Family and Community Health Survey (FACHS), a prospective study of 889 African American adolescents. Survey participants were aged 10-12 at time 1, and data were gathered 4 times over an 8-year period. In addition to assessing perceived racial discrimination and sexual behaviors, the survey also contained measures of deviant peer affiliations and parenting quality. Structural equation modeling that controlled for age, gender, socioeconomic status, and early sexual onset revealed that perceived discrimination at time 1 was associated with more risky sexual behavior at later waves. Furthermore, this relationship was mediated by deviant peer affiliations, parenting, and interactions between these two constructs. Specifically, early discrimination increased the likelihood of affiliating with deviant peers, which in turn promoted higher sex-risk behaviors. Deviant affiliations at early waves also appears to have prompted more effective parenting, and increases in effective parenting, in turn, indirectly protected against subsequent increases in risky sex, by way of a reduction in ensuing deviant peer affiliations. These results bear implications for the relation between racial discrimination and risky health behaviors during adolescent development, and are particularly consequential given the disproportionately high incidence of human immunodeficiency virus (HIV) within the African American community.

### E227

**SUNSCREEN USE AMONG RECREATIONAL CYCLISTS: MODERATORS OF HOW INTENTIONS PREDICT REPORTED BEHAVIOR** C. Raymond Knee<sup>1</sup>, Kristen N. Petty<sup>1</sup>, Aaron K. Joseph<sup>2</sup>; <sup>1</sup>University of Houston, <sup>2</sup>Baylor College of Medicine – Sunscreen use is known to be a major cancer-preventive behavior for those often exposed to the sun. Recreational cyclists are a unique group who spend prolonged time in the sun but who otherwise tend to be motivated for improved health and fitness. We examined social cognitive predictors of intentions and reported sunscreen use among a national sample of 927 (696 male) recreational cyclists. The online survey included measures of perceived rewards, costs, and self-efficacy of sunscreen use, as well as perceived susceptibility to photoaging. Intentions to use sunscreen and reported sunscreen use were the primary criteria. Potential moderators of the intention-behavior link were frequency of outdoor cycling, family history and personal experience with skin cancer, desirability of being tan, and having a skin type that is more likely to burn. Descriptive analyses revealed considerable variability in sunscreen use. Multiple regression analyses supported a model in which perceiving susceptibility to photoaging, perceiving fewer costs of sunscreen use, and having higher self-efficacy predicted stronger intentions to use sunscreen. Importantly, moderation analyses indicated that the association between intentions and sunscreen use was stronger among those who ride more frequently, those who have a family history or personal experience with skin cancer, those who tend to not burn easily, and those who find tanned skin less desirable. These findings suggest several avenues for prevention research on a population that normally is not considered at high risk for negative health behaviors.

### E228

**WHY ARE SELF-GENERATED ARGUMENTS PERSUASIVE?: AN EXAMINATION OF TWO POTENTIAL CAUSAL MECHANISMS IN HEALTH BEHAVIOR** Austin S. Baldwin<sup>1</sup>, Mark W. Vander Weg<sup>2,3</sup>, Alan J. Christensen<sup>2,3</sup>, Alexander J. Rothman<sup>4</sup>; <sup>1</sup>Southern Methodist University, <sup>2</sup>University of Iowa, <sup>3</sup>CRIISP, Iowa City VAMC, <sup>4</sup>University of Minnesota – People tend to be more persuaded by their own arguments than by someone else's, thus self-generated arguments may be an effective form of behavior change. Yet their effectiveness in changing behavior is limited by a lack of understanding the causal mechanisms underlying their effect. The purpose of this study was to test two possible underlying mechanisms: people being the source of the arguments (source effect), or the content of the arguments being naturally tailored (matching effect). Participants (N=109) were smokers who, prior to the experimental session, identified aspects of smoking most and least concerning to them. To test the research question, we used a 2 (argument source: self vs. other) X 2 (matched content: matched vs. mismatched) factorial design. Participants either wrote (self-generated) or read (other-generated) arguments with content based on aspects of smoking most (matched) or least (mismatched) concerning to them. Participants then evaluated the arguments and reported their intention to quit. There were no effects of argument source. However, matched argument participants (both self- and other-generated) evaluated the arguments to be of higher quality, more helpful in quitting smoking, and more personally relevant than did mismatched participants ( $ps < .001$ ). They also listed more positive and fewer negative thoughts about the arguments than did mismatched participants ( $ps < .003$ ). Moreover, perceptions of argument quality were associated with greater intention to quit smoking ( $p = .006$ ). The results suggest that self-generated arguments are effective because of a matching effect and not a source effect. The theoretical and applied implications of the findings will be discussed.

**E229****NOT SIMPLY "IN THEIR HEADS:" BEING BULLIED PREDICTS HEALTH PROBLEMS ABOVE AND BEYOND KNOWN INDIVIDUAL DIFFERENCES ASSOCIATED WITH HEALTH**

Priya A. Iyer<sup>1</sup>, Jennifer M. Knack<sup>2</sup>, Lauri A. Jensen-Campbell<sup>1</sup>; <sup>1</sup>University of Texas at Arlington, <sup>2</sup>University of Ottawa – Bullied children and adults are likely to report more health problems. However, no research to date has examined whether being bullied continues to predict health after controlling for personality differences known to influence both victimization and health. In Study 1, college students (N = 1182) completed online surveys that assessed bullying, health, and personality. In study 2, college students participated in a short-term longitudinal study (N = 69) that examined whether (1) fall victimization predicted health changes; (2) increases in victimization led to increased health problems; and (3) fall health predicted spring victimization when personality was taken into consideration. Victimization predicted negative health outcomes even after controlling for individual differences and was related to more negative health problems over time. These findings suggest that the influence of bullying on health may be occurring due to physiological changes rather than individual differences associated with both bullying and health.

**E230****INDIVIDUAL TRAITS AND INTERPERSONAL RELATIONSHIPS ARE ASSOCIATED WITH WOMEN'S RISK PERCEPTIONS FOR CHRONIC DISEASE**

Jada G. Hamilton<sup>1</sup>, Marci Lobel<sup>2</sup>; <sup>1</sup>Cancer Prevention Fellowship Program, National Cancer Institute, <sup>2</sup>Stony Brook University – Perceptions of disease risk are critical motivators of behavioral changes that can improve and protect people's health. Yet, little is known about social and personality factors that contribute to disease risk perceptions. Research suggests that traits such as optimism may influence how people think about their susceptibility to disease. Interpersonal relationships, such as the presence of disease-afflicted others in one's social networks, are also likely to contribute to risk perceptions. Additionally, factors that objectively increase disease risk are likely to affect risk perceptions. This study used structural equation modeling to test hypothesized associations of traits (optimism, health locus of control), interpersonal relationships (social exposure to disease, perceptions of stigmatization), and objective risk factors (family disease history, age, body mass index, preventive health behaviors) with women's risk perceptions for cardiovascular disease, breast cancer, and lung cancer. Hypothesized models were tested separately in 454 younger (ages 18-25) and 180 older (ages 40+) women who completed psychometrically-robust study measures. Results indicate that objective risk factors were largely unrelated to women's risk perceptions. Predictors of disease risk perception differed for younger and older women: Interpersonal relationships contributed to heightened risk perceptions in both groups, whereas individual traits were associated with decreased risk perceptions in older women only. Results underscore the central role of social and personality factors in affecting how women view their health risks and suggest that differences in the factors that reduce perceived vulnerability with advancing age reflect attempts to cope with elevated risk for chronic disease.

**E231****FEELINGS OF INSECURITY CAUSE GREATER PHYSICAL SYMPTOM REPORTING**

Diane Eaton<sup>1</sup>, Matthew Giddens<sup>1</sup>, James Hamilton<sup>1</sup>; <sup>1</sup>The University of Alabama – This study investigated the relationship between attachment style and self-reported symptoms of physical illness. Previous research has indicated a link between insecure attachment and medically unexplained symptoms, but the nature of that relationship is poorly understood. One possibility is that persons with insecure attachment use illness behavior as an interpersonal strategy to buffer themselves against rejection and criticism. We hypothesized that an insecure attachment prime would increase symptom reporting, particularly for individuals with an anxious attachment style. Participants completed a screening measure of physical symptoms. In the main portion of the study they read one of three randomly assigned stories that included (1)

a secure attachment prime, (2) an insecure attachment prime, or (3) no attachment prime. After reading the story, participants repeated the physical symptom checklist. As expected, participants primed with the insecure attachment story reported more physical symptoms (comparing pre to post test measure) than participants in the two other conditions. Furthermore, results indicated that the relationship between the prime condition and increased self-reported symptoms was mediated by the degree to which participants believed they would feel unsupported and unappreciated had the events described in the story happened to them. However, general negative affective reactions to the priming story did not mediate the effect. None of the effects were moderated by pretest measures of attachment. These results support the possibility that physical symptom reporting might reflect a means of coping with attachment threats.

**E232****THE DAILY UPS AND DOWNS: USING ECOLOGICAL MOMENTARY ASSESSMENT TO UNDERSTAND HOW WITHIN-PERSON VARIABILITY IN PSYCHOSOCIAL FACTORS AFFECTS WEIGHT CONTROL**

Jutta Mata<sup>1</sup>, Teresa Santos<sup>2</sup>, Paulo N Vieira<sup>2</sup>, Marlene N Silva<sup>2</sup>, Sílvia R Coutinho<sup>2</sup>, Pedro J Teixeira<sup>2</sup>; <sup>1</sup>Technical University Lisbon & Stanford University, <sup>2</sup>Technical University Lisbon – Objective: Higher levels in psychosocial factors such as motivation and self-efficacy are known to help successful weight control. However, the effects of their within-person fluctuation over time on weight loss and maintenance are unknown. Design: This study uses a process-oriented method, ecological momentary assessment with daily measurements in two 3-week assessment periods at three and ten months into a one-year weight control intervention. Participants were 109 women (age M=38.67 years, BMI M=31.70 kg/m<sup>2</sup>). Main Outcome Measures: Determinants of weight-related health behavior, such as exercise and eating self-efficacy, exercise motivation, and physical self in a natural context. We investigated the extent of fluctuation in those factors and how well their fluctuation predicted weight loss and other weight-related outcomes. Results: We found substantial amounts of within-person fluctuation for all psychosocial variables at both assessment points. Importantly, the amount of fluctuation in eating self-efficacy and physical self at three months predicted weight loss at twelve months. Also, instability in key variables such as physical activity self-efficacy and exercise motivation was associated with level of depressive symptoms and general self-esteem at twelve months. Conclusion: These findings underline the importance of investigating within-person variability in psychosocial factors to better understand weight control.

**E233****COLLEGE STUDENTS' PERCEPTIONS OF BEING "EXEMPT" FROM THE NEGATIVE CONSEQUENCES OF BINGE DRINKING: ABSENT-EXEMPT THINKING AND ALCOHOL POISONING**

Miko Wilford<sup>1</sup>, Michelle L. Stock<sup>2</sup>; <sup>1</sup>Iowa State University, <sup>2</sup>The George Washington University – Absent-exempt is the belief that if one has not yet experienced negative consequences, despite engaging in risky behavior, then one is unlikely to in the future (Weinstein, 1989). The purpose of the present study was to design and test an absent-exempt construct for alcohol poisoning (AP) due to alcohol consumption. This study also examined the associations between absent-exempt, willingness and intentions to binge drink, perceived vulnerability (PV) to the negative consequences of drinking, and binge drinking behaviors among three samples of college students (total N = 1924). A 5-item absent-exempt endorsement scale regarding feelings of being exempt from future AP among drinkers was created and found reliable ( $\alpha$ s = .85, .84, .77). On average, 71% of participants reported binge drinking and 38% reported experiencing AP in the past. Absent-exempt endorsement was strongly associated with reports of binge drinking ( $r$ s = .17, .34, .16,  $p$ s < .001). In addition, absent-exempt endorsement was associated with higher levels of willingness ( $r$ s = .13, .30, .16,  $p$ s < .005) and intentions to binge drink ( $r$ s = .13, .26, .11,  $p$ s < .005). Although absent-exempt correlated highly with PV ( $r$  = -.31, -.16, -.19,  $p$ s < .02), factor analyses revealed that for all datasets they loaded onto their

own construct. Independent samples t-tests revealed that the men reported higher levels of absent-exempt endorsement than the women ( $t > -4.9$ ,  $ps < .001$ ). These results suggest that lowering absent-exempt endorsement could be an effective method to lowering participation in risky binge drinking behaviors.

#### E234

##### **A MOTIVATIONAL UNDERSTANDING OF THE RELATION BETWEEN MEDICALLY UNEXPLAINED SYMPTOMS AND DEPRESSION** Julie

Cunningham<sup>1</sup>, Courtney Worley<sup>1</sup>, Lauren Hayes<sup>1</sup>, Jim Hamilton<sup>1</sup>; <sup>1</sup>University of Alabama – There is a connection between the reporting of medically unexplained symptoms and depression, however, the exact nature of this relation is unknown. In this investigation, we hypothesized that depressed individuals' enactment of the sick role may be motivated by various esteem and interpersonal needs. For instance, these individuals may view the sick role positively because it affords them the opportunity to feel special if they are presenting a unique illness, or an illness can function as an excuse personal or social failings. College students completed questionnaires measuring self-appraised health and attitudes towards the sick role, as well as a depression screener. Regression analyses replicated the finding from earlier research that depression is related to poor self-rated health. Our analyses also confirmed our own hypotheses that medical uniqueness and medical excuse making – two variables measuring positive attitudes toward the sick role – mediate this relation. These results support interpersonal and self-enhancement theories of medically unexplained symptom reporting.

#### E235

##### **RACIAL DISPARITIES BETWEEN LATINA AND CAUCASIAN WOMEN IN FACTORS ASSOCIATED WITH HPV VACCINATION** Rachel Reimer<sup>1</sup>, Amy

Houlihan<sup>2</sup>, Melissa Deer<sup>3</sup>, Andrea Lund<sup>4</sup>; <sup>1</sup>Des Moines University, <sup>2</sup>Texas A & M - Corpus Christi, <sup>3</sup>Simpson College, <sup>4</sup>University of Minnesota - Morris – The purpose of the current research was to examine social and behavioral factors that contribute to the documented racial disparity in prevalence of human papillomavirus (HPV) and risk for cervical cancer. This research is important because HPV is the most common sexually transmitted infection in the United States and Latina women are at a disproportionate risk of cervical cancer relative to other racial/ethnic groups. Research on the prevalence and predictors of HPV vaccination is emerging, but often methodologically flawed, atheoretical, and conducted without a focus on the most at-risk population (i.e., Latinas). Three hundred Latina and Caucasian women aged 15-30, were recruited from Primary Health Care Clinics to participate in a survey study. Measures from the Integrated Behavioral Model and the Prototype Willingness Model included: religiosity, acculturation, machismo, knowledge about STDs and HPV, descriptive and injunctive norms, beliefs and attitudes about HPV and the HPV vaccine, vaccination status, mother-daughter communication, and previous health protective and risk behaviors. A series of ANCOVAs and hierarchical linear regressions were conducted. Covariates included education, income, marital status, and age. Vaccine rates were quite low (10%) and no race differences emerged. Results indicated that Whites ( $M = 15$ ) initiated sexual activity earlier than Latinas ( $M = 17$ ), and had more lifetime sexual partners ( $M_s = 10-12$  vs.  $7-9$ ). Mother-daughter communication was associated with higher HPV knowledge among Latinas, but not among Whites. Results suggest that significant differences between Latina and White women with respect to social and behavioral factors are important for HPV prevention behaviors.

#### E236

##### **I EXERCISE THEREFORE I DRINK: STRESS, ALCOHOL USE, AND EXERCISE ADHERENCE** Susan Whitbourne<sup>1</sup>, Catherine Sanderson<sup>2</sup>;

<sup>1</sup>University of Massachusetts Amherst, <sup>2</sup>Amherst College – A paradoxical finding in the health literature on undergraduates is the positive association between exercise adherence and alcohol use. The present study extends prior work by examining the role of stress in mediating this relationship. 166 undergraduates completed measures of stress, exercise

adherence, and a variety of health-related behaviors. Although there was no direct association between ratings of stress intensity and exercise adherence, students who engaged in high risk health behaviors showed distinct patterns of exercise adherence. First, students who drank more frequently had higher exercise adherence scores. Second, and not surprisingly, smokers were more likely to exercise than were non-smokers. Arguing against the interpretation that high stress is associated both with greater propensity to exercise and greater tendency to drink, there was no association between stress and either exercise or alcohol use. Individuals with high self-rated stress stated that they were more likely to exercise for reasons related to health rather than for non-health related reasons, although their exercise adherence scores were no higher than those who exercised for social reasons. Thus, although stress was related to exercise motivation, the perception of high levels of stress did not moderate the relationship between exercise adherence and frequency of alcohol consumption. The present findings extend previous literature showing the relationship between alcohol use and exercise frequency and present yet a further paradox, that although perceived stress is related to the stated desire to exercise for health reasons, there are no objective differences in exercise frequency for low and high stressed individuals.

#### E237

##### **CHILDREN'S ASCRIBED MOTIVATIONS FOR SMOKING ELICITED BY PROJECTIVE QUESTIONING** Merrie Brucks<sup>1</sup>, Paul M. Connell<sup>2</sup>, Dan

Freeman<sup>3</sup>; <sup>1</sup>The University of Arizona, <sup>2</sup>Stony Brook University, <sup>3</sup>University of Delaware – The goal of this study was to generate a theoretical model for processes involved in children's learning of lifestyle associations with adult-themed products. Because we suspected that children's lifestyle associations have been learned implicitly, and because social desirability biases are a threat to validity in substance use research, we employed projective interviewing techniques. We conducted 271 interviews with second and fifth graders using advertisements and pictures of people who have various personal and lifestyle characteristics as stimuli to elicit responses. Each child saw two cigarette ads cigarettes embedded in a series of five ads (including unrelated products). For each ad, children selected pictures of people who might be likely or unlikely to use that product. Each child was probed with follow-up questions to reveal motivations attributed to these people. Qualitative data analysis revealed three broad motives attributed to characters in the images: social, esteem, and relaxation. Themes within the social motive included smoking for fun in social situations and smoking to impress others, whereas themes within the esteem motive included issues with weight and thinness. Themes within the relaxation motive included needing to escape one's troubles or smoking for leisure. We argue that similarity of lifestyle picture selections and attributed motivations between the second and fifth graders, in combination with the non-verbal nature of the second graders' associations, suggests that children did not purposefully and thoughtfully develop them. This pattern is consistent with an associative processing model of memory, in which advertisements, media images, and personal observations are encoded pre-consciously.

#### E238

##### **A MODEL OF HIV TESTING AND DISCLOSURE IN SOUTH AFRICA** Lauren

Wong<sup>1</sup>, Heidi Van Rooyen<sup>2</sup>, Precious Modiba<sup>3</sup>, Linda Richter<sup>2</sup>, Glenda Gray<sup>3</sup>, James McIntyre<sup>3</sup>, Christine Dunkel Schetter<sup>1</sup>, Thomas Coates<sup>4</sup>; <sup>1</sup>Department of Psychology, UCLA, <sup>2</sup>Human Sciences Research Council, Pretoria, South Africa, <sup>3</sup>Perinatal HIV Research Unit, University of Witwatersrand, South Africa, <sup>4</sup>Program in Global Health, UCLA – Background: HIV-positive diagnoses are high among South Africans and continues to rise. The current study presents a theoretical model of the psychosocial determinants and consequences of HIV disclosure. Methods: Cross-sectional survey from random community samples of men and women in urban and rural South Africa ( $n = 217$  HIV positive individuals, 89% female). Results: The proposed model was well supported. Two thirds of all known HIV-infected adults in these communities had disclosed their status to sexual

partner(s). On average, individuals who disclosed were 2 years older, higher in socioeconomic assets, and had known their HIV status 7 months longer than those who had not told their sexual partner(s). People who eventually disclosed their HIV status to sexual partner(s) were significantly more likely to report always or more frequently using condoms, reducing their number of sexual partners, and/or becoming monogamous. Among individuals who disclosed their HIV status, 77% reported increases in social support, with families providing the most support.

### E239

**RISK UNDERESTIMATION FOLLOWING RECEIPT OF POSITIVE MELANOMA GENETIC TEST RESULTS PREDICTS IMPROVEMENTS IN PREVENTION AND SCREENING** Jennifer M. Taber<sup>1</sup>, Lisa G. Aspinwall<sup>1</sup>, Sancy A. Leachman<sup>2,1</sup>, <sup>1</sup>University of Utah, <sup>2</sup>Huntsman Cancer Institute – A major goal of predictive genetic testing is to alert people to their elevated risk prior to the development of illness, when early detection and prevention are still possible. In the case of melanoma, a pathogenic CDKN2A/p16 mutation confers a 76% lifetime risk of this aggressive and potentially fatal cancer. A great deal of evidence suggests that people process threatening health information defensively, but little is known about how people adjust to such highly self-relevant and consequential health-risk information over time as they consider risk-management options. We examined changes in both subjective risk perceptions and recall for the risk estimates provided in conjunction with their genetic test results among 62 adult members of melanoma-prone families over a 2-year period. Unaffected members (those without a personal history of melanoma) who received positive test results consistently reported subjective lifetime risk estimates that were approximately 29% lower than what they were actually told. These differences were obtained immediately after test reporting and were maintained at 1 month and 2 years. Of particular interest, participants who explicitly indicated that their risk was lower than what the counselor told them reported prospective improvements in prevention and screening behavior over the 2-year period. Such underestimation was not observed among patients with a melanoma history, who reported risk estimates for new melanomas that equaled or exceeded what they had been told. These findings suggest that less-than-complete acceptance of one's risk for serious disease may coexist with, reflect, or even foster efforts to manage one's risk.

### E240

**THE IMPACT OF PROVOCATION AND SOCIAL SUPPORT ON CARDIOVASCULAR REACTIVITY AND DISPLACED AGGRESSION.** Laura Matthews<sup>1</sup>, William Pedersen<sup>1</sup>, Joaquin Castro<sup>1</sup>, Melissa Drysdale<sup>1</sup>, Jennifer Eifler<sup>1</sup>, Holly Gomez<sup>1</sup>, Marianne Grosvenor<sup>1</sup>, Kasey Fong<sup>1</sup>, Naoko Kitabayashi<sup>1</sup>, Kristian Miranda<sup>1</sup>, Yasmin Renteria<sup>1</sup>, Alison Sheldon<sup>1</sup>; <sup>1</sup>California State University, Long Beach – Previous research has demonstrated that cardiovascular reactivity predicts hypertension, coronary disease, and possibly contributes to the development of cardiovascular disease (Christenfeld et al., 1997). Social support has been shown to have protective effects against stressors and behaviors that negatively impact mental and physical health (Cohen & Wills, 1985). The aim of this study is two-fold, in that it is the first to examine the interaction of social support and provocation on cardiovascular reactivity, and investigate how receiving social support can impact subsequent displaced aggression after a provocation. Participants were either provoked or not provoked, then did or did not receive social support during a stressful situation. Participants then were given the opportunity to displace aggression against an innocent other. As expected, those who were provoked and then received social support had lower systolic blood pressure and displayed less displaced aggression relative to those who did not receive social support. Implications of social support in the reduction of cardiovascular reactivity and displaced aggression are also discussed.

## Self-Esteem

### E241

**FRAGILE SELF-ESTEEM: HIGH LEVELS OF SELF-ESTEEM INSTABILITY IN RESPONSE TO DAILY EVENTS** Loraine F. Lavalley<sup>1</sup>, Cherisse L. Seaton<sup>1</sup>, Cheyenne R. Murray<sup>1</sup>, Joanna A. Pooley<sup>1</sup>; <sup>1</sup>University of Northern British Columbia – The vast majority of North Americans report that they feel quite positively about themselves (Heine, Lehman, Markus & Kitayama, 1999). The number of people who view themselves positively, however, seems remarkably high given the cultural preoccupation with maintaining and increasing self-esteem. We postulated that people report positive self-regard but nevertheless remain concerned about their self-esteem because, in general, their positive self-regard is fragile and frequently shaken in daily life. To examine this proposition, we conducted two daily diary studies on undergraduates (N=129; 85) and assessed how frequently they experienced declines in self-esteem following their most negative daily events during a two week period. In pretest surveys we assessed self-esteem levels and desire for higher self-esteem. Global self-esteem scores conformed to the typical negatively-skewed distribution indicating that the majority of participants (81%) had self-esteem scores above the mid-point of the scale. Nevertheless, a large proportion of participants (72%) endorsed the statement "I would like my self-esteem to be higher". In terms of self-esteem instability, in both samples participants on average reported decreases in self-esteem for about half of the negative events (56%, 45%); in other words, every other day participants typically experienced an event that decreased their self-esteem. Gender did not moderate these findings. Thus, just as positive self-esteem is pervasive, fragile self-esteem appears to be as well. Regression analyses demonstrated that people with low self-esteem and people with unstable high self-esteem were more likely to desire higher self-esteem than people with stable high self-esteem.

### E242

**WHAT PSYCHOSOCIAL RESOURCES CAN BUFFER AGAINST NEGATIVE EFFECTS OF IMPLICIT AND EXPLICIT SOCIAL EXCLUSION?** Kuniaki Yanagisawa<sup>1</sup>, Chikae Isobe<sup>1</sup>, Mitsuhiro Ura<sup>1</sup>; <sup>1</sup>Hiroshima University – Extensive research has confirmed that social exclusion evokes negative affects in socially excluded individuals. Also, previous research found social exclusion accentuates social pain which is reflected in activation of the anterior cingulate cortex. This accentuation occurred not only as a result of explicit social exclusion (i.e. individuals were prevented by other players from participating in a social activity: ESE) but also resulted from implicit social exclusion (i.e. individuals were unable to join other players in a social activity because of extenuating circumstances: ISE) (Eisenberger, Lieberman & Williams, 2003). Thus, even if the social exclusion is subtle, it elicits negative affects for the excluded individuals. However, some recent studies suggest that people with high psychosocial resources suffer less negative effects after social exclusion (e.g., Gardner, Pickett & Knowles, 2005). Therefore, the present experiment was conducted to investigate whether psychosocial resources can buffer against negative effects of ISE and ESE. In particular, we focus on the distinct effects of trait self-esteem and general trust as psychosocial resources. University freshmen (n=72) individually participated in a laboratory experiment that ostensibly used instant messaging through a computer network. Results showed that higher trait self-esteem predicts lower negative affects in ISE conditions, but the level of general trust is not effected by ISE conditions. In contrast, results showed that higher general trust predicts lower negative affects in ESE conditions, but the level of self-esteem is not effected by ESE conditions. Finally, we discussed the function of psychosocial resources on the adaptation process after social exclusion.

**E243****CONTINGENT SELF-ESTEEM AND AGGRESSION IN MALE AND FEMALE ADOLESCENTS: EVIDENCE FOR DEFENSIVE PROCESSES**

Arjan Bos<sup>1</sup>, Eric Rassin<sup>2</sup>, Ayla Gözek<sup>2</sup>, Ana Salgado Dominguez<sup>2</sup>; <sup>1</sup>Maastricht University, The Netherlands, <sup>2</sup>Erasmus University Rotterdam, The Netherlands – Contingent self-esteem refers to the extent to which self-esteem is contingent upon outcomes and achievements (Kernis, 2002). People with contingent self-esteem are preoccupied by their performance and evaluations of others. Their self-esteem levels fluctuate depending on success or failure. It is conceivable that persons with high contingent self-esteem engage more in defensive processes and display more physical or verbal aggression, anger and hostility than those with low contingent self-esteem. The relationship between contingent self-esteem and aggression has received limited attention, and has never been examined among adolescents. Adolescents (171 boys and 144 girls; Mean age 13.83 years) filled out a questionnaire, containing Rosenberg Self-Esteem Scale (Rosenberg, 1965), the Self-Worth Contingencies Questionnaire (Burwell & Shirk, 2003) and the Aggression Questionnaire (Buss & Perry, 1992). Unique and interactive effects of global and contingent self-esteem on the four subscales of the Aggression Questionnaire were examined by means of hierarchical regression analyses. Results revealed no significant effects of both self-esteem measures on physical or verbal aggression. Global self-esteem was negatively related to anger in boys ( $\beta = -.27$ ) and girls ( $\beta = -.34$ ). Global self-esteem was also negatively related to hostility in boys ( $\beta = -.36$ ) and girls ( $\beta = -.37$ ). Contingent self-esteem was positively related to hostility in boys ( $\beta = .31$ ) and girls ( $\beta = .23$ ). Results show that global and contingent self-esteem are related to reactive forms of aggression in adolescents rather than proactive forms. Furthermore, the results provide more evidence for the link between contingent self-esteem and defensive processes.

**E244****EMBODIED SELF-ESTEEM: CHAIR HEIGHT INFLUENCES SELF AND SOCIAL STATUS EVALUATIONS**

Neville Todd<sup>1</sup>, Jamin Halberstadt<sup>1</sup>; <sup>1</sup>University of Otago – Recent views of "embodied cognition" (e.g., Barsalou, 2008; Niedenthal, 2007) assume that concepts are grounded in the sensory-motor experiences accompanying them. As a result, activation of a concept results in a partial re-instantiation of the associated behaviors and, conversely, the behaviors are sufficient to activate the concept. Several studies have already reported changes in particular self-perceptions (e.g., power; Schubert & Koole, 2009) as a function of participants' immediate behavior (e.g., making a fist). In the current study, we provide evidence to suggest that self-esteem itself can be embodied by one's physical position and/or visual angle. Participants completed measures of self-esteem and social status while seated in either a tall or a short chair, requiring them to look down or up to the computer monitor, respectively. Results show that participants in a tall chair reported greater status-related self esteem and viewed themselves higher in the social hierarchy. Women in high chairs also rated their surname initial more positively in the name letter task, a measure of implicit self esteem. The results were not due to mood or comfort differences across the two conditions. It appears that people feel better about themselves when they are literally looking down on others.

**E245****"I NEED YOU, I NEED YOU NOT" THE ROLE OF RELATIONSHIP-CONTINGENT SELF-ESTEEM IN RELATIONSHIP COMPARISONS**

Craig Vollert<sup>1</sup>, Amy L. Bush<sup>1</sup>, Alma Correa<sup>1</sup>, C Raymond Knee<sup>1</sup>; <sup>1</sup>University of Houston – The relationships of others can be a valuable source of information about one's own close relationship (Buunk, Collins, Taylor, VanYperen, & Dakof, 1990). Relationship comparisons involve examining how one's romantic relationship fares in comparison to others' relationships. Individuals generally vary in their concern with and tendency to engage in comparisons with others (Buunk, 2006). One factor expected to influence this individual difference was Relationship-Contingent Self-Esteem (RCSE; Knee, Canevello, Bush, & Cook, 2008). Relationship-Con-

tingent Self-Esteem is an unhealthy form of self-esteem that pertains specifically to romantic relationships, and reflects the degree to which one's sense of self depends on one's romantic relationship. Those who are higher in RCSE are more sensitive to relationship events and the implications that they carry. We hypothesized that those higher in RCSE would be more likely to compare their relationship with others' relationships, especially when unsatisfied with their romantic partner. Couples (N=71) in relationships of 1 month or longer completed a written survey that included measures of RCSE, satisfaction with one's partner, and tendency to engage in relationship comparisons. Multilevel modeling revealed that those higher in RCSE reported more frequent comparisons between their own relationship and others' relationships, but only when they were less satisfied with their partner. Thus, when one's self-worth is largely based on romantic relationships and one is less satisfied with his or her partner, frequent relationship comparisons may be one way individuals obtain additional information about where their relationships stand.

**E246****DO PEOPLE WITH HIGH SELF-ESTEEM ALWAYS BOOST THEIR INDEPENDENCE THROUGH EGO THREAT? ASYMMETRY EFFECT OF TASK-RELEVANT AND INTERPERSONAL THREAT ON CULTURAL SELF-CONSTRUAL.**

Ken'ichiro Nakashima<sup>1,2</sup>, Kuniaki Yanagisawa<sup>1</sup>, Mitsuhiro Ura<sup>1</sup>; <sup>1</sup>Hiroshima University, <sup>2</sup>Research fellow of the Japan Society for the Promotion of Science – Previous research (Heatherton & Vohs, 2000; Vohs & Heatherton, 2001) has indicated that people with high trait self-esteem become more independent after experiencing a task-relevant threat, whereas low trait self-esteem people become more interdependent. However, in these studies, it remained an open question as to whether interpersonal threat has the same effect. The purpose of this study was to clarify whether the level of trait self-esteem moderates what type of threat is related to independent or interdependent self-construal. It was hypothesized that for high self-esteem people, the level of task-relevant stress would be positively (or negatively) related to their independence (or interdependence), whereas the level of interpersonal stress would have an opposite effect. In order to examine the hypothesis, we conducted a longitudinal questionnaire survey with a 3-month interval. Respondents were 126 undergraduates. They completed a questionnaire consisting of scales regarding trait self-esteem, cultural self-construal (independence / interdependence), and the frequency of task-relevant and interpersonal stressful events. The results of a multi-population analysis of structural equation models were consistent with our hypothesis. Only for those with high self-esteem was the increase of task-relevant stress positively related to their independence, while the increase of interpersonal stress was related to their lowered independence and heightened interdependence. These findings suggest that task-relevant and interpersonal threat have an asymmetry effect on cultural self-construal for high self-esteem people.

**E247****THE "OPENNESS" OF A SOCIETY DETERMINES THE RELATIONSHIP BETWEEN SELF-ESTEEM AND SUBJECTIVE WELL-BEING:**

Kosuke Sato<sup>1</sup>, Masaki Yuki<sup>1,64</sup>; <sup>1</sup>Hokkaido University, Japan – Previous studies have shown that the impact of self-esteem on subjective well-being (SWB) is stronger in North America than in East Asia. While this difference is typically explained by the theory of cultural self-construals, we propose a more generalizable theory to explain it in terms of differences in relational mobility (RMob), a socio-ecological factor reflecting the general amount of opportunity to form new relationships in a given society/ social context. We hypothesized that the association between self-esteem and SWB should be moderated by RMob. In high (vs. low) RMob society where people have to compete with others to acquire desirable new relationships, one's self-esteem or "relational value" predicts the success to form them thus self-esteem should have a higher impact in predicting SWB. Our previous research using multi-methods (such cross-national, cross-regional, and priming experimental studies) obtained consistent

results supporting our hypothesis. In the current study, we tested our hypothesis with another method-- a cross-situational comparison with Quasi-experimental design. We compared the moved and non-moved freshmen who just entered university. Freshmen moved for university are in a situation higher in RMob than non-moved ones because, having left physically from their previous relationships, they need to find new partners and establish new relationships. On the contrary, non-moved freshmen are in a situation lower in RMob because they still retain their previous relationships, such as their family and friends from high school. As predicted, we found stronger positive correlations between self-esteem and SWB among the moved freshmen than non-moved freshmen.

#### E248

**SOME CONSEQUENCES OF BASING SELF-WORTH ON BEING VIRTUOUS** Ryan P. Gladding<sup>1</sup>, Lora E. Park<sup>1</sup>; <sup>1</sup>University at Buffalo, The State University of New York – Researchers have identified seven primary domains in which people may base their self-worth (Crocker, Luhtanen, Cooper, & Bouvrette, 2003). To this point, researchers have focused primarily on contingencies that rely mostly on others for validation (e.g., appearance). Little research has been conducted on contingencies (e.g., virtue) that are thought to be less reliant on external validation. The present studies investigated the effect of basing self-worth on virtue (i.e., adherence to one's moral standards) on prosocial behavior and attitudes about societal issues following a threat to one's sense of virtue. Participants completed initial questionnaires assessing contingencies of self-worth, trait self-esteem, volunteer motivations, and dimensions of moral values. Next, participants were randomly assigned to receive either positive (i.e., boost) or negative (i.e., threat) bogus computerized feedback about their morality and virtuousness compared to other students, or to receive no feedback (control). Afterwards, they completed measures of state self-esteem, mood, and a measure of helping behavior (Study 1) or a measure of attitude change (Study 2). Regression analysis revealed significant two-way interactions, controlling for relevant measures. Following threat, participants who strongly based self-worth on virtue reported less positive affect ( $\beta = -.31, p < .01$ ; Study 1), decreased state self-esteem ( $\beta = -.25, p < .05$ ; Study 2), were significantly less likely to help ( $\beta = -.40, p = .01$ ; Study 1), and reported more conservative attitudes ( $\beta = -.13, p < .01$ ; Study 2). Basing self-worth on virtue thus appears to be at least partially susceptible to external validation and threat.

#### E249

**DISCRIMINATING AGAINST PEOPLE WITH LOW SELF-ESTEEM: ARE LSES EACH OTHER'S WORST ENEMY?** Jennifer C. D. MacGregor<sup>1</sup>, Jessica J. Cameron<sup>2</sup>, John G. Holmes<sup>1</sup>; <sup>1</sup>University of Waterloo, <sup>2</sup>University of Manitoba – Our previous research suggests that low self-esteem (LSE) is perceived as an undesirable characteristic. The purpose of this research was to examine real-world implications of this stigma. Participants evaluated an applicant for a Data Entry/Analyst position after reading the applicant's resumé, reference letter and a job ad. Half the participants were led to believe that the applicant had low self-esteem; the other half were not. We also manipulated whether or not excellent social skills were a job requirement in order to examine the extent to which treatment of LSEs varied as a function of the relevance of self-esteem to the position. Results indicated that even when excellent social skills were not required, participants with higher self-esteem (HSEs) discriminated on the basis of applicant self-esteem, having less confidence in the LSE applicant and rating him/her as less suited for the position than the control applicant. However, when excellent social skills were required, only LSEs rated the LSE applicant less favourably, suggesting a lower pay rate and hiring likelihood. Surprisingly, LSEs in this condition also over-extended their negative view of the LSE applicant to other qualities such as how intelligent and interesting to talk to the applicant seemed. This study reveals that LSEs may be better than HSEs at understanding the role of self-esteem as it relates to situational demands. However, it also

suggests that, on a personal level, LSEs are overly harsh on their fellow LSEs, perhaps projecting their own insecurities about deservingness onto similar others.

#### E250

**IS MERITOCRACY BENEFICIAL FOR LOW STATUS GROUPS? EVIDENCE THAT MERITOCRACY PROTECTS SELF-ESTEEM BY INCREASING PERCEIVED CONTROL** Joseph D. Wellman<sup>1</sup>, Shannon K. McCoy<sup>1</sup>, Ellen E. Newell<sup>1</sup>, Brandon Cosley<sup>1</sup>, Laura Saslow<sup>2</sup>; <sup>1</sup>University of Maine, <sup>2</sup>University of California - Berkeley – In America, some groups and individuals have more power and access to social goods than other groups and individuals. This unequal status hierarchy is maintained in part by endorsement of beliefs that legitimize the status quo (e.g. meritocracy). Many scholars have argued that while endorsing status legitimizing beliefs is beneficial for the stability of the system, it is likely detrimental for the psychological wellbeing of members of low status groups - leading to low self-esteem and neuroticism (e.g. Jost & Hunyady, 2002; Marx & Engels, 1846; Valian, 1998). However, meritocracy provides a ready explanation for the existence of disadvantage (e.g. lack of hard work) while simultaneously providing the illusion of control over one's future outcomes (e.g. simply work harder). In the current research we examine whether meritocracy is protective of self-esteem for members of one low status group: women. A community sample of women (N=558; 58.8% White, Age: 19-65) completed multiple measures of meritocracy, perceived control and self-esteem. Using SEM, we found that meritocracy was positively associated with self-esteem ( $\beta = .24, p < .05$ ) and perceived control ( $\beta = .34, p < .001$ ). Further, we demonstrated that perceived control mediated the relationship between meritocracy and self-esteem both by eliminating the relationship between meritocracy and self esteem ( $\beta = -.05, p = .28$ ) and by demonstrating overall model fit. Alternative conceptualizations of status in these data (e.g. ethnicity, SES) were also examined. Our findings suggest that meritocracy may be protective for even members of low status groups by encouraging the perception of personal control.

#### E251

**SELF-ESTEEM AND BINGE DRINKING: THE MODERATING ROLE OF IMPLICIT SELF-ESTEEM** Alicia Wood<sup>1</sup>, Ruth C. Lewis<sup>1</sup>, Michelle Rai<sup>1</sup>, Samantha Fields<sup>1</sup>, Daniel R. Berry<sup>1</sup>, Megan Smith<sup>1</sup>, Chad E. Lakey<sup>1</sup>, Shawn K. Acheson<sup>2</sup>; <sup>1</sup>East Tennessee State University, <sup>2</sup>Duke University – Heavy episodic drinking, or binge drinking (BD), is an especially common and problematic occurrence, particularly on college campuses. Various theorists have discussed the role of self-esteem (SE) for BD, yet notably weak and inconsistent findings have emerged between these two constructs. One possible means to address this situation is to examine self-esteem as a multifaceted construct with secure and fragile forms that differentially relate to adaptive behavior and positive psychological outcomes (Kernis, 2003). Discrepant high esteem (DHSE; i.e., high explicit self-esteem coupled with low implicit self-esteem) represents one form of fragile self-esteem, and research supports the self-enhancement and defensive tendencies inherent to it. In this research, we sought to test the possibility that maladaptive drinking behavior would be especially common among people with DHSE. Freshmen college students (n = 106) completed the Rosenberg (1965) Self-esteem Scale and the Name-Letter Task (Nuttin, 1987) as the measures of explicit and implicit self-esteem, respectively, and a questionnaire about their drinking history. About one month later, they completed the drinking history questionnaire again, this time specifically worded to address drinking behavior over the 30 days. Using separate hierarchical regression analyses, we found that the small bivariate relations between a) explicit self-esteem and overall drinking frequency as well as b) explicit self-esteem and binge drinking frequency were moderated by the expected explicit X implicit self-esteem interaction, even controlling for gender, drinking history, and fraternity/sorority status. Our discussion focuses on the role of DHSE for drinking motivations and maladaptive drinking behaviors.

**E252****IS ANONYMOUS DISCLOSURE OF PERSONAL SECRETS MORE PROTECTIVE OF PSYCHOLOGICAL WELL-BEING THAN DISCLOSURE OF SHARED SECRETS?** Ryan Pickering<sup>1</sup>, Brandon Cosley<sup>1</sup>, Shannon K. McCoy<sup>1</sup>, <sup>1</sup>University of Maine – Although one might expect that disclosure of painful experiences (or a troubling secret) might be accompanied by negative emotions, research suggests that when such disclosures are made in a journal, to a trusted friend, or anonymously online, they are accompanied by feelings of relief and positive emotions (Pennebaker, 1997). In fact, providing individuals an outlet to express suppressed inner problems may be quite beneficial to psychological wellbeing and has real consequences for life outcomes (for a review see Pennebaker, 2007). But does the type of information disclosed affect self-esteem? To examine this hypothesis, participants (volunteers) were randomly assigned to write about personal secrets ("something you've never told anyone") or shared secrets ("something you've shared with close friends") in an anonymous web-based survey. While participants wrote equivalent amounts, they had significantly higher self-esteem than participants in the shared secrets condition. Because these differences may be based on what people are writing about, we applied a textual analysis method (LIWC, Pennebaker, 1997) to explore the relationship between the content of the writing, perceived disclosure, and psychological wellbeing. Thus, we examined what aspects of disclosure and writing content are most strongly predictive of self-esteem and mood. Our findings further our understanding of when and why anonymous disclosure of personal secrets may be beneficial to psychological wellbeing.

**E253****HOW LOW CAN YOU GO? THE STIGMATIZATION OF LOW SELF-ESTEEM** Jessica J. Cameron<sup>1</sup>, Christine Hole<sup>1</sup>, Jennifer C. D. MacGregor<sup>2</sup>, John G. Holmes<sup>2</sup>, <sup>1</sup>University of Manitoba, <sup>2</sup>University of Waterloo – Self-esteem is no longer a purely academic concept. Popular culture has been inundated with reports of the suspected negative effects of low self-esteem, bookstore shelves are lined with self-help books promoting high self-esteem and several private and public institutions have incorporated programs designed to boost self-esteem. What has the public learned about self-esteem from these initiatives? Two studies are reported that investigated lay theories of self-esteem. In Study 1, just over 200 undergraduate participants completed an online survey that asked them to report their views of lower self-esteem people (LSEs) and higher self-esteem people (HSEs) in both closed-ended and open-ended formats. Results revealed that participants viewed LSEs as more interpersonally difficult and as having a more negative standing on almost all characteristics than HSEs. The open-ended questions revealed a very similar story: People described LSEs in very negative terms and described HSEs in more glowing terms. In Study 2, we asked 200 undergraduate participants in an online survey to indicate how much the characteristics derived from participants' descriptions in the first study were indicative of LSEs and HSEs. Results revealed that participants, again, had very negative views of LSEs. When an individual was described as having a negative trait, participants thought it was more likely that individual would have LSE whereas individuals who were described as possessing positive traits were thought to have HSE. Overall, it seems that people use an implicit theory whereby they trust a person's own self-evaluation to infer that person's value.

Self-esteem is no longer a purely academic concept. Popular culture has been inundated with reports of the suspected negative effects of low self-esteem, bookstore shelves are lined with self-help books promoting high self-esteem and several private and public institutions have incorporated programs designed to boost self-esteem. What has the public learned about self-esteem from these initiatives? Two studies are reported that investigated lay theories of self-esteem. Results revealed that participants, again, had very negative views of LSEs. When an individual was described as having a negative trait, participants thought it was more likely that individual would have LSE whereas individuals who were described as possessing positive traits were thought to have HSE. Overall, it seems that people use an implicit theory whereby they trust a person's own self-evaluation to infer that person's value.

**E254****HIGH OR LOW, FRIEND OR FOE? SELF-PROTECTION AND CONNECTEDNESS GOALS MEDIATE THE ASSOCIATION BETWEEN SELF-ESTEEM AND NEGATIVE INTERPERSONAL BEHAVIOURS** Tara Galagher<sup>1</sup>, Kelley J. Robinson<sup>1</sup>, Jessica J. Cameron<sup>1</sup>, <sup>1</sup>University of Manitoba – Despite a fundamental need to form and maintain close relationships with significant others, individuals often sacrifice the benefits of closeness by knowingly engaging in acts that may harm or even destroy relationships. Individuals with low self-esteem are particularly likely to engage in such destructive interpersonal behaviours (e.g., Mur-

Despite a fundamental need to form and maintain close relationships with significant others, individuals often sacrifice the benefits of closeness by knowingly engaging in acts that may harm or even destroy relationships. Individuals with low self-esteem are particularly likely to engage in such destructive interpersonal behaviours (e.g., Mur-

ray et al., INSERT YEAR). What motivates lower self-esteem individuals to engage in destructive behaviours to the detriment of their valued relationships with significant others (i.e., friends, family, romantic partners)? The present research used a risk regulation perspective to address this question. From this perspective, the higher self-protection goals and lower connectedness goals of those lower in self-esteem may lead them to "lash out" or "run away" after feeling hurt by a significant other's behaviour. Inadvertently, these self-protective behaviours may damage the relationships that lower self-esteem individuals need to satisfy their chronically unfulfilled need to belong. Over 350 participants completed online self-report measures of self-esteem, self-protection goals, connectedness goals, and destructive relationship behaviours. In order to determine whether high self-protection goals and low connectedness goals explain the association between harmful relationship behaviours and low self-esteem, a mediation model was tested. Path analysis revealed that lower self-esteem individuals reported more negative reactions to feeling hurt by a significant other and that these self-reported behaviours were mediated by both self-protective and connectedness goals. Results suggest that interventions aimed at reducing self-protective goals and enhancing connectedness goals may reduce lower self-esteem individuals' tendencies to react destructively to hurts in their relationships.

**E255****UNDERSTANDING THE PSYCHOLOGICAL MAKE-UP OF PEOPLE WITH DISCREPANT HIGH EXPLICIT AND LOW IMPLICIT SELF-ESTEEM** Daniel R. Berry<sup>1</sup>, Michelle Rai<sup>1</sup>, Ruth C. Lewis<sup>1</sup>, Alicia Wood<sup>1</sup>, Samantha Fields<sup>1</sup>, Chad E. Lahey<sup>1</sup>, <sup>1</sup>East Tennessee State University – Previous empirical research supports that high explicit self-esteem mated to discrepant low implicit self-esteem is a manifestation of fragile self-esteem fraught with tendencies to discriminate against others (Jordan et al., 2005), self-enhance (Bosson et al., 2003), verbally defend the self (Kernis et al., 2008), and fail at self-regulation (Lambird & Mann, 2006). Questions remain, however, as to the underlying psychological make-up of these individuals. To address this situation, we had participants complete Rosenberg's (1965) Self-Esteem Scale and the Name-Letter Task (Nuttin, 1987) as measures of explicit and implicit self-esteem, respectively. Participants also completed the Self-Determination Scale (e.g., Sheldon, 1995) and a measure of Unrealistic Optimism (e.g., Bosson et al., 2003). Finally, participants completed twice-daily assessments of their explicit self-esteem over the next week to measure their self-esteem stability (Kernis, 2005). A series of hierarchical regression analyses revealed statistically significant explicit self-esteem X implicit self-esteem interactions. As predicted, we found that when compared to their congruent high explicit and implicit self-esteem counterparts, people with discrepant high self-esteem were a) more unrealistically optimistic in their attitudes and judgments (thereby replicating Bosson et al., 2003), b) less self-determined in their behavior, and c) more unstable in their explicit feelings of self-worth. Our findings suggest that the defensive nature inherent to individuals with discrepant high self-esteem stems from their tenuous psychological make-up that includes a sense-of-self that is highly unstable, is inclined to bias self-related judgments, and is prone to engage in behaviors for reasons due to external pressures rather than self-determined reasons.

Previous empirical research supports that high explicit self-esteem mated to discrepant low implicit self-esteem is a manifestation of fragile self-esteem fraught with tendencies to discriminate against others (Jordan et al., 2005), self-enhance (Bosson et al., 2003), verbally defend the self (Kernis et al., 2008), and fail at self-regulation (Lambird & Mann, 2006). Questions remain, however, as to the underlying psychological make-up of these individuals. **E256****THE MOTIVATION TO RESOLVE IMPLICIT-EXPLICIT SELF-ESTEEM DISCREPANCIES AND ITS RELATION TO SEXUAL BEHAVIOR** Valerie L. Laws<sup>1,2</sup>, Luis M. Rivera<sup>1</sup>, <sup>1</sup>California State University, San Bernardino, <sup>2</sup>Kansas State University – Based on the Meta-Cognitive Model (Petty & Briñol, 2006) of the structure and formation of attitudes, individuals can simultaneously possess different degrees of implicit vs. explicit self-esteem because attitudes can be linked to disparate yet jointly activated evaluations about the self. Furthermore, these implicit-explicit self-esteem discrepancies (SED) can lead to implicit ambivalence, which is an internal evaluative conflict outside of conscious awareness. We posit that implicit ambivalence rooted in SED can motivate individuals to engage in discrepancy reduction as a way to obtain an overall positive and consistent self-image. More specifically, just as explicit ambivalence (e.g., cognitive

Based on the Meta-Cognitive Model (Petty & Briñol, 2006) of the structure and formation of attitudes, individuals can simultaneously possess different degrees of implicit vs. explicit self-esteem because attitudes can be linked to disparate yet jointly activated evaluations about the self. Furthermore, these implicit-explicit self-esteem discrepancies (SED) can lead to implicit ambivalence, which is an internal evaluative conflict outside of conscious awareness. We posit that implicit ambivalence rooted in SED can motivate individuals to engage in discrepancy reduction as a way to obtain an overall positive and consistent self-image. More specifically, just as explicit ambivalence (e.g., cognitive

dissonance) leads to changes in conscious attitudes and feelings to meet an individual's desire to restore their self-image, so can implicit ambivalence lead to changes in nonconscious attitudes and feelings to meet self-image maintenance needs. We examined this hypothesis across two studies in which SED was either measured (Study 1) or manipulated (Study 2), and then we assessed automatic attitudes toward condoms. Study 1 demonstrated that individuals with strong SED held relatively positive implicit (but not explicit) attitudes toward condoms. Study 2 tested the conditions under which SED shift by providing affirming (positive) versus threatening (negative) feedback after completing an intelligence test. Participants who received threatening feedback exhibited larger self-esteem discrepancies and, in turn, more negative implicit attitudes toward condoms when compared to those participants in the affirmation and control conditions. This research suggests that individuals are motivated to reduce implicit-explicit self-esteem discrepancies in order to achieve an overall positive and consistent self-image.

**E257**

**PHYSICAL AGGRESSION IS RELATED TO LOW–NOT HIGH–UNSTABLE SELF-ESTEEM** Gregory D. Webster<sup>1</sup>, John B. Nezek<sup>2</sup>, Lee A. Kirkpatrick<sup>2</sup>, <sup>1</sup>University of Florida, <sup>2</sup>College of William & Mary – Does high or low unstable self-esteem relate to aggression? In Study 1, a mini meta-analysis of 6 studies (N = 566) showed significant convergent validity between temporal and self-reported measures of self-esteem instability. In Studies 2 and 3, 116 and 552 undergraduates provided measures of trait self-esteem, self-esteem instability, and physical aggression. In Study 4, 67 undergraduates provided measures of state self-esteem and self-esteem instability, and participated in a laboratory experiment in which they had an opportunity to aggress against a person they believed had given them negative feedback on an essay that they had written by allocating hot sauce for them to consume. Studies 2-4 revealed significant self-esteem level × self-esteem instability interactions; the effects of self-esteem on physical aggression became more negative as instability increased. People with low, unstable self-esteem were the most aggressive. The measurement of self-esteem instability and its importance to the self-esteem/aggression debate is discussed.

## Social Judgment/Decision-Making

**E258**

**INFLUENCE OF PICTURES ON PERCEPTIONS OF MORALITY** Cory J. Clark<sup>1</sup>, James Leonhardt<sup>1</sup>, David Tannenbaum<sup>1</sup>, Peter H. Ditto<sup>1</sup>; <sup>1</sup>University of California, Irvine – In recent months, considerable controversy has occurred over the effect of pictures on the public's moral perceptions of recent government decisions and real world events. No research has shown pictures to affect moral judgments, and in general the role of "vividness" has been equivocal. Two studies were conducted to assess whether (and how) pictures influence perceptions of morality. In study 1, 116 subjects evaluated four moral dilemmas while seated at a desk where inconspicuously sat a framed picture of either a baby (treatment group) or a rock (control group). Two of the dilemmas involved acts that required harm to children in order to achieve a greater good, and the other two dilemmas were unrelated to children. Participants in the treatment group perceived harmful acts toward children to be significantly less morally acceptable than participants in the control group. There were no group differences for scenarios not involving children. Study 2 (N=78) examined whether the effect of the baby picture was due to incidental affect. No differences in self-reported positive or negative affect were found between participants exposed to the baby versus the rock picture, and there were no significant correlations between positive or negative affect and responses to other classic moral dilemmas. These findings argue against mood as the cause of the picture effect. The results of these studies are consistent with a moral intuitionist perspective. Pictures may affect moral judgments if they generate specific intuitive reactions (e.g., sympathy) to a moral agent.

**E259**

**BODY SHAPES THE MIND: THE POSTURAL FEEDBACK HYPOTHESIS** Andy J. Yap<sup>1</sup>, Dana R. Carney<sup>1</sup>, Amy J. C. Cuddy<sup>2</sup>; <sup>1</sup>Columbia University, <sup>2</sup>Harvard University – What is mental and what is physical is not clearly separated. Research has shown that behavior shapes mental states, for example, research on facial feedback proposes that an unobtrusive smile elicits feelings of happiness. This research proposes the Postural Feedback Hypothesis, which suggests that the body shapes the mind. Specifically, we demonstrated that unobtrusively engaging in High Power (HP)/ Low Power (LP) postures heightened one's sense of Powerfulness, and influenced one's tolerance for risk-taking. Individuals who engaged in High Power poses took more risk in a gambling game. Contrastingly, those who performed Low Power poses were more risk averse. In this study, employing a between-subjects design, participants in the HP condition imitated an actor on the computer screen and performed postures that powerful individuals are known to exhibit, such as open-body postures that are erected, and take up physical space. Contrastingly, those in the Low Power condition imitated closed-body postures that slouch, and take up less space. They then participated in a gambling dice-game where participants were first offered \$2 and asked to call a number. They would earn another \$2 if the dice showed the number that was called. However, the initial \$2 would be confiscated if the number called was not shown. Nonetheless, participants could keep the initial \$2 if they chose not to play. Our results demonstrate that participants who engaged in HP poses were more likely to take the risk and play the game. This suggests that what the body acts, influences what the mind thinks.

**E260**

**LOOK BUT DON'T TOUCH: SHIFTS IN ATTENTION FOR IMPULSIVE VERSUS REFLECTIVE STATES** Chantal Den Daas<sup>1</sup>, Michael Häfner<sup>1</sup>, John De Wit<sup>1</sup>; <sup>1</sup>Utrecht University – People tend to make riskier decisions in impulsive states as compared to reflective states. We address the question why and focus on one particular explanation. We examine the hypothesis that reflective and impulsive states not only affect information processing but also attune the focus of attention. Whereas people in reflective states are assumed to integrate all available information and distribute their attention over the available information, people in impulsive states are assumed to focus their attention on central information. Two experiments tested our hypothesis. In Experiment 1, participants judged the sexual attractiveness of photographs of (attractive or unattractive) people in stimulating or inhibiting backgrounds. Impulsive participants based their judgement solely on the person's attractiveness and did not take into account additional information, whereas background did influence reflective participants. In Experiment 2, participants searched for two differences in two almost identical photographs. One difference was in the person, the other in the background. As predicted, impulsive participants were slower in detecting differences in a person when the person was sexually attractive. Reflective participants showed no differences in speed for differences in the persons but were slower for differences in the background of a sexually attractive person. These results suggest that impulsive people differ in their attention to certain aspects of information. When judging attractiveness they do not take into account additional information and while performing an unrelated task they take their time when a photograph is sexually attractive. It is discussed how these behaviours can lead to riskier decisions when tempted.

**MONEY REDUCES CONNECTION TO AND INTEREST IN NATURE** F. Stephan Mayer<sup>1</sup>, Cynthia McPherson Frantz<sup>1</sup>, Sarah Epstein<sup>1</sup>, Vasil Zlatev<sup>1</sup>, Case Lovell<sup>1</sup>; <sup>1</sup>Oberlin College – Previous research has demonstrated that priming people with money makes them feel more independent from and less altruistic towards other people. Two studies tested whether money makes people feel more independent from nature, and less interested in spending time in nature. High school students (N = 29) and col-

lege students ( $N = 54$ ) were paid to participate in a study either before completing a questionnaire (money prime condition) or after (control condition). All completed a measure of connection to nature. They also indicated their preference for a series of solitary vs social activities, and indoor vs outdoor activities. Replicating past work, those primed with money showed greater preference for solitary activities to social ones. In addition, those primed with money showed a lower sense of connection to nature and lower preference for outdoor activities. The results suggest that the effect of money as a prime for independence is not limited to the social world, thus extending the potential implications of this effect. The results also have implications for well-being and pro-environmental behavior in a consumer-based, materialistic culture. Exposure and connection to nature have physical and mental health benefits, and increase environmentally responsible behavior. Reminders of money may undermine interest in nature and its protection.

### E262

**THE FOLK CONCEPT OF FREE WILL: SCHOLARS' ASSUMPTIONS AND THE FOLK'S (EMPIRICAL) REPLY** Andrew Monroe<sup>1</sup>, Bertram Malle<sup>1</sup>; <sup>1</sup>Brown University – Psychology has recently seen a surge of interest in the issue of free will. However, confusion remains over what scientists and ordinary people mean when referring to this concept. Our research seeks to clarify two common assumptions about the folk concept of free will. First, scholars assume that this concept contains untenable beliefs about a “soul,” non-determinism, and “uncaused” causes. Second, scholars assume that the expression of free will requires full conscious control over action, an assumption seemingly contradicted by research on unconscious causes of behavior. Two studies tested these assumptions against data gathered about people’s actual concept of free will. Study 1 asked participants to provide a brief description of what it means to have free will. Responses were coded for the most central and shared definitional features. Study 2 presented participants with a challenge from neuroscientists that “all of our behavior is caused by our neural impulses, and feelings of control are illusory.” Participants were asked whether they accepted the claim, and if not, to provide a rationale for rejecting it. The results suggest that the folk concept of free will is defined as the mental process of choice, free from severe constraints (e.g. coercion, brain damage) and consistent with one’s desires and beliefs. Further, most participants reconciled their concept of free will with the neuroscience challenge, arguing that unconscious causes of behavior may function as antecedents to choice, part of choice, or as something that choice can influence.

### E263

**THE EFFECT OF MORTALITY SALIENCE ON FACIAL PREFERENCES IN FEMALES** James Vaughn<sup>1</sup>, Shelia Kennison<sup>1</sup>, Kristopher Bradley<sup>1</sup>, Jennifer Byrd-Craven<sup>1</sup>; <sup>1</sup>Oklahoma State University, Stillwater, Oklahoma – Previous research has shown that individuals who are reminded of death show an increased desire for offspring compared to individuals who were not reminded of their mortality. The present research investigated whether being reminded of mortality affects facial preference judgments in women. Prior research on mate selection has shown that women prefer more masculine faces when they are ovulating (i.e., high risk for pregnancy) than when they are experiencing menses (i.e., low risk for pregnancy). The present research tested the hypothesis that reminding women of their mortality would increase their preference for masculine features in male faces. Using a QuickTime movie of morphing faces ranging from extreme masculine to extreme feminine from Johnston (2001), women who were not taking hormone-based contraception were tested either during menses or during the week of ovulation. Participants were randomly assigned to either a mortality salience or control condition. The results showed that women’s choice of the attractive male face was determined by an interaction between ovulation status and condition. In control conditions, ovulating women preferred a significantly more masculine face than women who were not ovulating. In MS conditions, ovulating women preferred a significantly less masculine (i.e.,

more average) face than women who were not ovulating. The results indicate that biological processes involved in mate selection can be influenced by environmental factors, such as death reminders.

### E264

**CAUSAL REASONING AND HINDSIGHT BIAS** Jennelle Yopchick<sup>1</sup>, Nancy Kim<sup>1</sup>; <sup>1</sup>Northeastern University – What processes underlie the ubiquitous phenomenon of hindsight bias, whereby the outcome of an event appears obvious only after the fact? According to the causal reasoning hypothesis (Wasserman, Lempert, & Hastie, 1991), when a causal link can be easily constructed from the event to its outcome, the outcome will appear inevitable and hindsight bias will result. However, empirical support for this hypothesis is not yet clear. In two experiments, we tested the causal reasoning hypothesis as an alternative to the assumption that simply knowing the outcome is sufficient to elicit hindsight bias (Fischhoff, 1975). In Experiment 1, we explicitly manipulated the ease with which a causal link could be drawn from the event to the outcome by supplying an additional event-related factor of either high or low plausibility and high or low relevance to the outcome (as pre-rated by a separate group). Hindsight bias occurred only when this factor was both highly plausible and highly relevant to the actual outcome, supporting the causal reasoning hypothesis. Experiment 2 investigated the phenomenon known as reverse hindsight bias (Mazursky & Ofir, 1990). In accord with the causal reasoning hypothesis, we found that when it is easier to draw a causal link to the alternative outcome than to the actual outcome, there is a reversal of likelihood estimates. Overall, Experiments 1 and 2 provide the first empirical support for the causal reasoning hypothesis of hindsight bias. Implications of these results for both the cognitive and motivational camps of hindsight bias research are discussed.

### E265

**APPLICATION OF PSYCHOPHYSICS TO SOCIAL JUDGMENTS** Sandra Stershic<sup>1</sup>, Sean Stevens<sup>1</sup>, David Wilder<sup>1</sup>; <sup>1</sup>Rutgers University – Two experiments examined the applicability of Weber’s classic research on physical judgments to social stimuli. It was hypothesized that the perception of a change in social behavior is dependent on the extremity of the initial behavior. More extreme behaviors require greater change to be detected. In the first experiment, subjects rated fictitious people on extremity of a behavior and indicated how much more of that behavior would be necessary to increase the rating. Results supported the hypothesis that with increasing extremity of the initial rating, a greater degree of change was required to be noticed. Experiment 2 extended this finding to judgments of people in groups. It was hypothesized that a deviant group member would be more readily detected when the group stereotype was moderate than when extreme. Borrowing again from Weber’s Law, when the stereotype is moderate, persons should be more sensitive to small changes in the behavior of group members than when the stereotype is extreme. Results supported the hypothesis on some but not all measures. Taken together, the two experiments provided some, but not complete, support for the argument that social judgments are subject to the same principles as have been found for sensory judgments in psychophysics research.

### E266

**WHY PROCESSING FLUENCY IS A UNITARY CONSTRUCT** Christian Unkelbach<sup>1</sup>, Myriam Bayer<sup>1</sup>; <sup>1</sup>Universität Heidelberg, Germany – Mental processes vary along a fluency dimension; people experience the ease or difficulty for perceiving stimuli, retrieving memories, or solving logical problems. This experienced fluency has profound influences on social judgments and evaluations: fluently processed statements are judged to be true (i.e., the truth effect), faces to be likeable (i.e., the mere exposure effect), and events to be frequent (i.e., the ease-of-retrieval effect). However, theoretically, it is unclear whether the same construct underlies these effects or if they are distinct phenomena. Although there is suggestive evidence, for example, when different fluency manipulations result in similar effects, direct experimental proof is lacking that indeed the same construct underlies these effects. Here, we present evidence from

fluency effects on memory and truth, showing that the same dimension underlies fluency manipulations such as repetition, contrast, or mental rotation. In three experiments, participants learned an interpretation of a specific fluency manipulation; for example, that easy-to-read statements are false. This learned interpretation was spontaneously transferred to the interpretation of fluency experiences from other sources; for example, after learning that high contrast statements are false, repeated statements were judged to be false as well. Thus, the only connecting construct between these differing manipulations was indeed processing fluency. The transfer from learned fluency effects across different manipulations strongly supports that processing fluency is a unitary construct. This insight allows establishing general principles of how processing fluency influences social judgments and evaluations.

**SALIVARY ALPHA-AMYLASE LEVELS AND REJECTION OF UNFAIR OFFERS IN THE ULTIMATUM GAME** Haruto Takagishi<sup>1</sup>, Fujii Takayuki<sup>2</sup>, Shinya Kameshima<sup>2</sup>, Michiko Koizumi<sup>1</sup>, Taiki Takahashi<sup>1</sup>; <sup>1</sup>Hokkaido University, <sup>2</sup>Kansai University of Welfare Sciences – Recent neuroeconomics studies have shown the importance of emotions in responses to unfair allocation of resources (Sanfey et al., 2003; Van't Wout et al., 2006; Tabibnia et al., 2008). Sanfey and his colleagues showed that the activation of anterior insula which is related to emotional awareness was observed when participants faced the unfair offers in the ultimatum game. In this study, we measured salivary alpha-amylase (sAA) as an indicator of emotional arousal to examine the role of emotion in rejection of unfair offers in the ultimatum game. Thirty-seven participants played a one-shot ultimatum game. All participants were assigned to the role of the responder and faced unfair offers by the proposer (a proposer: US\$ 8, a responder: US\$2). The participants could accept or reject the unfair offers. When the participants accept the proposers' offer, both receive the amount of money according to the proposers' offer. However, when the participants reject the offer, both receive nothing. Salivary alpha-amylase (sAA) was assessed prior and after the ultimatum game. Forty-four percent of the participants rejected the unfair offers. Results showed that while sAA levels of the participants who rejected the unfair offers increased between prior and after the ultimatum game, sAA levels of the participants who accepted the unfair offers did not. Emotional arousal was observed when the participants rejected the unfair offers but not when they accepted the unfair offers. These results showed the importance of emotion in social decision-making.

**E269**

**THE PEN IS MIGHTIER THAN THE WORD: OBJECT PRIMING OF EVALUATIVE STANDARDS** Abraham Rutchick<sup>1</sup>, Michael Slepian<sup>2</sup>, Bennett Ferris<sup>3</sup>; <sup>1</sup>California State University, Northridge, <sup>2</sup>Tufts University, <sup>3</sup>Phillips Exeter Academy – We argue that, despite teachers' efforts to free themselves from extraneous influences when grading, the very act of picking up a red pen can bias their evaluations. Because red pens are closely associated with error-marking and poor performance, the use of red pens when correcting student work can activate these concepts. Study 1 demonstrated that people randomly assigned to use a red pen to correct an essay marked more errors than people assigned to use a blue pen. Study 2 showed that people using red pens to complete a word-stem task completed more words related to errors and poor performance than did people using black pens, suggesting that these concepts were more accessible when red pens were being used. The findings contribute to the emerging literature on object priming, and have clear practical implications for issues in teaching and student evaluation.

**E270**

**THE IMPACT OF SOCIAL RELATIONSHIPS ON MORAL JUDGMENTS ABOUT BREAKING PROMISES** Gul Gunaydin<sup>1</sup>, David A. Pizarro<sup>1</sup>; <sup>1</sup>Cornell University – Breaking a promise is widely regarded as immoral, partly because knowing that others will keep their promises is critical for a cooperative society to survive. But the prohibition against promise-breaking can become a dilemma in cases where keeping a promise may lead to a worse overall outcome. We hypothesized that in such cases, individuals would still judge promise-breaking as immoral despite the negative consequences, unless the promise was made to a stranger. Accordingly, we used a desert island scenario in which a promise is made between a healthy survivor and a dying one. Participants (N=92) were assigned randomly to one of two versions: in one scenario the survivors were described as close friends, and in the other they were described as strangers. In both scenarios the person promised the dying survivor that he would use her wealth to protect her prized orchid collection, but subsequently broke his promise and used the money to save human lives. Participants who read the "close friends" version of the scenario considered promise-breaking more immoral than those who read the "strangers" version, were more likely to report that they would keep their promise to a dying friend than to a dying stranger, and were more likely to judge that the "close friend" promise-breaker was a worse person overall. This study provides evidence that moral prohibitions are not treated invariantly, but that social relationships play an important role in how rigidly we apply these moral rules, and in how we judge these violations in others.

**E271**

**WHO SHOULD BE SAVED? –IT DEPENDS ON HOW YOU ASK!** Meng Li<sup>1</sup>, Gretchen Chapman<sup>1</sup>, Alison Galvani<sup>2</sup>; <sup>1</sup>Rutgers, the State University of New Jersey, <sup>2</sup>Yale School of Public Health – Who should be saved when health resources are limited? We investigated how the public values life when evaluating vaccine allocation policies on an Internet survey right after the recent H1N1 flu outbreak. 1039 participants (age 18-89) completed a web-survey describing a hypothetical scenario where 1000 people were expected to die from the H1N1flu. Subjects rated the acceptability of 12 vaccination policies on a 0-100 scale. In the lives saved condition, policies were described as saving 500 people of specified age (ranging from 5-80), who were either ill (with 2 years to live) or healthy (living to full life). The lives lost condition described the same 12 policies phrased as resulting in 500 lives lost. Afterwards, they also chose an explicit metric in evaluating life. We found that people's ratings of the acceptability of policies were dramatically influenced by question framing. In the lives-saved version, people judged policies based on total number of life years saved, consistent with a "years left" metric; however, in the lives-lost version, people judged policies based on the age of beneficiaries, and prioritized young targets over older targets even if both would live just 2 years. In addition, young targets were judged as more valuable in general, but young participants valued young targets even more than elderly participants did. Ironically, when explicitly asked, the majority of participants (58%) chose an "all lives equal" metric, instead of "years left" (23%) or "age per ce" (11%) metrics.

**E272**

**PERCEPTIONS OF UNFAIRNESS AND SOCIAL PROTESTS AMONG JAPANESE: EFFECTS OF THE IMMUTABILITY BELIEF** Nobuyoshi Kawashima<sup>1,2</sup>, Ken-ichi Ohbuchi<sup>1</sup>, Tomohiro Kumagai<sup>1</sup>, Nobuko Asai<sup>1</sup>; <sup>1</sup>Tohoku University, <sup>2</sup>The Japan Society for the Promotion of Science – In contemporary Japan, a public concern about social inequalities has been increased. Although the equity theory (Adams, 1965) expects that the perception of unfairness motivates people to redress it, Japanese people generally do not appear to be actively engaged in activities for social reforms. We assume that though many Japanese recognize that the society is unfair, only a few of them feel that they are personally treated unfairly. Then, we predict that the perception of unfairness based on the mere recognition (social unfairness) will less lead to social protests than

that based on personal experiences (personal unfairness). As an alternative explanation of the low level of social protests, Ohbuchi (2007) postulated that Japanese generally have an immutability belief that the society is unchangeable. Thus, our second prediction is that Japanese having the belief will not actively engage in social protests even if they feel unfairness. We sent a questionnaire to 3600 residents in Japan and obtained 1386 respondents. The results showed that while 65.6% of respondents perceived social unfairness, only 12.4% perceived personal unfairness. A regression analysis revealed that both the perceived personal unfairness and that of social unfairness led the respondents to social protests but the effects of the perceived personal unfairness were larger. It was also found that only among those low in the immutability belief, the perceptions of unfairness led to social protests. The findings suggest that different types of perceived unfairness differently affect social protesting activities and the immutability belief moderates the relationships between them.

### E273

**NEURAL DISSOCIATIONS BETWEEN REWARD EXPECTATION AND REGRET IN A SIMULATED GAMBLING TASK** Wei Zhang<sup>1</sup>, Hackjin Kim<sup>1</sup>, Taekyun Hur<sup>1</sup>, <sup>1</sup>Korea University – Recent neuroimaging studies revealed the reward-related neural mechanisms involved in both reward expectation and regret elicited by counterfactual thinking. Although reward expectation and regret are clearly distinguished from each other in many aspects, so far little has been done to investigate the differences between these two mechanisms. In the present study using functional magnetic resonance imaging (fMRI), participants performed a simple decision task resembling a card gambling, which was designed to elicit and compare between monetary gain/loss expectations as and rejoice/regret following revealed alternatives. As a result, the ventral striatum, known as a key reward center in the brain, showed increased (or decreased) activation, when an experienced outcome was higher (or lower) than expectation, which is consistent with its well-known role in encoding prediction error. In regret condition, however, the ventral striatum showed increased activation when the alternatives were better than the chosen options, suggesting that regret may not be only negative emotional experience but may also help to facilitate behavioral motivation towards rewarding values of alternatives. In summary, the present study provides novel biological evidence that reward expectation and regret have distinctive functional recruitments of shared neural circuitry, which is strongly implicated in reward processing.

### E274

**REACTIONS TO SINGLE VERSUS MULTIPLE UPWARD AND DOWNWARD COMPARISONS** Kathryn Bruchmann<sup>1</sup>, Suls Jerry<sup>1</sup>; <sup>1</sup>University of Iowa – Many social comparison studies have found effects on self-evaluations when participants compare themselves to a superior or inferior target (Morse & Gergen, 1970; Stapel & Koomen, 1991). However, little is known about reactions to multiple targets and reactions to being simultaneously outperformed by someone but underperformed by someone else (see Ahrens, 1981). Two experiments examined how people responded to single versus multiple comparisons which were upward, downward or both. In Experiment 1, participants were given false feedback about their performance on a lie detection test and the performance(s) of co-participants. Experimental conditions included: no comparison information, upward comparison, downward comparison or both. Also, in some conditions, there was exposure to one vs. two comparison targets. There was little effect of self-evaluations of being exposed to single vs. multiple comparison targets, regardless of direction. However, if there was a downward comparison target available, participants rated their satisfaction and lie detection ability higher than control groups ( $p$ 's < .05), even if someone else also simultaneously outperformed them. A second experiment replicated the design, but also manipulated information about average student performance. Even when participants "learned" that they performed comparably to most students, they still responded differentially to a downward comparison target ( $p$  < .05). The findings suggest exposure to single vs. multiple tar-

gets or to aggregate feedback (Buckingham & Alicke, 2002) may not be critical, but exposure to a downward comparison target has special significance for self-evaluations.

### E275

**THE IMPACT OF EXPERTISE LEVEL: A COMPARISON BETWEEN FAST AND FRUGAL AND LOGISTIC REGRESSION MODELS** Neda Kerimi<sup>1</sup>, Lars G Backlund<sup>2</sup>, Ylva Skaner<sup>2</sup>, Lars-Erik Strender<sup>2</sup>, Henry Montgomery<sup>1</sup>; <sup>1</sup>Stockholm University, <sup>2</sup>Center for Family and Community Medicine, Karolinska Institutet – Fast & Frugal (F&F) and regression models are popular methods for judgment analysis. These have shown to be differently suitable at modeling decision behavior. However, little attention has been paid to whether these models are differently suitable depending on the level of the expertise of the decision maker. In this study we compared and cross validated the fit and prediction of three logistic regression models (each model using different cue inclusion methods) and two F&F models (Take The Best and an extended version of Take The Best) on clinical judgments of doctors with different expertise levels. The three expertise groups were: 21 medical students, 27 general practitioners, and 22 cardiologists. The task was to judge the probability of heart failure in 40 real patient cases, each case consisting of ten cues. Results showed that the fit and prediction did not differ significantly in the f&f models for the different expertise levels. In LR, however, general practitioners had the worst fit and prediction while cardiologists had the best fit and prediction. This can be explained by the "intermediate-effect" for medical expertise (Schmidt, Boshuizen, 1993) which means general practitioners decide more according to guidelines, while the students decide more based on intuition because they do not have enough knowledge, and cardiologists have more automated decision making. Nevertheless the results of this study also shows that in judgment analysis, the level of expertise has an important impact on the modeling, and LR models are better at capturing this impact.

### E276

**BLACK AND WHITE OR SHADES OF GREY: HOW DIFFERENT CONCEPTIONS OF MORALITY SHAPE PERCEPTIONS OF THE WRONGNESS OF ACTIONS** Kimberly A. Hartson<sup>1</sup>, David K. Sherman<sup>1</sup>; <sup>1</sup>University of California, Santa Barbara – How does seeing morality as a black and white construct versus a spectrum in which actions may be more or less wrong affect individuals' perceptions of acts and their willingness to do acts? The present study examined how two conceptions of right and wrong, as black and white categorical constructs or as continuous constructs in a spectrum of shades of grey, affect participants' ratings of acts and their willingness to do similar acts. Participants rated the rightness or wrongness of several scenarios, each describing an instance of academic dishonesty, on either a categorical scale, as right or wrong, or on a continuous scale, from 1-right to 100-wrong. Following each rating, participants indicated the extent to which they would do the act if in a similar situation. Results indicate that the scale on which participants rated the act significantly affected how they thought of the act with more individuals rating the acts as wrong, on average, in the continuous rather than the categorical condition. Additionally, the differing scales affected participants' later willingness to do the act with those in the categorical condition indicating more willingness to do a similar act than those in the continuous condition. The results suggest that it's easier for people who view morality as continuous to judge actions as wrong because they need only judge them as somewhat wrong, while those who view morality as categorical are forced to make stronger judgments, that actions are absolutely wrong. Discussion centers on implications for psychological research and moral decision-making.

### E277

**ADAPTIVE RELIANCE ON FLUENCY IN JUDGMENTS OF TRUTH** Sabine Czenna<sup>1</sup>, Rainer Greifeneder<sup>1</sup>, Herbert Bless<sup>1</sup>; <sup>1</sup>University of Mannheim, Faculty of Social Sciences, Germany – Past research has reliably demonstrated that repeated statements are more frequently judged to be true (e.g., Hasher, Goldstein, & Toppino, 1977). This so-called truth-effect is

often explained in terms of metacognitive experiences of fluency, suggesting that repeated statements are more frequently judged to be true because they are processed more fluently. Interestingly, while most prior research focused on why fluency influences truth judgments, less is known about when fluency is used as a cue in judgments of truth. Three studies addressed the moderating role of fluency's perceived validity. In particular, we hypothesized that participants use fluency as a source of information if fluency has proven to be a valid cue in the past. In contrast, if relying on fluency has proven to be a misleading cue, individuals should not use fluency as a source of information. To test this hypothesis, we manipulated participants' experiences with the validity of fluency as a source of information in a learning task (valid vs. not-valid) and then assessed reliance on fluency in subsequent tasks. These tasks were either identical, similar, or different from the learning task. The experiments consistently demonstrate that fluency is used as signal of truth particularly if fluency has proven to be a valid cue in the past. This suggests that the use of fluency in truth judgments is not an inevitable automaticity, but an adaptive process that reflects cue validities. Consequences for our understanding of the truth-effect and the adaptive use of fluency are discussed.

### E278

**"I KNOW THIS IS BIASED, BUT...": EFFECTS OF KNOWINGLY ENGAGING IN A BIASED PROCESS** Katherine Hansen<sup>1</sup>, Emily Pronin<sup>1</sup>, <sup>1</sup>Princeton University – People are reluctant to see themselves as biased even while they readily recognize bias in others. This error in self-perception, or "bias blind spot," is due to the unconscious nature of bias; when introspecting, people do not find any conscious evidence of bias in themselves and therefore assume objectivity. How far does this tendency go? Two experiments examined whether people would claim objectivity even in cases where they were aware that the process leading to their judgment was biased (e.g. when that process involved evaluating the validity of a test by focusing only on its weaknesses). Participants took a test, received failure feedback on it, and then were asked to assess the test's quality by using either a biased process (focusing only on the test's weaknesses) or an unbiased one. Participants who were instructed to use a biased evaluative procedure rated that procedure as biased, engaged in it, and then claimed to have been objective in their evaluation of the test. In other words, participants knowingly engaged in a biased process, but in the end still claimed objectivity. These experiments suggest the difficulty of inducing people to recognize the presence of bias in their judgments. Even when people recognize that their judgmental processes may be biased, they nonetheless appear inclined to view the decisions resulting from those processes as objective.

### E279

**WHAT MAKES YOUR HEART BEAT FASTER?: CARDIOVASCULAR STRESS REACTIVITY, RISK PERCEPTION, AND EXPECTED BENEFITS** Wan H. Ellen Yeung<sup>1</sup>, Elaine Perea<sup>1</sup>, Michelle N. Shiota<sup>1</sup>; <sup>1</sup>Arizona State University – Previous studies of the relationship between stress and risk-taking have produced inconsistent findings. Several studies have found that state stress increases people's risk-taking, whereas other studies find that individuals showing high dispositional stress reactivity are more likely to be risk-averse. Many of these studies emphasize risk perception as the key link between stress and risk. However, the risk-return model argues that risk behavior is the result of a tradeoff between perceived risk and expected benefit (Sarin & Weber, 1993), and stress may influence the latter component as well. The present study examined the relationship between intensity of physiological responses to psychosocial stress and dispositional risk-taking, risk perception and expected benefit. Participants completed a questionnaire assessing these three aspects of dispositional risk (Weber et al., 2002) during prescreening. Then, cardiac interbeat interval (IBI, the inverse of heart rate) was measured while participants performed a stressful mental arithmetic task with negative social feedback in the laboratory. Greater baseline-to-trial reduction in IBI was significantly associated with higher self-reported risk behavior. Risk perception showed no relationship with cardiac reactivity. However,

those with greater cardiac reactivity tended to score higher on expected benefit associated with risk. Our findings highlight the importance of expected benefits in models of risk behavior, and suggest that accounting for both perceived risk and expected benefits in such models may help clarify the relationship between stress and risk.

### E280

**THE EFFECT OF STRATEGIZING ON THE SUBJECTIVE IMPORTANCE OF DECISIONS** Aaron S. Wallen<sup>1</sup>, Malia F. Mason<sup>1</sup>; <sup>1</sup>Columbia University – We investigated whether strategizing for a decision affected its subjective importance to the decision-maker. Central to our prediction is the notion that people overestimate the importance of decisions when they fail to adequately plan how much to invest in a given decision. We predicted that, when considering decision options prior to strategizing for a decision, people would ascribe greater importance (measured by time allocated and number of reasons generated for options) to a decision compared with people who considered options after strategizing. To test this prediction we recruited adult participants (N = 154) and presented each participant with four decision scenarios. Each scenario differed with respect to timing of strategizing (before or after generating reasons to support each option). The data were subjected to a mixed-model regression (participant effects were treated as random) using Hierarchical Linear Modeling. A statistically significant main effect suggested that, when participants did not strategize regarding how much time to invest in a decision prior to considering their options, they expected to allocate more time to a decision ( $p < .05$ ) and identified more reasons to support selection of each option ( $p < .05$ ) than when they explicitly strategized prior to consideration of response options. These results supported our prediction that failing to strategize for a decision prior to consideration of alternatives can lead to overestimation of decision importance. We discuss implications of these findings for theory and decision-making in several contexts.

### E281

**IDEAL ATTRIBUTES OF POLITICAL CANDIDATES IN NEAR AND DISTANT FUTURE ELECTIONS** Kate Jassin<sup>1</sup>, Jeremy Ginges<sup>1</sup>; <sup>1</sup>The New School for Social Research – Consider the characteristics you would like to see in the next President of the United States. Common sense might suggest that your preferences about such an important issue will remain relatively stable over time; your decision about which candidate best fits your ideal may change but presumably your ideal should remain constant. Construal Level Theory (CLT; Liberman & Trope, 1998) suggests different predictions. According to CLT, temporal distance influences the way we think about objects or events; the greater the temporal distance the more we invoke and rely on higher level construals that are more schematic, abstract, and rely more on the central features of events or objects. CLT has been supported by a number of studies that typically involve hypothetical and mundane scenarios (e.g., moving into a house, negotiation games, buying a clock radio or sitting for an exam). Thus it is unclear whether temporal distance will influence the way people think about a non-mundane issue: ideal attributes for the next President of the United States. One week before the New York primaries we manipulated temporal distance by asking participants to list the ideal attributes they look for in a presidential candidate in the New York state primaries (near future) or the general presidential election (distant future). Participants in the distant future condition listed more abstract attributes (e.g. personality traits) than in the near future condition, and fewer concrete attributes (e.g. leadership skills). We discuss implications for understanding changes in preferences for candidates to elected office over time.

**E282****FUTURE ACTION INFLUENCES THE CONTENT OF SPONTANEOUS AUTOBIOGRAPHICAL MEMORY: A NEW PARADIGM**

Meredith Lanska<sup>1</sup>, Avi Ben-Zeev<sup>1</sup>, Ezequiel Morsella<sup>1,2</sup>; <sup>1</sup>San Francisco State University, <sup>2</sup>University California, San Francisco – Social cognition research has revealed that daydreaming and wandering thoughts are far from indeterminate and can be influenced by goals, future tasks, and evaluations of past events. For example, in our previous (content analysis-based) study, intrusive cognitions (about geography) were triggered automatically by anticipating a future task (geography quiz) that could benefit from forethought. Can such data be collected using continuous measures? In a paradigm examining whether the contents of autobiographical memory are also influenced by future tasks, participants ( $n = 30$ ) were told that they would later have to interact with an expert in chemistry (a challenging task). (Controls,  $n = 29$ , were told that they would later view an expert lecture about chemistry.) After the experimental manipulation, participants were asked to reflect freely upon their autobiographical memories. Using a new method of assessing memory content, participants were then shown a series of photographs of different daily settings – academic, artistic, competitive, familial, professional, and recreational – and asked to rate on a continuous scale how representative each setting was of their autobiographical memory. Faced with the challenge of interacting with an expert in chemistry, and consistent with prior research, experimental participants had more autobiographical memories about recreational environments than did controls,  $F(1, 58) = 7.682, p < .05$ , but they did not have more academic-related memories, which was our primary prediction. A follow-up study is re-examining this intriguing effect. More generally, this paradigm provides an effective way of assessing mental (episodic memory) content using a continuous measure.

**E283****BROTHER, CAN YOU SPARE A DIME? HOW RELIGION AND GOD PRIMING AFFECT INGROUP AND OUTGROUP SWINE FLU DONATIONS DIFFERENTLY**

Ivan Hernandez<sup>1</sup>, Jesse Lee Preston<sup>1</sup>; <sup>1</sup>University of Illinois at Urbana-Champaign – Past research has used religion and God primes interchangeably. However, the function and development of these two concepts have been theorized as serving distinct purposes. Religion is thought to have evolved as a way of aiding survival by associating with similar others and disassociating with dissimilar outgroups. God, on the other hand, is theorized as being associated with positivity and vigilance. In this study, the proposed dichotomy between religion and God was examined in the context of prosocial behavior. Priming religion should lead to more ingroup protective behaviors while priming God should lead to more outgroup favoritism. After being primed with either religion, God, or a control condition, 88 participants around the University of Illinois campus completed a brief survey informing them of the Swine Flu epidemic, and asking them to allocate a portion of a 99 cents between the American (ingroup) and the Mexican Red Cross (outgroup). Participants in the control condition showed an ingroup bias, donating more to the US than to Mexico as did participants primed with religion. However, participants primed with God showed a reverse effect, allotting more money to the outgroup. When primed with religion, however, total donations decreased to both the ingroup and outgroup. Further analyses revealed that this decrease occurred only among religious participants. The results suggest that the treatment of religion and God as equivalent in priming is perhaps unwarranted, and that the two concepts have distinct mental representations.

**E284****MENTAL STATE DECODING IN DYSPHORIC INDIVIDUALS: THE ROLE OF SOCIAL MOTIVATION**

Brooke M. Sinclair<sup>1</sup>, Kate L. Harkness<sup>1</sup>, Jill A. Jacobson<sup>1</sup>, Emilie Chan<sup>1</sup>, Kevin Rounding<sup>1</sup>; <sup>1</sup>Queen's University – Individuals with mild to moderate depression (i.e., dysphoria) show an enhanced ability to decode others' mental states (e.g., Harkness et al., 2005). According to Weary et al. (1993), dysphoric individuals' expectations of

uncontrollability often are accompanied by uncertainty about their ability to understand, predict, and control the social world. These feelings are hypothesized to elicit a goal of accurate causal understanding resulting in a more sensitive, effortful, and vigilant search for and processing of social information. Such processing could yield more accurate or at least less biased social judgments. The goal of the current research was to investigate social motivation as an underlying mechanism contributing to dysphoric individuals' greater mental state decoding accuracy. Participants engaged in a mental state decoding task that involved attributing emotions to photographs of eyes. Before the task, participants were randomly assigned to one of three motivation conditions. In the control condition, participants received no additional instructions. In the monetary motivation condition, they expected to receive more tickets for a cash prize drawing, the more emotions they identified correctly. The instructions for the social motivation were adapted from Twenge et al.'s (2001) social exclusion manipulation. Specifically, participants were told that poorer performance on the task was predictive of greater loneliness and social problems later in life. Dysphoric individuals showed the greatest accuracy under the social motivation followed by the monetary motivation and then the control condition. Nondysphoric individuals, in contrast, performed best under the monetary motivation with no difference between the social motivation and control conditions.

**E285****THE PROJECTION OF MOTIVATIONAL ORIENTATIONS AS A FORM OF EGOCENTRIC BIAS**

Karl-Andrew Woltin<sup>1</sup>, Vincent Yzerbyt<sup>1</sup>, Olivier Comeille<sup>1</sup>; <sup>1</sup>Catholic University of Louvain at Louvain-la-Neuve, Belgium – Egocentric biases in social predictions of others are well-documented in social psychology (e.g., Krüger, 1998) and initial evidence has been found for the projection of implicit and explicit goals (Kawada et al., 2004). However, research has so far not investigated the projection of motivational orientations, independent of specific goals, which is the aim of the current research. While regulatory focus (Higgins, 1998) differs chronically between individuals, it can also be induced by situational framing. In line with the distinction between strong and weak situations (Snyder & Ickes, 1985) we assume that in strong situations (concerning the self) individuals will be sensitive to the situational promotion or prevention framing. However, in weak situations (concerning others) we assume individuals to rely on their chronic regulatory focus and thus to project. Study 1 measured chronic regulatory focus and used a prevention focus framing of a situation that depending on condition concerned either the self or another student. Prevention- and promotion-emotion ratings were assessed as dependent variables. Results confirmed our hypothesis and indicated that in predicting their own emotions, individuals' chronic prevention focus indeed did not have an impact. However, when predicting others' emotions, the chronic orientation is projected. Study 2, using a promotion focus framing, replicated the results for promotion focus and additionally found evidence for projection on measures of behavioral reactions. Taken together, not only attitudes and goals are projected, but also very basic motivational processes. These findings potentially shed a new light on scenario studies due to regulatory focus projection.

**E286****THE EFFECT OF REGRETS ON REPEATED MISTAKES**

Rumiko Dohke<sup>1</sup>; <sup>1</sup>Asia University Junior College – Previous research has shown that regrets caused by the upward counterfactuals lead to improved future performance. However, people sometimes fail to learn from regrets and they make the same mistake again. The present study aimed to examine when people make the same mistake as last time. It was predicted that they would make the same mistake when the intensity and the salience of regrets were reduced. Participants read a scenario in which a person made a mistake to feel regret about. To manipulate the intensity of regret, the end of the event in the scenario was described either positive or negative. Participants in the salient regret condition rated the likelihood that the target person would make the same mistake in the future, immediately after reading the scenario. Participants in the less salient

regret condition judged it following the filler task which was conducted to decrease the regret salience. As expected, participants in the salient regret condition judged that the target person would be more likely to repeat the same mistake when the end of the event was positive than when it was negative. Participants in the less salient regret condition judged high likelihood of the same mistake whether the end of the event was positive or negative. The result of this study indicated that regrets could help to prevent the same mistakes only when people have the great intense and high salient regret.

### E287

#### **EGOCENTRIC PREDICTIONS ABOUT OTHER PEOPLE'S EMOTIONAL STATES: WHEN WE DON'T PROJECT OUR OWN EMOTIONAL EXPERIENCE TO PREDICT OTHER PEOPLE'S EMOTIONAL STATES.**

**Eriko Kudo<sup>1</sup>**; <sup>1</sup>Tokyo Woman's Christian University – People tend to overestimate negative emotion they experience after negative events (impact bias). If we rely on our own experience to predict others' emotional states, those who have actually experienced the negative event might not overestimate the emotional impact of the same negative event on others. On the other hand, we might egocentrically make predictions about others' emotional states. Such that we might not project our own experience because we think our experience is unique. Sixty six female undergraduate students were randomly assigned to role (experience or forecaster) and margin (narrow or wide) conditions. They missed or asked to imagine they had missed a reward by a narrow margin or by a wide margin. And they were also asked to imagine the emotional state of an average student in the same situation. Those participants who missed a reward by a narrow margin experienced regret but much less than they had expected. However, those participants didn't project their emotional states to an average student when asked to predict her emotional state. Their predictions didn't differ from those who not experiencing the event and had no chance of knowing their predictions were wrong. Overall, the estimated regret for an average student was more intense. The actual experience of negative event and regret didn't produce any difference in the prediction of others' emotional experience. These results suggest that we egocentrically make predictions about others' emotional states not projecting our own unexpected experience because we think our own experience is unique.

### E288

#### **BIASED ABOUT OTHERS' BIASES? NAIVE BELIEFS ABOUT OTHERS' MOTIVATED CONSENSUS PERCEPTION**

**Joanne Kane<sup>1</sup>, An Oskarsson<sup>2</sup>, Leaf Van Boven<sup>3</sup>**; <sup>1</sup>Princeton University, <sup>2</sup>University of California, Davis, <sup>3</sup>University of Colorado, Boulder – Individuals tend to be unaware of their own biases, but able to perceive bias in others' judgments. The goal of the present research was to investigate the explanations people give for others' social projection. In Experiments 1 and 2 we found that individuals believe other people exhibit both false consensus and false uniqueness biases in strongly self-serving ways. In Experiment 3, we explicitly manipulated others' level of motivation and found that the overestimation of the false consensus effect in others is moderated by people's beliefs about the strength of the others' motivations to maintain favorable self-views. The results of the three experiments suggest that individuals expect others to exhibit self-enhancing biases, and believe that the strength of the self-enhancing bias depends on others' motivations and personalities.

### E289

#### **QUANTIFYING THE COSTS OF THE NATURALNESS BIAS**

**Chia-Jung Tsay<sup>1</sup>, Mahzarin Banaji<sup>1</sup>**; <sup>1</sup>Harvard University – In previous research on the judgment of musical talent, we demonstrated a dissociation between an explicit endorsement of hard work ("strivers") and the actual preference for innate talent ("naturals"). This naturalness bias was visible in the data of music experts but not novices. In this experiment, we quantify the costs of the naturalness bias using conjoint analysis, a methodology which allows the deduction of preferences from the tradeoffs made when choosing between sets of attributes. Participants (N=466) encountered target individuals who differed on several attributes, some of

which were objective (positive critic reviews, repertoire size, prior performance record); others of which were not (natural/striver, ethnicity). The attributes of musicians that were created for this purpose allowed us to include an additional variable, ethnicity, a social category that we have not tested previously and that may be related to the naturalness bias. In addition to replicating the naturalness bias in experts, we found that those with the greatest level of expertise were most likely to trade off better-qualified musicians in favor of hiring the natural musician. We also found that experts were more likely to select on the basis of group membership, with group membership itself being viewed as a proxy for naturalness. Some domains, like music and the arts, where judgment criteria for talent are subjective, are prone to the presence of disparities between beliefs that are proclaimed (such as faith in hard work) and actual preferences exhibited in judgment and decision-making.

### E290

#### **SELF-CONSTRUALS AND RISK TAKING**

**Jo Sasota<sup>1</sup>**; <sup>1</sup>The Ohio State University – Two studies examine whether self-construals influence risk taking. Interdependent self-construals were hypothesized to result in less risk taking than independent self-construals. Because an interdependent individual tends to construe the self within the context of his social relationships, he will take into account his interpersonal relationships when making decisions that involve risk; however, because an independent individual tends to construe the self as stable and separate from interpersonal connections, he will not take into account his interpersonal relationships when making decisions that involve risk (Markus & Kitayama, 1991). Presumably, one can assume more risk when one only thinks of oneself than when one has to consider others. Participants were induced to construe the self independently vs. interdependently by circling independent (e.g., I, mine) vs. interdependent (e.g., we, ours) pronouns (Study 1, Brewer & Gardner, 1996) or by thinking of a decision involving a non-family vs. a family member (Study 2, Trafimow et al., 1991). Participants then completed the Choice Dilemma Questionnaire (CDQ) (Kogan & Wallach, 1964). The CDQ measures risk taking by asking individuals to respond to hypothetical situations. Each situation presented a choice between two courses of action: (a) a high-risk, high-reward action or (b) a low-risk, low-payoff action. Individuals select the minimum odds for success they would require before pursuing the high-risk option. As predicted, in both studies, participants who were induced to construe the self independently were willing to assume more risk (i.e., higher CDQ scores) than participants who were induced to construe the self interdependently.

### E291

#### **IN THE MOOD FOR CONTROL: NEGATIVE MOOD FACILITATES RULE-BASED DECISION MAKING IN A SIMPLE RULE GAME**

**Eefje Rondeel<sup>1</sup>, Marieke De Vries<sup>2</sup>, Rob W. Holland<sup>3</sup>, Niek Wijngaards<sup>1</sup>, Masja Kempen<sup>1</sup>, Ad van Knippenberg<sup>3</sup>**; <sup>1</sup>D-CIS Lab/TRT-NL, The Netherlands, <sup>2</sup>Leiden University Medical Center, The Netherlands, <sup>3</sup>Behavioural Science Institute, Radboud University Nijmegen, The Netherlands – Previous research showed that positive mood individuals are more likely to base their decisions on recent experiences than negative mood individuals. We tested the complement idea that a negative mood facilitates rule-based decision making. In order to follow a specific rule, individuals should be able to inhibit tendencies to act on experience. The latter suggests that, in addition to mood, cognitive control is of importance in rule-based decision making. Subjects participated in a task that investigated rule versus experience-based decision making. Beforehand, individual differences in cognitive control were assessed. Participants repeatedly chose between two gambles: gamble A with a 50 % chance of winning 500 points and a 50 % chance of winning 50 points, and gamble B with a 50 % chance of winning 250 points and a 50 % chance of winning 50 points. Sticking to the simple rule of always choosing gamble A would increase winnings. Individual differences in mood were measured afterwards. In line with our hypothesis the results showed that a more positive mood was associated with more switches from gamble A to B. Interestingly, the number of games subjects played before switching to gamble B was found to be

dependent on the interaction between mood and cognitive control. Less positive mood states resulted in more rule-based decision making, but only when subjects had high levels of cognitive control. Apparently, when in a negative mood, the use of cognitive control is triggered by the characteristics of the situation.

**E292**

**UNCONSCIOUS THOUGHTS? MOOD, NOT LEVEL OF CONSCIOUSNESS, PREDICTS DECISION QUALITY** E. Samuel Winer<sup>1</sup>, Daniel Cervone<sup>1</sup>, Marina Fiori<sup>1</sup>, Ritu Tripathi<sup>1</sup>, Jennifer Veilleux<sup>1</sup>, Dariusz Barwacz<sup>1</sup>; <sup>1</sup>University of Illinois at Chicago – Unconscious Thought Theory (Dijksterhuis & Nordgren, 2006) posits that people make better complex decisions when allowed sufficient time to process information unconsciously. In one study, Dijksterhuis et al. (2006, study 1) found that when considering four cars of varying quality, people who consciously deliberated about a car purchase made poorer choices than people who were distracted before choosing. A recent critique of this study (Lassiter et al., 2009), has shown that the task's instructions alter participants' goals at the stage of encoding. Similarly, people in the conscious condition may face a more unfamiliar task than those in the unconscious condition, because they are overloaded with information that is beyond the limits of short term memory. Thus, the effect may have resulted from impaired conscious encoding as opposed to facilitated unconscious encoding. We therefore altered the order of car attributes presented to make the task complex yet manageable, while retaining the unconscious and conscious conditions. We predicted that this would increase conscious, but not unconscious, choice quality. We also assessed mood to determine whether it was associated with performance regardless of condition (e.g., Schwarz et al., 1991). We found that conscious and unconscious conditions did not differ in choice quality, Wald (1, N = 74) < 1, ns, despite unconscious performance remaining at approximately the same percentage as in Dijksterhuis et al. As well, we found that positive mood predicted performance, regardless of condition, with those reporting a higher positive mood more successfully choosing the best car, Wald (1, N = 74) = 3.96, p < .05.

**E293**

**VERB ASPECT AFFECTS MENTALIZING AND ATTRIBUTIONS OF PSYCHOLOGICAL AGENCY** William Hart<sup>1</sup>; <sup>1</sup>National Opinion Research Center (NORC) at the University of Chicago – People often view agents along a continuum of psychological agency; some agents are viewed as possessing small amounts of purpose, intention and forethought behind their actions and others are viewed as possessing large amounts of these psychological characteristics. We predicted that the verb used in a linguistic description of an agent's prior actions might influence tendencies to mentalize (i.e., attribute psychological states to an agent) and, in turn, judgments of an agent's level of psychological agency. In four experiments, we tested whether describing an agent's prior actions in terms of what the agent was doing versus did would enhance mentalizing and psychological agency judgments. In each experiment, participants read action descriptions conveyed in terms of either what the agent of the actions was doing or did (e.g., "Keith was making/made small talk with his neighbor"). Subsequently, participants completed measures to assess the accessibility of the mentalizing process and the amount of psychological agency attributed to the agent. In Experiment 1, we found that the reading of what an agent was doing (vs. did) enhanced psychological agency attributions by promoting mentalizing. Experiments 2 and 3 established the generality of this linguistic effect on psychological agency attributions, and Experiment 4 showed that this effect required cognitive resources. All in all, this research contributes to the understanding of the language-thought interface, and it provides novel evidence of how language influences mentalizing and psychological agency attributions.

**E294**

**ENVIRONMENTAL GROUP DECISION MAKING** Juliana A. Smith<sup>1</sup>, Nicole A. Yoskowitz<sup>1</sup>, Gaby Reijseger<sup>2</sup>, Michel J.J. Handgraaf<sup>2</sup>, Elke U. Weber<sup>1</sup>; <sup>1</sup>Columbia University, <sup>2</sup>University of Amsterdam – Decisions related to the environment typically involve uncertainty about outcomes that are realized at different points in time, and often generate conflict between material and moral/ethical goals. Environmental decisions are also frequently made by groups, in part because support by a large number of people is necessary for their successful implementation. Our study therefore examined environmental decision making in a group context. Three-person groups were asked to consider a scenario that described different types of windmills to reduce carbon emissions. The two windmill types varied in the certainty about carbon emission reduction and when it would occur. Half of the 50 groups (predecided) had previously individually considered the decision, whereas the other half (naïve) saw it for the first time in the group. The decision was how much out of a specified development budget to allocate to one or both of two types of windmills. Group discussions were videotaped and transcribed. After the group decision, participants could revise their individual decisions anonymously. There was no significant difference in the group decisions between predecided and naïve groups. However, individual decisions prior to the group discussion influenced the frequency with which arguments supporting prior decisions were raised in the group discussion. Decision makers from predecided groups also seemed more satisfied with the group decision, i.e., they were less likely to deviate from the decision made by their group than individuals from naïve groups. These results have implications for the design of group processes for environmental decisions.

**E295**

**THE MODERATING ROLES OF CHRONIC REGULATORY FOCUS IN THE REVERSED REFLECTION EFFECT OF DECISION MAKING** Taekyun Hur<sup>1</sup>, Yulwoo Park<sup>1</sup>, Moonki Hong<sup>1</sup>; <sup>1</sup>Korea University – The reflection effect of the prospect theory in which people are more likely to take risks in loss domains but avoid risks in gain domains has been robust in numerous studies. But a few recent studies proposed and found that the reflection effect could be reversed in fun-related contexts (taking risks in gain domains and avoiding risks in loss domains) rather than in traditional materialistic contexts (Hur, Namkoong, & Roese, 2008). The Regulatory focus theory has been proposed to underlie such reversal, since people are relatively promotion-focused in leisure and prevention focused in work. The present study examined directly the role of chronic regulatory focus on the reversal of the reflection effect. 146 college students completed a chronic regulatory focus and then made decisions in 4 leisure- and 4 work-related contexts framed as either gain or loss (the last frame condition was a between-subject factor). The results revealed that chronically promotion-focused participants preferred risky choices in the gain-framed leisure contexts. Among chronically prevention-focused participants, an interaction effect was reported in which risks in loss (vs. gain) domains was preferred in work contexts and vice versa in leisure contexts. The results replicated the reversal of the reflection effect and, more importantly, partially supported the moderating role of chronic regulatory focus in the reversal of the reflection effect. Implications of the results were also discussed in psychological mechanisms underlying fun-effects in decision making and cultural and individual differences.

# Poster Session F

Saturday, January 30, 12:30 – 2:00 pm, Grande Ballroom

## Culture

### F1

**CULTURE, SOCIAL SUPPORT, AND SEXUAL RISK** Jeffrey M. Hunger<sup>1</sup>, Paul Robert Appleby<sup>2</sup>, John L. Christensen<sup>2</sup>, Lynn Carol Miller<sup>2</sup>, Steven J. Read<sup>2</sup>; <sup>1</sup>California State University-Fullerton, <sup>2</sup>University of Southern California – For some men who have sex with men (MSM), intercourse with a primary partner as well as non-primary partners is common. Previous research has shown that condom use with a non-primary partner is greater than with a primary partner; within a primary relationship, the lack of a condom during intercourse reflects trust and intimacy, leading to their diminished use. However, individuals in a relationship who engage in unprotected anal intercourse (UAI) with a non-primary partner can put their primary partner at a greater risk for HIV and sexually transmitted infections. There is a need to explicate individual and socio-cultural factors that promote greater condom use during intercourse outside of the primary relationship in order to create tailored safer sex interventions. In a sample of 244 MSM with both primary and non-primary partners, the relationship between perceived social support and sexual risk (i.e., UAI with non-primary partners) was examined across ethnicities. Controlling for age and attitudes toward condom use, negative binomial regression analyses revealed that significant other support (for African Americans and Caucasian MSM) and family support (for African American MSM) predicted less UAI with non-primary partners. Conversely, family support was paradoxically related to a greater amount of UAI with non-primary partners among Latinos. Although further research is needed to clarify the exact mechanisms underlying these findings, the current results stress the importance of a culturally-tailored approach to behavioral interventions.

### F2

**SEXUAL MINORITY STATUS AND SUBSTANCE USE OUTCOMES IN EMERGING ADULTHOOD** Amelia Talley<sup>1,2</sup>, Kenneth Sher<sup>1,2</sup>; <sup>1</sup>University of Missouri, <sup>2</sup>Midwest Alcoholism Research Center – The current study sought to examine developmental changes in substance use patterns among sexual minority and majority individuals. The analyses also attempted to address a number of methodological limitations in the extant longitudinal literature. (i.e., timing of sexual identification assessment; linear growth modeling). Data from a longitudinal study of incoming first-time college students at the University of Missouri–Columbia were used in the current study. Participants were asked to complete a Web-based survey every fall and spring for four years (n = 2854). Latent growth models revealed that sexual minorities in emerging adulthood demonstrated significant heterogeneity with regard to substance use trajectories, controlling for age, race, ethnicity, and gender. Also, initial levels of and changes in the frequency of substance use over emerging adulthood were distinct, generally, for sexual minority individuals, as compared to their heterosexual peers. The timing of the assessment of sexual minority status influenced the conclusions drawn from the results. Additionally, curvilinear models supported that some sexual minorities were especially prone to accelerate in their frequency of certain substance use behaviors over time (i.e., drunkenness; cannabis use). Findings may inform models of sexual identity development by providing information regarding the etiology and course of risk behaviors for the GLB community. The results also suggest, in the very least, sexual minority individuals may need to be exposed to interventions prior to their early twenties, to prevent the acceleration of problematic substance use.

### F3

**THE RELATIONSHIP BETWEEN LINGUISTIC EXPRESSIONS AND SELF-CONSTRUAL -- AN EMPIRICAL STUDY USING JAPANESE SAMPLE** Victoria Wai-lan Yeung<sup>1</sup>, Masaki Yuki<sup>1</sup>, Melody Chao<sup>2</sup>; <sup>1</sup>Hokkaido University, Japan, <sup>2</sup>University of Illinois at Urbana-Champaign, United States – Many researchers have noted the cultural difference in linguistic expression: Eastern communicators tend to use implicit and indirect expressions, whereas Western communicators tend to use explicit and direct expressions. They explain this in terms of the differences in individualistic vs. collectivistic cultures, low- context vs. high-context cultural system (Hall, 1976; Ting-Toomey, 1985), and independent vs. interdependent self-construal (Gudykunst et. al, 1996). However, these conclusions were not empirically-based. In this paper, using Japanese samples, we tested if Japanese would be more likely to use indirect than direct expressions, and how the directness would be related to cultural self-construals. One hundred and one Japanese read 20 scenarios and in each scenario rated how likely they would use each of the presented utterances (direct, indirect, and very indirect). Results showed that Japanese were more likely to use indirect and very indirect utterances than direct utterances. And female (male) were more likely than male (female) to use indirect (direct) expressions. Participants also completed Takata's (2000) self-construal scale. Results showed that the higher participants' independent self-construal score, the more likely they used direct utterances, and the higher their interdependent self-construal score, the more likely they used indirect utterances and less likely they used direct utterances. This study, using Eastern sample, provides empirical evidence for the claim that was made in the past research.

### F4

**PERCEPTIONS OF SOCIAL SUPPORT AMONG CAUCASIANS, ASIANS, AND LATINOS** Christine Chu<sup>1</sup>, Belinda Campos<sup>1</sup>, Roxane Cohen Silver<sup>1</sup>, Eric Knowles<sup>1</sup>; <sup>1</sup>University of California, Irvine – Research on cultural influences on social support processes has typically focused on East-West differences. We extend previous work by examining perceptions of social support among Caucasians, Asians, and Latinos in the United States. Among Caucasians, social support from family and friends has been found to be beneficial when it does not diminish the self (Bolger & Amarel, 2007). Emerging research shows that Asians consistently benefit from perceived social support but are more reluctant to seek it than Caucasians (Taylor et al., 2004). Latinos, however, are more likely to endorse explicit social support seeking (Campos et al., 2008). In the present study, 1,001 university students (247 Caucasians, 294 East Asians, and 117 Latinos) completed an online survey that included measures of demographics, acculturation, perceptions of social support, and personality. As expected, Asian Americans and Latino Americans, members of two distinct interdependent cultures, varied in their perceptions of emotional/informational support, tangible support, affection and perceptions of positive social interaction. Asian Americans consistently reported the lowest levels of social support. In contrast, Latino Americans reported comparable or higher levels of social support than Caucasians. Level of acculturation to the US and the participants' culture of origin had different associations with the various types of social support for Asian Americans and Latino Americans. Although Asians and Latinos may appear to share relationship process similarities because they are both members of interdependent cultures that highlight the importance of the group, the cultural scripts of harmony and *simpatía* emphasize different approaches to relationships.

**F5****RESIDENTIAL MOBILITY AND INTERDEPENDENCE WITH PLACE** Kate

Pickett<sup>1</sup>, Tugçe Kurtis<sup>1</sup>, Glenn Adams<sup>1</sup>, <sup>1</sup>University of Kansas – Environmental psychology and cultural psychology hold in common that places are psychologically constituted and constitutive of the psychological. Research in cultural psychology has focused on the experience of embeddedness in relational contexts (e.g. Markus & Kitayama, 1991; Oishi, Lun, & Sherman, 2007; Anderson, Adams, & Plaut, 2008). However, in the present study we extend this idea of embeddedness in social-relational context to consider embeddedness in physical-place context. Specifically we consider interdependence with place: the extent to which people experience self and identity as embedded (versus abstracted from) particular locations. The present study focuses on the relationship between interdependence with place and residential mobility. University students completed potential measures of interdependence with place including the Rootedness Scale (McAndrew, 1998), attitudes about place connections, and inclusion of place (and community) in the self. They also reported their history of residential mobility and rated likelihood of future relocation. Results revealed that indicators of interdependence with place showed hypothesized negative relationships with both a history of personal residential mobility and intentions to relocate in the future. Discussion focuses on the mutually constituting relationship between place and subjectivity and possible refinements to understanding interdependence with place.

**F6****CULTURAL VARIATIONS IN SPONTANEOUS TRAIT INFERENCES**

Jinkyung Na<sup>1</sup>, Shinobu Kitayama<sup>1</sup>, <sup>1</sup>University of Michigan – Previous studies on Spontaneous Trait Inferences (STI) showed that while observing a behavior of another person, people spontaneously inferred the corresponding trait of the actor and ascribe the trait to him or her. However, we propose that STI is a cognitive procedure that is grounded in a cultural assumption of a person as a separate and independent entity. Thus, we hypothesized that STI would be relatively unique to people with Western cultural backgrounds. To test the hypothesis, European and Asian Americans were recruited. In the first phase of the study, they were presented with many pairs of a face and a behavior. In the second phase, they were asked to make a lexical judgment (word or non-word) and previously shown faces were served as a fixation. For the half of the word trials (congruent trials), a trait word was preceded by the face of the actor whose behaviors implied the "very" trait word. For the remaining half (control trials), the face was paired with an irrelevant trait. We found that European Americans showed a STI effect such that a lexical judgment of a trait word was faster in congruent trials than in control trials. Moreover, the STI effect was positively correlated with their memory on information presented in the first phase. In contrast, for Asian Americans, there was no difference in RT between congruent and control trials. Furthermore, the correlations between STI and memory were not significant although they remembered as much information as European Americans did.

**F7****POST-DECISIONAL JUSTIFICATION IN THREE TYPES OF INTERPERSONAL RELATIONSHIPS: A STUDY ACROSS FOUR ACADEMIC INSTITUTIONS AND FOUR CULTURAL GROUPS** Etsuko Hoshino-Browne<sup>1</sup>, Barry Schwartz<sup>1</sup>,

Anjali Thapar<sup>2</sup>, Sean Duffy<sup>3</sup>, Steven Fein<sup>4</sup>, Sharon Goto<sup>5</sup>; <sup>1</sup>Swarthmore College, <sup>2</sup>Bryn Mawr College, <sup>3</sup>Rutgers University, <sup>4</sup>Williams College, <sup>5</sup>Pomona College – Past research found that strong interdependence prevalent in collectivistic East Asian culture motivates East Asians to be concerned for and justify their interpersonal decisions, compared to North Americans (Hoshino-Browne et al., 2005). Does this mean that individualistic North Americans would not have any interpersonal concerns at all? Research (e.g., Brewer & Gardner, 1996; Oyserman, Coon, & Kenmelmeier, 2002; Tajfel & Turner, 1986; Yuki, 2003) suggests that individualistic and collectivistic orientations are not mutually exclusive, but they co-exist, albeit they may be manifested in relatively different

degrees in different cultures. Then, individualistic North Americans could be concerned for their interpersonal choices, depending on different social relationships. The current research investigated this question with three different interpersonal relationships as a target for an interpersonal decision (i.e., a family member, a close friend, and an acquaintance), among middle class European American and Asian American college students, working class college students, and the elderly (age 60–90). The consistent finding across these different cultural groups was a significant gender difference: females justified their choices for others, regardless of relationship types. However, each cultural group also showed a different pattern of post-decisional justification depending on relationship types. In particular, middle class European American and Asian American college students showed an interaction between their gender and relationship types in their justification, whereas working class college students and the elderly showed only a main effect of their gender. The result indicates variations in post-decisional justification across different SES and age groups within the US.

**F8****CULTURAL DIFFERENCES IN RESPONSE TO OTHER'S SETBACKS: THE****ROLE OF PRAISE AND SYMPATHY** Felicity F. Miao<sup>1</sup>, Shigehiro Oishi<sup>1</sup>;

<sup>1</sup>University of Virginia – Some individuals respond to a friend's setback by providing praise, while others respond with sympathy and compassion. In other words, some individuals choose to boost their friend's self-esteem, while others choose to remind their friend about possessing a self-critical attitude. Although both patterns of responding theoretically exist in all cultures, we predicted that within a friendship context, European Americans would be more likely to respond to a friend's setback by providing praise, while Asian Americans would be more likely to respond to a friend's setback by providing sympathy. In Study 1, we examined how European Americans and Asian Americans responded when their same-sex and same-ethnicity friend received a low score on a test. As predicted, European Americans provided praise, approval, and admiration more and sympathy and compassion less than Asian Americans. In Study 2, we sought to understand whether these patterns of responding differ when participants interacted with a stranger. We predicted that the culturally prevalent ways of responding to another person's setback would differ. Specifically, we predicted that within a same-ethnicity stranger context, European Americans would be more likely to respond to a stranger's low score on a test by providing sympathy, while Asian Americans would be more likely to respond to a stranger's low score on a test by providing praise. We found results in the expected direction for European Americans, but did not find cultural differences in the amount of praise provided. These findings provide empirical support for theoretical models of culture, social relations, and well-being.

**F9****CULTURE AND THE POSTER DESIGN: COMPARING THE COMPLEXITY PREFERENCES OF EASTERNERS AND WESTERNERS** Huaitang Wang<sup>1</sup>,**Takahiko Masuda<sup>1</sup>; <sup>1</sup>University of Alberta, Edmonton, Canada** – Previous

cultural research found that East Asians are more likely than Westerners to prefer context-rich information to context-impooverished information (Masuda, Gonzalez, Kwan, & Nisbett, 2008; Miyamoto, Nisbett, & Masuda, 2006). Recent findings suggest that homepages in eastern societies are more complex than western ones (Masuda, Wang, & Ito, 2008). We hypothesized that such cultural patterns of preference also exist in conference presentations. To test this hypothesis, we randomly collected 247 conference posters from the SPSP conference in 2008/09. Posters were categorized into three groups according to the first authors' names and their working locations: Easterners, Westerners and authors from the unmatched group. Easterners were scholars with eastern names, who were working in East Asia (e.g., China, Japan, and Korea); Westerners were those with North American names, who were working in North America (e.g., USA and Canada); and authors from the unmatched group were those with eastern names working in North America or vice versa. Posters were analyzed by four criteria: words, characters, pictures and tables. The results indicated that: (1) Eastern posters were more

complex than posters produced by Westerners and authors from the unmatched group when posters contained two or more studies; (2) there was no cultural effect when posters contained only one study. The results reinforced the previous cultural research on physical scenes, pictorial representations and homepage designs, and suggested that Easterners were more likely than Westerners to prefer complex designs.

### F10

#### SHOW IT OR HIDE IT? CULTURAL DIFFERENCES IN SELF-PRESENTATION STRATEGIES

Albert Lee<sup>1</sup>, Li-Jun Ji<sup>1</sup>; <sup>1</sup>Queen's University – Self-presentation is the process by which people influence the impressions other people form of them by behaving in a certain way. In highly competitive situations, such as in a boxing match or a poker tournament, self-presentation offers a useful means to create stress or anxiety in one's opponents, which may, in turn, compromise their performance. The present study examined the different ways European Canadians and Chinese present themselves in a competitive context. Their respective preference for self-presentation strategies frequently appears in historical texts, novels, movies, and other cultural products of these two cultures. In this study, we asked participants from both cultures to read scenarios involving competitions in various domains (e.g., rivalry between two athletic contestants or business firms). Participants' task was to choose a self-presentation strategy that they believed can maximize the chance of success in these situations. The results showed an interesting cultural difference: whereas European Canadians believed that revealing their strengths to their opponents is a better strategy for success, Chinese believed that concealing their strengths from their opponents is a more effective approach. Possible underlying mechanisms are discussed.

### F11

#### BI-CULTURE COMPARTMENTALIZATION AND INTEGRATION EFFECTS OF PSYCHOLOGICAL ADJUSTMENT

Weifang Lin<sup>1</sup>, Yicheng Lin<sup>1</sup>, Chinlan Huang<sup>2</sup>; <sup>1</sup>National Taiwan University, <sup>2</sup>National Taiwan University of Science and Technology – Modernization and globalization have brought values and concepts of diverse cultural together. It remains unclear, however, how one could successfully resolve these potential bi-cultural conflicts. Yang (2003) proposed that compartmentalization and integration are two ways to resolve the bi-cultural conflicts. The present research followed Showers' (1992) card sorting task to measure individual differences in the degree of compartmentalization and integration and compared the effect of compartmentalization and integration on psychological adjustments. Moreover, Zhong-Yong thinking style was hypothesized to be the underlying mechanism that leads to successful integration. Study 1 compared the differential effect of compartmentalization and integration of traditional and modern values on psychological adjustments. The results, however, were unstable. It is possible that because the current college students tended to be significantly high on modernity and low on traditionality, contrasting traditional and modern values became insensitive to index cultural conflicts. Thus, in Study 2, progressive and humble adjectives were used as material to measure degree of compartmentalization and integration. Results showed that for those people who adopted both progressive and humble values, integration strategy significantly outperformed the compartmentalization strategy on its effect on psychological adjustments. Furthermore, the integration tendency significantly correlated with Zhong-Yong thinking style. That is, people who are able to integrate the seemingly conflicting values also showed the tendency to think globally and behave flexibly. The hypothesis that Zhong-Yong thinking style is a key component to integration was supported. The implications for bi-cultural conflict resolution were discussed.

### F12

#### THE EFFECT OF RELATIONAL MOBILITY ON THE FORMATION OF INTERPERSONAL RELATIONSHIPS: A WITHIN-"CULTURE" INVESTIGATION

Joanna Schug<sup>1</sup>, Masaki Yuki<sup>1</sup>, Kosuke Sato<sup>1</sup>, Kosuke Takemura<sup>2</sup>; <sup>1</sup>Hokkaido University, <sup>2</sup>University of British Columbia – Previous studies have found that many cultural differences observed between Japan and the United States, such as the degree of similarity between friends, the impact of self-esteem on happiness, and differences in causal attribution styles, can be explained by a socio-ecological factor we call relational mobility. Relational mobility is defined as the amount of opportunities to form new relationships when necessary in a given social context, and had been found to vary across cultures. However, one benefit of taking into account socio-ecological factors such as relational mobility is that the theoretical hypotheses which apply to between-culture analysis are equally relevant to within-culture analysis. In this study, we used a representative sample of 608 adults in the United States in order to further examine the impact of relational mobility on the formation of interpersonal relationships. We predicted that relational mobility would moderate the relationship between the desire to form new relationships and the actual amount of new relationships formed in the recent past. Consistent with this prediction, we found that participants who were motivated to form new relationships were more likely to have actually done so in the recent past if they perceived their surrounding society to be high, rather than low, in relational mobility. Furthermore, a state-level analysis found that self-reported perceptions of relational mobility in one's immediate society were strongly correlated with the actual availability of new relational partners in one's state, providing evidence for the validity of different assessments of relational mobility. Future directions are discussed.

### F13

#### PROTOTYPICAL HONOR-RELEVANT SITUATIONS AND ASSOCIATED EMOTIONAL REACTIONS: A CULTURAL APPROACH

Cansu Alozkan<sup>1</sup>, Ayse K. Uskul<sup>2</sup>, Susan E. Cross<sup>3</sup>, Berna Gercek-Swing<sup>3</sup>, Bilge Ataca<sup>4</sup>; <sup>1</sup>Istanbul Bilgi University, <sup>2</sup>University of Essex, <sup>3</sup>Iowa State University, <sup>4</sup>Bogazici University – Conceptions of honor vary across cultures. We examined honor-relevant situations in Turkish and Midwestern American cultural contexts to examine features of situations that are viewed as most or least prototypical and associated emotional reactions. In Study 1, Turkish and American participants freely generated examples of situations viewed as attacks to one's honor. In Study 2, situations generated in each cultural group were rated for centrality to the prototypical honor-attacking situation by respective members of that cultural group. Honor-attacking situations rated as most prototypical by Turkish participants were more likely to have a relational reference and to include an audience than those rated as most prototypical by American participants. In Study 3, we took the most and least prototypical situations from both groups in Study 2 and asked both Turkish and American participants to rate different emotions these situations would evoke. Situations rated as most prototypical by Turkish participants evoked the most negative feelings in both samples, followed by situations rated as most prototypical by American participants. The two criteria for demonstrating prototype structure (that participants find it meaningful to judge situations in terms of their centrality and that centrality affects psychological functioning (Fehr, 1988)) were met. In sum, prototypicality of honor-relevant situations differed in the two cultural groups and prototypical Turkish situations were more potent in generating negative emotional ratings. These findings extend the study of prototypes to include situations and reveal how honor is experienced differently through prototypical situations in Turkey and the US.

**F14**

**HOW LONG CAN I SEE YOUR EMOTION? CULTURAL DIFFERENCES IN EMOTION PERCEPTION** Claudia Marinetti<sup>1</sup>, Michelle Yik<sup>2</sup>, Batja Mesquita<sup>1</sup>, Ashleigh Haire<sup>3</sup>, <sup>1</sup>University of Leuven, <sup>2</sup>Hong Kong University of Science and Technology, <sup>3</sup>Wake Forest University – In daily life facial expressions are not isolated. Rather, emotional intentions change constantly as a function of shifting relational aims (Parkinson, 2008). In this study, we were interested in the cross-cultural similarities and differences of the perception of time dynamics of emotions. We examined how long Chinese (n = 30) and American (n = 30) respondents perceived an initial emotion on faces using morphing movies that changed from an emotion expression to another. Respondents were asked to stop the movie when they ceased to see the original target emotion. The faces in the morphing movies varied in ethnicity (Caucasian vs. Asian), gender (female vs. male), and initial emotion shown (happiness vs. anger). Results showed that perception of emotion signals depended on the observer's culture as well as on the target's ethnicity and initial emotion expressed, with stronger effects for female targets than male ones. Interestingly, both respondent groups ceased to perceive anger later than happiness, this effect being stronger for Chinese than Americans. Moreover, while all respondents saw happiness longer on Asian faces than on Caucasian ones, anger was seen by both Americans and Chinese longer on ingroup faces than on outgroup ones. Finally, while Chinese judged the face in the frame at which they stopped seeing happiness as happier than Americans, Americans judged the frame at which they stopped seeing anger as angrier than Chinese. These results show that cultural differences together with environmental factors (i.e. the nature of the target) can lead to variability in emotion perception.

**F15**

**FRIEND, ALUMNI OR STRANGER, DO THEY DESERVE SAME BLAME? CULTURAL DIFFERENCE BETWEEN CHINESE RELATION-BASED AND AMERICAN GROUP-BASED RESPONSIBILITY ATTRIBUTION** Xiaowei Lu<sup>1</sup>, Kaiping Peng<sup>1</sup>, <sup>1</sup>University of California at Berkeley – Previous research on trust behavior has shown that Americans give more trust to those who share same category membership with them, whereas Chinese give trust based on interpersonal relationships. The current study explored how these category-based and relation-based cultural tendencies would influence people's perception of responsibility, blame and punishment. Two scenarios were provided to participants about bad decisions committed in working environment. Participants were assigned into four conditions in which they had different relationships with main character in each scenario: close friend, potential friend, fellow alumnus or stranger. Participants were asked to read the scenarios first, and then rated on a nine-point scale how much responsibility, blame and punishment would be assigned to main character and company in each story. One hundred and seven undergraduate students from Tsinghua University in China and UC Berkeley in US participated into the study. In the Chinese sample, participants assigned most responsibility, blame and punishment in the alumnus condition, whereas least to characters who were close friends or strangers. However, American participants assigned most responsibility, blame and punishment in the stranger condition. The results revealed that Chinese would give harsher judgment to those who shared same category membership with them, but milder judgment to those who had relationship with them. The Americans would give harsher judgment to those who have no relationship with them. The implications of the results were discussed.

**F16**

**INFORMATION GATHERING AND SELF-CONCEPT FORMULATION: DO JAPANESE DIFFER FROM NORTH AMERICANS?** Lindsay M. Schaefer<sup>1</sup>, Li Jun Ji<sup>1</sup>, Keiko Ishii<sup>2</sup>, <sup>1</sup>Queen's University, <sup>2</sup>Hokkaido University – Previous research with North Americans shows that, when people are asked questions about themselves, they recruit information that is consistent with the direction of the question, and consequently, formulate self-concepts that are congruent with the question (Kunda, Fong, Sanitoso, & Reber,

1993). The present research, however, suggests that this tendency may not be true of Japanese people. Japanese participants responded to one of two social life questions: "Are you happy with your social life?" or "Are you unhappy with your social life" (Study 1), or one of two personality questions: "Are you extroverted?" or "Are you introverted?" (Study 2). For the social life questions in Study 1, unlike North American participants in Kunda et al.'s (1993) study, Japanese' self-ratings did not differ between conditions, although participants in the happy condition reported more happy thoughts than did those in the unhappy condition. For the personality questions in Study 2, participants in the extroverted condition rated themselves as more extroverted than did those in the introverted condition; however, in contrast to Kunda et al.'s (1993) findings with North Americans, the number of extroverted and introverted thoughts Japanese wrote down did not differ between conditions. In sum, unlike North Americans, a disconnection lies between the type of information Japanese gather when answering questions about themselves and the self-concepts they construct, indicating that the thoughts they recruit and the self-concepts they develop are not always consistent with the direction of self-relevant questions.

**F17**

**"THANKS, BUT I'M NOT THAT SMART AND NEITHER IS MY DAUGHTER:" CULTURAL DIFFERENCES IN FIRST-PERSON AND THIRD-PERSON COMPLIMENT RESPONSES** Karen Choi<sup>1</sup>, Michael Ross<sup>1</sup>, <sup>1</sup>University of Waterloo – Four studies examined cultural differences in responses to compliments. Study 1 found that Asian-Canadian students were less accepting of hypothetical compliments about the self (first-person compliments) than European-Canadian students. This cultural difference was evident on both measures of public responses to compliments and private feelings about compliments. Study 2 demonstrated that the cultural difference is robust and generalizes to compliments about close others (third-party compliments). Asian-Canadian mothers were less accepting of compliments about their child, and deemed these compliments to be less accurate, than European-Canadian mothers. Public responses to the third-party compliments also did not differ from private feelings about the compliments. Study 3 replicated the cultural difference in third-party compliment responses, while showing that mothers of both cultural groups were highly and equally satisfied with their relationship with their child. Acceptance of third-party compliments was unaffected by the child's presence or absence. In Study 4, an analysis of interviews with female golf tournament winners showed that East Asian players were less accepting of compliments than their Western counterparts. Together, these studies provide strong evidence for cultural differences in both first-person and third-person compliment responses.

**F18**

**TASK FRAMING AND CULTURAL BELIEFS PREDICT STUDENTS' CHOICE OF ACADEMIC TASKS** Sylvia Rodríguez<sup>1</sup>, Rainer Romero-Canyas<sup>1</sup>, Geraldine Downey<sup>1</sup>, E. Tory Higgins<sup>1</sup>, <sup>1</sup>Columbia University – Previous research has found that a fit between one's beliefs about the interdependence of the self and the message conveyed by a task predicted better performance on challenging math tasks and increased engagement in those tasks. In these previous studies, participants were randomly assigned to a task framed in a way that did or did not reflect their beliefs about the interdependence of the self. In this study we asked: do individuals choose tasks that fit their beliefs about the self? Participants first read what seemed like a legitimate newspaper article describing research that had identified two types of math questions that were linked to different professional and personal outcomes: one that was linked to service and societal development and one that was linked to personal uniqueness. Participants were then provided with a chance to select solving one of two sets of math problems, one that was associated with societal development or one that was associated with personal uniqueness. We hypothesized that higher interdependence would predict choosing a task associated with societal development while beliefs about the uniqueness of the self (horizontal individualism) would predict choosing a task associated with personal uniqueness. Results sup-

port our hypotheses. The research extends previous work on the relevance of beliefs about the self to achievement by showing that under certain circumstances individuals will seek out challenging tasks that mirror their beliefs. Implications for fit, engagement and achievement are discussed.

#### F19

**EQUALITY, HARMONY, AND THE ENVIRONMENT: AN ECOFEMINIST APPROACH TO UNDERSTANDING CULTURAL IMPACTS ON CLIMATE CHANGE** Brittany Bloodhart<sup>1</sup>, Janet K. Swim<sup>1</sup>; <sup>1</sup>The Pennsylvania State University – This research investigated the associations between gender equality, cultural values, and environmental protection. Psychologists have largely studied domination of people over other people (e.g., men over women) rather than domination of people over the environment. Ecofeminism, however, theorizes that hegemonic systems of power and oppression materialize both as domination of men over women and as domination of people over the environment, leading to degradation of the ecosystems. Consequently, cultural tendencies to value hierarchy (v. egalitarianism) of people and mastery (v. harmony) over the environment should be related to negative impacts on climate change. Data from the United Nations (2007) on gender equality and women's empowerment, Schwartz's (2008) assessment of cultural value orientation, and Yale's Environmental Performance Index (2008) for 74 countries partially support ecofeminist predictions. Controlling for GDP, gender empowerment is related to a country's tendency to endorse egalitarianism more than hierarchy,  $r = .28$ ,  $p < .05$ . Further, egalitarianism is highly correlated with a country's tendency to endorse harmony with (rather than mastery over) the environment,  $r = .60$ ,  $p < .001$ , and both values (egalitarianism,  $r = .29$ ,  $p < .05$ , and harmony,  $r = .32$ ,  $p < .01$ ) are significantly related to a culture's protection of the ecosystem. That is, the more egalitarian and harmonious with nature a culture is, the less impact that culture has on the ecosystem via less production of greenhouse gases, better water quality, and less air degradation. Implications and future directions for research on gender and the environment are discussed.

#### F20

**CULTURE THAT 'FITS': CULTURAL CONGRUENCY INCREASES PERSISTENCE FOR AND PLEASURE FROM GOAL PURSUIT** Bobby Cheon<sup>1</sup>, Joan Chiao<sup>1</sup>; <sup>1</sup>Northwestern University – Cultural variation in how the self is defined relative to others is an influential factor underlying culturally-valued behaviors and goals. Individualistic cultures (i.e. North America) tend to value personal goals, while collectivistic cultures (i.e. East-Asia) tend to emphasize socially-shared goals. However, little is known about whether pursuing goals that are congruent with one's cultural values affects task motivation. Here we examined the effect of culturally-congruent goal pursuit on motivation. 41 Asian-American and 49 Caucasian-American participants thought about either individualistic (personal goals for oneself) or collectivistic (goals shared with their mother) goals. Following cultural priming of independent or collectivistic goals, participants completed a cognitively-demanding reasoning task. Results indicate that participants that received culturally-congruent primes (e.g. Asian-Americans thinking of goals valued by their mothers and Caucasian-Americans thinking of personal goals) devoted more time to solving problems and exhibited greater persistence throughout the duration of the task compared to participants that received culturally-incongruent primes. Furthermore, participants who thought of culturally-congruent goals reported more positive subjective experiences with the demanding task, reporting lower perceived difficulty, frustration and unpleasantness associated with the task. These findings suggest that activation of culturally-valued goals may boost motivation and self-regulation, which may lead to increased engagement, effort and enjoyment towards overcoming subsequent goal-pursuit challenges. Furthermore, the study suggests that cultural congruency, or a match between one's cultural background and the relevance of a goal to fulfilling cultural values, may be a potent means by which a sense of "fit" between one's phenomenological state and goal-directed action is fostered.

#### F21

**BRIDGING THE CULTURAL DIVIDE: SOCIAL INFERENCES ACROSS CULTURES** Holly Oh<sup>1</sup>, Steve Guglielmo<sup>2</sup>, Bertram Malle<sup>2</sup>; <sup>1</sup>University of Oregon, <sup>2</sup>Brown University – We examined whether people's ease and speed of making social inferences from behavior (e.g., about intentionality, goals, and personality) differs by people's own cultural background and the level of cultural familiarity with the observed behavior. European American students and students from mainland China, Japan, and South Korea were recruited during their first term at the University of Oregon. Participants watched videos designed to be culturally specific for each cultural group and were probed, after each video, for one of the social inferences (e.g., intentionality, goal) or asked whether they could identify the video character's cultural origin. People's frequency of making inferences of each type and their speed of doing so were analyzed as a function of perceiver culture and behavior familiarity. Results showed that people were faster to identify the target person's culture than the person's mental states or personality traits. Moreover, consistent with recent studies, people were faster to infer the intentionality and goal of others' behavior than to infer others' personality. Most important, however, people's social inferences from behaviors that were culturally familiar to them were no faster than those from culturally unfamiliar behaviors (and this was true across all groups of participants). These results suggest that the processes underlying social inferences are highly consistent across culturally familiar and novel behaviors, which points to some common ground, not another divide, in intergroup perception.

#### F22

**THE ROLE OF ISSUE FRAMING AND SELF-CONSTRUAL IN POLICY OPINIONS** Christie Cathey<sup>1</sup>, Christopher Panza<sup>2</sup>, Jiangqun Liao<sup>3</sup>; <sup>1</sup>Missouri Southern State University, <sup>2</sup>Drury University, <sup>3</sup>Tsinghua University – Different social policies can be seen as presupposing different underlying notions about the basic nature of personhood. For example, some policies (e.g., freedom of speech policies and other so-called first generation rights) are generally understood to be aimed at protecting the individual from others and thus seem to be based on an independent conception of personhood. Other policies (e.g., universal health care policies and other so-called second generation rights) are aimed at ensuring that people within a society share in meeting one another's basic needs and thus seem to be based on an interdependent conception of personhood. We examined the possibility that the same policy can be given different frames that appeal differently to people depending on their own self-construals. Seventy-eight Chinese university students read one of two sets of persuasive essays about a proposed educational policy. Half the participants read an essay arguing in favor of the policy that was framed in terms of the need to protect individuals from others (pro-protection essay) and an essay arguing against the policy that was framed in terms of the need to meet people's basic needs (con-provision essay). The other half read a pro-provision essay and a con-protection essay. Contrary to predictions, results showed that higher levels of interdependence predicted greater policy support in the pro-protection/con-provision framing condition and that this support was mediated by participants' reception of the protection policy framing. These unexpected results are discussed in terms of the notion of protection as understood within the Confucian ideal of jen.

#### F23

**DIFFERENT AFFECTS ON THE SAME MORAL BEHAVIORS ACROSS CULTURES** Sieun An<sup>1</sup>, David Trafimow<sup>1</sup>; <sup>1</sup>New Mexico State University – An and Trafimow (2007) found differences in moral attributions for Americans and Koreans: Americans had more moral attributional weight after perfect duty violations (e.g. dishonesty, disloyalty) than imperfect duty violations (e.g. unfriendliness, uncharitability). Koreans did not differentiate between perfect and imperfect duties. Subsequently, responses to moral violations were tested to assess the role of affect: Koreans did not appear to use affect in making attributions about moral violations. However, another study involved manipulating affect

of participants and suggested that Koreans do use affect in response to moral violations in making moral attribution, but do so differently. Therefore, differences in evoked affect may cause differences in moral attributions. To test this idea we chose the four basic negative affects: fear, anger, sadness, and disgust. The results replicated previous findings about the number of immoral behaviors needed to override previous impressions. Participants indicated how they felt about others' immoral behaviors, and which was the most negative of the four emotions. Importantly, there were differences between Koreans and Americans for types of negative affective response to immoral behaviors: Koreans reported sadness most strongly; Americans reported anger most strongly for unfriendly behavior. Only two Americans reported fear as the most negative affect. In contrast, more than half of the Koreans reported fear at least once as the most negative affect in response to immoral behaviors. These results suggest that people in different cultures have different affective responses, and this may reflect in their behaviors. Specifically, processes surrounding moral judgments differ across cultures.

#### F24

**SOME THINGS ARE THE SAME ALL OVER: SIMILARITIES BETWEEN CHINESE AND AMERICAN PERCEPTIONS OF POWER** Melissa Sanders<sup>1</sup>, Fiona Lee<sup>1</sup>; <sup>1</sup>University of Michigan – Undergraduates at a large American Midwestern university and a Chinese university completed a checklist of power behaviors for course credit. The checklist contained examples of different types of power use (relational vs. independent) used by either high or low status individuals which were developed to be relevant in both cultural contexts. Analysis showed that a similar factor structure emerged in both samples. Both Chinese and American participants were more likely to recognize actions undertaken by high status individuals as power than actions undertaken by low status participants. Independent actions were recognized as power by both American and Chinese participants more often than relational actions. This suggests that cultural understandings of power using this taxonomy (type of behavior and status of user) are similar in both collectivistic and individualistic cultures.

#### F25

**"NEITHER EAST NOR WEST:" LAY THEORIES OF CHANGE IN THE MUSLIM MIDDLE EAST** James Greenberg<sup>1</sup>, Jeanne Tsai<sup>1</sup>, Hazel Markus<sup>1</sup>, Sanad Haider<sup>2</sup>; <sup>1</sup>Stanford University, <sup>2</sup>University of Aden – Lay theories of change, i.e. implicit beliefs about how trends develop over time, differ in North American and East Asian settings (Ji et al. 2001). Most people in the former hold a linear theory, assuming that past trends will continue unchanged, whereas most in the latter hold a cyclical theory, assuming that past trends will reverse themselves. Analytic reasoning appears to foster a linear theory and holistic reasoning appears to foster a cyclical theory (Nisbett 2003). Given that individuals in the Muslim Middle East tend to engage in holistic reasoning (Norenzayan et al. 2007), we anticipated that a cyclical theory of change would be prevalent in this region. To test this hypothesis, we presented 50 Yemenis and 25 European-Americans with 12 graphs depicting global trends in non-controversial social and economic phenomena (e.g. deaths due to traffic accidents) over the past 6 years (2002-2008), and asked them to indicate where data points would fall in 2010 and 2012 (cf. Ji et al. 2001, Study 3). Yemenis and European-Americans significantly differed in their predictions. European-Americans forecast a continuation in the direction and rate of past trends. Yemenis, however, exhibited a "pessimistic" theory of change. If a past trend indicated increasingly positive outcomes, Yemenis forecast a reversal in the trend's direction. If a past trend indicated increasingly negative outcomes, Yemenis forecast that the trend would continue or accelerate. These findings suggest that factors other than analytic-holistic reasoning may shape lay theories of change and highlight the need for research on other non-Western cultures.

#### F26

**SCRIPTING STALKING: EXAMINING THE PORTRAYAL OF UNWANTED PURSUIT BEHAVIORS IN THE MEDIA** John Mac Arthur<sup>1</sup>, Jessie Weiss<sup>1</sup>, H. Colleen Sinclair<sup>1</sup>; <sup>1</sup>Mississippi State University – There has been considerable conjecture about the media's portrayal of stalking; however, no one has empirically examined what message the media is actually providing. Examining media messages is important because past research has shown that the media conveys norms that affect our feelings, cognition, and behavior (e.g., Anderson, 1997). While much research focused on the media's portrayal and effects on aggression in general, the present archival study sought to specifically examine media's portrayal of stalking-related behavior. Consistent with the literature, we expected to find 1) that stalking-related behavior would be portrayed positively (e.g., as normal, acceptable, & successful), on average, & 2) this would be even more evident in men's pursuit of women, than vice versa due to gender norms that depict men as the romantic pursuers. We coded a random selection of 200 popular movies and found that pursuers employed an average of 9.15 different stalking-related behaviors and these behaviors were portrayed negatively just as often as positively. However, if the pursuer was male, the tactics were portrayed more positively than negatively, and male pursuers were more successful than female pursuers at using stalking to win their love interest. Implications are tied into Gentile et al.'s (in review) General Learning Model as the first step toward understanding what influence the media's portrayal of stalking tactics have on the prevalence of stalking is to first chronicle how the media is, in fact, portraying stalking.

#### F27

**CULTURAL DIFFERENCES IN ATTENTION TO THE FUTURE** Tiejuan Guo<sup>1</sup>, Li-Jun Ji<sup>2</sup>, Ye Li<sup>3</sup>; <sup>1</sup>University of Macau, <sup>2</sup>Queen's University, <sup>3</sup>Huazhong Normal University – Past research indicates that because the past can serve as the context for the present on the time dimension, Chinese people attend to past information more than do North Americans (Ji et al., 2009). We believe that the future can serve as the context for the present as well. Therefore, Chinese people may attend to future information more than do North Americans. Two studies were conducted to test this hypothesis. In Study 1, we found that when future events were equally distant in time across cultures, Chinese perceived the future events as being closer to the present than did Canadians. In Study 2, we adopted an event-listing approach and found that the future events listed by Chinese participants were further away from the present than those listed by Canadian participants. These studies provided converging evidence that Chinese attend more broadly into the future than do their North American counterparts.

#### F28

**ATTENTIONAL BIAS PREDICTS HISPANICS' WILLINGNESS TO SEEK HELP** L. Omar Rivera<sup>1</sup>, Stephanie Quezada<sup>1</sup>, Michael Zarate<sup>1</sup>; <sup>1</sup>University of Texas at El Paso – To improve our understanding of disparities in healthcare seeking behavior between Hispanics and Non-Hispanic Whites, cognitive behavioral research has investigated the causal attributions that Hispanics make for their illnesses. Not only are Hispanics more likely than Non-Hispanic Whites to attribute their illnesses to external forces, external attributional bias positively predicts the amount of time Hispanics remain ill before seeking healthcare services. Based on research suggesting a relationship between attributional bias and attentional bias, we predicted that attentional bias would account for unique variability in Hispanics' willingness to seek healthcare services. Our hypothesis was that attentional bias toward contextual (or background) information would predict less willingness to seek healthcare services, even after external attributional bias was taken into account. Hispanic subjects (N = 94) completed an attentional bias measure that provided an index of attentional bias toward focal (or central) information and an index of attentional bias toward contextual (or background) information. They also completed a behavioral attribution measure and a willingness to seek healthcare services questionnaire. We regressed willingness to

seek healthcare services on external attributional bias, contextual attentional bias, and focal attentional bias. Although external attributional bias predicted less willingness to seek help ( $\beta = -0.57, p = 0.05$ ), contextual attentional bias did not ( $p > 0.05$ ). Instead, focal attentional bias predicted less willingness to seek help ( $\beta = -0.41, p = 0.02$ ). These results deviate from prediction, yet nonetheless provide preliminary evidence that attentional bias accounts for unique variability in Hispanics' willingness to seek help.

### F29

**HEALTH CONSEQUENCES OF EMOTION REGULATION ON DIFFERENT CULTURAL POPULATIONS: A COMPARISON OF ASIAN AND EUROPEAN AMERICANS** Elizabeth A. Lee<sup>1</sup>, Christopher Perez<sup>1</sup>, Jose A. Soto<sup>1</sup>, <sup>1</sup>The Pennsylvania State University – Emotion regulation is one aspect of emotional functioning with important consequences for health. Suppression of emotion (hiding emotionally expressive behavior) was found to relate to lower well-being, whereas reappraisal of emotion (changing the meaning of an emotion-eliciting event) was found to relate to enhanced well-being (Gross & John, 2003). Little research has examined the possibility that consequences of emotion regulation may vary according to contextual factors. For instance, East Asian cultures are known for instilling moderation of emotional responses, which contrasts with mainstream American culture that emphasizes freedom of expression. The purpose of this study is to assess how the relationship between emotion regulation and health outcomes that have been demonstrated in prior research are observed in different cultural populations, namely Asian American and European American students. Asian and White college students completed a survey reporting emotion regulation tendencies, indicators of health, and measures of ethnic identity. Asians reported higher levels of suppression than Whites, however, both groups reported equal frequencies of reappraisal. Post-hoc analysis that separates the Asian sample into those whose ethnicity is either East Asian or South Asian showed that South Asians reported more suppression than East Asians. Suppression related to diminished health outcomes for Asians, whereas appraisal mainly factored into improved health for Whites. Additionally, individual differences in identification with the ingroup related to increased health for all groups. Our findings support the need for further research on emotion regulation across cultural contexts.

### F30

**UNITED WE STAND, DIVIDED WE FALL: COLLECTIVISM AND ITS CONSEQUENCES FOR KENTUCKY APPALACHIAN COLLEGE STUDENTS** Jodi R. Treadway<sup>1</sup>, Victoria C. Plaut<sup>1</sup>, Jonathan S. Gore<sup>2</sup>, Kristina R. Wilburn<sup>2</sup>, <sup>1</sup>The University of Georgia, <sup>2</sup>Eastern Kentucky University – This study contained two aims: (1) to develop a cultural psychological portrait of Appalachia, an American regional subculture that varies from the mainstream in several ways, and (2) to determine the effects of aspects of that culture on the success of college students from that region. Previous research (Wilson & Gore, 2009) has suggested that Appalachia is more collectivistic than mainstream American culture. We sought not only to find evidence consistent with that hypothesis, but also to examine the role of collectivism in college achievement. We hypothesized that Appalachian students who maintained collectivistic tendencies would have greater success in college than those who did not. Online questionnaires were distributed to 171 students at a medium-sized public university in Kentucky. Participants completed the Chen, Brockner, & Chen (2002) Group Value scale, and provided information on familial histories, GPA, and demographics. Analyses revealed that Appalachian natives were more likely to be from rural areas, reported greater family support for their educational goals, and visited their relatives much more frequently than non-Appalachians. In particular, Appalachian natives visited their mother's relatives far more frequently, although they were only marginally more likely to live near them. Moderated regression analysis revealed a significant interaction of Appalachian background and collectivism on GPA. Simple slopes analysis revealed a negative association between collectivism and GPA for non-Appalachians but a positive asso-

ciation for Appalachians. This analysis helps to establish a cultural psychological profile for Appalachia, and has practical implications for improving and maintaining college success among students from this region.

### F31

**COMPASSION AND MINDFULNESS MEDITATION: BOTH ROADS LEAD TO A CALM IDEAL** Birgit Koopmann-Holm<sup>1</sup>, Camaron Ochs<sup>1</sup>, Jeanne L. Tsai<sup>1</sup>, <sup>1</sup>Stanford University – Previously, we predicted that cultural practices like meditation alter how people ideally want to feel more than how they actually feel. We found that engagement in mindfulness meditation promoted the valuation of calm states but minimally altered the actual experience of calm states, assessed globally over an 8-week program. In the present study, we examined whether these findings generalize to daily assessments of ideal affect and to another form of meditation, compassion meditation, which focuses on cultivating compassion towards others. Seventy-four participants were randomly assigned to a mindfulness or compassion meditation class, an improvisational theater class (to control for effects of learning a new skill, being part of a social group), or a no intervention control group. We assessed global as well as daily ideal and actual affect (i.e., how much people ideally wanted to experience and actually experienced different affective states over the course of a typical week/over the course of the day) during the 8-week program. As predicted, participants in the two meditation classes showed a larger increase in the value they placed on calm states at both the global and daily levels, compared to the two control groups. The global and daily actual experience of calm states increased only slightly among participants in both meditation classes. These findings suggest that meditation shapes ideal more than actual affect and that different forms of meditation have similar effects on global and daily emotional ideals. Future studies should examine when practices begin to alter ideal as well as actual affect.

### F32

**DEVELOPING AN UNDERSTANDING OF POLITICAL HUMANISM** Carl Henthorn<sup>1</sup>, Matt Motyl<sup>2</sup>, <sup>1</sup>University of Colorado at Colorado Springs, <sup>2</sup>University of Virginia – Derived from various humanist manifestos penned over human history, the political humanism scale provides an initial attempt to understand a group often neglected in social and political psychological research: liberals. Social psychology, in particular, tends to be fascinated by conservatives and often focuses on conservatism as pathological. The present study marks an attempt at understanding liberal, political humanist beliefs which may serve as a springboard for future research that will allow scientists to begin to paint as complete a picture of liberal political humanists as currently exists of political conservatives. The Political Humanism scale (PHS) consists of 28 items intended to measure people's belief in humanist ideals. The 28 items contained in the PHS were entered into a principal components analysis and revealed a two-factor solution with factor loadings ranging from .40 to .85. The items within the first factor, religious humanism, rendered an eigenvalue of 6.53, accounting for 35.38% of the variance within the subscale. The items within the second factor, social humanism, rendered an eigenvalue of 4.76, accounting for 21.85% of the variance within the subscale. These two subscales were correlated with one another and demonstrated excellent internal reliability. Construct validity for the PHS was demonstrated by positive correlations between self-reported liberalism, support for peacemaking behaviors, perception of a common humanity, and support for President Obama. Furthermore, negative correlations between the PHS and religious fundamentalism, right-wing authoritarianism, social dominance orientation, support for war, support for Senator John McCain for the presidency, and self-reported conservatism.

**F33****CULTURAL DIFFERENCES IN REASONING ABOUT CRITICISM AND PRAISE FROM OTHER PEOPLE** Rie Toriyama<sup>1</sup>, Kang Lee<sup>1</sup>, Shoji Itakura<sup>2</sup>;

<sup>1</sup>University of Toronto, <sup>2</sup>Kyoto University – Background: In this study, we tried to examine how we perceive evaluations from other people in a different situations and cultural differences in it. Regarding the cultural difference in the reasoning about evaluations from others, following 3 components seem to play important roles. The first one is situation where the evaluation is given, which is public situation or private situation. The second one is the type of the evaluation, which is positive or negative. The third one is congruency with evaluations on others such as everybody received the same evaluation or the one person received a different one from others. Method: 24 Canadians and 25 Japanese undergrads participated in this study. They read hypothetical situations in which they were given evaluations by their teacher. There were 8 conditions, which is 2 situations x 2 types x 2 congruencies. Participants were asked to answer how much they believe the evaluation in each condition. Results: The results suggest that Japanese believe the evaluations more in the private situation than in the public situation while Canadian seemed not to distinguish these two situations. Compared to Canadians, when everyone received the same evaluations, Japanese believe it less. We also found that Japanese feel significantly more comfortable to be praised in a private situation than in a public situation. Possible mechanisms behind these cultural differences will be discussed.

**F34****MULTICULTURALISM AS A MECHANISM OF MINORITY EMPOWERMENT** Moira Shaw<sup>1</sup>, Andreanna Duron<sup>1</sup>, Nazanin Heydarian<sup>1</sup>, Verenice Quiroz<sup>1</sup>, Perla Pena<sup>1</sup>, Michael Zarate<sup>1</sup>;

<sup>1</sup>University of Texas at El Paso – The empirical debate about cultural contact should consider the effects of cultural change and contact on members of minority cultures' attitudes towards their own culture. Research demonstrates that exposure to multicultural ideologies causes members of Latino cultures to feel proud to be Latino. This study tests whether this sense of empowerment causes Latinos to work to maintain their culture. Latino participants were assigned to read either an article that espoused a multicultural approach to cultural contact in the United States, one that espoused an assimilation approach, or a control article. Afterwards, they expressed their support for pro-Latino legislation, completed a collective self esteem measure, and completed a measure of their perceptions cultural change. They were also given the opportunity to sign up for pro-Latino student groups. The results of this study indicate that Latinos who identify highly with their group are more likely to get involved in pro-Latino student organizations when they believe that the United States is becoming more multicultural. The results also indicate that Latinos believe they will have to change their cultural identity to accommodate a White-American majority when led to believe that the United States is becoming more assimilated. Also, participants' collective self esteem related to greater support for pro-Latino legislation. Together, this study suggests that Latinos who identify with their culture will work to maintain their own culture- but even more so in a multicultural society. It also suggests that Latinos do not see a place for their culture in an assimilated American society.

**F35****CULTURE MEETS FORM AND FUNCTION: BALANCING DESIGN AESTHETICS AND FUNCTIONALITY ACROSS CULTURES.** Thai Chu<sup>1</sup>,

Heejung Kim<sup>1</sup>;

(Culture: European American vs. Korean) × 2 (Website Interface: Simple vs. Complex) design to examine functional and aesthetic evaluations of different types of website design. Relative to Koreans, European Americans perceived more text and images in the complex website and reported less of a desire for additional functionality, suggesting a lower tolerance for complex designs. Although Koreans preferred more complex designs in terms of functionality, they aesthetically preferred the simple to the complex design. Furthermore, Study 2 found that for Koreans, higher aesthetic ratings are inversely related to functionality whereas Europeans Americans did not show this relationship. These results suggest cultural differences in the meaning of "beauty." In Asian cultures where dialectic thinking is common, products with visibly positive features (e.g., higher levels of aesthetics) are perceived to also possess negative features (e.g., lower functional value). These findings marry these traditional components of design as it impacts and is a product of the systematically varying psyches of different cultures.

**F36****DARK TRIAD TRAITS RELATED TO SEXUAL STRATEGIES ACROSS 58 NATIONS: PATTERNS AND UNIVERSALS ACROSS GENDERS, CULTURES, AND LOCAL ECOLOGIES** David Schmitt<sup>1</sup>;

<sup>1</sup>Bradley University – Three well-studied traits—Machiavellianism, Narcissism, and psychopathy—have been labeled the "Dark Triad" of personality. Previous studies suggest men have evolved to score higher on all three dimensions of the Dark Triad, and those who score higher on the Dark Triad tend to adaptively engage in more unrestricted mating strategies, including short-term mate poaching. To date, no previous study has examined the Dark Triad and its relationship to mating strategies in non-Western samples. In the current study, new findings from a cross-cultural survey of over 37,000 people across 58 nations demonstrate that those who score higher on Dark Triad dimensions generally do tend to engage in more unrestricted mating strategies. Significant sex differences in the Dark Triad traits were evident in nearly every culture. However, among nations with high levels of ecological and cultural stress (e.g., high pathogen loads, fertility rates, homicide rates, population densities), sex differences in were somewhat attenuated. This trend was largely due to women exhibiting especially elevated levels of anti-sociality in "high stress" cultures.

**F37****CULTURE, POSITIVE EMOTIONS, AND DEPRESSION SYMPTOMATOLOGY: THE MEDIATING ROLE OF EMOTIONS IN THE STRESS PATHWAY AMONG EUROPEAN AMERICANS AND ASIANS** Janxin Leu<sup>1</sup>, Jennifer Wang<sup>1</sup>, Kelly Koo<sup>1</sup>;

<sup>1</sup>University of Washington – It is important to develop culturally-relevant models of mental health for diverse communities in the US. Ethnicity may influence whether positive emotions, but not negative emotions, mediate the relationship between stress and depression. In a survey of over 600 European and Asian American college students, we predicted greater mediation of stress and depression symptoms by positive emotions among European Americans, compared with Asians. Evidence from mostly European American samples in the past ten years suggests that positive emotions may protect against stress and depression. However, the mediating effect of positive emotions on depression may be stronger among European Americans than Asian immigrant youth. While maximizing positive emotions is at the core of North American cultural contexts, pure pleasantness appears to be undesirable in many Asian contexts. European American (N = 347; 66% female) and Asian immigrant (N = 316; 69% female) college students completed an hour-long survey at the University of Washington in exchange for extra credit in a college course. Measures included a scale of perceived stress (Cohen, Kamarck, & Memelstein, 1983), positive and negative emotions (PANAS-X; Watson & Clark, 1994), and symptoms of depression (CES-D; Radloff, 1977). As predicted, positive emotions mediated the effect of stress on depression among European American, but not among immigrant Asian, youth. Negative emotions mediated stress and depression among both European American and immigrant Asian youth.

**SOCIAL INFLUENCES ON THE EMERGENCE OF INTERPERSONAL SYNCHRONY** Lynden K. Miles<sup>1</sup>, Joanne Lumsden<sup>1</sup>, Michael J. Richardson<sup>2</sup>, C. Neil Macrae<sup>1</sup>; <sup>1</sup>University of Aberdeen, <sup>2</sup>University of Cincinnati – The temporal coupling of behavior serves as a foundation for effective social interaction with synchronized actions moderating core components of social-cognitive functioning. Questions remain, however, regarding the precise conditions under which behavioral coordination emerges. In particular, does social context influence the dynamical systems that support interpersonal synchrony? To this end, the current investigation considered whether social factors modulate the extent to which people synchronize their movements with others. In experiment 1, the effects of negative feelings toward an interaction partner on the emergence of synchrony was examined. Participants performed a repetitive activity (i.e., stepping) with a confederate who either turned up for the experiment on time or was 15 minutes late. Their movements were recorded using a magnetic motion tracking system, and the degree of coordination assessed. Results revealed that coordination (i.e., in-phase synchrony) was substantially reduced when participants interacted with a tardy partner. In experiment 2, a minimal group situation was created in order to examine the effects of social group membership on the emergence of coordination. Participants performed arm curls while forming an impression of a confederate who was a member of either the same or different (minimal) group. Results revealed that although all participants coordinated with the confederate regardless of group status, those in the different group synchronized to a significantly greater degree. Taken together these results suggest that the self-organizing systems that govern interpersonal synchrony are sufficiently flexible to accommodate social goals and motives, underscoring the importance of coordinated action for effective social exchange.

### F40

**PUT ME IN, COACH: BEHAVIORAL CONFIRMATION IN FREE THROW SHOOTING** Jason Weaver<sup>1</sup>, Jennifer Filson<sup>1</sup>, Mark Snyder<sup>1</sup>; <sup>1</sup>University of Minnesota – People rarely enter a social situation without expectations. Previous research has revealed that individuals who hold expectations will often shape interactions so that their expectations of other people are confirmed (for a review, see Snyder & Stukas, 1999). Although this effect has often been demonstrated for personality traits, experimental research is less definitive in the realm of abilities. We recruited 127 undergraduate participants (79 male, 48 female) for a study utilizing a basketball free throw shooting paradigm to measure the effects of an ability-based expectation on performance. We gave some participants (“coaches”) false information regarding other participants’ (“players”) ability level. We hypothesized that coaches would give high expectation players more opportunities than low expectation players and that this preferential treatment would influence player performances. Consistent with our hypotheses, the manipulated expectations predicted coach selections ( $p < .01$ ) and marginally predicted player performances ( $p = .07$ ), even after controlling for actual player ability. The effect of coach expectations on player performance was mediated by the number of opportunities that the coach gives each player ( $p = .02$ ). Furthermore, player performances influenced player confidence levels ( $p < .01$ ). We propose that these confidence levels could influence future performances and serve to further confirm the coach’s original expectation. These effects could occur in athletics, business, education, or other social situations in which people develop ability-based expectations of others.

### F41

**INGROUP AS A SOCIAL RESOURCE: POLITICAL IDENTITY AS A TOOL FOR AFFIRMATION** Arina Goyle<sup>1</sup>, Joshua Correll<sup>1</sup>, Bernadette Park<sup>2</sup>; <sup>1</sup>The University of Chicago, <sup>2</sup>University of Colorado at Boulder – The assertion that groups are a source of individual self-worth warrants a qualification. Certainly, not all groups indiscriminately enhance self-worth. Instead, groups presumably differ in characteristics that render them psychologically meaningful. Correll & Park (2005) have recently proposed that it is a group’s perceived value, identification, and entitativity that determine its psychological utility or self-affirming potential. In a bid to provide initial support for this model, in study 1 we had participants rate the value, identification, entitativity, and utility for various social groups. Value, identification and entitativity emerged as independent dimensions in a factor analysis and each predicted unique variance in group utility. In study 2, we sought to demonstrate that high utility groups act as a psychological resource under threat. We hypothesized that when faced with a self-threat, writing about an ingroup (political party affiliation) would affirm individuals and bolster their self-esteem, but only when that group was rated as high in utility. We further predicted that utility is continuously re-evaluated. In particular one factor that could impact utility is the salience of the group. We thus collected data at three points of time - a year before elections (political identity low in salience), during elections (high salience), and after elections (moderately low salience). Results indicate that under self-threat, writing about one’s political identity bolstered self-esteem, but only if political affiliation was rated as high in utility. Further, this effect was determined by group salience, such that high-utility groups were affirming primarily when group identity was salient and meaningful.

### F42

**EMOTIONAL SYNCHRONY AS A GROUP BONDING MECHANISM** Selin Kesebir<sup>1</sup>, Jonathan Haidt<sup>1</sup>; <sup>1</sup>University of Virginia – In this study, we assessed the effect of collectively experiencing emotions on subsequent group interaction. We brought to the lab groups of three to six participants, who did not know each other beforehand. Before engaging in any interaction, participants together watched a video clip with either emotional or non-emotional content. The emotionally neutral video was a clip on painting techniques. One emotional video was from the Oprah Winfrey show, about a teacher who saved disadvantaged teenagers from a life of violence and drugs; and the other one was a documentary clip about Lance Armstrong’s brave battle with cancer and subsequent world championship. After watching the clip, participants told each other an embarrassing memory. Supporting our hypothesis, those who watched an emotional video together reported substantially more liking for each other than those who watched the neutral video (average Cohen’s  $d = 0.71$ ). Moreover, participants who reported stronger emotional reactions to the video liked other group members more ( $r = .33, p < .01$ ). Our codings revealed non-significant trends such that participants in the neutral condition were less open, wrote and told less embarrassing stories, and gave less support to group members when listening to each others’ stories. These results suggest that emotional synchrony may bring group members closer, even if these emotions originate from outside the group.

### F43

**COLLECTIVE GUILT MEDIATES THE EFFECTS OF INCLUSIVE TEMPORAL CATEGORIZATION ON WILLINGNESS TO ACT ON BEHALF OF FUTURE GROUP MEMBERS** Mark Ferguson<sup>1</sup>, Nyla Branscombe<sup>2</sup>; <sup>1</sup>University of Calgary, <sup>2</sup>University of Kansas – Present group actions can harm future group members, but is thinking about the effects on future members sufficient to lead present members to act on their behalf? Based on self-categorization theory (Turner, Oakes, Haslam, & McGarty, 1994), we suggest that categorizing future group members as part of the ingroup increases willingness to act on their behalf, and that such willingness is mediated by collective guilt (Wohl & Branscombe, 2005). In Experiment 1, 40 participants listed three ways that students in 10 years would be similar to or different from present students. They then read about a tuition policy

change that benefitted present students but harmed future students. Afterwards, they completed a measure of collective guilt for the policy change. Participants in the similar condition reported more collective guilt than did those in the different condition. In Experiment 2, 84 participants listed three ways that Americans would be the same in 20 years, different in 20 years, or did not do either. They then read about how climate change would harm Americans in 20 years. Afterwards, they completed measures of collective guilt for greenhouse gas emissions and willingness to engage in pro-environmental behavior. Participants in the same condition reported more willingness than did those in the other conditions. These effects were mediated by collective guilt. The results suggest that acting on behalf of future group members necessitates thinking about them as ingroup members. The implications of these results for research on collective guilt and pro-environmental behavior will be discussed.

#### F44

**EXPLORING GROUP PERCEPTION: THE COHESION-ENTITATIVITY DISTINCTION** Joel Thurston<sup>1</sup>, David Hamilton<sup>1</sup>; <sup>1</sup>University of California Santa Barbara – Research on group perception has extensively studied the concepts of cohesion and entitativity, which are generally assumed to be related. However, the exact nature of this relationship has never been systematically examined. We hypothesize that, although similar, cohesion and entitativity are conceptually distinct properties. On the basis of this premise, we predicted that individuals would sort a large number of exemplar groups into different categories when prompted with the two concepts. Additionally, we predicted that intramural basketball teams would report different levels of cohesion and entitativity over the course of their season and that these two concepts would be differentially related to a number of antecedent behaviors as coded by independent observers. A Brunswick Lens model was used to map the relationship between specific antecedent behaviors, the perception of entitativity among teams, and levels of team cohesion. Our analysis supported the hypothesis that cohesion and entitativity, while related, are distinct group properties.

#### F45

**FEMALE VOTERS' AND FRATERNITY MEMBERS' REACTIONS TO INGROUP VICTIM'S BEHAVIOR: THOSE WHO FORGIVE ARE MATURE BUT INCOMPETENT** Chris Goode<sup>1</sup>, Rachel Hersh<sup>1</sup>, Heather Smith<sup>1</sup>; <sup>1</sup>Sonoma State University – To err is human; to forgive divine. Do observers agree with Alexander Pope that forgiveness is the best choice? When an ingroup member forgives an offender, observers might view the victim negatively because their behavior violates shared group values or makes the group appear weak to outsiders. In the first study, 103 fraternity members read that a fellow member learned via a Facebook web posting that his girlfriend had been unfaithful. The member either, 1) forgave the girlfriend, 2) slashed her tires or 3) left her. In the second study, 114 women, ranging in age from 20 to 79, read a similar scenario in which a female politician learns, as part of a front page news story, that her husband had been unfaithful. Across both studies, respondents rated a victim who forgave the offender or took revenge as less competent and less vote worthy in comparison to a victim who left his or her partner. These differences occurred even though respondents did not rate a forgiven offender as less blameworthy or less likely to cheat again in comparison to the other two experimental offender descriptions. Ratings of whether the victim damaged the group's reputation predicted ratings of victim weakness for both samples and voting behavior for fraternity members. Ratings of whether the victim behaved appropriately predicted ratings of victim competence and vote worthiness for both samples. When a victim forgives an (outgroup) offender, they can repair the interpersonal relationship but they also can harm their relationship with other group members.

#### F46

**AFFIRMING THE SELF BY NOT CONFORMING TO THE GROUP: FEELING GOOD NOW DESPITE EXPECTING TO FEEL BAD LATER** Nicholas P. Aramovich<sup>1</sup>, Brad L. Lytle<sup>1</sup>, Linda J. Skitka<sup>1</sup>; <sup>1</sup>University of Illinois at Chicago – The choice of whether to express our true beliefs when faced with opposition from a group of peers presents a dilemma. Should we abandon our original position and conform to the majority to gain acceptance and avoid punishment? Or should we publicly affirm our beliefs thereby maintaining a favorable view the self but risking punishment and disenfranchisement from the group? Previous research suggests that the choice not to conform is associated with negative emotions likely due to fears of ridicule and rejection (Asch, 1956; Berns, et al., 2005). However, an alternative view suggests that because conformity threatens one's sense of integrity, nonconformity may be self-affirming, and therefore should be associated with positive, agentic emotions, especially when people express their beliefs regarding important, self-relevant issues. To test this latter prediction, we employed an Asch-style paradigm in which participants shared their opinion about the use of torture on suspected terrorists after learning that all or a majority of group members disagreed with their opinion. Consistent with the self-affirmation perspective, results indicated that participants who maintained their position felt stronger positive emotions (e.g., powerful, assertive) than those who conformed. Those participants for whom the issue was the most self-relevant reported the strongest positive emotions, but also stronger negative expectations about future interaction with the group. For nonconformists, positive emotion mediated the relationship between issue self-relevancy and negative future expectations, suggesting that those who felt the most positive about affirming their beliefs expected to do so again, despite creating tension in the group.

#### F47

**THE INFLUENCE OF DOMINANCE, NARCISSISM, AND TESTOSTERONE ON HIGH STATUS BEHAVIOR** Scott Liening<sup>1</sup>, Robert Josephs<sup>1</sup>; <sup>1</sup>University of Texas at Austin – Research on the relationship between status and behavior generally focuses on competitive environments. Few studies have examined status-seeking behaviors in the context of cooperation. The present study examined how personality constructs, such as dominance and narcissism, would influence individuals' behaviors in a cooperative setting. Two participants were told they would be working together on a series of cooperative tasks, with one participant assigned to the high status position of leader. After rating how strongly they wanted to be the leader, they were randomly assigned to their positions. The leader was given the choice of helping their partner or watching television while their partner worked alone. After the first task, the partner was told about the leader's options and made a hypothetical choice between helping and television. Participants re-rated their desire to be leader. Dominance interacted with testosterone to predict choice. Among participants high in dominance, higher testosterone levels increased the likelihood they would choose television. The inverse effect was found for those low in dominance. Narcissism also interacted with testosterone to predict choice independent of dominance. Among participants high in narcissism, higher testosterone levels increased the likelihood they would choose television. Those high in narcissism with a strong desire for the leader position also experienced a decrease in testosterone following the task, independent of status condition or choice. These findings suggest that different constructs can drive similar behaviors, either cooperative or selfish, for individuals in high status positions.

#### F48

**DOES SELF-CONCEPT STRUCTURE SERVE A PROTECTIVE FUNCTION FOR BLACK INDIVIDUALS?** Aisha Baker<sup>1</sup>, Virgil Zeigler-Hill<sup>1</sup>, Alicia Limke<sup>2</sup>; <sup>1</sup>University of Southern Mississippi, <sup>2</sup>University of Central Oklahoma – Previous research has shown that self-concept structure is associated with psychological adjustment (see Showers & Zeigler-Hill, 2003, for a review). The present study examined whether self-concept structure may be especially important for Black individuals. The underlying ratio-

nale was that Black individuals are likely to encounter a variety of negative racial stereotypes about their group during the course of their daily lives. The manner in which they organize self-knowledge may provide at least a partial buffer from these negative stereotypes. The model of self-concept structure examined in the present study was evaluative organization, which focuses on the distribution of positive and negative beliefs across an individual's self-concept. This model identifies two forms of self-concept structure: compartmentalization and integration. Compartmentalization refers to the tendency to separate positive and negative attributes into distinct self-aspects such that each contains primarily positive or primarily negative information about the self. In contrast, integration refers to the tendency to combine positive and negative information into the same self-aspects. The present results from 348 undergraduates (138 Black participants and 210 White participants) found a stronger association between compartmentalization and lower levels of depressive symptoms among Black individuals than was observed for White individuals ( $\beta = -.19, p < .01$ ). These results suggest that compartmentalization may serve a protective function for Black individuals that may be similar to the idea of a "dual consciousness." Discussion will focus on the potential role that self-concept structure may play in buffering minority group members from the negative consequences of prejudice.

#### F49

##### **INGROUP AS A SOCIAL RESOURCE: THE IMPACT OF SOCIAL THREAT AND SELF-INTEGRITY ON GROUP NORM COMPLIANCE** Jessica J. Sim<sup>1</sup>, Joshua Correll<sup>1</sup>, <sup>1</sup>The University of Chicago

Group membership provides individuals with a range of physical and psychological resources. Integrating the diverse functions of groups, the Model of the Ingroup as a Social Resource (MISR) proposes that groups ultimately serve a more general concern for self-worth (Correll & Park, 2005). Drawing on the MISR, we predict that ingroups may serve as a social resource in the face of a social threat; however, ingroups may be less consequential following a boost to self-worth or self-integrity. To test these predictions, undergraduates recalled either an experience of social exclusion, engaged in a self-affirmation, or wrote about their daily activities (control condition). Participants were then presented with a fictitious campus issue and were led to believe that the majority of their fellow students were in favor of (or opposed to) the issue. Participants were then asked for their own attitudes toward the issue. As predicted, participants who recalled an experience of social exclusion were particularly likely to go along with peer consensus opinion; however, participants who engaged in a self-affirmation did not vary their attitudes as a function of peer consensus. The findings suggest that ingroups matter to individuals because of their psychological utility, or capacity to boost feelings of self-worth. Whereas self-affirmed individuals were less sensitive to group opinion, socially threatened individuals appeared to strive to connect with the ingroup by adjusting their attitudes to be consistent with specific group norms.

#### F50

##### **WHAT DO THEY THINK OF ME? EVALUATIVE UNCERTAINTY DURING INTERGROUP INTERACTION** Yumiko Sakamoto<sup>1</sup>, Jacquie Vorauer<sup>1</sup>, <sup>1</sup>University of Manitoba

Intergroup contact is often awkward due to individuals' concern with evaluation. Indeed, this preoccupation frequently leads to negative intergroup contact experiences, involving outcomes such as activation of negative meta-stereotypes regarding how the outgroup views the ingroup and reduced self-disclosure. Evaluative concerns can actually be almost as damaging as prejudice. One potential strategy for reducing evaluative concerns involves reducing individuals' uncertainty regarding how outgroup members view them (Vorauer, 2006). However, to date no empirical studies have investigated evaluative uncertainty. Thus, the first goal of the present investigation was to develop measures of evaluative uncertainty. The second goal was to test the contention of the information search model (Vorauer, 2006) that evaluative uncertainty is higher in intergroup than in intragroup interaction. The study followed a 2 (Participant Group Status: Majority vs. Minority) x 2 (Contact Type: Intergroup vs. Intragroup) design. Twenty-three

majority group members (12 female and 11 male European/Caucasian Canadians), and twenty-four minority group members (11 female and 13 male) were recruited for an Interethnic Interaction Study. The minority group consisted of participants with Asian ethnic backgrounds: 11 Chinese, 7 Korean, 5 Japanese and 1 participant with Filipino background. They engaged in an ostensible interaction with a 21 year-old fellow student either "Mark" (minority or majority male) or "Amanda" (minority or majority female), depending on the participant's sex, background, and the assigned condition. Evaluative uncertainty was measured using indirect measurements (e.g., response latency). In line with predictions, higher evaluative uncertainty was observed for both majority and minority group members during intergroup contact.

#### F51

##### **THE IMPACT OF TEAMWORK IN HIGHLY COMPETITIVE AND LESS-COMPETITIVE PROFESSIONAL BASKETBALL GAMES** Andy Martens<sup>1</sup>, Jeff Schimel<sup>2</sup>, Chad Forbes<sup>3</sup>, <sup>1</sup>University of Canterbury, <sup>2</sup>University of Alberta, <sup>3</sup>University of Arizona

Though somewhat inconsistent, the bulk of evidence suggests that teamwork improves the performance of sports teams (Carron et al., 2002). To further examine the impact of teamwork we looked at its effects on winning in conjunction with game difficulty/competitiveness in professional U.S. basketball games from the 2006-2007 season. The social facilitation and social loafing literatures suggest that low individual accountability/focus can improve performance on difficult tasks (e.g., by reducing evaluation apprehension) but can worsen performance on easy tasks (e.g., by triggering social loafing). Drawing from this work we hypothesized that teamwork—because it should lessen individual accountability and self-focus—may be particularly beneficial in competitive/difficult games but counterproductive in easier/less-competitive games. We used a team's average assists per game (controlling for shots attempted) as a proxy for teamwork. An assist occurs when a player passes the ball to a teammate in a way that leads to a score. As a proxy for the competitiveness of the game, we examined whether games were played against teams with similar winning percentages or against teams with worse winning percentages. The results showed that, although there was not a main effect for assists on the game outcomes, assists did interact with the competitiveness of the games. In competitive games, teams that averaged more assists won significantly more than teams averaging fewer assists. However, in less competitive games, more assists predicted less winning. No other statistical category (e.g., steals, blocks, rebounds) interacted with game competitiveness to predict winning.

#### F52

##### **IF VALUES ERODE, PUNISHMENT PREVAILS? THE EFFECT OF GROUP-VALUE THREAT ON LAYPERSONS' PUNITIVE RESPONSES** Livia Keller<sup>1</sup>, Mario Gollwitzer<sup>1</sup>, <sup>1</sup>University of Koblenz-Landau, Germany

In order to understand laypersons' attitudes concerning retributive and restorative sanctions, recent theoretical approaches have stressed the role of group values (Wenzel, Okimoto, Feather, & Platow, 2008). A transgression poses a threat to a group's (or society's) value system; punishment has the potential to revalidate these values. However, relatively little attention has been given to the relation between perceived value threat and severity of punishment. Across three studies, value threat was found to be a valuable predictor of punishment severity. In a first study, value threat enhanced support for harsh, retributive punishment, but not for consensual, restorative sanctions. A second study replicated these results and showed that the relation between value threat and punishment severity cannot be explained by individual differences in authoritarianism. Furthermore, Study 2 tested the predictive value of threat compared to the seriousness of a transgression. Although the variables were highly correlated, they explained unique variance proportions in punishment severity. In the third study, value threat was experimentally manipulated, and ingroup identification was measured beforehand. As expected, higher threat led to harsher punishment recommendations, both for low and high identifiers. In sum, the results demonstrate that in order to understand laypersons' attitudes, it is crucial to study the social

context of the transgression. People's sense of how much an offender should be punished depends on whether societal values have been threatened.

### F53

**TOWARD FORGIVENESS BETWEEN GROUPS: INTERGROUP APOLOGY AND THE REGULATORY FUNCTION OF INTERGROUP EMOTION** Diana J. Leonard<sup>1</sup>, Wesley G. Moons<sup>2</sup>, Diane M. Mackie<sup>1</sup>, Eliot R. Smith<sup>3</sup>; <sup>1</sup>University of California, Santa Barbara, <sup>2</sup>University of California, Los Angeles, <sup>3</sup>Indiana University, Bloomington – Although apology may be an effective way to resolve conflicts, this has not yet been demonstrated in the intergroup context. We sought to examine the role of intergroup emotions in regulating the reaction to an apology made by an offending outgroup. Undergraduate participants were falsely informed that the faculty had published a letter insulting the students as a group. After reading about this intergroup insult, participants reported the emotions they felt toward the faculty and whether they thought their group should forgive them. Next, we told participants that the ingroup had protested the event or that they had not done so, and that the faculty had ultimately apologized or not. Finally, participants completed a second round of the emotion and forgiveness measures. Interest in forgiveness was promoted when the ingroup successfully responded to the insult (i.e. protested and received an apology) but was weakened by an unsuccessful response (i.e. the ingroup protested and did not receive an apology). However, intergroup apology appeared to have no significant impact on forgiveness in the absence of ingroup protest. As predicted, these outcomes were regulated by the intergroup emotions experienced toward the outgroup (Maitner, Mackie, & Smith, 2006). That is, although intergroup anger uniquely predicted forgiveness directly following the insult, satisfaction took over this role once participants were told how the ingroup and outgroup had subsequently responded. These findings represent early evidence that forgiveness can be promoted via intergroup apology and also provide support for the regulatory function of intergroup emotions in this process.

### F54

**THE ROLE OF MOTIVATION TO RESPOND WITHOUT PREJUDICE IN THE PERCEPTION OF OUTGROUPS.** Claire R. Gravelin<sup>1</sup>, Elizabeth L. Ewell<sup>1</sup>, Jennifer J. Ratcliff<sup>1</sup>; <sup>1</sup>The College at Brockport, State University of New York – Research shows robust gender differences in attitudes toward gay men, with females expressing less prejudice than males (Herek, 1988). Recent evidence suggests that these gender differences are partially mediated by females' greater internal motivation to respond without prejudice (IM), and that this greater IM derives, in part, from females' stronger endorsement of a feminine self-concept as true of the self (Ratcliff et al., 2006). The primary purpose of the present work was to extend these findings by demonstrating that regardless of gender, viewing the self as more feminine—in response to a conceptual priming task—would lead to corresponding increases in IM. In addition, the present work examined whether experimentally enhancing IM would result in a greater liking for, and willingness to interact with, gay men. Finally, given that IM was shown to impact liking for and willingness to interact with sexual minorities, the current study also examined the mechanism by which IM influences these variables. Specifically, the extent to which gay speakers were individuated and categorized was measured via Klauer and Wegener's (1998) multinomial model of social categorization. Results revealed that enhancing femininity self-ascriptions elicited increases in IM, and that IM was associated with increases in both categorization and individuation of gay speakers. Consistent with predictions, IM was positively related to both liking and willingness to interact with gay men. Additionally, for individuals who received the femininity prime, individuation increased liking, whereas individuation decreased liking for those in the control condition. The implications of these findings will be discussed.

### F55

**MORALITY SHIFTING IN THE CONTEXT OF INTERGROUP VIOLENCE** Bernhard Leidner<sup>1</sup>, Emanuele Castano<sup>1</sup>; <sup>1</sup>The New School for Social Research, New York – Recent research (Castano & Giner-Sorolla, 2006; Leidner, Castano, Giner-Sorolla, & Zaiser, 2008) on moral disengagement from ingroup atrocities raises the question whether people suspend morality altogether or whether they stick to morality without judging the ingroup actions as immoral. We propose that the latter is the case, via a process called morality shifting. This process alters the influence of moral principles on moral judgments, with the goal to protect people's identity. Two experiments investigated morality shifting in the context of intergroup violence. We predicted that only ingroup violence threatens people's identity, so they shift their morals away from harm and fairness, allowing for the judgment "not immoral" and identity protection. In Study 1 (N = 140), participants read about atrocities committed by either an ingroup or an outgroup and then completed, in an allegedly unrelated study, the Moral Foundation Questionnaire (Haidt & Graham, 2007). It was found that both harm and fairness were rated as less important and relevant than loyalty and authority in the ingroup-perpetrator as compared to the outgroup-perpetrator condition. The reverse was true for loyalty. Study 2 (N = 40) was a conceptual replication of Study 1, but using an implicit measure of concept accessibility (Lexical Decision Task). It was found that loyalty and authority were more accessible in the ingroup-perpetrator as compared to the outgroup-perpetrator condition, while the reverse was true for harm and fairness. This research demonstrates that people engage in morality shifting under identity threat. Implications and consequences for intergroup relations are discussed.

### F56

**WHEN PARTING IS SWEET SORROW: PREDICTORS OF NOSTALGIA WHEN LEAVING GROUPS.** Ilka H. Gleibs<sup>1</sup>, Janelle M. Jones<sup>1</sup>; <sup>1</sup>University of Exeter, School of Psychology – According to social identity theory (e.g., Tajfel, 1982), individuals derive identities from their social group memberships. They may also be motivated to leave these groups when they no longer provide a sufficient basis for identification (e.g., low status, minority, or marginalized groups). Yet, it may not only be when groups are no longer of use that individuals leave them behind. Individuals are often forced to leave groups for a variety of different reasons including life transitions (e.g. graduation), opportunities (e.g., a new job), or circumstances (e.g. arbitrary assignments). The aim of this research was to examine the characteristics of groups that would make parting more poignant for individuals, leading to increased nostalgia about the left group membership. Study 1, where we manipulated identity salience (group vs individual) and choice (choice vs no-choice) in group assignment, found that nostalgia was highest for participants who had to leave a group that they had chosen when group identity was salient. Study 2, where we manipulated group cohesion (high vs low) and who leaves the group (self only vs everyone), found that nostalgia was highest when leaving cohesive groups, yet, in a non-cohesive group, nostalgia was higher when the complete group dissolved. These results are discussed in relation to identity (dis)-continuity and previous research on nostalgia.

### F57

**LOW STATUS MEMBERS JUSTIFY AMERICAN IDEALS NOT AMERICAN OUTCOMES** Jennifer Zimmerman<sup>1</sup>, Caitlin Minarchek<sup>1</sup>, Christine Reyna<sup>1</sup>; <sup>1</sup>DePaul University – System justification theory posits that all people legitimize the status quo. Motives to justify the system are congruent with motives to justify the self and group for high status members but incongruent for low status members. Thus, it is reasoned that if low status members legitimize American systems, they prioritize system needs over self and group needs. However, previous studies rely predominantly on perceptions of American ideals rather than actual outcomes. We predict that people's perceptions of what should be happening and what is actually happening in America will be similar for high status members but quite divergent for low status members. We also predict

that people of low status will prioritize self and group needs over system needs. Seventy-eight non-college adults rated the extent to which they support the ideals and outcomes of the Protestant work ethic. They also rated a series of items asking the extent to which they support raising taxes so that government programs would benefit different groups. Results indicate that low status members support the ideals of the PWE more so than high status members; however, high status members endorse the belief that PWE is a reality more so than low status members. We also found that low status members support raising taxes in order to benefit themselves, their family, and their community over America. These findings suggest that high status members are truly justifying the status quo. Low status members are only justifying the ideals of a system and prioritizing self and group needs.

#### F58

**MEMORY BIAS FOR THE OUTGROUP RELATIVE TO INGROUP: THE DIFFERENTIAL EFFECTS OF POSITIVE AND NEGATIVE OUTGROUP MESSAGING** Priscila Diaz<sup>1</sup>, Delia Saenz<sup>1</sup>; <sup>1</sup>Arizona State University – Recent research has extended the self-reference effect (SRE; Rogers, Kuiper, & Kirker, 1977), in which information related to the self and related groups may enhance memory recall. Specifically, memory for the outgroup may vary according to prejudice level (Diaz & Saenz, 2009). The present study examined how memory recall may vary based on primed negative or positive messages of cultural, religious ingroups and outgroups. White, Christian college students (N=135) read a positive or negative message about Arab Muslims, or read a neutral message defining social psychology. Following the passage, the participants completed a similar SRE task with neutral adjectives paired with self referent (i.e., does this word describe you), ingroup referent (i.e., does this word describe White Christians), and outgroup referent (i.e., does this word describe Arab Muslims). The participants were then given a cognitive distracter task followed by a surprise recall test of the adjectives. Overall, recall for the self was significantly higher than for White Christians and Arab Muslims, as expected. However, individuals primed with negative messages had a higher recall for Arab Muslims than for White Christians, relative to individuals primed with positive messages. The results show how different types of information about groups may influence how attentive we are when that group is referenced. This study reflects how societal messages may be a factor in how relevant certain cultural religious groups are to our perceptions and future studies can further examine the mechanisms behind memory and prejudice.

#### F59

**EXCLUSION TYPICALITY MODERATES THREATENED NEEDS AND STATE SELF-ESTEEM IN RESPONSE TO RECALLED EXPERIENCES OF EXCLUSION** Douglas Cooper<sup>1</sup>, Jamie Goldenberg<sup>1</sup>; <sup>1</sup>University of South Florida – The present study examined the interaction of exclusion typicality and exclusion on psychological needs and state self-esteem. Reactions to exclusion are thought to be part of an evolved ostracism detection system designed to quickly detect and react to real or imagined experiences of exclusion (Sporer & Williams, 2006; Williams & Zadro, 2005). Thus, the degree to which one feels that exclusion is typical of their life experiences influences negative expectations of exclusion in social situations and may also exacerbate one's reactions to exclusion. To test this, one-hundred eleven participants were asked to indicate the extent to which they felt exclusion or inclusion was typical of their life experiences and then wrote about a time they were excluded or included in a group. Participants subsequently completed the Needs Threat Scale (Williams et al., 2000), which assesses mood, levels of belonging, self-esteem, control, and meaningful existence, as well as a measure of state self-esteem (Rosenberg, 1965). Participants high, but not low, in exclusion typicality responded to recalled experiences of exclusion with decreased perceptions of control and self-esteem, as well as a decrease in state self-esteem. In contrast, writing about inclusion, for those high, but not low in inclusion typicality, increased perceptions of belonging,

mood, and meaningful existence. The findings suggest that chronic experiences of exclusion moderate reactions to exclusion, having differential effects on psychological needs.

#### F60

**POOR BUT FAIR: THE ROLE OF OUTCOMES VS. PROCEDURES IN GROUPS BASED COMPARISON AND INTERGROUP RELATIONS** Avital Mentovich<sup>1</sup>, Tom Tyler<sup>1</sup>; <sup>1</sup>New York University – Past research in social psychology has shown the central role of social comparison in generating meaningful judgments about one's self, group and culture. Such social comparisons have been mainly investigated in the context of relative material resources or outcomes. This research separately investigates the different effects of outcomes and procedures as the basis of intergroup comparisons and intergroup relations. We hypothesize that outcomes and procedures will be different. First, we predict that procedures will have more information value and therefore will have a stronger impact on intergroup relations. Second, we predict that the positive distinctiveness dynamics found with outcomes will be weaker with procedures. Four studies examine the effects of outcome vs. procedure based intergroup comparisons. As expected both outcomes and procedures influenced intergroup attitudes. Both arguments receive support. First, procedures had a generally stronger influence on intergroup relations and intergroup biases. Second, procedures were less influenced by comparative judgments. These findings have important implications for political systems because they suggest that groups should focus more heavily upon procedural issues when designing institutions, and less upon issues of outcome distribution.

#### F61

**OLDER ADULTS' PERCEPTIONS OF ANTI-AGING ACTIONS** Alexander M. Schoemann<sup>1</sup>, Nyla R. Branscombe<sup>1</sup>, Kristopher J. Preacher<sup>1</sup>; <sup>1</sup>University of Kansas – Youth is valued in Western culture and older people are targets of discrimination. To avoid such consequences, increasing numbers of older adults attempt to look younger. Older adults who attempt to look younger are a threat to the distinctiveness of young adults' social identities and are disliked by young adults (Schoemann & Branscombe, 2009). In this study, we examine how older adults who attempt to look younger are viewed by other older adults. We hypothesized that older adults who attempt to look young will cause ingroup members to feel shame and therefore be disliked. The study manipulated "passing" (attempting to look young) and gender of a target older adult. Older adult participants (age M=73.24) read a description of a male or female target who was attempting to "pass" or not. Participants rated their shame and target likeability. Participants disliked a target who attempted to look young, regardless of gender, and this effect was moderated by age group identification. Highly identified older adults disliked a target that was passing more than low identified older adults. Participants felt more shame about a target who attempted to look young, regardless of gender, and this effect was moderated by age group identification. Highly identified older adults felt more shame about a target that was passing than low identified older adults. Shame mediated the relationship between target passing and liking. Older adults are spending increasing sums of money in attempts to look younger, however, attempting to look younger results in negative evaluations from ingroup members.

#### F62

**CONFESSING OUR SINS: THE EFFECT OF INGROUP-AFFIRMATION ON COLLECTIVE GUILT AND COLLECTIVE SHAME** Gregory R. Gunn<sup>1</sup>, Anne E. Wilson<sup>1</sup>; <sup>1</sup>Wilfrid Laurier University – The defensive strategies employed by perpetrator groups to protect their social identity may have the unfortunate effect of undermining collective guilt and its pro-social consequences. However, if collective guilt and identity threat are distinct processes, then perpetrator groups may be able to alleviate threat without undermining guilt. Extending self-affirmation theory, the current research examines whether reflecting on valued aspects of the ingroup effectively buffers against identity threat, thus reducing defensiveness and allowing greater collective guilt. Moreover, in light of the theoretical

distinction between collective guilt and collective shame, the effect of ingroup-affirmation on each emotion is examined. In Study 1, the perpetrator group was more willing to acknowledge both guilt and shame once the threat to their social identity had been attenuated by ingroup-affirmation. We expected that when social identity is threatened (non-affirmation condition), shame would predict compensation as a means of restoring positive identity. However, when threat is disarmed (ingroup-affirmation condition), guilt would predict compensation out of concern for the victims. As predicted, affirmation moderated the relation between each emotion and compensation. When controlling for each other, only collective shame predicted compensation in the non-affirmation condition, whereas collective guilt was the sole predictor of compensation in the ingroup-affirmation condition. In Study 2, the effect of affirmation on each emotion was mediated by defensiveness. Specifically, after ingroup-affirmation, the perpetrator group was less likely to appraise their transgression defensively, and in turn more likely to acknowledge collective guilt and collective shame. Affirmation again differentially moderated the link between guilt/shame and compensation.

### F63

**WE'RE THE BEST, PERIOD: THE RELATIONSHIP BETWEEN THE NEED FOR CLOSURE AND INGROUP PREFERENCE** Corrie V. Hunt<sup>1</sup>, Emily Fisher<sup>1</sup>, Christopher M. Federico<sup>1</sup>; <sup>1</sup>University of Minnesota-Twin Cities – How a person defines a specific ingroup identity can interact with cognitive style to predict ingroup and outgroup attitudes. Prior research has demonstrated that a marked preference for clear, stable information over uncertainty can lead to relatively aggressive stances with regard to an outgroup (Federico & Golec, 2005). We extend these findings by examining how the need for closure interacts with perceived group status to influence ingroup bias. Because people high in the need for closure tend to seize and freeze on salient cues about the social environment, we predicted that high status should lead to greater ingroup bias. However, we expected the relationship between need for closure and ingroup bias to weaken for members of low status groups. To test our hypothesis, we first established ingroups and outgroups by informing participants that their answers to a questionnaire revealed that they were deductive thinkers, as opposed to inductive thinkers. We then manipulated the perceived status of the ingroup by telling participants that deductive thinkers tend to achieve higher (or lower) social and occupational status relative to inductive thinkers. Multiple regression analyses revealed that when in the high status group, people high in the Need for Closure tended to rate other deductive thinkers more positively ( $p < .05$ ). In addition, they showed a greater preference for working with deductive thinkers in an employment setting ( $p < .05$ ), on a problem solving task ( $p < .10$ ) and a creativity task ( $p < .05$ ). We address implications for preference for the status quo and intergroup relations in a hierarchical context.

### F64

**INTERGROUP OPTIMALITY OF THE SELF-ENHANCEMENT BIAS** Chris Kast<sup>1</sup>, Michael R Ransom<sup>2</sup>; <sup>1</sup>Iowa State University, <sup>2</sup>Ohio University – Research examining in-group effects have traditionally posited that individuals are prone toward an in group bias as a form of self enhancement. Recent research has demonstrated that this self enhancement on personal traits is limited to an optimal level trending away from the extremes (Borkenau, Zaltauskas, and Leising 2009). The present study attempts to explore differences in this optimal level of self enhancement in reference to an in-group out-group framework. Utilizing a Klee and Kandinsky minimal group paradigm all participants were privately informed that they expressed a preference for Klee and were subsequently given either positive or negative information about Klee or Kandinsky lovers or a fictional past participant who also expressed a preference for either Klee or Kandinsky artwork. Participants were then asked to make judgments about group members as a whole, a fictional past participant, and themselves. Results replicate the traditional phenomenon (Hewstone, Ruben, Willis 2002) with those who evaluated ingroup members giving them much higher ratings on the trait spontane-

ity than those who evaluated an out-group member. Finally paired samples T tests indicate that mean self ratings in a situation where both the individual and in-group members are designated as high performing is indistinguishable from the group mean. While self ratings where the individual and out-group members are designated as high performing are significantly higher than the group mean. This would suggest that the optimal level of discrepancy between group and self is higher in an out-group scenario.

### F65

**ARE YOU GOING TO EAT THAT? A NATURALISTIC EXAMINATION OF INTRAGROUP VARIABILITY IN CONSUMPTION BEHAVIOR** Rachel Burns<sup>1</sup>, Maryhope Howland<sup>1</sup>, Traci Mann<sup>1</sup>, Alex Rothman<sup>1</sup>, Jeff Simpson<sup>1</sup>; <sup>1</sup>University of Minnesota – Eating behavior is a central part of everyday life and is heavily influenced by those with whom a meal is shared. For instance, individuals tend to eat more in the presence of well-known others—a phenomenon known as social facilitation of eating (de Castro, 1994). The extended duration of a shared meal is an empirically-supported explanation of this phenomenon (Pliner, Bell, Hirsch & Kinchla, 2006). However, much of the work in this domain has been conducted in the laboratory, has required participants to monitor and record their own consumption behavior, and has neglected group-level outcomes. Our study attempts to expand upon the extant body of work by examining natural consumption behavior at the group, rather than individual, level; specifically we focus on the variability of food consumption within the group. Unobtrusive behavioral observation was used to examine the eating of 81 groups of students in a buffet-style dining hall. Consistent with prior research, meal length predicted the groups' mean number of calories taken, caloric intake, number of trips taken to the buffet and number of items taken to the table. Interestingly, meal length also predicted the within-group variability on each of the four outcome variables. Although the results support the extended duration explanation of social facilitation of eating, they also suggest that our current views of eating behavior may neglect a central dimension of group influence— in-group variability in eating behavior. Examination of this dimension would lead to a more nuanced and dynamic understanding of social eating behavior.

### F66

**PERCEIVED INTERRACIAL COMPATIBILITY IN AN ASIAN/ WHITE MATCHMAKING TASK** Curtis Yee<sup>1</sup>, Vani Murugesan<sup>1</sup>, Aston Tsui<sup>1</sup>, David Sears<sup>1</sup>; <sup>1</sup>UCLA – Asian-American men date and marry outside their race at much lower rates than Asian-American women (Census, 2006). One reason may be the perceived compatibility of interracial couples favoring White-male/ Asian-female couples, with media/ stereotypes portraying such couples as more compatible and normal, whereas Asian-male White-female couples are less so. We conducted a matchmaking experiment to examine perceived compatibility based on race and gender. In a 2x2x2 within-subjects study, participants (N=200) completed a matchmaking task, where they reviewed a profile of an Asian-American female, then a White female, and chose the best male match amongst 4 suitors. Of the 4 suitors, 2 were Asian and 2 were White. Also, we counterbalanced their dating profiles such that one of each was a good match with the target, and one of each was a poor match. In general, we found that Asian male matches were rated as less compatible compared to White matches, even though attractiveness was controlled for. Moreover, Asian matches were found to be less compatible with White women than White matches were. However, Asian matches and White matches were found to be equally compatible with Asian women. Finally, we also found that among the poorly matched suitors, White matches were still rated higher than Asian matches. Results did not support assortative mating theories, but instead supported a group-based Social Dominance hypothesis. We propose that lack of perceived compatibility may actually contribute to the disintegration of certain interracial relationships.

**F67**

**UNCERTAINTY, ENTITATIVITY, AND SOCIAL STATUS: IDENTIFICATION WITH GROUPS WITHIN AN INDIAN SAMPLE** Namrata Mahajan<sup>1</sup>, Michael A. Hogg<sup>1</sup>, <sup>1</sup>Claremont Graduate University – Participation and identification with groups has been a widely-studied phenomenon within social psychology. Uncertainty-Identity Theory (Hogg, 2007) suggests that people do not like to feel uncertain about their world, and identifying with groups allows them to reduce uncertainty because groups provide directions on how to feel, think, and act. The more people feel uncertain, the more they identify with groups that have clear boundaries, structure, and high internal homogeneity (i.e., high entitativity groups). The purpose of the current study was to understand how a group's social status affects the identification process. It was predicted that when uncertainty was high, people would identify with clearly-defined groups (i.e., groups high in entitativity). However, when uncertainty was low, people would identify with groups that were high in social status rather than entitativity. Data were gathered from 195 students at a university in India (mean age = 20.97). Participants read about a hypothetical company that would soon recruit employees in their community. Uncertainty, entitativity, and social status were manipulated and identification with the company was the dependent variable. The results indicated a significant 2-way interaction between uncertainty and entitativity. Specifically, data showed that as uncertainty increased, identification with low entitativity groups decreased and identification with high entitativity groups increased. In contrast to previous studies on status, this pattern of results was the same regardless of the group's social status. The results suggest that the entitativity of a group may play a greater role in the identification process than its social status.

**F68**

**TASK INTERDEPENDENCE IMPROVES RAPPORT, BUT NOT OTHER AFFECTIVE CONSTRUCTS** Jon Grahe<sup>1</sup>, Emily Hoppeler-Treichler<sup>1</sup>, <sup>1</sup>Pacific Lutheran University – Task Interdependence (Riggio, 2008) often increases group performance (Doorewaard, Van Hootegeem, & Huys, 2002), but can generate resistance in employees (Friberg, Segesten, Gedda, & Mattsson, 2008). The present research examined how Task Interdependence impacted experiences during the Dyadic Puzzle Task (Grahe & Sherman, 2007). Because Task Interdependence requires contributions from each member, the mutuality required to experience high rapport (positivity, attention, coordination; Tickle-Degnen, 2006) should improve rapport, but not other affective constructs (cohesion, enjoyment, frustration). Dyads (N = 64) completed an 8-piece puzzle under various Task Structure conditions where both members' contributions were necessary (Dyadic) or the worker could complete the task without the instructor's help (Individualistic). Dyads then completed a 25-piece puzzle and a brief questionnaire measuring their experiences (rapport, cohesion, enjoyment, frustration). Task Interdependence impacted rapport,  $F(4, 60) = 2.76, p < .05$ , such that dyads in the Individualistic condition (M = 6.10) reported lower rapport than any of the Dyadic conditions (blindfold, M = 6.52; shield, M = 6.63; shield+blindfold, M = 6.69; visual shield+mirror, M = 7.24). Task Interdependence did not impact cohesion, enjoyment, or frustration,  $Mdn F(4, 60) = .55, all ps > .34$ . Further analyses examined behavioral differences. These findings support the importance of mutuality to dyadic rapport. Additionally, rapport increased even though performance decreased under the more challenging conditions suggesting that implementation of Task Interdependence in the workplace should result in positive outcomes, even with initial resistance.

**F69**

**RACIAL IDENTITY AND RACE-RELATED STRESSORS: THEIR RELATION TO MENTAL HEALTH AMONG ASIAN PACIFIC AMERICANS** Nellie Tran<sup>1</sup>, Sabine Elizabeth French<sup>1</sup>, Noe Chavez<sup>1</sup>, <sup>1</sup>University of Illinois at Chicago – Using the risk and resilience model, the current study examined the risk of race-related stressors (racial discrimination, stereotype confirmation concern, and own-group conformity pressure) on the mental health of

Asian Pacific Americans (APIs) and the resilience of APIs through the potential protective role of racial identity (centrality, private regard, public regard, and other-group orientation). We found that race-related stressors in the form of perceptions of general discrimination, stereotype confirmation concerns, and own-group conformity pressures are risk factors to the mental health of APIs in this study. Second, we explored the protective role of dimensions of racial identity and found that the extent to which racial identity dimensions were protective for mental health depended on other factors. As expected, private regard was protective. However, the ability of racial identity to protect APIs from the negative influence of race-related stressors on their mental health is more complex. Racial identity only protects students' mental health when stereotype confirmation concerns are low. Additionally, centrality and private regard showed different patterns of protection against the effects of own-group conformity pressure on mental health outcomes. Findings are interpreted by addressing the racially diverse context that may create acculturative pressures and/or stereotype threat conditions.

**F70**

**ARE GROUPS WHO ARE OSTRACIZED MORE AGGRESSIVE THAN INDIVIDUALS WHO ARE OSTRACIZED?** Adrienne R. Carter-Sowell<sup>1</sup>, Ilja van Beest<sup>2</sup>, Eric van Dijk<sup>3</sup>, Kipling D. Williams<sup>1</sup>, <sup>1</sup>Purdue University, <sup>2</sup>Tilburg University, <sup>3</sup>Leiden University – The Model of Ostracism – ignoring and excluding by individuals or groups – (see Williams, 1997; 2001; 2007a; 2009) suggests that once ostracism is detected, the target reacts in lowered satisfaction levels of four basic needs: belonging, self-esteem, control, and meaningful existence, plus increased negative moods: anger and sadness. A theory-derived measure (Zadro, 2004) assesses two reaction stages (reflexive and reflective) following detection of being ignored and excluded. Two experiments were conducted to examine the reflexive (immediate) and reflective (delayed) responses of ostracized co-target groups compared to ostracized solo targets. Does sharing ostracism with a co-target dilute the impact (social impact theory) or do intergroup relations promote aggressive behavior (discontinuity effect)? For both experiments, participants were randomly assigned to play Cyberball either individually (with two other individual players) or in co-target groups (playing with two other co-target groups), and they were either included or ostracized during the game. For both experiments, immediately following the Cyberball session, self-reports of affect and need threat were measured. Next, aggression was measured using hot sauce allocations to other players (Experiment 2). To measure recovery from the inclusion manipulation and intergroup motivations to aggress, fundamental needs were assessed before and after the hot sauce allocations. The overall results suggested that in the reflexive stage, ostracism is universally distressing to both individuals and groups. With reflection, however, groups can recover satisfaction of basic needs quicker than individuals. Additionally, the findings show that co-target groups, compared to solo targets, behave more aggressively.

**F71**

**SOCIAL DOMINANCE ORIENTATION AND THE WILL TO POWER: SELF-ENHANCEMENT FOLLOWING UPWARD INTERRACIAL COMPARISON** Curtis D. Hardin<sup>1</sup>, Rick M. Cheung<sup>1</sup>, <sup>1</sup>Brooklyn College and Graduate Center, City University of New York – Just as self-enhancement motivation can lead people to respond to negative information about the self with enhanced self-esteem, social dominance motivation can lead people to respond to apparent inferiority with feelings of superiority. Two experiments demonstrate that white participants outperformed by non-whites self-enhance to the degree that they are high in social dominance orientation (SDO), whether relative performance is imagined (Exp. 1) or manipulated in a classic quiz-game procedure (Exp. 2). Findings suggest that when white superiority is interpersonally challenged, high-SDO whites may react by psychologically (re)establishing racial dominance.

**F72****HOW LEADERS INDUCE UNCERTAINTY: A CASE OF IDENTITY**

**AFFIRMATION AND NEGATION** Amber Gaffney<sup>1</sup>, David Rast, II<sup>1</sup>, Michael Hogg<sup>1</sup>, Richard Crisp<sup>2</sup>; <sup>1</sup>Claremont Graduate University, <sup>2</sup>Kent University – Uncertainty-identity theory posits that when individuals feel uncertain about themselves and their places in the world, they will seek to identify with groups that provide them with a clear and coherent identity (Hogg, 2007). Feeling uncertain may also lead individuals to support leaders who embody important group norms (i.e., are prototypical of their group). Research has yet to elucidate if leaders possess the ability to make their followers feel uncertain about themselves and their places in the world, and moreover research has yet to outline the ways in which leaders may induce uncertainty in their followers. One way in which leaders may induce uncertainty is to make followers feel as if they are non-prototypical or marginalized group members (e.g., Marques, Abrams, & Serôdio, 2001). The current study examined whether leaders can induce uncertainty in their followers by marginalizing or affirming their followers' group identities. Participants were university students (N = 103) who read a vignette in which we manipulated whether or not a leader highlighted that s/he and the majority of the student body shared in participants' opinions regarding tuition fees. Our findings suggest that among participants with a marginalized identity, as identification with their university increases, uncertainty increases,  $\beta = .42$ ,  $t(50) = 3.17$ ,  $p = .003$ . Conversely, among those with affirmed identities, identification is unrelated to uncertainty ( $p = ns$ ). These results suggest that leaders may have the ability to elicit uncertainty among their followers by affirming or marginalizing their followers' identities within their group.

**F73****HOW DO WE EXPERIENCE OURSELVES WHEN WE ARE IN SOCIAL**

**ENERGY?** Donnan Canavan<sup>1</sup>; <sup>1</sup>Boston College – In images of Obama's inauguration, the 9/11 clean-up, or John Kennedy's funeral, we see people mutually engaged in something meaningful. 'Social energy' as a desirable powerful social phenomenon in which a person (P) gets involved in an intrinsically motivated relationship with another person (O), and these people are mutually aware that they each have an independent intrinsic interest in a topic or activity (X). Canavan (2002) and her students have shown that social energy positively affects effort, concentration, performance, affect, and relationships. In this study 60 participants were randomly assigned in a 2X3 factorial design with high, medium, or low social energy and two levels of competition. Participants were asked to remember vividly a seminar/class experience they had that corresponded to one of the cells and to answer a series of questions that described dimensions of their self-experience. The Analyses of Variance revealed that In High Social Energy (HSE) compared to Medium or Low Social Energy (LSE), that participants described themselves as most involved in participation and relationship, and least involved in self/other evaluation. Similarly, HSE described themselves as most closely connected on the IOS Scale yet highest in Self Clarity, a combination that makes the HSE most psychologically independent. Interestingly as predicted, since participants attributed their differing experiences to the situation of social energy, there were no differences in self rated intelligence, or self-esteem. Finally, HSE rated themselves as highest in intrinsic motivation, energy, positive affect and quality relationship with the teacher.

**F74****THREAT CONTAGION DURING CROSS-RACE INTERACTIONS**

Katrina Koslov<sup>1</sup>, Elizabeth Page-Gould<sup>2</sup>, Wendy Berry Mendes<sup>1</sup>; <sup>1</sup>Harvard University, <sup>2</sup>University of Toronto at Scarborough – In the past decade much evidence has accumulated that observing or interacting with racial outgroup members results in fear, cardiovascular threat responses, and amygdala activation, which is associated with fear and uncertainty. Much of this research has focused on the majority group members' experience with interacting with a minority or stigmatized group member. A parallel line of research has examined the effects of being a minority group member

in a society that historically discriminates against one's group. There has been very little research that has attempted to bridge these research traditions to examine affective, behavioral, and physiological responses during ongoing social interactions among two naïve participants, even though it is the reciprocal nature of these interactions that is likely to shed light on the affective consequences of intergroup interactions. In this study we recruited two naïve participants matched on age, gender, and current occupation/student status. More than half of these dyads were cross-race, specifically White and African-Americans. We obtained baseline physiological responses prior to the dyad meeting, and then recorded their on-line physiological responses, affective reactions, and non-verbal behavior during a variety of tasks, several of which were designed to activate the two primary stress systems. Consistent with past research, intergroup interactions resulted in more threat responses than same race interactions. Importantly, these data allow us to extend prior research by examining the contagiousness of threat responses, which is how affective and behavioral responses of one member of the dyad leaks out to influence the other member's reactions.

Poster withdrawn.

**F76****INGROUP ALLOCATION MODEL – LANGUAGE AS A TOOL TO REDISTRIBUTE RESOURCES**

Marie Gustafsson<sup>1</sup>, Sverker Sikström<sup>2</sup>; <sup>1</sup>Stockholm University, <sup>2</sup>KTH, Royal Institute of Technology, Stockholm – We present a theory – the Ingroup Allocation Model (IAM) that propose how language may function as a tool for influencing behaviors of other to boost resources of the speaker. Resources can be increased either by recruiting members to the ingroup, leading to that other people engage in behaviors that share the speakers goal and diminished threat from the outgroup, or by redistributing individual resources to collective resources, leading to greater possibility of using resources collected by other ingroup members. This framework is supported by empirical data on how social groups are valued in text corpora. These values are measured by semantic spaces in large text corpora. We measure values of social groups by studying the valence of the context of personal pronouns. The personal pronouns are semantic markers for individual or collective identity, as well as for ingroup and outgroup belonging. Different inflection of the pronouns also signals activity and ownership. The IAM framework is further supported by results of a computer simulation showing how allocation of resources leads to greater fitness of speakers. We discuss how previous theories such as social identity theory (Tajfel & Turner, 1979), and self expansion model (Aron & Aron, 1996) can be integrated in the IAM framework where language is seen as a tool to redistribute wealth.

**F77****GOOD FEELINGS AND POOR PERFORMANCE: THE REVERSE "OBAMA EFFECT"**

Jamie Barden<sup>1</sup>, Edward Orehek<sup>1</sup>; <sup>1</sup>Howard University, <sup>2</sup>University of Maryland – Evidence of the impact of Barack Obama on the academic task performance of Blacks has been mixed, with some studies showing improvements (Marx, Ho, & Freidman, 2009), but others not (Aronson, Jannone, McGlone, & Johnson-Campbell, 2009). In the current study, Black student participants viewed a video of similar press conferences given by either Obama or George W. Bush followed by an anagram task framed as a separate study. Low academic achievers (lower GPA) performed better on the anagram task following the Obama than Bush video, showing the Obama effect. However, high achievers (higher GPA) performed worse following the Obama video than the Bush video, showing a reverse Obama effect. Critically, positive emotions elicited by the Obama video fully explained performance decrements among high achievers, but were unrelated to low achiever performance. So, while various explanations have been postulated for performance enhancements, the current results establish that positive affective responses to Obama can have an ironic detrimental impact on performance, particularly for a critical group, high achieving Blacks.

## Individual Differences

**F78**

**IT'S A MIRACLE! LAY PEOPLES' CONCEPTIONS OF MIRACLES** Michael R Ransom<sup>1</sup>, Mark D Alicke<sup>1</sup>; <sup>1</sup>Ohio University – Many people believe in miracles. A 2008 survey in AARP magazine discovered that 80% of their sample, consisting of 1315 people, believed that miracles occur today as they did in ancient times (Anderson, 2008). Additionally, philosophers have weighed in on the concept of miracles asserting that miracles must violate natural laws and be caused by a deity/supernatural force (Hume, 1748). However, there is scant research investigating what lay people think about miracles and whether their miracle definitions/conceptions mirror those of famous philosophers and theologians. A total of 145 participants answered a wide-variety of miracle-related questions such as if they personally believed in miracles (81.4% of our sample indicated they did believe in miracles) and if so, why they think miracles occur. Participants also defined a miracle. We then coded, using two independent raters, participants' miracle definitions into three categories: low probability, beneficial outcome, and divine intervention. Their miracle purpose responses were coded into two categories: to demonstrate God's power/presence and to instill hope/faith in people. The most represented miracle definition category was low probability; 48% of participants alluded to low probability in their definitions, followed by beneficial outcomes and divine intervention. 41.4% of participants mentioned that the purpose of miracles was to give hope/restore peoples' faiths and 24.1% of the surveys were classified into the second category, power/presence. These results match well with scholars' miracle notions which characterize miracles as highly improbable events and maintain that miracles restore people's faiths and show God's power/presence in the natural world (Brown, 1984).

**F79**

**PERCEIVED CONTROL AS A PREDICTOR OF MORTALITY: THE MODERATING ROLE OF HEALTH VALUE** Judith Chipperfield<sup>1</sup>, Raymond P Perry<sup>1</sup>, Reinhard Pekrun<sup>2</sup>, Petra Barchfeld<sup>2</sup>, Loring P Chuchmach<sup>1</sup>; <sup>1</sup>University of Manitoba, <sup>2</sup>University of Munich – Perceiving little control over the maintenance of one's health care has been shown to predict mortality (Chipperfield, 1993). However, Krause and Shaw's (2000) study showed that perceived control predicted mortality only in the context of highly valued roles. These findings and the Control Value Theory (Pekrun, 2006) suggest that the effect of perceived control may be qualified by the value placed on an outcome. We systematically examined whether health value (HV) moderated the role of perceived control (PC) over health in predicting survival 13 years later among a representative sample of older adults (n=325). A significant HV x PC interaction (Beta = -.10; Wald = 4.1, p < .05) emerged in a logistic regression that controlled for age, gender, education, marital status, and emotional, functional and physical well being. The HV x PC interaction illustrated that health value moderated the effects of perceived control on mortality. Moreover, the pattern of findings conformed to the expectation that a protective effect of PC would only emerge when health value was high. In particular, by follow-up, approximately 40% of those with strong perceptions of control over their health had died compared to about 60% of those with weak perceptions of control. These findings imply that feelings of control have a survival benefit, but only when health is valued.

**F80**

**ONLINE GAMING: NEGATIVE RELATIONS WITH PERSONALITY TRAITS AND SOCIAL SUPPORT** Mallori L. Warren<sup>1</sup>, Tera D. Letzring<sup>1</sup>; <sup>1</sup>Idaho State University – The internet is becoming an increasingly popular source of information and social networking for many people. Online gaming, specifically, is a phenomenon that is quickly becoming main stream. Many people use this outlet for social interaction, relaxation, and an escape from everyday life. Discussions about online gaming can be heard on talk radio shows and seen on nightly news broadcasts. Researchers have examined how internet use is related to real world

relationships in adolescents (Sanders, Field, Diego, & Kaplan, 2000), perceptions of social support and well-being among people with spinal cord injury (Miller, 2008), and communication with family members, social circle size, depression, and loneliness among new internet users (Kraut et al., 1998). The current research focuses on college students and examines the relations of personality traits and social variables with self-reports of time spent playing online games. Results show that males and people in less committed romantic relationships spend more time in online gaming. Even more interestingly, participants who reported spending more time in online gaming were lower in agreeableness (especially the facets of cooperation, morality, sympathy and trust), conscientiousness (especially achievement striving, orderliness, and self-discipline), satisfaction with life, happiness, perceptions of social support, and ego-control; and higher in openness (especially imagination and liberalism) and loneliness. Overall, results show that more time spent in online gaming is related to less desirable personality traits and a lack of connectedness with others in the real world.

**F81**

**RIGHT-HAND MAN OR THE MAN UPSTAIRS? HOW DOES THE CONCEPT OF THE DIVINE INFLUENCE VISUAL ATTENTION?** Alison L. Chasteen<sup>1</sup>, Donna C. Burdzy<sup>1</sup>, Jay Pratt<sup>1</sup>; <sup>1</sup>University of Toronto – How strongly do we associate "God" and "Devil" with our physical world? Humans have long used spatial metaphors for abstract concepts of the divine, ranging from Mt. Olympus and the underground Hades in ancient Greece to the current conceptions of Heaven and Hell. Such metaphors are useful as they provide a common metric, physical space, to which abstract information can be bounded and communicated to other people. Indeed, such spatial metaphors are so pervasive in divine concepts that many religious and cultural traditions have representations in either or both vertical and horizontal space. Given the reliance on spatial metaphors in concepts of the divine, it is possible that merely thinking of concepts of God or Devil might invoke brain activity associated with the processing of spatial information and orient people's attention to associated locations. To examine if exposure to divine concepts shifts visual attention, participants completed a target detection task in which they were first presented with God and Devil-related words. We found faster RTs when targets appeared at locations compatible with the concepts of God (up/right locations) or Devil (down/left locations), and also found that these results do not vary by participants' religiosity. These results demonstrate the power of metaphors associated with the divine, as merely activating those concepts influences low-level cognitive processes such as orienting visual attention. As well, the lack of individual differences in this effect indicates the robust influence of divine concepts on cognition across a variety of religious and cultural groups.

**F82**

**WHAT MAKES NEGATIVE COMMUNICATIONS BECOME THE SOCIAL SKILLS?** Yukako Ishii<sup>1</sup>; <sup>1</sup>Graduate School of Literature and Human Sciences, Osaka City University – Traditional social skill studies have treated only Positive (so-called desirable) Communications such as assertion and relational maintenance as social skills. However, under the circumstance of real life, we often use Negative-Communications including deception, lying, avoiding, and aggression as useful communication tools. To reconsider the definition about social skills and the possibility of Negative-Communications to be social skills must be examined. In this study, I did the questionnaire investigation about the relationship between social adjustments and Negative-Communications which are potential to be social skills. 284 male and female participated to the survey (mean age was 22.5). The result of ANOVA, there were some interaction effects. When meta-cognition about one's communication situations were exerted, using Negative-Communications reduced negative emotions, and the person who could combine both Positive-Communications and Negative-Communications tended to increase positive emotions. In conclusion, Negative-Communications can be the social skills under the specific conditions, and detailed studies of its functional capabilities are needed.

**F83****SOCIAL DOMINANCE ORIENTATION AND PERCEPTIONS OF RESOURCE ENTITLEMENT**

Leslie Janes<sup>1</sup>, Victoria Esses<sup>2</sup>, Lynne Jackson<sup>3</sup>, Constance Sibanda<sup>1</sup>, <sup>1</sup>Brescia University College, <sup>2</sup>The University of Western Ontario, <sup>3</sup>Kings University College – This research examined whether individuals from western nations are more likely to criticize other countries for damaging the environment to benefit themselves than for damaging the environment in order to provide resources for western nations. Participants read one of six bogus newspaper articles that discussed a strip-mining project producing bauxite in either Romania, Vietnam, or Jamaica. Half of the articles stated that the bauxite was for homebuilding use in those countries, whereas the other half stated that the bauxite would be exported to participants' own country for this use. The strip mining project was described as environmentally disastrous, creating both air and water pollution and defacing the land. After reading the article, participants were asked to evaluate the acceptability of the environmental impact of the mining project. Individual differences in Social Dominance Orientation (SDO) were also assessed. It was hypothesized that participants would find environmentally-damaging projects more problematic if the resources obtained from these projects were intended for the source country as opposed to participants' own country. Additionally, it was hypothesized that individuals higher in SDO would be especially likely to show these effects. Results indicated that participants higher in SDO rated the damage as more acceptable if their own country was to benefit than if the source country was to benefit, whereas participants lower in SDO showed the opposite effect. Results are discussed in terms of western nations' feelings of entitlement regarding the world's resources, and their perceptions of the costs and benefits of harvesting these resources.

**F84****RELATIONSHIP BETWEEN INDIVIDUAL DIFFERENCES AND REGIONAL CONTACT WITH US REGIONAL PERSONALITY STEREOTYPE ACCURACY**

Kate Rogers<sup>1</sup>, Dustin Wood<sup>1</sup>, <sup>1</sup>Wake Forest University – Recent research indicated that people's impressions of how personality traits vary across cultures may be no more accurate than chance (Terracciano et al., 2005). As this has not been investigated in other contexts, we explored whether Americans can accurately describe the typical personality differences between people in different regions of the US. By cluster analyzing US state similarity ratings provided by 16 participants, 20 regions were created. Using these regions, 93 participants completed surveys rating people from each region on their Big Five personality characteristics. Finally, we compared perceived regional personality profiles to regional personality profiles found from actual self-ratings by Rentfrow, Gosling, and Potter (2008). We explored individual differences and regional contact as possibilities for accuracy. We used two measures of personality (the Big Five Inventory and the Inventory of Individual Differences in the Lexicon) to find the relationship between individual differences and US regional personality stereotype accuracy. While some individual differences correlated with accuracy, we found no systematic pattern. Furthermore, contrary to expectations, we found little evidence that residency in a region was associated with increased accuracy in judgments. Instead, we found that individuals reported trait levels of a region to be more positive if they had lived in the region. Thus, individuals from a region reported higher levels of agreeableness, conscientiousness and extraversion and lower levels of neuroticism. The results suggest that people are able to obtain accuracy in regional personality judgments, but indicate that more work needs to be done to understand the reasons for accuracy.

**F85****STUDENT BELIEFS ABOUT EFFECTIVE TEACHING AND LEARNING AND THEIR RELATIONSHIP TO PERSONALITY TRAITS**

Brian Pauwels<sup>1</sup>, Bettina Zengel<sup>1</sup>, <sup>1</sup>Doane College – Many popular notions of classroom learning espouse approaches to teaching that promote so-called "active learning," in contrast to presumably passive, lecture-based classrooms. In addition, such notions often promote the importance of the individual learning

styles or classroom preferences of the students. However, these conceptions of learning have been criticized recently by some cognitive scientists for being overly simplistic or ineffective. Given the apparent popularity of such models among some teachers and students, the present study examined the personality and cognitive correlates of belief in such models in a sample of college students. A correlational study examined the relationships between student beliefs regarding the nature of effective learning, several personality traits, and academic performance. One hundred eleven college students (48 men, 63 women) completed a questionnaire assessing a) their beliefs about the effectiveness of lecture vs. other pedagogical approaches in a classroom environment, b) their beliefs about the existence and relevance of different learning styles among students, and c) personality traits including academic self-handicapping and need for cognition. Consistent with predictions, preference for lecture-based approaches was associated with higher college GPA, higher need for cognition scores, lower academic self-handicapping scores, and less endorsement of learning-style models of education. The data suggest that student endorsement of some popularized notions of education (e.g., the importance of students' presumed individual learning styles, the general inferiority of lecture-based pedagogy) may not be entirely desirable.

**F86****CHANGING CAUSAL UNCERTAINTY BELIEFS OVER TIME: THE ROLE OF DIFFERENTIAL RECALL OF PAST UNCERTAIN EVENTS**

Ryan P Brunner<sup>1</sup>, Gifford Weary<sup>1</sup>, <sup>1</sup>The Ohio State University – Recent research has shown that a reflective memory perspective can aid in the reduction of negative feelings associated with past events (Kross, Ayduk, & Mischel, 2005; Kross & Ayduk, 2008). The current study seeks to examine the relationship between the level of chronic causal uncertainty (CU) and how past uncertain memories are recalled. Feelings of CU, or the feeling that one is unable to understand causes, are associated with negative affect and lead to the generation of action plans to reduce uncertainty. Thus, although it is a chronic goal to reduce feelings of uncertainty, research has shown that CU feelings remain chronically available for many people over time (Weary & Edwards, 1994, 1996). The present study builds upon previous work showing that individuals with chronically available CU are more likely to recall uncertain past events from an immersed visual perspective. Participants were asked to recall either an uncertain event or a visit to the dentist. They then were asked to rate the memory on a number of different dimensions. Results showed that participants with higher levels of measured CU recalled past uncertain events with more intensity, focused more on the details of the event, had less confidence in their ability to understand similar events in the future, and used significantly fewer causal words when describing the event. These findings provide further evidence for how chronic CU beliefs are maintained over time. The implications for work on memory perspective and chronic belief states will be discussed.

**F87****DESIRE FOR CHANGE AND COGNITIVE UNCERTAINTY INFLUENCE PREFERENCES FOR GAIN FRAMED SURE-THING CHOICES**

Verlin B. Hinsz<sup>1</sup>, Jared L. Ladbury<sup>1</sup>, <sup>1</sup>North Dakota State University – Uncertainty

avoidance assesses a person's comfort with and reactions to elements of the world that are uncertain. We hypothesize that uncertainty avoidance should relate to sure thing and risky choices, but previous research demonstrates this is only true if the sure thing is framed in terms of gains. We extend previous research by (1) using multiple measures of uncertainty avoidance including emotional reactions to uncertainty (EU), desire for change (DFC), and cognitive reactions to uncertainty (CU), and (2) assessing choices in relatively context-restricted problems which involve gaining or losing money versus the relatively context-rich "Asian Disease" problem. Participants (N=945) completed uncertainty avoidance measures from the Uncertainty Response Scale (Greco & Rogers, 2001) and chose between a sure monetary gain/loss or a risky choice that could result in a greater gain/loss or nothing. The disease problem involved choosing between saving a subset of people infected with a dis-

ease or risk a treatment that could save all or none of them. Logistical regression results replicate and extend prior findings. No effects are found for EU or in problems framed as losses. For problems framed as gains, DFC and CU predict choice preference in the monetary problem. DFC and the interaction between DFC and CU predict preference for risky options in the disease problem such that an individual's DFC impacts choices only when CU is low. Thus, uncertainty avoidance relates to risky choices, but only when those choices appear in a context that engages the proper cognitive and affective systems.

### F88

**THE EFFECT OF PERSONALITY FACTORS IN PREDICTING INFORMATION DISCLOSURE ONLINE** Emily Christofides<sup>1</sup>, Amy Muise<sup>1</sup>, Serge Desmarais<sup>1</sup>; <sup>1</sup>University of Guelph – Privacy is an underdeveloped area, and the role of information disclosure in the negotiation of privacy has not been fully explored. In addition, new technology is changing the way that privacy is experienced, and is changing people's ability to control what information they share and keep private. In previous work, one of the current authors theorized that individual factors affect privacy orientation and that situational factors affect privacy goals (Christofides, unpublished manuscript). The current research attempted to elucidate which personality factors affect disclosure behavior on the popular social network site, Facebook. In order to explore this, we conducted an online survey with a sample of university undergraduates. Regression analysis showed that the need for popularity predicted likelihood of disclosing on Facebook. However, self-esteem and trust, two factors that have previously been associated with disclosure (Ellison, Steinfeld, & Lampe, 2007; Henderson & Gilding, 2004), did not predict disclosure on Facebook, but they did predict the likelihood that someone would use the Facebook privacy settings. While all of the factors we measured were hypothesized to be individual factors, it could be that the need for popularity makes people more open to situational factors. If the Facebook environment provides cues that indicate that disclosure is expected and safe, and sharing information online is the main way of accessing popularity, then Facebook may be an environment that normalizes disclosure. As such, the nature of the relationship between privacy and disclosure may be different in this environment than in other, less public, environments.

### F89

**DEPENDABLE MOST OF THE TIME: THE ROLE OF EXCUSES IN RATIONALIZED MISCONDUCT** Michael Tamborski<sup>1</sup>, Ryan Brown<sup>1</sup>; <sup>1</sup>The University of Oklahoma – Almost by definition, the processes that facilitate rationalized misconduct, such as certain forms of cheating, should include self-deception. However, previous research has found no link between rationalized cheating and general self-deceptive enhancement (von Hippel, Lakin, & Sakarchi, 2005). We propose that a more narrow form of self-deception, excuse-making, might more accurately underlie the rationalization process. Participants completed multiple questionnaires related to excuse-making and dependability and later completed a computerized arithmetic task with a design feature allowing participants to engage in both deliberative, overt cheating and subtle, rationalized cheating. An item-level factor analysis of the questionnaires revealed three latent variables: dependability, locus of control, and willpower. Dependability was positively associated with deliberative cheating, but dependability and willpower interacted to predict rationalized cheating. Participants low in willpower engaged in more rationalized cheating than those high in willpower, but only among those high in dependability. Participants low in dependability engaged in rationalized cheating regardless of willpower levels. This pattern is consistent with an excuse-making interpretation, such that dependable individuals could only cheat if they claimed they had little willpower. Undependable individuals, on the other hand, needed no such excuse to cheat. Future studies are planned to test the validity of this interpretation by experimentally manipulating excuse-making ability.

### F90

**MITIGATING THE EFFECTS OF THREAT ON AUTHORITARIANISM** David Winter<sup>1</sup>, Sara Konrath<sup>1</sup>; <sup>1</sup>University of Michigan – Authoritarians are characterized by their obedience to authority, outgroup aggression, and traditional values. Research has consistently found that authoritarianism increases under various types of threat (e.g. economic threat, ego threat). In two studies we attempt to mitigate increases in authoritarianism after threat by giving participants information about how to manage the threat. In Study 1 online participants received information about what to do in case of potential national emergencies (e.g. possible terrorist attack). Participants in one condition were randomly assigned to receive this information before completing personality measures, including the authoritarianism scale, while participants in our control group received it after completing personality measures. In Study 2 college students completed a conceptually similar study, except that the source of threat was more applicable to a college setting (e.g. possible campus shooter). In Study 1, we find that authoritarianism remains level when participants are exposed to a threat in combination with preparedness information. In Study 2, we include a manipulation check finding that participants i) indeed felt more threatened in the high threat condition, and ii) also felt more prepared in this condition. We also replicate the finding that authoritarianism remains level when threat is combined with preparedness information. Our findings suggest that authoritarianism, typically shown to rise in people facing threat, remains level when presented with information on how to deal with threat. We suggest that perhaps the increase of authoritarianism typically seen in threatened persons can be mitigated or even counteracted when they are supplied with relevant information.

### F91

**THE RELATIONSHIP BETWEEN INDIVIDUAL DIFFERENCES IN DEATH-THOUGHT ACCESSIBILITY AND DEFENSIVE BEHAVIOR** David Webber<sup>1</sup>; <sup>1</sup>University of Alberta – Research on Terror Management Theory (Greenberg, Pyszczynski, & Solomon, 1986), has consistently demonstrated the importance of one's cultural worldview in defending against death. The current study further examined this finding by assessing if holding a fragile, easily threatened cultural worldview leads to increased defensive behavior. It was proposed that individual differences in death-thought accessibility (DTA) may indicate the state of one's worldview, such that dispositionally high DTA may be a proxy of a fragile cultural worldview. Thus, it was hypothesized that individuals with high dispositional levels of DTA would behave more defensively than their low DTA counterparts, but that this defensive tendency would dissipate if given the opportunity to validate their worldview. Participants completed a word fragment task to measure the accessibility of death-thoughts, and read one of three webpages designed to validate, threaten, or not manipulate their worldview belief. Subsequently, defensive behavior was measured by giving participants an opportunity to self-handicap prior to completing a bogus intelligence test. Results supported the predictions. In the control condition, in which worldview belief went unaltered, individuals high in DTA engaged in greater self-handicapping. On the other hand, worldview validation led to a significant decrease in self-handicapping among those dispositionally high in DTA, and participants both high and low in DTA did not differ in their amount of self-handicapping. Although this study provides an initial foray into understanding worldview fragility and the use of DTA as an individual differences variable, more research is needed before any definitive conclusions can be made.

### F92

**CONTEXTUALIZED PERSONALITY ASSESSMENT: IDENTIFYING SITUATION DIMENSIONS ASSOCIATED WITH BEHAVIORAL CONSISTENCY AND SITUATION SPECIFIC BEHAVIOR.** Robert Griffo<sup>1</sup>, C. Randall Colvin<sup>1</sup>; <sup>1</sup>Northeastern University – Current social and personality perspectives agree that behavior is determined by an interaction between characteristics of persons and situations. However, theoretical and empirical

progress towards understanding what constitutes a "situation" and how behavior is systematically related to situation variables is limited. The current research sought to: (a) develop a method for identifying relevant situation dimensions, (b) evaluate the extent to which these situation dimensions can be used to determine situation similarity and predict behavioral consistency, and (c) examine the ability of these situation dimensions to directly predict situation specific behavior. Each participant engaged in four videotaped dyadic social interactions, which differed on two objective dimensions, partner and task. Following each interaction, participants provided subjective ratings of each interaction on a series of situation characteristics, affects, motives, and behaviors. Finally, each participant's behavior in the four lab interactions was observed and coded using the Riverside Behavioral Q-Sort. Consistent with previous research, results: (a) reveal five subjective situation dimension used to describe situations (Positive Affect, Negative Affect, Situation Strength, Agency and Communion); (b) indicate that while subjective situation similarity can be used to predict behavioral consistency, the relationship is moderated by participant gender, accuracy of self-perception, and objective situation similarity (same partner vs. same task); and (c) extend previous research by demonstrating that subjective situation dimension ratings can be used to predict non-self-reported situation specific behavior.

### F93

**THE NEED TO BELONG AND THE NEED FOR COGNITION AS PREDICTORS OF DISPOSITIONAL EMPATHY** Mónica E. Muñoz<sup>1</sup>, Mary R. Chavez<sup>1</sup>, <sup>1</sup>Texas A&M International University – Dispositional empathy can be understood as a multidimensional concept, consisting of both affective (empathic concern and personal distress) and cognitive (perspective taking and fantasy) components (Davis, 1983; 1996). This model has been useful in predicting prosocial tendencies, aggression and social behaviors such as communication and conflict management (Davis, 1996). Few studies, however, have explored predictors of the various components of dispositional empathy. Using regression analysis, the current research explored the predictive potential of two constructs: the need to belong (Leary, Kelly, Cottrell, & Schreindorfer, 2007) and the need for cognition (Cacioppo, Petty, & Kao, 1984). Higher need to belong scores were expected to predict increased scores on all the dimensions, given that empathic tendencies may aid in building the social connections that satisfy this need. Higher need for cognition scores were expected to predict increased perspective taking and fantasy, given that these reflect the type of mental effort that may fulfill this particular need. No significant relationships with scores on the affective dimensions were expected. Results showed that higher need to belong scores predicted only increased empathic concern and personal distress. Higher need for cognition scores predicted increased perspective taking and, surprisingly, decreased personal distress. Those with a high need to belong may rely on affective experiences to promote the process of building social connections. However, individuals with a strong preference for cognitive activity (i.e., high need for cognition) may have a general distaste for affective experiences, especially if they involve the negative feelings characteristic of personal distress.

### F94

**PREDICTING PHYSICAL HEALTH USING PROSPECTIVE MEASURES OF PERSONALITY** Grant W. Edmonds<sup>1</sup>, Yusuke Takahashi<sup>2</sup>, Joshua J. Jackson<sup>1</sup>, Brent W. Roberts<sup>1</sup>, <sup>1</sup>University of Illinois at Urbana-Champaign, <sup>2</sup>University of Tokyo – Personality has established relationships with physical health. Most research demonstrating these effects has been cross-sectional, and fails to control for background variables and other health related factors. Using data from the Health and Aging Study of Central Illinois (HASCI), we evaluated prospective relationships between Big Five personality dimensions and health. The HASCI study includes a representative sample from the state of Illinois (n = 312) measured at two time points three years apart. Personality was measured using the AB5C. Health was measured using the physical health scale of the sf36. Health behaviors were measured using the Health Behaviors Checklist. We first correlated time

one personality, age, and gender with time two physical health. Age was negatively related to physical health ( $r = -.15$ ,  $p = .01$ ). Education was positively related to physical health ( $r = .38$ ,  $p = .00$ ), while sex was not related to physical health. All of the Big five traits measured at time one showed small significant relationships with physical health at time two ( $r$ 's ranging from .11 to .23). We next conducted a multiple regression analysis where time two physical health was regressed on all five time one Big Five personality traits while controlling for age, sex, and health behaviors. Time one emotional stability predicted time two physical health ( $\beta = .24$ ,  $p = .00$ ); the other big five traits were not significant predictors of time two physical health. Implications for research relating personality to health within the larger context of other known health predictors are discussed.

### F95

**SELF-RATED HEALTH PREDICTS DIRECTLY OBSERVED BEHAVIOR IN A PERSONALITY INTERVIEW** Christopher Nave<sup>1</sup>, Ryne Sherman<sup>1</sup>, David Funder<sup>1</sup>, Sarah Hampson<sup>2,3</sup>, Lewis Goldberg<sup>2</sup>, <sup>1</sup>University of California, Riverside, <sup>2</sup>Oregon Research Institute, <sup>3</sup>University of Surrey, Guildford, UK – Directly observed behavior is understudied in psychological research (Baumeister, Vohs, & Funder, 2007; Furr, 2009). Particularly rare is research linking directly observed behavior to measures of health. The present study analyzes data from the Hawaii Personality and Health cohort which include comprehensive assessments of current health and videotaped personality interviews. Behaviors seen on the videotapes (N = 160) were coded by four research assistants using the Riverside Behavioral Q-Sort (Funder, Furr, & Colvin, 2000). For the current analyses, health was assessed through self-report measures of health status and alcohol use. Among correlates of the self-report measures, individuals who described themselves as healthy were seen to be physically active ( $r = .35$ ), appeared to regard themselves as physically attractive ( $r = .26$ ), showed high enthusiasm and energy ( $r = .25$ ), were not unusual or unconventional in appearance ( $r = -.26$ ), and did not show physical signs of tension or anxiety ( $r = -.25$ ). Individuals who reported a past period of heavy drinking were seen to exhibit an awkward interpersonal style ( $r = .27$ ), sought advice ( $r = .24$ ), did not exhibit a high degree of intelligence ( $r = -.40$ ), did not show interest in intellectual or cognitive matters ( $r = -.35$ ), and did not speak fluently ( $r = -.31$ ). Future research is needed to further test and explain the relationship between various measures of health and directly observed behaviors.

### F96

**PSYCHOLOGICAL MOTIVATIONS FOR ARCHITECTURAL PREFERENCES WITHIN PERSONAL LIVING SPACES** Lindsay T. Graham<sup>1</sup>, Samuel D. Gosling<sup>1</sup>, <sup>1</sup>University of Texas at Austin – What are the psychological roots of people's architectural preferences? Israel (2003) has theorized that individuals' current preferences are rooted in their past environmental experiences. Specifically, the seeds of the sense of home—a place in which the occupant can feel safe, secure, and comfortable—are planted during childhood. Past research has focused on the objective quantification of items in living spaces (Gosling, Craik, Martin, & Pryor, 2005a, b; Kasmar, 1970) but there have been no empirical studies of the psychological experiences that may drive the decisions about the acquisition, arrangement, and design of spaces and the items within them. To take the first steps in mapping the psychological underpinnings of architectural preferences we present an empirical content analysis of in-depth interviews with individuals engaged in building a new home for themselves. The data are based on a set of psychologically oriented exercises and questions designed to elicit people's associations with their personal living space preferences. For example, "what words describe how you feel in your perfect home?", and "what would you be proud to show your parents in your ideal home?". Content analyses of data from 15 participants (6 male, 9 female, mean age = 48.90, SD = 13.09) identified a number of themes, including togetherness, security, and relaxation. The themes emerging from this exploratory analysis will lay the groundwork

for the creation of a standardized instrument that can be used in larger samples to tap the psychological roots of people's connections to their physical environment.

#### F97

##### **EGO DEVELOPMENT INFLUENCES ON THE RELATIONSHIP OF THE BIG FIVE TO PSYCHOLOGICAL WELL-BEING.** Jenny L. Lang<sup>1</sup>, John D. Mayer<sup>1</sup>;

<sup>1</sup>University of New Hampshire – The present study examined the influence of ego development on the relationship of the big five personality traits to psychological well-being. Ego development assesses cognitive complexity, and increasing ego development levels are thought to render progressively more sophisticated perceptions of self and others. Multivariate analyses of (co)variance ( $N = 366$ ) showed that the relationship of ego development to the six dimensions of psychological well-being (PWB) differs for college-aged men and women. For example, ego development level was associated with PWB-autonomy for men but not for women. Controlling for ego development level in subsequent analyses, however, did not alter the significance of relationships between the big five (BF) personality traits and the six dimensions of PWB. The differences that emerged in these relationships remained consistently located along gender lines. Interestingly, BF-openness was associated with PWB-autonomy for women but not for men. Additional analyses revealed that ego development may instead influence relationships between the big five personality trait items and psychological well-being. The association of BF-openness items to PWB-autonomy varied according to ego development level. Overall, the findings suggest that the influence of individual differences such as ego development level on the relationships of the big five personality traits to important outcomes may not always be evident because the influence occurs at a different measurement level.

#### F98

##### **SEEING MORALITY IN BLACK AND WHITE: PURITY CONCERNS PREDICT ASSOCIATIONS OF SIN WITH BLACK AND VIRTUE WITH WHITE** Gary

Sherman<sup>1</sup>, Gerald Clore<sup>1</sup>, Jonathan Haidt<sup>1</sup>; <sup>1</sup>University of Virginia – The color black symbolizes physical impurity which in turn symbolizes sin. Thus, being concerned with purity, whether physical or moral, may predispose one to associating sin with black, a hypothesis we tested in two studies. In study 1 ( $N = 1,123$ ), we assessed automatic immorality-blackness associations with an online moral Stroop task (Sherman & Clore, 2009). Participants identified the font color of immoral, neutral, and moral words presented in either black or white font. Participants were faster when the word's meaning and font were congruent (e.g., "sin" in black) than when they were incongruent (e.g., "sin" in white). Moreover, this moral Stroop effect was greatest for those that deemed black a contaminant (i.e., agreed that "a drop of black paint would ruin a cup of white paint"). In Study 2 ( $N = 1,916$ ), participants performed an online visual matching task: each word from Study 1 was presented one at a time in a randomly selected shade of gray. Below the word appeared a grayscale spectrum showing the range of possible shades, from which participants selected the shade matching the shade of the word. Those that considered purity violations to be moral violations (i.e., those who scored high on the Purity subscale of the Moral Foundations Questionnaire; Graham, Haidt, & Nosek, 2009) overestimated the darkness of immoral words and underestimated the darkness of moral words. These findings suggest that concerns related to both physical and moral purity may predispose one to seeing morality in black and white.

#### F99

##### **THE PROFILE OF THE VULNERABLE CONSUMER: A DATA-MINING APPROACH TO PROBLEMATIC SPENDING** G. Tarcan Kumkale<sup>1</sup>, Gulen

Sarial Abi<sup>1</sup>, Zeynep Gurhan Canli<sup>1</sup>; <sup>1</sup>Koc University, Istanbul, Turkey – According to reports, the number of customers who have revolving credit card debt has increased by %2500 over the last five years. Overspending, obviously, is not a recent phenomenon. However, the recent financial crisis highlighted one more time that it is necessary to identify characteristics of individuals who are more or less likely to spend excessively. Based on an extensive review of the literature and recent models

of self-regulation, we first present the nomological net around overspending and then identify complex interactions among individual difference variables associated with overspending. Thus, the goal of this research was to identify clusters of individuals who are more or less likely to experience spending-related problems. Past research showed that being high on materialism, impulsivity, present-time orientation, but low on self-control ability may be associated with overspending. Our analyses from four survey studies and an experiment, however, showed that these relationships are complicated by complex interactions. Thus, being materialistic or being too present-minded may be vulnerabilities; but they are not necessarily directly associated with problematic spending. Our analyses using various data-mining algorithms showed that these two variables reliably interact with self-concept clarity and attention to social comparison information. Thus, our research contributes to the literature in two important ways. First, it demonstrates for the first time that self-concept clarity affects overspending. Second, our research extends previous studies by showing that a failure to consider potential consequences or being high on materialism increases overspending only if self-concept clarity is low.

#### F100

##### **THE STRUCTURE OF WORD USE ONLINE: SELF-EXPRESSION IN BLOGS, WALL POSTS, AND UPDATES** Adam D. I. Kramer<sup>1</sup>; <sup>1</sup>University of Oregon –

The Internet has rapidly become an avenue for personal expression amongst people of all ages. Social and personality psychology is has responded accordingly, addressing differences and similarities among self-expression media. I present a formalized, holistic method via which to evaluate the way that people use words across online social contexts, allowing for examination of and comparison across online self-expressive contexts. Using Pennebaker and colleagues' Linguistic Inquiry and Word Count (LIWC) dictionaries, I analyzed word usage in a large-scale representative sample of three online social media: anonymized Facebook status updates (short, to-the-point updates, provided as information to the user's friends;  $M=9.3$  words/update) and wall posts (updates sent directly to a specific friend, but visible to all friends;  $M=19.4$  words/post) for  $n=1,049,286$  users, and  $n=1,846,445$  weblogs from Blogger.com ( $M=1,098$  words/post). Utilizing a new approach in word-count analysis—principle components analysis for examining covariation among LIWC dictionaries—I found that, across all three formats, online word use varies consistently along three linguistic dimensions: Affect (including sad and negative emotion words for bloggers but positive words for Facebook users), Ranting (including anger, sexual, swearing, and self-focus words), and Occupation (including work, school, and job words). Status updates and blogs (which have a more self-disclosive purpose) also showed a Social Engagement category, including home, leisure, sports, TV, and music words, while the conversationally-oriented wall posts did not. I discuss this structure in light of other lexical analyses (e.g., the Big 5), and implications of using word factor structures to evaluate differences within across people in online contexts.

#### F101

##### **INDIVIDUAL DIFFERENCES IN SITUATION SELECTION AND AVOIDANCE SIGNATURES** Sofie Frederickx<sup>1</sup>, Iven Van Mechelen<sup>1</sup>; <sup>1</sup>University of Leuven,

Departement of Psychology – In personality psychology, researchers often consider situations as static entities persons passively end up in. However, people not only react to the situations or conditions they encounter, but are also actively involved in the selection of them. Moreover, the kind of situations people select and avoid may considerably differ across persons. In this study, our primary objective is to chart the structure of individual differences in selection and avoidance behavior in a broad range of situations. Secondly, we want to unveil the dynamics underlying individual differences in selection/avoidance of situations in terms of various kinds of cognitive-affective forecasts. Participants were presented a broad set of situations in which a conversation with another person was to be started; each situation was to be rated on selection/avoidance. In addition, we also collected dispositional measures of potentially relevant cognitive-affective forecasts. Results indicate that

different groups of persons can be distinguished, each with their own distinctive situation selection/avoidance profiles. These groups primarily differ in differential sensitivity to three key situational features: whether one is certain versus uncertain about the topic of the conversation, whether the conversation partner is an acquaintance versus a stranger, and whether the partner does versus does not contribute to the conversation. Differences in selection and avoidance profiles further appeared to have close links to cognitive-affective self-efficacy-related forecasts.

### F102

**WHEN SOCIAL PAIN ISN'T AUTOMATIC: PERSONALITY DISORDERS BUFFER OSTRACISM'S IMMEDIATE NEGATIVE IMPACT** James Wirth<sup>1</sup>, Donald Lynam<sup>1</sup>, Kipling Williams<sup>1</sup>; <sup>1</sup>Purdue University – Ostracism's strong immediate negative effect has been shown to be resistant to a variety of individual differences (see Williams, 2009). This is consistent with the argument that detecting ostracism quickly is evolutionarily advantageous; it gives individuals a chance to reconcile, preventing their social demise. However, if individual differences are to be found, they are likely to be those that are sufficiently abnormal that they veer away from being evolutionarily adaptive. We explored personality disorders (PDs) as potential moderators of ostracism's immediate negative impact, including social pain. Cluster A PDs are characterized by severe interpersonal distrust, detachment, and/or discomfort. Individuals with Cluster A PDs may find social interactions so aversive that being removed from interacting with others may provide relief. Personality disorders were assessed using individuals' Five Factor Model profiles. One hundred and eleven participants were ostracized or included during a virtual 30 ball-toss game, Cyberball, and immediately after, completed measures of social pain, basic need satisfaction, and affect. Possessing traits characteristic of Cluster A personality disorders, but not Cluster B or C disorders, significantly buffered ostracism's impact on social pain, basic need satisfaction, and positive affect, but not negative affect. Because possessing a Cluster A PD buffered feelings of social pain following ostracism, basic need satisfaction and positive affect were similarly buffered. This study provided evidence for the proposition that ostracism's effects are buffered by possessing a unique and possibly dysfunctional constellation of traits that reduces social pain from social ostracism.

### F103

**DOES COMPUTER-MEDIATED-COMMUNICATION EXACERBATE OR ELIMINATE SOCIAL DEFICITS IN AUTISM?** A. Taylor Newton<sup>1</sup>, Daniel N. McIntosh<sup>1</sup>, Adam D. I. Kramer<sup>2</sup>; <sup>1</sup>University of Denver, <sup>2</sup>University of Oregon – Despite its popularity, computer-mediated-communication (CMC) seems more stilted than face-to-face interactions. This can result in miscommunications characteristic of social deficits, perhaps because it removes cues such as eye contact, facial expression, and gestures. Conversely, other evidence suggests these same cues actually trip up individuals with autism spectrum disorder (ASD). People with ASD have a strong online presence, often in the form of weblogs. Could the absence of these cues equalize or facilitate communication for those with ASD? We compared word usage of bloggers with ASD ( $n = 40$ ) to the general population of bloggers (Kramer & Rodden, 2008), and found tiny effect sizes ( $d$ 's between  $-.007$  and  $.14$ ) suggesting no mean differences. Moreover, bloggers with ASD used social words ( $M = 7.73$ ,  $SD = 1.37$ ) much more than bloggers with multiple sclerosis ( $n = 40$ ;  $M = 6.30$ ,  $SD = 1.29$ ), a non-social neurological disability,  $t(78) = 4.80$ ,  $p < .001$ . Removing cues that are difficult for those with ASD appears to make their communication "virtually" indistinguishable from typical individuals, and may even uniquely facilitate social communication. Findings support the importance of nonverbal cues to differences in ASD communication and suggest potential utility of CMC for helping those with ASD communicate.

### F104

#### THE UPS AND DOWNS ASSOCIATED WITH THE DARK TRIAD Peter

Jonason<sup>1</sup>; <sup>1</sup>University of West Florida – The darker side of individual's personality is quickly becoming an important topic in understanding human nature. In this poster I argue that the darker side -- measured by the Dark Triad -- represents a set of adaptive individual differences. Specifically they represent one potential social strategy that may facilitate the short-term exploitation of others in pursuit of immediate desires/needs. In Study 1 I demonstrate that the Dark Triad are related to solving at least one adaptive task: vis-a-vis correlations with short-term, but not, long-term mating tendencies. In Study 2 I demonstrate how the Dark Triad is associated with a neophilic mating tendency in which individuals poach mates from others, abandon current mates for new ones, but pay the costs of this neophilia in the loss of mates. In Study 3 I document how the Dark Triad appear to be related to a short-term mindset measured through criminality, risk-taking, and time-discounting. In Study 4 I document how in order to take advantage of opportunities for exploitation, the Dark Triad are associated with a very specific set of personality traits; they are extraverted, open, with high self-esteem, but have low neuroticism and conscientiousness. They also appear to be more motivated by individualistic and competitive social motives than prosocial or altruistic ones. All in all, I argue that the Dark Triad represent, with varying effectiveness, a single, latent social strategy that may have evolved to solve important adaptive tasks.

### F105

#### WHAT TRAITS DO LEADERS VALUE IN OTHER LEADERS? AN EXAMINATION OF THE EFFECT OF LEADERSHIP EXPERIENCE ON TRAIT IMPORTANCE

Austin Lee Nichols<sup>1</sup>, Catherine A. Cottrell<sup>1</sup>; <sup>1</sup>University of Florida – Do more experienced leaders have a different view of leadership than less experienced leaders? In particular, do people with different amounts of leadership experience differentially value specific characteristics in other leaders? We focused here on attributes related to dominance versus those related to cooperation. We hypothesized experienced leaders would value cooperative traits more than less experienced leaders would, while the importance of dominant traits would remain relatively constant regardless of leadership experience. Participants reported the importance of 12 traits, related to either dominance or cooperation, for an ideal leader. While dominance-related traits were highly valued across different amounts of leadership experience, cooperation-related traits varied as a function of leadership experience – participants with more leadership experience valued cooperative traits more than did participants with less leadership experience. Overall, these findings suggest leaders may learn to value different traits as they gain leadership experience. We discuss the implications of these findings for leader selection.

## Motivation/Goals

### F106

#### SHEDDING LIGHT ON INSIGHT: PRIMING BRIGHT IDEAS

Michael L. Slepian<sup>1</sup>, Max Weisbuch<sup>1</sup>, Abraham M. Rutchick<sup>2</sup>, Leonard S. Newman<sup>3</sup>, Nalini Ambady<sup>1</sup>; <sup>1</sup>Tufts University, <sup>2</sup>California State University, Northridge, <sup>3</sup>Syracuse University – Previous research has characterized insight as the product of internal processes, and has thus investigated the cognitive and motivational processes that immediately precede it. In this research, however, we investigate whether insight can be catalyzed by a cultural artifact, an external object imbued with learned meaning. Specifically, we exposed participants to an illuminating light bulb -- an iconic image of insight -- prior to or during insight problem solving. Across three studies, exposing participants to an illuminating light bulb improved insight problem solving in three different domains (spatial, verbal, and mathematical), but did not improve general (non-insight) problem solving.

**F107**

**UNCONSCIOUS THOUGHT EXCELS WHEN CHALLENGED** Maarten W Bos<sup>1</sup>, Ap Dijksterhuis<sup>1</sup>; <sup>1</sup>Behavioral Science Institute, Radboud University Nijmegen – Various cognitive tasks suffer from decreased performance resulting from pressure (choking), especially when the task requires conscious guidance. We tested the prediction that unconscious thought (Dijksterhuis, Bos, Nordgren, & Van Baaren, 2006) is not impaired by pressure. Participants were given information about cars they had to choose from and were told their decision task would either be easy or difficult. After either thinking about the information consciously or after being distracted for a period of time, participants were asked to rate the cars. In line with earlier work (Baumeister, 1984), conscious thinkers underperformed or "choked" when pressured, in that they made poor decisions. Conversely, when pressured, unconscious thinkers were better able to decide. Interestingly, we found that conscious thinkers performed well when they had been told their task would be easy. We conclude that telling participants in the unconscious thought condition their task would be difficult challenged them and gave them the goal to perform well, which increased performance. The increased performance for conscious thinkers when told their task would be easy could indicate that participants in this specific condition relied on natural decision processes, possibly including both conscious and unconscious thought processes.

**F108**

**LITERAL VS. SYMBOLIC IMMORTALITY: EXPLORING THE RELATIVE STRENGTHS OF RELIGIOUS PATHS TO SELF-TRANSCENDENCE.** Jacob Juhl<sup>1</sup>, Clay Routledge<sup>1</sup>; <sup>1</sup>North Dakota State University – According to terror management theory, religious cultural worldviews provide protection from concerns about mortality by providing feelings of literal immortality (conscious life after death) and symbolic immortality (the essence of, or some part of, one's self or identity living after death). Though research is consistent with the assertion that both feelings of literal and symbolic immortality provide a defense against mortality concerns, to date, no studies have sufficiently partitioned these two forms of immortality in a single experiment in order to test their relative strength. In the current research, to investigate the relative strength of each form of immortality, three studies made mortality (MS) or a control topic (pain: Studies 1-2, failing exam: Study 3) salient and then made salient aspects of religion that provide literal or symbolic immortality (or a religiously neutral topic—Study 1, or the social and relational aspects of religion—Study 3). Subsequently, religious worldview defense (Study 1), search for meaning (Study 2), and presence of meaning (Study 3) were measured. Results revealed that, compared to the salience of literal immortality (or controls), the salience of symbolic immortality 1) increased religious worldview defense after MS, 2) mitigated MS engendered search for meaning, and 3) increased meaning after MS. Taken together, these studies suggest that feelings of symbolic immortality provide a better defense against mortality concerns than feelings of literal immortality.

**F109**

**THE EFFECTS OF POWER ON ATTENTION ORIENTING** Letitia Slabu<sup>1</sup>, Ana Guinote<sup>2</sup>, David Wilkinson<sup>1</sup>; <sup>1</sup>University of Kent, Canterbury, UK, <sup>2</sup>University College London, London, UK – Past research found that social power importantly affects the basic cognitive processes of individuals, in the way that powerful people manifest an increased attentional inhibition and flexibility (Guinote, 2007). Recently, Smith and colleagues (2009) indicated that power affects executive functions: updating, inhibiting and planning. Present research extends these findings and examines the effect of power on attention orienting. In order to do this, the spatial cuing task (Posner, 1980) was used, and participants were asked to indicate the location of a target when they were presented with valid cues (correctly indicating the target location), invalid cues (incorrectly indicating the target location) and neutral cues (no cue). In Study 1, participants primed with the concept of high-power and low-power were

asked to respond to a spatial cuing task. The target was presented at two different SOAs: 500ms and 1000ms. Results showed that only at 500ms SOA powerful people had a lower cue validity effect, which translates into faster disengagement from the invalid location, compared to powerless people. Study 2 replicated these findings at 400ms SOA (vs. 500ms SOA) and indicated that at the shorter SOA powerful individuals had lower cue validity effects due to faster RTs on invalid trials rather than valid ones compared to powerless people. These findings highlight the advantage of powerful people in disengaging their attention from an incorrect cue compared to powerless individuals. Implications for goal pursuit are discussed.

**F110**

**CONFLICT AND COMPETITION: DOES BEING ON A TEAM ALLEVIATE THE NEGATIVE EFFECTS OF CONFLICT?** Christopher Rozek<sup>1</sup>, Judith M. Harackiewicz<sup>1</sup>; <sup>1</sup>University of Wisconsin-Madison – Sociocognitive conflict occurs when people present differing points of views to each other in social contexts. Past research (Darmon et al., 2007) has shown that conflict can lead to better performance when an individual is cooperating (because individuals can learn from the other person's responses) but worse performance when an individual is competing (because the other person's answers are threatening in this context). We examined how these typically negative responses to conflict during competition may change if participants were put in a situation that simultaneously compelled cooperation and competition: a team competition. Additionally, we hypothesized that an individual's level of achievement motivation would moderate their response to conflict because achievement motivation is a powerful predictor of enjoyment in competitive situations (Epstein & Harackiewicz, 1992) and because caring about doing well could affect whether conflict was perceived as threatening or helpful. We had four participants at a time play an enjoyable word game (Boggle) in a team competition. Participants first completed a practice task and received fictitious responses from another participant (the participant's teammate or one of the opponents). These fictitious responses were either differing or matching and thereby effectively led to disagreement or agreement. Results showed that achievement-motivated individuals performed better when receiving conflicting answers from an opponent whereas low achievers showed a performance increase when the source of conflicting answers was their teammate. These results suggest that conflict is not always deleterious in competitive situations and can be beneficial if some aspect of cooperation is included.

**F111**

**VISUALIZING USING THE THIRD-PERSON PERSPECTIVE: THE MODERATING ROLE OF BEHAVIORAL DIFFICULTY** Laura Rennie<sup>1</sup>, Peter Harris<sup>1</sup>, Thomas Webb<sup>1</sup>; <sup>1</sup>University of Sheffield, UK – Previous research has found that visualizing a behavior (voting, studying) from the third-person perspective results in stronger motivation to enact the visualized behavior than the first-person perspective (Libby, Schaeffer, Eibach, & Slemmer, 2007; Vasquez & Buehler, 2007). Drawing on Action Identification Theory (Vallacher & Wegner, 1986), it was predicted that the advantageous effect of visualizing using the third-person perspective would be limited to behaviors that were relatively easy to enact. Therefore, in the present research the difficulty of the visualized behaviors was manipulated in addition to perspective in order to explore the moderating role of behavioral difficulty. Participants visualized themselves engaging in an easier (eating more fruit; doing more moderate exercise) or more difficult (eating more vegetables; doing more strenuous exercise) behavior from either the first- or third-person perspective. Subsequently, motivation to enact the visualized behavior (Experiments 1 and 2) and one-week later performance of the behavior (Experiment 2) were measured. Consistent with predictions, in both experiments the third-person perspective resulted in stronger motivation to perform the easier, but not the more difficult, behavior suggesting that behavioral difficulty moderates the effect of perspective on motivation. This pattern of results also extended to behavior (Experiment 2), such that in the easy condition the third-person perspective resulted in significantly more sessions of exer-

cise in the week following the intervention, but in the difficult condition perspective had no effect. This research furthers understanding of the third-person perspective effect and in addition suggests its potential as a health promotion tool.

### F112

**PERCEIVED EDUCATIONAL PAYBACK DRIVES EARLY ACADEMIC MOTIVATION** Mesmin Destin<sup>1</sup>, Daphna Oyserman<sup>1</sup>; <sup>1</sup>University of Michigan – Minorities and youth from low income families express a strong desire to do well in school and reach high levels of academic attainment, like a college degree, but are more likely to perform poorly in school and show decreased effort and motivation, despite lofty long-term goals. The way that young students visualize their possible future contributes to this trend, and educational goals must be cognitively linked to other important future goals, like financial success, to motivate current action. Two studies demonstrate that when the connection between future education and future income is salient, young students will exhibit more productive academic plans and behaviors. In a sample of Detroit middle-school students (n = 149), Study 1 finds that students show generally high plans for academic attainment, but they are only weakly associated with expected future earnings (log r = .20, p < .05), and expectations for future earnings are not predictive of current effort in school (homework time  $\beta = -.094$ , SD = .07, p = .21). Study 2 (n = 295) manipulates the salience of educational pathways to financial success vs. non-educational pathways (ie. sports & entertainment careers) showing that Detroit-area middle-school students plan to do more homework (F(1,293) = 6.340, p < .05) and are more likely to actually complete an assigned extra-credit opportunity (F(1, 59) = 5.741, p < .05) after hearing about how education can lead to more income. Immediate school plans and behaviors were enhanced by drawing students' attention to the long-term financial benefits of doing well in school.

### F113

**WOMEN AND (DIS)INTEREST IN GOVERNMENT: HOW THE STATUS QUO AFFECTS ATTITUDES TOWARD FEMALE POLITICIANS AND THE DESIRE TO PARTICIPATE IN POLITICS** Justin Friesen<sup>1</sup>, Danielle Gaucher<sup>1</sup>, Aaron C. Kay<sup>1</sup>; <sup>1</sup>University of Waterloo – Past research has shown that when people are motivated to justify their socio-political systems they come to view the current status quo as the most desirable status quo—a process termed injunctification (Kay, Gaucher, Peach, Friesen, Zanna, & Spencer, in press). We present two studies showing that injunctification processes can affect women's interest in politics. In Study 1, 64 female undergraduates first read a passage designed to heighten their system justification (SJ) motive or a control passage. They were then provided with information about the current status quo suggesting there are many women or few women in federal politics. Participants with their SJ motive heightened construed the status quo as most desirable, so that those who read there were many women in politics showed a more positive attitude towards the inclusion of women in politics than those who read that there were few women in politics. In Study 2, using 90 female undergraduates, we again manipulated the SJ motive and supplied them with information about impending changes in the number of women in politics (a fake poll projecting there would be a sharp increase or decrease in the number of female politicians following an upcoming election). Participants with a heightened SJ motive who read there would be increased numbers of women after the upcoming election reported more interest in voting and participating in politics, compared to those who read that there would be decreased numbers of women in politics. Implications for gender inequality and social change are discussed.

### F114

**TASK CHALLENGE AND INTEREST MODERATE THE EFFECTS OF ACHIEVEMENT GOALS ON PERFORMANCE** Amanda Durik<sup>1</sup>, Corwin Senko<sup>2</sup>, Lily Patel<sup>1</sup>, Chelsea Lovejoy<sup>1</sup>, David Valentiner<sup>1</sup>; <sup>1</sup>Northern Illinois University, <sup>2</sup>State University of New York–New Paltz – A laboratory experiment (Study 1) and a classroom survey study (Study 2) were conducted to test the effects of university students' achievement goals on perfor-

mance under low vs. high challenge conditions. In Study 1, participants (N=106) learned and performed an engaging math technique after being assigned either a performance-approach or a mastery-approach goal. The goal manipulation was crossed with a second manipulation emphasizing that the technique was either highly challenging or relatively simple. The results of Study 1 revealed a significant interaction between goal and perceived challenge,  $\beta = .21$ , p < .05. When participants were assigned a performance-approach goal (but not a mastery-approach goal), those who believed the task was challenging performed better than those who believed the task was simple. Study 2 examined similar relationships in university courses. At the start of the semester, participants (N=213) reported their achievement goals separately for a course anticipated to be of high interest and a course anticipated to be of low interest. An independent sample of students provided ratings of how challenging these courses were believed to be. The results of Study 2 also revealed a significant Performance-approach Goal x Challenge Level interaction,  $\beta = .12$ , p = .05, but only for the high interest courses. For courses identified as high interest, performance-approach goals predicted performance more strongly in the high challenge than the low challenge courses. Performance goals did not predict performance in the low interest courses. Mastery-approach goals were unrelated to performance in both studies. Implications for goal theory are discussed.

### F115

**HOW CONVERSATION PARTNERS AFFECT THE DEVELOPMENT OF STUDENTS' INTEREST AND MOTIVATION** Dustin Thoman<sup>1</sup>, Carol Sansone<sup>2</sup>, Monisha Pasupathi<sup>2</sup>, Jessica Arizaga<sup>1</sup>; <sup>1</sup>California State University, Long Beach, <sup>2</sup>University of Utah – Traditionally, interest is thought to arise from the transaction between a person and a given activity at a single point in time; but when intrinsic motivation is considered within a continuous self-regulatory process, other people may be integral to the interest experience even AFTER the initial transaction. Research by Pasupathi & Rich (2005) and Thoman, Sansone, & Pasupathi (2007) suggests that one way other people affect the development of interest for a given activity is through listening behavior in conversations about the activity. In these studies, students who talked to a distracted friend about a novel lab activity reported a significant drop in interest relative to those who talked to attentive friends, and interest ratings at a 4-6 week follow-up were affected by the perceived responsiveness of listeners during spontaneous conversational retellings outside the lab. However, the question of whether listener responsiveness impacts interest in a meaningful ongoing activity remained unanswered. We present data from semester-long study in which students (n=59) reported on actual class-related conversations. Results suggest that perceptions of listener responsiveness in conversations about interesting class topics (but not conversations about exams) predicted students' subsequent ratings of interest and belongingness in the class, and these ratings of interest in turn predicted students' final class motivation, even when controlling for how well they performed in the class. Therefore, talking with attentive listeners about class related events can influence students' development of interest and motivation toward the class, particularly when discussing interesting topics as opposed to individual achievement (exams).

### F116

**COGNITIVE CONSTRUAL OF APPROACH AND AVOIDANCE REACTIONS** A. Carina M. Vogel<sup>1</sup>, Markus A. Maier<sup>2</sup>, Stephanie Lichtenfeld<sup>1</sup>, Reinhard Pekrun<sup>1</sup>; <sup>1</sup>University of Munich, <sup>2</sup>State University of New York at Stony Brook – In a study by Chen and Bargh (1999), participants had to react to attitude object words by pushing or pulling a lever. Participants were generally quicker to approach (pull lever) than to avoid (push lever) positive stimuli, and this pattern was reversed for negative stimuli. However, Seibt, Neumann, Nussinson, and Strack (2007) have provided evidence that the same muscle movement can be construed as an approach or an avoidance movement, depending on the point of reference that is adopted (self or object). In the present study we wanted to demonstrate that this construal process operates on a cognitive level requiring no approach-avoidance muscle movements. The "self" (a figure) and the "object" (a positive

or negative word) were displayed on a computer screen and one of these elements could be moved via computer keys. One group of participants was instructed to move towards or away from the word (reference point "object"). The other group was told to pull the word towards or away from themselves (reference point "self"). Regardless of the point of reference, participants were quicker to approach positive stimuli than to avoid them, and quicker to avoid negative stimuli than to approach them. Thus, we replicated the finding that approach and avoidance movements can be construed either with reference to the self or to the object. Moreover, the findings suggest that this construal process does not seem to require actual approach-avoidance muscle movements, but may operate on a more symbolic level as well.

#### F117

**AND THE EYEWITNESS SAID, "BUT, I WAS SURE SHE WAS A BRUNETTE!": MOTIVATED FALSE MEMORIES IN THE ABSENCE AND PRESENCE OF MISINFORMATION.** Troy Hiduke<sup>1</sup>, Ian Tinggen<sup>1</sup>, Suzanne Kaasa<sup>1</sup>, Peter Ditto<sup>1</sup>, Elizabeth Loftus; <sup>1</sup>University of California, Irvine – Innocent people encounter few matters with personal or legal consequences as potentially devastating as confronting the false memory (FM) of another. Accordingly, much research has been conducted on situations (e.g. eyewitness testimony and therapy sessions) and other factors (e.g. personality variables and misinformation effects) that can lead to the development of false memories (Okado & Stark, 2005; Porter, 2000). Yet, scant research has been conducted on the influence of self-serving motivation, a factor that may be prevalent in FM situations. Research has shown that self-serving motivations are highly influential in affecting "objective" judgments (Kunda, 1990) and even some types of memories (Schacter, 2002). In *Social Cognition*, Kunda boldly states, "On occasion, we all come to believe what we want to believe because we want to believe it." (Kunda, 1999) Might we remember what we want to remember, because we want to remember it? This study examined 1) if self-serving motivation can create a FM for an identifying detail viewed in person and 2) if motivation has additive effects on well-documented misinformation techniques. Experimental subjects were manipulated such that they had a self-serving motivation to 'remember' an impossible identifying trait of a person they interacted with for a half hour. As predicted, motivated participants exhibited significantly higher FM (measured as incorrect identification of the person interacted with) rates than controls. Furthermore, motivation and misinformation together exhibited significantly higher FM rates than misinformation alone. We discuss the implications of these findings for eyewitness memory, therapy sessions, and a general self-motivated view of memory.

#### F118

**THE EFFECT OF TALENTED AND HARD-WORKING ROLE MODELS ON MOTIVATION** Jennifer L. Fortune<sup>1</sup>, Penelope Lockwood<sup>1</sup>, Samantha Joel<sup>1</sup>; <sup>1</sup>University of Toronto – Though past research suggests that individuals can be inspired by others who have excelled in a relevant domain, research has not examined the extent to which the source of a role model's success will influence the motivation imbued by that model. We examined the possibility that in the domain of personal finance, models of talent would motivate individuals to maximize their innate abilities, whereas models of effort would motivate individuals to work exceptionally hard. Participants read an account, ostensibly written by another student, which described that individual's success with money, either through working hard or through a talent for investing. We then assessed participants' own motivation to make money through exploiting their own personal talents or through hard work. Control participants rated their motivation without first reading about a role model. Participants who were exposed to a role model of any variety experienced higher levels of motivation to engage in wealth-pursuing behavior than did control condition participants. Moreover, participants exposed to the talent condition role model reported greater motivation to exploit their talents for money than did effort or control condition participants. Participants in the effort condition reported marginally higher motivation to work hard to pursue wealth than participants in the other two

conditions. Thus, a role model of either talent or effort can inspire people to pursue corresponding strategies. By examining the factors that underlie individuals' financial behavior, we can better understand how to motivate individuals to engage in more effective financial strategies in the future.

#### F119

**WHY DO CONSCIENTIOUS STUDENTS PERFORM BETTER ACADEMICALLY?** Ashley Aikman<sup>1</sup>, Katherine Sullivan<sup>1</sup>, Lauri Jensen-Campbell<sup>1</sup>; <sup>1</sup>University of Texas at Arlington – Conscientiousness has been consistently linked to better academic performance (AP) (e.g., O'Connor & Paunonen, 2007). However, virtually no study to date has examined the possible micro-behaviors (mediators) that may explain this relationship (but see Chamorro-Premuzic & Furnham, 2003). In other words, are there certain academic behaviors that conscientious students engage in that help them succeed? This study examined whether conscientiousness predicted motivational style (intrinsic, extrinsic, amotivated), self-control, study habits, and actual AP. Moreover, motivational style, self-control, and specific micro-behaviors associated with study habits were expected to mediate the link between personality and AP. College students (N=299; Men=104) completed surveys that assessed personality, motivational style, self-control, and 63 behaviors/study habits and gave permission to access their grades. Conscientious students had lower levels of amotivation, which has been linked with poorer self-determination (Deci & Ryan, 1985). Amotivation in turn mediated the link between personality and AP ( $Z=1.98, p<.05$ ). In other words, conscientiousness was positively related to self-determined forms of motivation, which in turn predicted AP. Conscientiousness was also related to better general self-control, study habits, attendance, attitude toward schoolwork, material synthesis, academic goals, organization, preparation, and health habits and less distraction when studying. A positive attitude toward schoolwork, attending class, study habits, and lack of distracters while studying (e.g., television/music/phone) mediated the link between conscientiousness and AP. Additional analyses will examine these associations in more detail as well as examining possible moderators of these effects. These findings, however, provide preliminary evidence that conscientious students are behaving in ways that improve their AP.

#### F120

**FIXED, GROWTH, OR BOTH: AN INTERPERSONAL EVALUATION-BASED APPROACH TO ACTIVATING IMPLICIT BELIEFS ABOUT INTELLIGENCE** Sara Etchison<sup>1</sup>, Mark W. Baldwin<sup>1</sup>; <sup>1</sup>McGill University – Research on self-theories of intelligence has shown that children learn to treat intelligence as a fixed or expandable capacity based on feedback from parents and teachers (Dweck & Molden, 2005). However, little research has considered the ongoing role of interpersonal relationships in activating these beliefs once they form. We theorized that most people have received both entity and incremental feedback from different individuals – and thus, will have developed representations of both views that can be activated by certain social contexts. We tested this hypothesis by having participants visualize a person from whom they had received incremental or entity-based feedback and then assessing their performance and motivation on an anagram task. Results demonstrated that participants primed with incremental feedback providers (compared to entity feedback providers) reported having greater motivation and enjoyment of the task and attempted more anagrams. In two follow-up studies we used a computer-based task in which participants were given both entity and incremental feedback for each trial of a color-matching game, with only one type of feedback being paired with social approval (smiles and cheers). We found that participants in the incremental condition subsequently endorsed more incremental beliefs (Study 2a) and were slower to recognize interpersonal rejection words on a lexical decision task (Study 2b). These data support an interpersonal evaluation-based account of theories of intelligence and demonstrate the influence of the current social situation to differentially activate different theories of intelligence and their associated patterns of cognition, motivation, and performance.

**F121****THE EFFECT OF GREEN ON PERFORMANCE ATTAINMENT IN CREATIVE TASKS**

Stephanie Lichtenfeld<sup>1</sup>, Markus A. Maier<sup>2</sup>, Andrew J. Elliot<sup>3</sup>, Reinhard Pekrun<sup>1</sup>; <sup>1</sup>University of Munich, <sup>2</sup>University of Stony Brook, <sup>3</sup>University of Rochester – Recent research demonstrated that the perception of the color red impairs performance on a subsequent achievement task. Viewing red prior to an achievement task evokes the motivation to avoid making mistakes, which in turn ironically undermines performance attainment (Maier, Elliot, & Lichtenfeld, 2008). While red is related to errors and mistakes (as teachers frequently use red ink to mark incorrect answers), green seems to have more positive associations in the achievement context. It is associated with success, as can be seen from the link between green and the U.S. currency (i.e., greenbacks) or with signalling "go" in traffic lights or exit signs. Recent research supported this proposition by demonstrating that green is positively associated with success words, whereas red is positively associated with failure words (Moller, Elliot, & Maier, in press). Therefore, it seems worthwhile to examine whether green has a positive influence on performance in the achievement context. More specifically, the current study investigated if green leads to enhanced performance on a creativity task. In this task, participants had to create as many objects from an abstract figure as they could think of. We could indeed show that the perception of a green compared to a red or a gray cover page enhanced performance on the subsequent creativity task. Interestingly, performance differed between color conditions with respect to the diversity of ideas produced, whereas the number of ideas did not differ.

**F122****RELIGIOUS COPING: DAILY EFFECTS AND MOTIVATIONAL MODERATING FACTORS**

James N. Masciale<sup>1</sup>, Richard M. Ryan<sup>1</sup>; <sup>1</sup>University of Rochester – Religious coping can be defined as engaging in a specific behavior, or set of behaviors, in order to attenuate negative affect produced by a stressor(s). These behaviors, furthermore, are unique in that they specifically call upon an individual's particular religious/spiritual beliefs. Praying, attending religious services, reading a religious text, among others., fall under this definition. Previous work has shown that these behaviors, when stemming from autonomous/integrated regulation (vs. controlled/introjected), are associated with increased psychological well being, reduced negative affect, and even greater physical well being. Most of this work, though, has been cross sectional in nature and have not tracked the effects of prayer in people's day to day lives. The present study explores the role of prayer on a daily basis. Using daily diary methods, we tracked participants for a period of 14 days, assessing their mood in the morning and evening, along with basic need satisfaction, daily stressors, and other variables. Evening prayer, when integrated, was associated with reduced negative mood the following morning. Prayer stemming from introjected regulation was not associated with mood the following morning. Interestingly, though, participants with an introjected regulation toward their religion were twice as likely to pray during the diary period than those with an identified regulation. Further, participants who experienced autonomy support during the diary period were less likely to use prayer as a coping mechanism.

**F123****CONSIDERING OBSTACLES MATTERS: MENTAL CONTRASTING MEDIATES THE EFFECT OF VISUAL PERSPECTIVE ON ACHIEVEMENT MOTIVATION**

Noelia A. Vasquez<sup>1</sup>; <sup>1</sup>York University – Research suggests that the motivational impact of future imagery depends on the visual perspective that is adopted. Specifically, imagining future success on an upcoming academic task from a third-person rather than a first-person perspective increases achievement motivation (Vasquez & Buehler, 2007). However, Oettingen and Mayer (2002) posit that not all positive thoughts about the future will have motivational benefits. They argue that for a positive image of the future (i.e., fantasy) to be motivating, one must contrast this image with aspects of reality that may act as impediments to reaching the desired outcome, a process referred to as mental

contrasting. The present research suggests that visualizing a desired future through a third-person perspective facilitates the fantasy-reality juxtaposition that Oettingen and colleagues assert is crucial for motivation. To test this hypothesis, undergraduates identified an upcoming academic project, were prompted to imagine themselves performing it successfully from either a first- or third-person perspective, and then completed a series of mental contrasting (e.g., I recognize certain obstacles that I must overcome to succeed on this task) and achievement motivation (e.g., I intend to do all I can to "ace" this task) items. As hypothesized, participants reported greater mental contrasting when they envisioned their successful performance from a third-person rather than a first-person perspective. Furthermore, mediational analyses revealed that third-person imagery increased achievement motivation by prompting students to engage in mental contrasting. Visual perspective also affected students' self-reported effort and commitment towards the task, and their intentions to attend a study skills workshop.

**F124****CHOICE, PREDICTION, AND SELECTIVE INFORMATION EXPOSURE**

Aaron M Scherer<sup>1</sup>, Paul D Windschitl<sup>1</sup>, Andrew R Smith<sup>1</sup>, Jason P Rose<sup>2</sup>; <sup>1</sup>University of Iowa, <sup>2</sup>University of Toledo – Research on selective information exposure has primarily emphasized the role of choice and focused on defense motivation as the primary mechanism that leads to selective exposure. However, it is unclear what constitutes a "choice" to individuals. Does information quality regarding the decision options impact whether a decision is construed as an actual choice? If the quality of the information about the decision options is poor, do individuals feel less committed to their decision as evidenced in their post-choice search for information? In the current study, participants' choices were in the form of predictions. Participants were asked to make predictions about which work of art was preferred by college students. Participants had to make these predictions/choices based on blurred versions of the art or simply color segments from the art. The "full" artwork was then revealed to allow potential discrepancies between the prediction made with partial information and the prediction they would make with full information. Finally, participant could select information that did or did not support their prediction. Results reveal that simply making a prediction/choice, regardless of quality of information, is sufficient to induce selective exposure to confirmatory information.

**F125****WHAT ARE RESEARCHERS LIKE? STEM MAJORS' PERCEPTIONS OF RESEARCHERS IN THEIR FIELD**

Anna Woodcock<sup>1</sup>, Sara Branch<sup>1</sup>, Ida Ngambeki<sup>1</sup>, William Graziano<sup>1</sup>, Demetra Evangelou<sup>1</sup>; <sup>1</sup>Purdue University – Women are chronically under-represented in many STEM research careers, particularly engineering (NSF, 2009). Perhaps representation is related to sex differences in students' beliefs and expectancies about research in STEM and the people who do it. This issue has received little empirical attention. Using survey data from 557 undergraduate engineering, life sciences and psychology majors, we discovered that STEM majors in these fields hold different perceptions about the research process, what researchers are like, and expectations about what researchers do. Three different stereotypes about researchers in STEM fields emerged: the loner "disorganized and unimaginative," the artist "natural talent and artistic expression" and the precision scientist "detail-oriented and systematic." Life sciences, psychology, and engineering majors varied in their perceptions of researchers in their field. Gender and major interacted as predictors of the perception of researchers as precision scientists,  $F(5,535) = 3.83, p=.022$ , whereby engineers were significantly more apt to perceive researchers in terms of precision scientists compared with life scientist and psychology students. Female engineering majors were more likely to hold this perception than male students in general, but this pattern was reversed for life scientists and psychologists. This perception did not vary by whether participants had been involved in research themselves. Intention to pursue a research career was differentially predicted by perceptions of researchers and orientation toward "things" compared with "people". We explore the anteced-

ents and consequences of our finding that the most under-represented group (women engineers) in our sample perceives research and researchers differently than those more equitably represented.

#### F126

**PRIMING AN ALTERNATIVE TO A THREATENED GOAL PREVENTS DEFENSIVENESS** Mike Prentice<sup>1</sup>, Kyle Nash<sup>1</sup>, Ian McGregor<sup>1</sup>; <sup>1</sup>York University – Goal shielding research suggests that people inhibit stimuli that interfere with a focal goal. In the present study, we examined the effect of priming goals that are either relevant or irrelevant to a prior goal-specific threat. We tested the hypothesis that priming people with a goal unrelated to a previous threat would allow them to goal shield and thus avoid defensiveness. Participants were 121 undergraduates randomly assigned to either belongingness threat or control task followed by either a belongingness or achievement nonconscious goal prime. Results revealed that, when the prime matched the antecedent threat, participants exhibited compensatory defensiveness typically found in threat research. However, when the prime presented an alternative goal from the threatened domain, participants were no more defensive than controls. We conclude that goal shielding may function similarly to self-affirmations in allaying defensiveness after threat. Further, these results point to the important role of goal conflict in compensatory reactions to threat.

#### F127

**ARE AVOIDANCE GOALS ALWAYS BAD FOR PERFORMANCE? THE ROLE OF SOCIAL COMPARISON** Katherine S. Corker<sup>1</sup>, Joseph Cesario<sup>1</sup>; <sup>1</sup>Michigan State University – Prior research on achievement goals (e.g., Elliot & McGregor, 2001) has shown that performance avoidance goals are associated with poorer performance than performance approach goals, but recent research has shown that this need not always be the case (Corker & Cesario, 2009). The present study was designed to examine one variable that might be responsible for such reversals: social comparison. Researchers have typically defined performance goals as necessarily including social comparison: approach (avoidance) goals are defined as striving for success (failure) relative to others. Performance goals can be defined without reference to social comparison, however, by focusing instead on the simple success/failure (i.e., valence) distinction. In a between-subjects design, participants' goal frame (approach vs. avoidance) and social comparison focus (present vs. absent) were manipulated for an achievement task (playing pinball). We predicted that participants in the social comparison present condition would set higher levels of aspiration (LOAs) and perform better when the task goal was framed in approach (compared to avoidance) goal terms. Conversely, in the social comparison absent condition, participants were predicted to set higher LOAs and perform better when the task goal was framed in avoidance (compared to approach) goal terms. Results supported the predictions (for men). The results suggest that goal valence alone is not responsible for the negative effects of avoidance goals on performance and that the nature of avoidance goals need not be conceptualized as inherently negative.

#### F128

**MORTALITY SALIENCE OR JUST WORLD THREAT?** Anomi Bearden<sup>1</sup>, John Ellard<sup>1</sup>; <sup>1</sup>University of Calgary – Terror management theory (TMT) conceptualizes the belief in a just world (BJW) as a worldview people are motivated to maintain when their mortality is salient (Hirschberger, 2006; Landau et al., 2004). However, just world theorists claim that the BJW is an autonomous motive that may be the basis for mortality salience (MS) effects if death thoughts are only threatening when associated with injustice (e.g., Hafer & Begue, 2005; Lerner, 1997). The current study examined the motive underlying MS effects. Community college student participants (N = 101) completed a three-level MS manipulation (death, dental pain, severe chronic pain) followed by a delay task and then completed a word completion task (death, justice, control words) and a modified Stroop task (death, justice, control words). Death salient, compared to dental pain participants evidenced greater MS (more death words

completed, but not justice words) and greater just world threat (more Stroop interference on justice words, but not death words). Given that word completion assesses accessibility, whereas modified Stroop assesses emotional threat, findings suggest that MS induces justice rather than death threat. Consistent with this interpretation, analysis of participants' mortality salience manipulation descriptions found evidence of justice restoring content (e.g., positive afterlife) that in turn was positively related to Stroop interference on justice but not death words. Thus, as previous TMT research has shown, proximal defense of threat, in this case justice-restoring thoughts, does not address the unconscious just world threat associated with one's death.

#### F129

**MINDFULNESS AND PROFIT FOCUS IN FINANCIAL DECISION-MAKING: THE MEDIATING ROLE OF SATISFICING TENDENCIES** Ruth Lewis<sup>1</sup>, Daniel Berry<sup>1</sup>, Alicia Wood<sup>1</sup>, Samantha Fields<sup>1</sup>, Michelle Rai<sup>1</sup>, J. Logan Tindell<sup>1</sup>, Chad E. Lakey<sup>1</sup>; <sup>1</sup>East Tennessee State University – Mindfulness is a quality of consciousness that entails heightened awareness of and attention to the present moment. It relates to sundry positive outcomes, including psychological well-being, self-regulatory capabilities, low ego-involvement, and adaptive judgment and decision-making focused on positive long-term outcomes (e.g., Brown & Ryan, 2003; Lakey et al., 2007). Research also supports that mindfulness promotes an intrinsic value orientation focused less on monetary outcomes than ecologically responsible behavior (Brown & Kasser, 2005). This evidence suggests that, in business settings, mindful individuals might, for example, sacrifice immediate profits to curtail layoffs. It is also possible that such a stance toward business-related profit might be productively explained (i.e., mediated) by a tendency to employ satisficing, versus maximizing, strategies (Simon, 1957), whereby one settles for something that meets a minimum, "good enough" threshold of acceptability (i.e., satisficing) instead of attempt to maximize the outcome (e.g., profit). To test this possibility, participants (n = 254) completed measures of mindfulness, satisficing / maximizing, and a 10-vignette questionnaire to assess their attitudes towards business-related financial decisions from the role of company CEO. Hierarchical regression analyses demonstrated that, as predicted, mindful individuals endorsed, for example, community outreach endeavors, not terminating employees, or reducing the price for a service, even when such decisions sacrificed immediate profit. This relation was mediated by their tendencies to satisfice, and held even after controlling for participant income, age, gender, and political ideology. Discussion focuses on the role of mindfulness for adaptive long-term decision-making and responsible corporate behavior.

#### F130

**COMMON MOTIVATIONS FOR BINGE DRINKING AMONG ADOLESCENTS AND ADULTS IN THE UK: ASSESSMENT WITH THE BDMQ-SORT** Bradley Platt<sup>1</sup>, James Lambdon<sup>2</sup>, Thomas Oliver<sup>3</sup>, Peary Brug<sup>3</sup>; <sup>1</sup>University College London, <sup>2</sup>University of Chichester, <sup>3</sup>St Mary's University College – The rising rates of 'binge drinking' are a growing concern in western society, including the UK, as it constitutes a threat to the population's health and well-being, and a drain on public health and welfare services. Despite this, it still remains unclear why so many people binge drink in western society. Motivational models of binge drinking have predominantly tested binge drinking motivations with Likert scale-based questionnaires. These are likely to disguise individual's primary motivations for binge drinking, as participants have a tendency to strongly agree or disagree with different motivations. Seeking to elucidate these common motivations, the present study developed the Binge Drinking Motivation Q-Sort (BDMQ-Sort). To create the set of statements for the BDMQ-Sort, participants provided five different statements to describe the positive and negative effects of binge drinking. In addition to this, a thorough literature review was conducted on binge drinking motivations. Thereafter, the BDMQ-Sort was administered to binge drinkers in the UK. Principal component analysis with varimax rotation was used to identify groups of people who sorted the BDMQ-Sort items in similar ways. This analysis extracted four distinct motivations, which are discussed in

detail: Social celebration of achievement, relieve depressive symptoms and develop self-concept, socialise and experience excitement, enhancement of frequency and quality of sexual experiences. Using the participant's comments and demographic information, these findings are discussed in terms of the participant's positive expectancies of alcohol consumption, with an emphasis on age and gender effects.

### F131

**GROUP AND INDIVIDUAL DYNAMICS AS PREDICTORS OF TEAM PERFORMANCE** James Lambdon<sup>1</sup>, Peary Brug<sup>2</sup>, Daniel Handanos<sup>2</sup>; <sup>1</sup>University of Chichester, <sup>2</sup>St. Mary's University College – Traditional aspects of group dynamics within sport are most often studied separately (Rees et al. 2005), though they do not occur in isolation (Lambdon, 2008). Therefore, our understanding of how such dynamics influence success and/or failure might be limited. Using a participant sample of athletes from both professional and semi-professional teams, the present study measured group factors, including collective efficacy and team motivation as well as individual factors, such as personality traits and sport value. These factors were analysed in conjunction with team performance. Results demonstrated that team performance was positively correlated with team dynamics as well as more positive individual factors. However, some variation existed among teams that had either strong team dynamics or positive individual factors. The findings tend to support previous research into team dynamics (e.g., Greenlees et al., 2005). For example, the results demonstrated that athletes from more successful teams made more internal and stable attributions. In addition, the findings also found team-referent attributions had a strong relationship with both collective and self efficacy. The latter result is consistent with theoretical findings of Bandura (1986) and Weiner (1985) who suggest a link between self-efficacy and attributions. The study highlights the important role of psychological factors, both group and individual, with regard to more successful (and possibly more effective) team performance.

### F132

**EXTRINSIC FORESHADOWING: SPOILERS MAY ENHANCE ENJOYMENT OF FICTION** Jonathan Leavitt<sup>1</sup>, Nicholas Christenfeld<sup>1</sup>; <sup>1</sup>University of California, San Diego – Readers recognize that their enjoyment of fiction depends on the psychological experience of suspense, and so most are intuitively opposed to finding out the ending of a story before reading it. (Two thirds of our subjects reported feeling this way, versus fewer than one in twenty who appreciate learning an ending.) But is this intuition correct? Our previous experiments have demonstrated that spoilers need not detract from enjoyment of a story, and suggested a distinction between intrinsic and extrinsic spoilers: While spoilers embedded in the titles of classic stories detracted from hedonic ratings, spoilers communicated by an experimenter did not. In the current experiment, classic stories were spoiled with text that appeared on a separate page, so it was extrinsic to the story, or on the first page, where it appeared intrinsic. Spoiler texts were brief paragraphs discussing story themes, so endings could be described without subjects recognizing the intent. Since spoiler text is identical in each condition, this approach allows us to isolate the intrinsic vs. extrinsic dimension of spoilers, and test whether it differentially affects enjoyment. Each subject rated three classic stories, including one intrinsic spoiler, one extrinsic spoiler, and an unspoiled story. Spoiled versions of classic stories were generally preferred. Extrinsic spoilers were rated higher than unspoiled stories, while intrinsic spoilers fell between the two. Stories with positive outcomes were preferred, but stories with negative outcomes benefitted more greatly from spoilers, suggesting that anticipation of an undesired outcome may dampen its negative impact.

### F133

**EFFECTS OF NEED FOR AUTONOMY SATISFACTION AND AUTONOMY-ORIENTATIONS ON PSYCHOLOGICAL ADJUSTMENT** Arielle Bonneville-Roussy<sup>1</sup>, Geneviève Lavigne<sup>1</sup>, Robert Vallerand<sup>1</sup>; <sup>1</sup>Research Laboratory on Social Behavior, Université du Québec à Montréal – The need for autonomy (need to experience opportunity for choice and self-actualisation concerning one's behaviors, as opposed to feeling controlled and pressured; Deci & Ryan, 2000) is one of the pillars of the Self-Determination Theory. While it is typically assumed that such a need is basically invariant in people, Lavigne et al. have proposed that some individual differences may exist (Lavigne, Vallerand, & Braud, under revision). Specifically, two forms of autonomy orientations were proposed: a growth orientation (intrinsic orientation toward self-actualisation and personal development) and a deficit orientation (extrinsic orientation toward autonomy deficit reduction or repair). Lavigne and colleagues (under revision) showed that a deficit orientation predicts lower levels of intrapersonal and interpersonal psychological adjustment compared with a growth orientation. The objective of the present study was twofold. First, we sought to validate the autonomy orientations scale. Second, we examined the relationships between autonomy satisfaction and growth-deficit orientations on psychological adjustment. Orientations were measured at T1, while autonomy satisfaction and two indices of psychological adjustment (life satisfaction and vitality) were measured at T2. Results showed interaction effects between autonomy satisfaction and growth-deficit orientations on both dependent variables. Simple effects showed no differences of psychological adjustment between the high and low autonomy satisfaction groups in the growth orientation group. However, in the deficit orientation group, individuals had significantly lower life satisfaction and vitality when they had low autonomy satisfaction compared with high autonomy satisfaction. Implications of the present research on the need for autonomy associated to growth-deficit orientations are discussed.

### F135

**DINNER WITH THE DEVIL: CONSTRUALS AND THE MOTIVATED MORALIZATION OF HEALTHY EATING** Katherine Darwent<sup>1</sup>, Kentaro Fujita<sup>1</sup>; <sup>1</sup>Ohio State University – Previous research (Rozin, et al., 1997; Rozin & Singh, 1999) has suggested that moralizing a behavior could promote self-control. Although moralization often occurs at the societal level, it can also occur at the individual level (Rozin, 1999). Thinking about a goal from a moral perspective makes the global implications of one's behavior more apparent. It was hypothesized that construing behavior more abstractly would encourage consideration of the global implications (Trope & Liberman, 2003). Recent research has demonstrated that construals impact self-control (Fujita, et al. 2006); specifically, when construing an event more abstractly (high-level), participants were more likely to behave in line with their goals than when construing an event more concretely (low-level). The current research examined whether high-level construals lead to motivated moralization of goal relevant behaviors as a form of prospective self-control. Participants first completed a construal manipulation that asked them to generate either superordinate ends (high) or subordinate means (low) of an instrumental action (Freitas et al., 2004) and then indicated how virtuous or sinful several behaviors were, including eating healthy and unhealthy foods. Finally, the importance of a healthy diet was measured. As predicted, when participants valued a healthy diet, participants rated eating unhealthy food as more sinful at the high-level than at the low-level. They also rated eating healthy food as more virtuous at the high-level than at the low-level when a healthy diet was important. Results suggest that moralization of behaviors can be a form of prospective self-control.

**F136****ABSTRACT MENTAL CONSTRUALS AFFECT PROSPECTIVE EVALUATION OF TEMPTATIONS**

Joseph Roberts<sup>1</sup>, Karen MacGregor<sup>1</sup>, Kentaro Fujita<sup>1</sup>,  
<sup>1</sup>The Ohio State University – Past research has shown that thinking abstractly improves self-control (Fujita, Trope, Liberman, & Levi-Sagi, 2006). Construal Level Theory (Trope & Liberman, 2003) identifies this result as being a function of greater attention to global concerns (such as important goals) when people are thinking at abstract, high-level construals relative to concrete, low-level construals. However, past research only examined self-control in the moment of choice, and thus may not address whether construal levels affect prospective evaluations, or anticipated enjoyment, of goal-relevant objects in future experience. We suggest that construal levels may alter anticipated evaluations as a strategy for easing self-control in future choices. The present research examines the possibility that construal levels affect anticipated evaluations as a way of achieving prospective self-control over future choices. Participants generated either superordinate category labels (high-level) or category examples (low-level) for 30 items to manipulate construal level, and reported the value they placed on healthy diets. Participants then predicted how enjoyable they would find a chocolate truffle that they could take after the study. As predicted, construal level and goal importance interact to predict anticipated enjoyment of the temptation. Specifically, participants at high-level construals and who valued dieting anticipated less enjoyment of the truffle than those who rated dieting as less valuable. By contrast, participants at low-level construals showed no decrease in anticipated enjoyment of the truffle as a function of goal importance. These results support a construal level approach to self-control, suggesting that high-level construals increase the prospective recruitment of strategies to ease future self-control.

**F137****THE ROLE OF INSPIRATION IN THE CREATIVE PROCESS: TEMPORAL DIRECTION OF THE RELATION BETWEEN CREATIVE IDEATION AND INSPIRATION**

Laura A. Maruskin<sup>1</sup>, Todd M. Thrash<sup>1</sup>; <sup>1</sup>College of William and Mary – The particular role that inspiration plays in the creative process has been the topic of much theoretical discussion within the humanities, but little empirical research. We conceptualize inspiration as a motivational state that is evoked in response to getting a creative idea, and that compels the individual to translate the creative idea into a creative product (Thrash & Elliot, 2003, 2004). Our primary focus in this research was the relationship between creative ideation (i.e., the occurrence of creative ideas) and the experience of inspiration. In particular, we aimed to (1) establish the discriminant validity of these constructs, and (2) test the temporal direction of the relation between them. Implementing a four-wave, cross-lagged longitudinal design, participants (N=165), completed weekly measures of creative ideation and inspiration. To address our first aim, we used confirmatory factor analysis to examine whether creative ideation and inspiration variables were factorially distinct. Results supported the discriminant validity of the two constructs at each of the four waves. To address our second aim, we tested whether inspiration functions as an antecedent of creative ideation using a cross-lagged analysis. As predicted, creative ideation had a longitudinal effect on inspiration and there was no evidence of a reciprocal effect. Taken together, this research supports the discriminant validity of creative ideation and inspiration, and establishes the temporal precedence of the former. In more recent research, we are testing the hypothesis that inspiration mediates the relationship between creative ideation and the creativity of the resulting product.

**F138****UNACCOMPLISHED GOAL ACTIONS AND WEIGHT LOSS: A LONGITUDINAL STUDY**

Kyle Conlon<sup>1</sup>, Joyce Ehrlinger<sup>1</sup>, Will Crescioni<sup>1</sup>, Jessica Alquist<sup>1</sup>, Gareth Dutton<sup>1</sup>; <sup>1</sup>Florida State University – The present study explores the consequences of goal focus in a longitudinal weight loss study. Past research shows that focusing on unaccomplished goal actions can provide greater motivation in single measurement occasions

than focusing on accomplishments when individuals are committed to the goal. We predicted that a focus on unaccomplished goal actions would lead to more successful goal pursuit than accomplishment focus when explored in an important longitudinal setting. Participants were randomly assigned to a condition designed to focus them on what they had already achieved (accomplishment focus), what they had yet to achieve (goal focus), or a control condition. This focus was achieved through weekly questions about what they had and had not achieved as well as graphs highlighting weight lost, weight left to lose, or simply weight over time. We tracked the weight, diet, and exercise of participants while they completed a program consisting of weekly in-person meetings modeled after a successful weight loss program. Multilevel model analyses revealed that goal focused individuals lost a higher percentage of their baseline weight than did accomplishment focus and control participants over the course of the 12 weeks. Thus, keeping one's eyes on the prize seems to be an effective means of attaining important goals over time.

**F139****ACHIEVEMENT GOALS AND SELF-HANDICAPPING EXCUSES**

James W. Fryer<sup>1</sup>, Andrew J. Elliot<sup>2</sup>; <sup>1</sup>St. Lawrence University, <sup>2</sup>University of Rochester – The present research offers an extension of the relationship between achievement goals and self-handicapping behavior. Self-handicapping is a self-protective process through which individuals may externalize or excuse their failures. Behavioral self-handicapping uses objective behaviors to incur a detrimental effect on the task outcome, and claimed self-handicapping is concerned with providing a rationale (e.g. anxiety, illness, etc.) to explain away suboptimal results. Both forms of self-handicapping can be used in an attempt to render the task result devoid of useful information regarding one's competence. Achievement goals provide an individual with standards that can be used to determine competence in a particular situation. As such, students who rely on different standards to determine their competence may also rely on different strategies in order to protect their competence. In two studies, undergraduate students were asked to select reasons that may have had a negative impact on their initial exam performance, as well as their achievement goals for a subsequent exam. Factor analysis identified sets of excuses that conceptually map on to the behavioral and claimed distinction – excuses were either the responsibility of the student (internal) or the environment (external). The pattern of relations between achievement goals and excuses extends the characteristic profile of each achievement goal. Mastery-approach goals were negatively related to internal excuses, and not significantly related to external excuses. Performance-avoidance goals were significantly related to both forms of excuses. The profiles for mastery-avoidance and performance-approach goals were mixed, reflecting the combination of achievement motives on which those goals are based.

**F140****EXPERIENCE OF MOTIVE-SPECIFIC EMOTIONS AND RELATIONSHIP SATISFACTION**

K. Bernecker<sup>1</sup>, V. Job<sup>1</sup>, C.S. Dweck<sup>1</sup>; <sup>1</sup>Stanford University – Recent research showed that couple's experience of arousing vs. mundane emotional states in shared activities predicts higher relationship quality (Aron et al., 2000). Based on recent research (Job & Brandstätter, in press) about emotions as motive-specific incentives we postulate that motive dispositions (affiliation, achievement, and power) moderate this effect. We assume that emotions experienced with the partner have to fit individual's implicit motive dispositions to be related to relationship satisfaction. 140 participants who were in a romantic relationship for at least one year, filled in an online-survey, including standard measures of implicit motives (TAT, Murray, 1943) and relationship satisfaction. Participants further indicated how often they experience certain motive-specific emotions when engaging in activities with their partner. Results show that people with a high affiliation motive disposition report higher relationship satisfaction the more often they feel calm and relaxed with their partner. People high on the implicit power motive are more satisfied with their relationship the more often they feel strong, proud, and

self-assured together with their partner. Interestingly the same pattern of results was found in the domain of work: job satisfaction was related to the frequency of experiencing motive-congruent emotions at work for people with a high affiliation motive. The results support the idea that implicit motives are needs for specific affective experiences. Frequent experience of specific emotions leads in people with a high corresponding motive disposition to enhanced satisfaction and well-being.

##### **DON'T FEAR THE REAPER? REACTIONS TO MORTALITY SALIENCE AMONG ATHEISTS, AGNOSTICS, AND RELIGIOUS BELIEVERS** Jarret Crawford<sup>1</sup>;

<sup>1</sup>The College of New Jersey – Terror management theory (TMT) predicts that individuals will seek to bolster those cultural worldviews that provide them meaning in the face of reminders of death. Religious faith serves as a salient cultural worldview for the majority of Americans, and some evidence suggests it may be bolstered in the face of mortality salience (MS). But what of those without religious faith? In Study 1, religious believers reported less doubt in God's existence in the MS condition relative to the control condition, whereas agnostics reported more doubt in God's existence in the MS condition relative to the control condition. Atheists were unaffected by the MS manipulation. Study 2 introduced an uncertainty prime condition and measured participants' prior religious experience and commitment. Results indicated that atheists raised in religious environments reported more religious feelings after the uncertainty prime relative to the control and MS conditions. However, atheists not raised in religious environments reported less religious feelings after the uncertainty prime relative to the control and MS conditions. These results suggest that mortality may be a more salient existential concern for religious believers than atheists. They also suggest that uncertainty is a more salient existential concern for atheists than mortality, and that prior religious experience and commitment predicts responses to such existential crises.

#### F142

##### **LOSING THE WILL: AUTOMATIC REACTIONS TO THE INDIFFERENCE PERCEIVED IN OTHERS** N. Pontus Leander<sup>1</sup>, James Shah<sup>1</sup>;

<sup>1</sup>Duke University – Three studies examine individuals' implicit sensitivity to others' lack of motivation for goals and how the nature of this sensitivity may vary by the individuals' own goal orientations. Participants were nonconsciously primed with either indifference towards achievement or not, after which their own striving for achievement was assessed. Results indicated that, although mere exposure to others' indifference generally undermined participants' own goal striving, such influence was often overcome by participants who had been primed in advance with a non-conscious achievement goal (Study 1), who took an action-oriented approach to goals (Study 2), and who held a preexisting belief that they had put too much into their pursuit of achievement to give up on it (Study 3). These varying responses were found in all three studies to occur largely without participants' conscious intent or awareness.

#### F143

##### **INVESTIGATING EYEWITNESS TESTIMONY USING SEMANTIC SPACES** Torun Lindholm<sup>1</sup>, Sverker Sikström<sup>2</sup>;

<sup>1</sup>Stockholm university, <sup>2</sup>Royal Institute of Technology, Sweden – A large body of research on eyewitness testimony has been devoted to examining differences in real and fabricated memories. It seems plausible that general aspect of semantic content may discriminate between true and false eyewitness statements. In this study we use, for the first time, latent semantic analysis (LSA) to investigate differences in semantic content between correct and incorrect eyewitness statements. Based on previous findings on semantic memory, we expected that witnesses would be less certain when responses were inaccurate rather than accurate, and that this uncertainty would induce a sense of incompetence as well as a reduction in perceived power and status in the witness. We hypothesized that witnesses might compensate for such reduced status by being warm and friendly, and that this would be reflected in the semantic content of responses. In the study participant-witnesses were videotaped while being interviewed about their

memory of a crime event. The interviews were transcribed verbatim and witnesses' responses were coded for accuracy. All statements that provided either accurate or inaccurate information about a specific detail were selected and used in LSA. Results confirmed differences in the semantic context of words used in inaccurate vs. accurate responses on dimensions related to competence and warmth. Using these differences in context, LSA could discriminate fairly well between correct and incorrect eyewitness responses. Since extant research show that people often have difficulty discerning eyewitness accuracy, LSA could be considered as a tool for improving judgements of witnesses' memories.

#### F144

##### **EXPLORING THE INTERACTION OF BODILY AND PSYCHOLOGICALLY SELF-PROTECTIVE GOALS** Julie Huang<sup>1</sup>, Joshua Ackerman<sup>2</sup>, John Bargh<sup>1</sup>;

<sup>1</sup>Yale University, <sup>2</sup>Massachusetts Institute of Technology – This research explores the implicit link between the goal to protect the physical body and the goal to protect the psychological self. Specifically, two studies explore how experiences with physical safety interact with the psychological domain. Study 1 offers initial evidence that participants perceive themselves as more susceptible to biases in judgment and other people are less biased following a physical safety prime. Study 2 examines how inducing feelings of physical safety in participants who are currently pursuing an affiliation goal decreases their desire for contact with current relationship partners (compared to participants who are not currently pursuing affiliation and participants who did not receive the safety prime). Taken together, the current research provides support for the intertwining of goals for protection of the physical body with goals for protection of the psychological self. Future studies will explore this relationship, ultimately contributing to the greater literature on how pursuing goals in one domain has implications for how people pursue goals in other domains.

#### F145

##### **NEUROBIOLOGICAL AND AUTONOMIC EVIDENCE FOR VIGILANT WITHDRAWAL MOTIVATION AFTER MORTALITY SALIENCE** Spee

Kosloff<sup>1</sup>, Jeff Greenberg<sup>1</sup>, John J. B. Allen<sup>1</sup>, Andy Martens<sup>2</sup>;

<sup>1</sup>University of Arizona, <sup>2</sup>University of Canterbury – Previous research has shown that reminding individuals of their inevitable death (mortality salience; MS) heightens vigilance against threats to their cultural identity. However, little is known about the intervening neurobiological processes via which MS-induced defensive orientations arise. Consistent with evidence that defensive responses to MS stem from concerns with reducing potential anxiety (e.g., Greenberg et al., 2003), we examined whether MS-induced vigilance against threat is implemented via neural circuitry associated with withdrawal-oriented emotion regulation, namely, relative right-frontal EEG activity. In this experiment, individuals highly invested in their American identity either completed two open-ended questions about their mortality or, in the control condition, completed questions regarding an aversive but non-death-related topic. Resting EEG activity was assessed before and after this manipulation. Subsequently, participants viewed a series of images, including anti-American pictures, as well as negatively valenced IAPS images with no relevance to America. During this task, 95 db auditory probes provoked eyeblink startle responses (an autonomic index of vigilance against threat). Results showed that, relative to control participants, MS participants exhibited a shift to greater relative right frontal cortical activity and showed heightened startle responses during anti-American image presentations but not during presentations of America-irrelevant negative images. Furthermore, the MS-induced right frontal shift in cortical activity predicted greater startle response during anti-America image presentations, but did not relate to startle during the America-irrelevant negative images. These findings suggest that a neurobiologically-based behavioral withdrawal system implements vigilance against cultural identity threat following mortality reminders.

**F146**

**ACHIEVEMENT GOALS AND SOCIAL JUDGMENTS: THE COSTS AND BENEFITS OF PERFORMANCE-APPROACH GOALS ENDORSEMENT AT UNIVERSITY** Benoit Dompnier<sup>1</sup>, Céline Damon<sup>2</sup>, Fabrizio Butera<sup>3</sup>; <sup>1</sup>University of Lausanne (Switzerland), <sup>2</sup>Clermont University (France), <sup>3</sup>University of Lausanne (Switzerland) – In achievement goal research, performance-approach goals are defined as the desire to outperform others. It is argued that the level of endorsement of these goals not only affects academic behaviors, but also the way one is perceived and judged by others. Most of the time, researchers discourage the use of performance goals in classrooms. However, University's functioning, and in particular its selection function encourages such goals. Thus, it is hypothesized that students who strongly endorse performance-approach goals should be perceived in a negative way in term of social desirability (judgement of warmth). They should however be perceived as persons who have great chances to succeed at University (judgement of competence). Three experiments documented this ambivalence. High endorsement of performance-approach goals was associated with being judged as dislikeable (it reduced social desirability), but it enhanced judgement of competence (social utility). A fourth experiment indicated that the social utility of performance-approach goals was stronger when one judged from the teachers' point of view. The social undesirability of performance-approach goals was stronger when one judged from his/her peers' point of view. The discussion focuses on the possibility that goals might be more or less endorsed to satisfy social motivations, such as being judged as a nice or a competent person by others.

**F147**

**CURBING IMPULSIVITY BY REFLECTION-PROMOTING IMPLEMENTATION INTENTIONS** Frank Wieber<sup>1</sup>, Peter M. Gollwitzer<sup>1,2</sup>, J. Lukas Thürmer<sup>1</sup>, Georg Odenthal<sup>1</sup>; <sup>1</sup>University of Konstanz, Germany, <sup>2</sup>New York University – Analytical reasoning strongly taxes people's cognitive capacities, leaving little room to apply effortful self-regulatory strategies in order to monitor and regulate behavior. As a result, people fall prey to impulsive responding (i.e., taking shortcuts) individually as well as in groups. We hypothesize that forming implementation intentions (i.e., if-then plans) which link reflective responding to critical cues should curb such impulsivity; this is because implementation intentions should trigger analytic reasoning reflexively. In a first study, implementation intentions to double-check the initial solutions discovered in an analytical reasoning test (Advanced Progressive Matrices; Raven, 1976) successfully reduced impulsive responding as indicated by taking more time which in turn enhanced test performance. In a second study, implementation intentions to double-check arguments in favor of possible solutions before making a group decision helped groups to uncover better alternatives in the hidden profile paradigm (Titus & Stasser, 1985). In this paradigm, only discussing the unshared unique information allows finding the best alternative (Study 2). Together, these findings suggest that forming reflection-promoting implementation intentions is an effective strategy to curb people's impulsivity (i.e., taking shortcuts) in performing demanding reasoning tasks. These findings also add to implementation intention research by showing that complex responses and not just simple one-shot responses can be delegated to situational cues that in turn trigger these responses reflexively.

**F148**

**COMPENSATORY CONTROL: HOW EXTERNAL SYSTEMS OF CONTROL ARE SUBSTITUTABLE FOR PERSONAL CONTROL, AND FOR ONE ANOTHER** Steven Shepherd<sup>1</sup>, Aaron C. Kay<sup>1</sup>; <sup>1</sup>University of Waterloo – External sources of control, such as the government and other social and political systems, are instrumental in providing people with the psychological comfort of knowing that outcomes in one's life are controlled and non-random. This process of turning to external systems of control in order to supplement both chronic and situationally low levels of personal control offers an explanation for why people are motivated to perceive social systems as fair and legitimate. Likewise, simply asserting personal control over

one's environment can also serve as a means of assuaging feelings of randomness in the world. Therefore, affirming personal control and endorsing external sources of control serve as two unique ways of achieving perceptions of control and order in the world. The current studies demonstrate that (i) socio-political systems are increasingly defended when control needs are not optimally met, and (ii) that once control needs are met, people become more willing to express dissatisfaction with socio-political systems. In Study 1, participants who did not bolster their sense of personal control, as compared to those who did, were more likely to support the government and showed less criticism of the government. In Study 2, participants who read an article depicting the government as having control over the struggling economy were more likely to reject the idea of a controlling God than those who read an article that described Canadian culture as a source of value and personal significance in life.

**F149**

**BEYOND MORTALITY AND THE SELF: MEANING AFFIRMATION FOLLOWING IMPLICIT ANOMALIES** Travis Proulx<sup>1</sup>, Daniel Randles<sup>2</sup>; <sup>1</sup>Simon Fraser University, <sup>2</sup>University of British Columbia – Following from Kierkegaard in the 19th century, existentialist theorists have argued that violations of expected associations provoke a common response: the affirmation of alternative meaning frameworks. More broadly, Kierkegaard argued that any anomaly may constitute a meaning threat, where efforts to affirm an alternative meaning framework may follow from a breakdown of personal identity, contemplation of a finite human existence... or finishing a beer and finding a live frog at the bottom of the mug. In two studies following from the Meaning Maintenance Model, we support the hypothesis that people will affirm alternative meaning frameworks following trivial anomalies that are either unrelated to one's self-conception or one's mortality. In Study 1, we exposed participants to reverse colored playing cards and found that an implicit awareness of this anomaly provoked compensatory affirmation of moral beliefs equivalent to a mortality salience prime. In Study 2, we found that exposing participants to absurd word pairings (e.g., 'orange idea') provoked moral affirmation equivalent to affirmation following death-related words. Taken together, these studies suggest a common cognitive response to absurdities both grand (mortality) and trivial (perceptual anomalies).

**F150**

**WHEN AVOIDANCE MOTIVATION PROMOTES CREATIVITY: THE ROLE OF MOTIVATIONAL ORIENTATION AND REGULATORY SUCCESS** Matthijs Baas<sup>1</sup>, Carsten K. W. De Dreu<sup>1</sup>, Bernard A. Nijstad<sup>2</sup>; <sup>1</sup>University of Amsterdam, <sup>2</sup>University of Groningen – Approach states generally boost creativity because they associate with positive, activating moods and enhanced cognitive flexibility. With regards to avoidance states, research evidence is less consistent, with some findings suggesting avoidance states promote creativity and other findings pointing to no or even negative effects. We propose and test the hypothesis that whether avoidance states boost creativity depends on regulatory success, the sense of success or progress towards fulfilling a goal. Specifically, we expected that avoidance states that activate the individual (unfulfilled avoidance motivation, fear) lead to similar levels of creativity as approach states, but that avoidance states that de-activate (successful avoidance, relief) lead to lower levels of creativity. Moreover, we predicted this effect would be mediated by feelings of activation. These predictions were tested in four experiments, two focusing on creative insight performance and two focusing on creative ideation. Motivational orientation was manipulated through self-generated imagery, or through an adapted version of the mouse-in-maze task by Friedman and Forster (2005). Regulatory success was experimental manipulated as well, or measured to serve in path analyses. Results provided consistent support for the predictions, regardless of specific manipulations of dependent measures. We also obtained initial evidence that the creativity-enhancing effect of avoidance motivation is due to cognitive persistence rather than cognitive flexibility.

**F151**

**MATING MOTIVES MAKE MEN LESS LOSS-AVERSE** Yexin Jessica Li<sup>1</sup>, Douglas Kenrick<sup>1</sup>, <sup>1</sup>Arizona State University – Loss aversion is the tendency for people to prefer avoiding losses to acquiring gains of the same magnitude. Though seemingly irrational, biases such as these can be adaptive, such as when men act risky to acquire mates. The present research merges research in economics, biology and psychology to investigate how loss aversion is affected by social motives. In line with differential parental investment and sexual selection theory, results indicate an erasure of loss aversion when men, but not women, are under a mating motivation. More broadly, results suggest decisional biases may operate under a predictable and adaptive 'deep rationality'.

## Person Perception/Impression Formation

**F152**

**DO YOU SEE WHAT I SEE? PERCEPTIONS OF POLITICAL CANDIDATES, SYSTEM JUSTIFYING BELIEFS, AND VOTING BEHAVIORS DURING THE 2008 PRESIDENTIAL ELECTION** Devin Wallace<sup>1</sup>, John Michel<sup>1</sup>; <sup>1</sup>Towson University – Two studies examined factors that influenced voting intentions and behaviors during the 2008 presidential election. In line with research suggesting that competence and warmth are important traits on which political candidates are judged and evaluated (Kinder, Peters, Abelson, & Fiske, 1980; Pancer, Brown, & Barr, 1999), participants in Study 1 rated the presidential and vice-presidential candidates in terms of their competence and warmth. We hypothesized that the winner of the election would be the candidate who was perceived as both competent and warm, even across political and ideological lines. Results revealed that Barack Obama was generally perceived as both competent and warm while John McCain engendered high competence and warmth ratings only from his supporters. Study 2 examined whether Barack Obama's election would influence system justifying ideologies differently for his adherents relative to his opponents. We expected system justification to increase after the election for Obama's adherents, but no post-election increase was expected for those who did not support him. Results supported this hypothesis. Together, these results demonstrate the role of perceived competence and warmth in voting behavior. In addition, we discuss the impact of President Obama's success on system justifying ideologies separately for liberals and conservatives.

**F153**

**PERSONALITY: DIFFERENTIAL PERCEPTIONS OF PERSONALITY DURING ONLINE AND REAL-WORLD SOCIAL INTERACTIONS** Oshrat A. Hodara<sup>1</sup>; <sup>1</sup>York University – Although personality perceptions during face-to-face interactions have largely been found to be accurate and reliable (Barrett-Feldman & Pietromonaco, 1997; Funder, 1999, 2003), perceptions of personality during online interactions are still being questioned (Markey & Wells, 2002). In online settings, personality perceptions were accurate when raters judged individuals based on their websites and email addresses (Back, Schmukle, & Egloff, 2008; Vazire & Gosling, 2004). However, once participants actively engaged in online interactions, their personality perceptions of each other were found to be inaccurate and deemed flawed (Rouse & Haas, 2003). It is plausible that accuracy in interpersonal perceptions may change once individuals become active participants of the virtual world, rather than mere observers who judge from a distance. That is, online interpersonal perceptions may be influenced by important situational and interpersonal factors (e.g., interaction partners' interpersonal style), which may shape self-other perceptions in interesting ways. The present research utilized the framework of interpersonal theory to examine perceptions of affiliation and dominance during online and face-to-face interactions. A total of 40 participants reported on their own interpersonal style and that of their interaction partners for 21 days. Results indicated that participants perceived their own interpersonal behaviors during online and face-to-face interactions to be unrelated. In addition, participants perceived self and other dominance to be higher during same-sex than opposite-sex interactions,

whereas they perceived self and other affiliation to be higher during online than face-to-face interactions. Gender differences and similarities in personality perceptions during online and face-to-face interactions are discussed.

**F154**

**I KNOW WHO FALLS FOR MY SEX-APPEAL: IMPLICIT PERSUASION THEORIES ABOUT ATTRACTIVENESS AND RECEIVER CHARACTERISTICS** Tobias Vogel<sup>1</sup>, Florian Kutzner<sup>1</sup>; <sup>1</sup>University of Heidelberg, Germany – A vast amount of evidence suggests that the physically attractive takes an advantage in achieving social goals (Feingold, 1992; Langlois, Kalakanis, Rubenstein, Larson, Hallam, & Smoot, 2000). Persuasion literature however suggests that these advantages are not universal but depend on characteristics of the receiver. More specifically, prominent theories of persuasion such as the Elaboration Likelihood Model (ELM, Petty & Cacioppo, 1986) propose that senders of persuasive messages most likely profit from physical attractiveness if receivers lack processing capacity and/or motivation. The present research focuses on the sender perspective. In a series of studies we investigate how perceived attractiveness translates into expectations of persuasive success. In a line of experiments we varied descriptions of the receiver (Vogel, Kutzner, Freytag & Fiedler, under review). Congruent with the hypothesis, perceived attractiveness was a better predictor of persuasive success if receivers processing motivation was apparently low than if it was high. This interaction replicates in a field study in which students were asked about their expectations of success in an oral exam. Expectations about investigators processing motivation mediated the relation between perceived attractiveness and expected grades (Vogel, in prep.). Taken together, findings show that lay persons' implicit theories of persuasion overlap to a large degree with scientific persuasion theories, such as the ELM. Moreover they indicate that physical attractiveness might translate into interpersonal success by strategic choices of the communication partner.

**F155**

**LANGUAGE ASSOCIATED WITH SELF VERSUS OTHER PERCEPTIONS OF STATUS** Ewa Kacwicz<sup>1</sup>, James W. Pennebaker<sup>1</sup>, Sanjay Srivastava<sup>2</sup>, Jennifer S. Beer<sup>1</sup>; <sup>1</sup>University of Texas at Austin, <sup>2</sup>University of Oregon – The current study examined accuracy and bias in self and other-perceptions of status based on natural language use. Seventy-nine participants worked in groups of 3-6 (20 groups) on a leaderless group discussion task. After the interaction, participants rated themselves and other group members on status. Videos of the interaction were transcribed and analyzed using Linguistic Inquiry and Word Count. Language was correlated with self-rated and other-rated status. The strength of the correlations between self and other were compared. Results suggest that in evaluations of status, the self pays more attention to internal states, whereas others pay more attention to the content and length of the conversation. People assume use of fillers (uhm, err), which can reflect anxiety or uncertainty, impacts their status, when in reality it does not influence other's perceptions of their status ( $z = 1.48$ ;  $p < .10$ ). The self fails to recognize the degree to which word count and use of positive and negative emotion is associated with other's impressions of their status ( $z = -1.8$ ,  $p < .05$ ;  $z = -1.45$ ,  $p < .10$ ;  $z = 1.78$ ;  $p < .05$ ). Despite these biases, some language dimensions feed into both self and other perceptions. Use of "we" and "you," which reflect other focus, in addition to six letter words, which can convey formality and insecurity, influence both self and other ratings of status. These findings suggest that linguistic markers can shed light on biases associated with self versus other perceptions of status and help elucidate why they exist.

**F156**

**CAN MIMICRY REDUCE STEREOTYPING?** Kris Ariyabuddhipongs<sup>1</sup>, Glenn D. Reeder<sup>1</sup>, J. Scott Jordan<sup>1</sup>, Donnie N. Johnson<sup>1</sup>; <sup>1</sup>Illinois State University, Normal, Illinois – Although people are typically unaware when they are being mimicked, mimicry tends to increase liking and promotes smooth interactions (Chartrand & Bargh, 1999). In this study, we investi-

gated the possibility that mimicked participants would rely less on stereotypes when judging a target person. Our 28 female participants were paired up. Each pair separately watched a live video of a female confederate (the target person) who was in another room. The confederate was ostensibly watching a movie, and participants were instructed to form an impression of her. The confederate wore a T-shirt with a large printed label designed to elicit either an extraversion stereotype ("Cheerleader") or an introversion stereotype ("Librarian"). Unbeknownst to participants, the confederate was actually watching and mimicking one of the participants in the pair via a live webcam. Therefore, each member of the pair saw the same body movement from the confederate, but only one of them was mimicked. Participants indicated no awareness of either the mimicry or of being watched via web cam. The results revealed a significant interaction between mimicry and T-shirt label on judgments of the confederate's extraversion. Non-mimicked participants demonstrated stereotyping by rating the confederate as more extroverted when she wore the "Cheerleader" T-shirt, as opposed to the "Librarian" T-shirt ( $M_s = 4.94$  vs.  $3.58$  on a 7-point scale). However, the ratings of mimicked participants did not differ significantly as a function of the confederate's T-shirt ( $M_s = 4.81$  vs.  $5.00$ ). The results suggest that the unconscious effects of mimicry could potentially reduce stereotyping.

### F157

#### ACCUMULATIVE EFFECTS AND LONG-TERM CONTINUITY OF SUBLIMINAL MERE EXPOSURE

Naoaki Kawakami<sup>1</sup>, Fujio Yoshida<sup>1</sup>; <sup>1</sup>University of Tsukuba – We examined accumulative effects and long-term continuity of distributed mere exposure. In experiments, the distributed exposure condition (100 exposures distributed over five days) and the massed exposure condition (100 exposures in one day) were used. Moreover, measurement was conducted using GNAT at Time 1 (just after), Time 2 (after three days), Time 3 (after two weeks), and Time 4 (after one month). In Experiment 1, a single figure of a fictitious character was shown subliminally for a total of 100 times. The results indicated the following: at Time 1, likeability was higher under the massed exposure condition than under the distributed exposure condition. However, after Time 2, likeability gradually decreased under the massed exposure condition, it did not decrease under the distributed exposure condition until Time 4. In Experiment 2, in order to investigate the effect of multiple exposure, five figures with different poses of the character used in Experiment 1 were shown 20 times each, in total 100 times. The results indicated that similar to Experiment 1, likeability did not decrease under the distributed exposure condition until Time 4. Moreover, an ANOVA was conducted integrating the data of Experiment 1 and 2: Exposure Method (distributed/massed) × Exposure Object (single/multiple) × Measurement Time (Times 1-4). First, a significant Exposure Method × Measurement Time interaction suggested that massed exposure had an instantaneous effect on likeability, whereas distributed exposure had a long-term continuous effect. Furthermore, a significant main effect of Exposure Object showed that multiple exposures strengthened the mere exposure effect.

### F158

#### YOU THINK I LIKE COSMO? OK, I'LL READ COSMO: THE ACCUMULATION OF SELF-FULFILLING PROPHECIES AND GENDER STEREOTYPES

Heather Nofziger<sup>1</sup>, Thomas Cain<sup>1</sup>, Elizabeth Salib<sup>1</sup>, Lee Jussim<sup>1</sup>; <sup>1</sup>Rutgers - The State University of New Jersey – This research examined the accumulation of self-fulfilling prophecies of gender stereotypes across perceivers. Specifically, we investigated the impact of gender stereotypes (masculine vs. feminine) over multiple perceivers. Rutgers University students were given profiles of people presenting gender stereotyped information (masculine, feminine, or neutral gender) and were asked to choose three articles for the person to read. Articles were pre-tested for masculine, feminine, or neutral gender stereotypes. Perceivers who read the masculine profile chose articles on masculine topics (e.g. science and technology), the feminine profile chose articles on feminine topics (e.g. Cosmopolitan or Vogue), and the neutral profile chose articles on neutral topics (e.g. airline or travel reviews). To examine accumulation, targets

were given a list of six articles, chosen by their partners, and were asked to choose three they would like to read. Targets were placed in one of five conditions where their article choices were constrained: most articles were masculine gender stereotyped, most articles were feminine gender stereotyped, half were gender stereotyped (masculine or feminine) and half neutral, or all neutral. Targets were led to believe that their partners thought they were gender stereotyped or not gender stereotyped based on the articles they were provided. Results indicated that when targets were constrained by the beliefs of others, they acted in a predictable way. Perceivers opted to apply gender stereotypes where they constrained the potential outcomes of others. Targets placed under these constraints, tended to align their behaviors in confirmatory manner.

### F159

#### KIND OR CALCULATING: EFFECTS OF IMPRESSION VERSUS NARRATIVE GOALS AND TRAIT/MOTIVE CUES ON SOCIAL JUDGMENTS

Kristi Costabile<sup>1</sup>; <sup>1</sup>Ohio State University – Psychological research has generally agreed that trait abstractions are regularly drawn from observations of social behavior, even from perceivers who are not attempting to form an impression of a target. Additionally, recent work suggests that a target's current motives can also be inferred from behavioral observation. The present experiments explore how two social information processing objectives (impression formation versus story construction) affect the types of inferences drawn from behavior (i.e., trait versus motive) which then guide evaluations of the observed target. Experiment 1 explored the role of narrative and impression objectives on explicit attributions made for observed behaviors. Participants read a series of sentences describing persons performing various behaviors. Half of the participants were asked to form an impression of the individuals described in the sentences, half were asked to form a narrative of the targets. As predicted, participants given impression formation goals were more likely to attribute behaviors the target's underlying disposition; whereas those given narrative instructions were more likely to attribute behaviors to the target's current motives. Experiment 2 examined how inferential information affected social judgments. Participants were asked to evaluate a target who performed a behavior (e.g., cut in line) on several dimensions. Results indicated that evaluations varied as a function of motive (e.g., hurry) or trait (e.g., rude) cues – even when such cues were provided merely in the form of narrative or impression instructions. Together, this work suggests social information processing goals can dramatically affect the social judgment process.

### F160

#### PERCEPTUALLY AMBIGUOUS GROUPS ARE CATEGORIZED AUTOMATICALLY

Nicholas Rule<sup>1</sup>, Nalini Ambady<sup>1</sup>, Neil Macrae<sup>2</sup>; <sup>1</sup>Tufts University, <sup>2</sup>University of Aberdeen – Previous research has shown that perceptually obvious groups (such as age, race, and sex) are categorized automatically. Here we show that automatic perception extends to other socially important groups that are not perceptually obvious, namely sexual orientation and religious group membership. Participants completed one of two lexical decision tasks (LDT). The first LDT asked participants to categorize strings of letters as words or non-words, wherein the words were stereotypically-associated with gay men or straight men. Each trial was preceded by a brief presentation of a gay man or straight man's face. Participants categorized gay-related words significantly faster when preceded by gay faces and straight-related words significantly faster when preceded by straight faces. The second LDT mirrored this design but presented words stereotypically associated with Jewish men or Christian men. Faces of Jewish and non-Jewish men were briefly presented before each lexical decision trial. Participants were again faster to categorize a Jewish-related word when it was preceded by a Jewish man's face and faster to categorize a Christian-related word when it was preceded by a non-Jewish man's face. These data suggest that mere perception of an individual's face can trigger thoughts about his group membership and facilitate processing of stereotypically-related concepts. Automatic categorization may therefore extend to groups outside of age, race, and sex, even when the boundaries between those groups (e.g., who is gay and

who is straight) are ambiguous and difficult to discern. The cognitive basis for automatic categorization may therefore be flexible, incorporating various important social groups.

### F161

#### **CANDIDATES UNDER FIRE: PINPOINTING THE MOST EFFECTIVE STRATEGY FOR COMBATING NEGATIVE POLITICAL ATTACKS** Justin S. Cheng<sup>1</sup>, Randall A. Renstrom<sup>1</sup>, Victor C. Ottati<sup>1</sup>; <sup>1</sup>Loyola University Chicago –

How should politicians respond to false attacks and incorrect accusations made against them? It may be wise for politicians to address attacks head-on by "explicit negation" (restating the attack and claiming it false). However, explicit negation might inadvertently strengthen the cognitive association between the negative attack information and the candidate. Furthermore, some voters may not have heard the attack in the first place, thus explicit negation might produce an association between negative information and the candidate where none existed previously. Therefore, it may be beneficial for politicians to counter attacks without repeating and reinforcing them. The present research compared these two response strategies. Participants were initially either exposed to a political attack against a candidate or had no prior knowledge of the attack. Then, they read a candidate statement that either repeated and explicitly negated the attack or, alternatively, simply asserted the truth without repeating the attack. Results showed attitudes toward the candidate were more positive when the candidate simply asserted the truth and more negative when the candidate repeated then negated the attack ( $F=5.2$ ,  $p<0.05$ ). Moreover, this effect was moderated by participants' prior knowledge of the attack ( $F=11.9$ ,  $p<0.05$ ). Explicit negation yielded more negative attitudes toward the candidate only among participants possessing no prior knowledge of the attack. Among participants who had heard the attack previously, candidate response strategy did not matter. These results suggest candidates should recognize that not all voters have heard attacks lodged against them and should refrain from repeating attacks in their rebuttal statements.

### F162

#### **GETTING TO KNOW YOU?: REGULATING EMOTIONS VIA SUPPRESSION INTERFERES WITH FRIENDSHIP AND SELF-PEER AGREEMENT** Daniel

Catterson<sup>1</sup>, Oliver P. John<sup>1</sup>, James J. Gross<sup>2</sup>; <sup>1</sup>University of California, Berkeley, <sup>2</sup>Stanford University – Habitual use of suppression has been linked to a number of negative psychological outcomes in both experimental and longitudinal studies. One particularly damaging consequence for individuals who suppress is lower relationship satisfaction (Butler et al., 2003) and relationship closeness (Srivastava et al., 2009). Moreover, individuals who suppress feel highly inauthentic because they are aware of the discrepancy between their inner experience and outer expression of emotion (English & John, 2009). One further consequence of this discrepancy between inner experience and outer expression for individuals who suppress is that their peers, who base perceptions on overt behaviors, may not be able to get to know the individual very well. A total of 190 college students rated themselves and were rated by at least two peers on a variety of affectively charged and neutral attributes and emotion regulation strategy use. Our findings suggest that individuals who habitually suppress are, in fact, rated as less well known by their peers. Because the use of suppression effectively conceals emotional information from their peers, self-peer agreement is lower for individuals who frequently suppress on affectively charged domains such as self-esteem and loneliness, but remains intact for affectively neutral domains such as time spent studying and socializing. Finally, peers perceive individuals who suppress as less emotionally close to others because, in part, they are less well known by their peers. These findings suggest that chronic suppression reduces the emotional information available to the social observer, and thus negatively affects both friendship formation and interpersonal-perception processes.

### F163

#### **INTERPERSONAL ANTECEDENTS AND CONSEQUENCES OF SELF-OBJECTIFICATION** Randi Garcia<sup>1</sup>, Valerie Earnshaw<sup>1</sup>, Diane Quinn<sup>1</sup>;

<sup>1</sup>University of Connecticut – Much of past objectification research has focused on what causes one to self-objectify such as media portrayals of objectified women (Fredrickson & Roberts, 1997) or on individual outcomes of self-objectification, such as performance (Fredrickson, Roberts, Noll, Quinn, and Twenge, 1998). Rarely do we study the direct influence of another person in one's environment. The current study examined how the sexism of a brief interaction partner can affect the extent to which both men and women self-objectify and the effects of self-objectification on attraction. Fifty mixed-sex dyads, which were not previously acquainted, interacted for 10 minutes after completing questionnaires that assessed sexism and trait self-objectification. Then participants were asked how frequently they thought about features of their partner's observable and unobservable characteristics, as well as how frequently they thought these things of themselves during the interaction. These post interactions questions were used to measure self-objectification. Using multilevel modeling and the Actor Partner Interdependence Model (APIM; Kenny, Kashy, & Cook, 2006), we found, that trait self-objectification significantly predicted self-objectifying thoughts during the interaction for both men and women. There was also a significant interaction of gender and the sexism of one's interaction partner such that women self-objectified more when interacting with a sexist man, but men self-objectified less when their interaction partner was sexist. Lastly, we found that an increase in a female participant's self-objectification during the interaction significantly reduced the male participant's attraction to her. Studying objectification dyadically is clearly important for understanding the interpersonal antecedents and consequences of self-objectification.

### F164

#### **UNCERTAINTY REPELS OTHERS: THE INFLUENCE OF CAUSAL UNCERTAINTY ON INTERPERSONAL ATTRACTION** Matylda Osika<sup>1</sup>,

Stephanie Tobin<sup>1</sup>; <sup>1</sup>University of Houston – Causal uncertainty (CU) is doubt about one's understanding of the causes of events (Weary & Edwards, 1996). CU is unpleasant and can prompt efforts to improve one's understanding. The present study investigated how CU affects interpersonal attraction. Attraction research suggests that individuals are most attracted to similar others (Byrne, 1967). However, some studies have indicated that this positive similarity-attraction relation can be altered (e.g., Herbst, Gaertner, & Insko, 2003). We hypothesized that CU is one variable that can alter the relation between similarity and attraction such that high CU individuals would be more attracted to low CU (dissimilar) rather than high CU (similar) others due to their need for uncertainty reduction. Low CU individuals were expected to show the "typical" attraction pattern and be more attracted to similar (low CU) others. A 2 (perceiver CU: low, high) X 2 (target CU: similar, dissimilar) design was used to test the hypotheses. First, participants filled out a measure of CU online. One week later, participants attended a lab session during which they evaluated a target based on the target's answers on a CU scale. Each participant viewed a completed CU scale that was tailored to his or her own responses, with the target responding similarly or dissimilarly on the majority of items. The results indicated that, as predicted, similarity bred attraction for low CU individuals. In contrast, high CU participants exhibited equally low liking for similar and dissimilar others. Thus, while sharing certainty fosters attraction, sharing uncertainty does not.

### F165

#### **ATTRIBUTIONS OF SEXUAL FLUIDITY: WOMEN ARE PERCEIVED TO BE MORE SEXUALLY FLUID RELATIVE TO MEN** Danielle Gentile<sup>1</sup>, Patrick

Boerner<sup>1</sup>, Elizabeth Ewell<sup>1</sup>, Justine Jaskier<sup>1</sup>, Jennifer J. Ratcliff<sup>1</sup>; <sup>1</sup>The College at Brockport, SUNY – The purpose of the present study was to examine the hypothesis that women are perceived as more sexually fluid than men – or more likely to change their sexual orientation over time. Previ-

ous research has suggested that women show greater flexibility in their sexual orientation and their sexuality across the lifespan than do men (Baumeister, 2000; Diamond, 2008; Kinnish et al., 2005). However, it has not been determined whether others attribute greater sexual fluidity to women relative to men. The current research sought to answer this question, and to this end, a 7-item measure of perceived fluidity was developed ( $\alpha = .84$ ) and the relationship between participant characteristics and perceived fluidity were examined. Results revealed that women are perceived to be more sexually fluid than are men, and this finding was not moderated by participant gender. Additionally, the measure was negatively related to prejudice toward lesbians and toward gay men, and negatively related to external motivation to respond without prejudice. Importantly, although fluidity was related to these more established measures, the overlap between them was relatively small. Interestingly, participant's own sexual orientation did not predict perceived fluidity in others, whereas participant beliefs regarding their own personal fluidity did. The implications of the finding that women are perceived to be more sexually fluid than are men will be discussed.

### F166

#### ACCURATE HEALTH ASSESSMENTS BASED UPON SNAP JUDGMENTS

Nicolas Brown<sup>1</sup>, Christopher Nave<sup>1</sup>, Ryne Sherman<sup>1</sup>, David Funder<sup>1</sup>, Sarah Hampson<sup>2,3</sup>, Lewis Goldberg<sup>2</sup>; <sup>1</sup>University of California, Riverside, <sup>2</sup>Oregon Research Institute, <sup>3</sup>University of Surrey, Guildford, UK – In everyday life, individuals use available behavioral information to make judgments about one another, and are often accurate even with limited periods of observation (Ambady, 1995, 2000; Funder, 1995). Few studies have been conducted to verify if this accuracy transfers to health-related judgments (Hunt et al., 1980; Spengler et al., 2009). The present study analyzes data from the Hawaii Personality and Health cohort, which include comprehensive assessments of current health and personality interviews. Four research assistants viewed five minutes of the videotaped interviews and judged the participants on 15 health dimensions, including general health, tobacco use, alcohol use, physical activity, sleep quality, cholesterol, and blood pressure. Judges were able to accurately assess a target's general health in comparison to self-rated general health ( $r = 0.32$ ), and current users of tobacco were accurately identified ( $r = 0.38$ ) although alcohol users were not ( $r = 0.02$ ). Judges could not accurately judge a participant's cholesterol ( $r = -0.19$ ). Judges strongly relied on participant's actual weight for judging cholesterol ( $r = .70$ ) yet actual weight and actual cholesterol were negatively related ( $r = -.18$ ). Intuitive snap judgments of aspects of health can be surprisingly accurate but more research is clearly needed to specify just when and how.

### F167

#### THE INTERACTION BETWEEN PERCEIVER RACE AND TARGET CATEGORY DURING SOCIAL CATEGORIZATION

Kyle T. Gagnon<sup>1</sup>, Cheryl L. Dickter<sup>1</sup>; <sup>1</sup>College of William & Mary – Decades of social cognition research have established that, during person perception, social perceivers categorize race and gender quickly and automatically. More recent psychophysiological research has demonstrated that the race of the perceiver plays an important role during the social categorization process. The purpose of the present research was to further examine how this interaction between the social categories of the perceiver and the person perceived affect behavior. In this study, Black and White participants completed a modified flanker task in which they identified the race of target individuals varying by race and gender that were presented among arrays of distracter photos, which also varied by race and gender. Behavioral results indicated that participants were sensitive to category information of target faces, such that Black male targets yielded the fastest reaction time (RT). Additionally, participants also attended to distracter information; RTs varied based on the compatibility of target race and distracter race and gender. Furthermore, this was moderated by participant race; that is, the interaction between target race and distracter compatibility differed between Black participants and White participants. Taken together, these results suggest that, for all perceivers, Black male targets are categorized more quickly during person perception than any other

targets. In addition, these results highlight the importance of the race of the perceiver during social categorization, as illustrated by different patterns of results with Black and White participants.

### F168

#### USING NEED FOR AFFILIATION TO PREDICT PERCEPTIONS OF TOUCH AS A POSITIVE INTERACTION OR NEGATIVE PERSONAL SPACE INVASION

Matthew J. Zawadzki<sup>1</sup>, Stephanie A. Shields<sup>1</sup>; <sup>1</sup>The Pennsylvania State University – Brief touches can be experienced as invasive gestures or as neutral, even positive interactions. This study examined the extent to which the touched person's need for affiliation (n-Aff) explains how positively/negatively the touched person perceives the touch. Humans have competing needs for personal space and affiliation (Burgoon, 1978) and use these needs to navigate social interactions (Altman, 1975; 1993). We proposed that because touch constrains personal space, responses to touch depend upon the touched person's n-Aff. We predicted that the higher participants' n-Aff, the more positive their rating of a touch, and the more positive their reactions to other components of the situation; in contrast, the lower their n-Aff the more negative their ratings. In a high-impact behavioral study, a confederate touched, leaned close to, or got the attention of (control condition) a participant ( $n=262$ ) after the participant's n-Aff was measured with a 14-item questionnaire ( $\alpha=.91$ ) designed for this study. A series of self-report items assessed the effect of the touch, lean or control and comprised the main dependent measures. The pattern of results supported the predictions such that participants' n-Aff influenced the participants' ratings of the valence of the interface. Ratings of the interface in turn affected ratings of the confederate's personality, reported desires to interact with the confederate in the short- and long-term, desire to escape the situation, and reported mood. Results suggest that while the physical act of a touch may be ambiguous, understanding a person's n-Aff may predict a person's reactions to that ambiguous touch.

### F169

#### WHAT MAKES YOU THINK YOU'RE SO SEXY, TALL, AND THIN? THE PREDICTION OF SELF-RATED ATTRACTIVENESS, HEIGHT, AND WEIGHT

Julie Pozzebon<sup>1</sup>, Beth Visser<sup>1</sup>, Anthony Bogaert<sup>1</sup>; <sup>1</sup>Brock University – Self-reports of attractiveness, height, and weight are frequently used in lieu of more objective measures of these constructs. However, research suggests that self-reports of personal attributes are often distorted, in that men report being taller, women report being lighter, and both sexes report being more attractive than they actually are. The present study examined discrepancies between self- and observer/actual reports of attractiveness, height, and weight, and investigated the role of both esteem and gender role scales in the prediction of such discrepancies. Results indicated that self-reports of attractiveness, height, and weight were distorted as hypothesized. Attractiveness discrepancies were predicted by high esteem and traditional gender role identification. Height discrepancies were predicted by agency, and weight discrepancies were predicted by self-efficacy. These findings indicate that esteem and gender role characteristics are important in the perception (and distortion) of self-relevant information.

### F170

#### FACING IMPRESSIONS: FROM EMOTION EXPRESSION TO TRAIT INFERENCE

Roberta A. Schriber<sup>1</sup>, Richard W. Robins<sup>1</sup>; <sup>1</sup>University of California, Davis – Social-personality psychologists and evolutionary psychologists acknowledge emotion expressions as a rich source of social information that can be tapped by perceivers to infer the thoughts, feelings, and interpersonal intents of a target. Via processes of overgeneralization and temporal extension, brief displays of emotion can also seed perceivers' inferences of targets' personality traits. Only a few studies have examined the effect of emotion expressions on trait impressions, and none have considered the role of self-conscious emotions, which arise in response to one's success or failure to meet social standards and whose expression could thus be deemed especially revelatory of a target's personality. 60 participants were shown photos of three self-con-

scious emotion expressions (pride, embarrassment, shame), 6 basic emotion expressions (anger, disgust, fear, joy, sadness, surprise), and a neutral expression, all posed by the same target per participant. Participants rated the target, as seen in each photo, on several personality dimensions, then performed an emotion recognition task. Results showed that pride and joy expressions elicited the most positive trait inferences, and were distinguished from each other by their relative standing on esteem/status versus warmth/amicability dimensions. Shame led to the lowest inferences of esteem/status. Interestingly, embarrassment signaled low status but conferred the target with a knack for making impressions similarly positive to those of joy and pride. Disgust and anger led to lowest inferences of amicability, and trailed pride in dominance but matched pride in hubris. Finally, accuracy of emotion recognition, and qualities of target and perceiver, also appeared to affect trait inference.

#### F171

**ACCURACY AND BIAS OVER TIME IN PERCEPTIONS OF SELF-DISCLOSURE IN A NEW RELATIONSHIP** Erin P. Hennes<sup>1</sup>, Patrick E. Shrout<sup>1</sup>, Tessa V. West<sup>1</sup>, Sean P. Lane<sup>1</sup>; <sup>1</sup>New York University – Self-disclosure is an important correlate of relationship quality in both romantic partnerships and close friendships (Collins & Miller, 1994). Reis & Shaver (1988) posit that intimacy results largely from a process of reciprocal self-disclosure. Indeed, Laurenceau, Feldman Barrett, & Pietromonaco (1998) found both reported self-disclosure and perceived partner's disclosure to be predictive of feelings of intimacy. Much of this literature is based on disclosure reports from one partner or one time point; little is known about how perceptions of disclosure vary over time and the extent to which this variation is driven by accuracy or bias processes. We examine this question in newly acquainted roommates pairs (N=65) using twice-weekly reports of self- and other-disclosure over a six week period within the first months of college. Accuracy and bias (Kenny and Acitelli, 2001) were estimated in the context of an indistinguishable dyads analysis (Kenny, Kashy, & Cook, 2006). Although both effects were significant, bias effects were seven times the size of accuracy. The strength of the bias effect varied reliably across students, but there was no evidence of systematic variation in the accuracy effect. The association between one's perceptions and one's partner's perceptions of each others' self-disclosure was negligible. Additionally, bias was associated with lower levels of perceived partner disclosure. In general, the current research supports the hypothesis that relational intimacy may be driven more strongly by one's own feelings than by one's partner's actual behaviors, suggesting that current relationship models may underestimate the bias of individuals' reports of their partners.

#### F172

**THE ROLE OF FACIAL HAIR IN SOCIAL PERCEPTION** Christopher Harriman<sup>1</sup>, Michael Baumann<sup>1</sup>; <sup>1</sup>The University of Texas at San Antonio – Inferring the traits and predicting the behaviors of others is deeply embedded in the human experience. Individuals use a variety of physical cues in this effort (e.g., Bodenhausen & Macrae, 2006). Research on one such cue, facial hair, has yielded mixed results. Facial hair is associated with attractiveness and positive traits in some studies (Barber, 2001) while being associated with unattractiveness and negative traits in other studies (Muscarella & Cunningham, 1996). Because growing facial hair may be considered an act of self-expression, people may perceive different configurations of facial hair to imply different traits and behaviors. The present study sought to clarify the impact of facial hair by examining this possibility. Participants (N = 365) were shown realistic computer-generated faces. Faces were displayed on a monitor one at a time. Participants rated each face on 68 trait words before proceeding to the next face. Within participant, each facial hair configuration (clean shaven, chin strip, mustache, van dyke, and full beard) was presented on a different base face. To minimize fatigue, each participant rated only 3 configurations. Order of presentation and combination of base with hair configuration were balanced across participants. Trait words were condensed into scales which were analyzed taking into account non-inde-

pendence resulting from the part within / part between design. Differences by facial hair were found on each scale, and distinct profiles emerged for each configuration. Possible explanations for these differences and implications for the role of facial in social perception are discussed.

#### F173

**THE FACE OF ISLAM: THE EFFECT OF SMILE ON THE PERCEPTION OF INDIVIDUALS WITH ISLAMIC HEADGEARS** Marianne LaFrance<sup>1</sup>, Ezgi N. Akcinar<sup>1</sup>; <sup>1</sup>Yale University – Wearing of the Hijab or Islamic headscarf has recently been at the center of considerable controversy worldwide. Social psychology has yet to address this important issue. This abstract describes one of the first empirical studies to assess perceptions of women and men who wear Islamic headgears. Our question concerned whether identifiable Muslims are more negatively evaluated. In addition, we speculated that these person perceptions would be moderated by the facial expression worn by the targets. Specifically, we predicted that a smile would moderate prejudice toward Muslim men and women. To test this hypothesis, participants were presented with photos of 3 female and 3 male targets that varied on headgear (Islamic headgear ["hijab" or veil for female targets; "taqiyah" or Islamic prayer cap for male targets], a baseball cap, or no headgear) and facial expression (smile or no smile). Dependent measures consisted of 7-point scales (e.g. trustworthiness, fanatical, educated). Results showed effects for both headgear and facial expression and especially for their interactions. For example, men wearing the taqiyah with a neutral expression received the highest rating on "fanatical", which was reversed when these male targets smiled. Results are discussed in terms of how Muslim men and women are typically presented in the media as well as the role of gender in these presentations.

#### F174

**MORE THAN JUST A PRETTY FACE? THE RELATIVE IMPORTANCE OF PHYSICAL ATTRACTIVENESS IN INITIAL ATTRACTION AND DATING** Lindsay Shaw Taylor<sup>1</sup>, Andrew T. Fiore<sup>1</sup>, G. A. Mendelsohn<sup>1</sup>, Coye Cheshire<sup>1</sup>; <sup>1</sup>University of California, Berkeley – The primacy of physical attributes in romantic attraction and mate selection is well established. Online dating provides an opportunity to evaluate the relative contribution of other attributes such as personality, interests, values, etc., when they are all simultaneously "on display." In this research, we used laboratory-based studies and assessments of actual online daters to explore the roles of physical attractiveness and other aspects of the self in both initial attraction and longer-term dating success. In Study 1, participants rated the attractiveness of online dating profiles, either in their entirety or broken down into photo and textual self-descriptions. Photos were significantly more important than self-descriptions for determining overall profile attractiveness. Moreover, having an attractive photo was necessary but not sufficient for being deemed attractive. In Study 2, we expanded our operationalization of attractive to include dimensions such as appearing warm and worthy of contacting. Photo attractiveness was the most important predictor of participants' ratings on most dimensions, including overall attractiveness and desire to contact, but self-descriptions mattered more for appearing trustworthy. Finally, in Study 3, actual online daters described someone they met first through online dating and subsequently face-to-face. Being pleasantly surprised (rather than disappointed) by a date's personality was an important determinant of relationship longevity, whereas being surprised or disappointed by a date's physical attractiveness was not. Together, the results suggest that physical attractiveness is a gatekeeper – necessary for considering someone as a potential partner upon first encounter – but not the most important determinant of moving from initial attraction to dating.

**F175****WHEN EXPERIENCING PHYSICAL WARMTH WILL NOT PROMOTES INTERPERSONAL WARMTH: A SOCIAL PSYCHOLOGY PERSPECTIVE**

Lei Wang<sup>1</sup>, Songqu Shi<sup>1</sup>, Shanshan Xiao<sup>1</sup>; <sup>1</sup>Peking University – Williams and Bargh (2008) claimed that experiences of physical warmth (or coldness) would increase feelings of interpersonal warmth (or coldness). However, a biased experimental design has led them to an over-generalized conclusion. We conducted two experiments to show that experiencing physical warmth can result in alternative responses such as interpersonal aversion. The results showed that experiencing warmth can lead to perceive more anger on other face (study 1) and be less willing to forgive other (study 2). These findings address the importance of the role social context plays in interpreting physical warmth.

**F176****THE CYCLE OF DEHUMANIZATION: CONSEQUENCES OF PERPETUATING INHUMANITIES.**

Brock Bastian<sup>1</sup>, Nick Haslam<sup>2</sup>; <sup>1</sup>University of Queensland, <sup>2</sup>University of Melbourne – We can't be human in isolation. Our humanness is intimately connected to the humanness of others and when we diminish the humanness of those others we dehumanize ourselves. Most research has focused on dehumanization from the perpetrators perspective and shows that viewing others a less human enables the disengagement of moral standards in their treatment. However, little work has focused on perceptions of the perpetrators. That is, how are perpetrators viewed by their victims and how are they viewed by others during attempts to morally disengage from their behavior? We pursue this direction in two ways. First, we present evidence from two studies that take the perspective of the victim. The findings demonstrate that people who are socially ostracized not only view themselves as less human but view the perpetrators of ostracism as less human also. This shows that behaving in ways that lead to the loss another's humanity also leads to the loss of one's own humanity (in the eyes of the victim). Second, we present research showing that when a perpetrator attempts to morally disengage from their actions, that is they deny their capacity to act responsibly, this has the desirable consequence of reducing the severity of their punishment but has the undesirable consequence of decreasing their perceived humanness (from the perspective of a third party). Together our findings point to the dehumanizing consequences of perpetuating inhumanities and the inescapable nature of this effect which is only increased by efforts to diminish moral responsibility.

**F177****MODELING MIND-READING: USING MULTI-LEVEL MODELING TO INVESTIGATE INFERENCE DIFFICULTY AND MOTIVATION IN EMPATHIC ACCURACY**

Sean M. Laurent<sup>1</sup>, Karyn L. Lewis<sup>1</sup>; <sup>1</sup>University of Oregon – In this research, we demonstrate how multi-level modeling is a useful technique for analyzing empathic accuracy data (e.g., Ickes, 1993). First, by modeling accuracy scores at the level of perceivers' inferences of a target's specific thoughts, rather than averaging across all of a perceiver's thought inferences, we avoid the assumption that empathic accuracy is measured without error within participants (i.e., factors may differentially impact accuracy for individual inferences). Second, by taking into account how perceivers' accuracy fluctuates across individual inferences, theoretically relevant variables at the level of inference, such as how difficult a particular thought is to infer, can be modeled. This allows us, for example, to predict how the relationship between inference difficulty and accuracy differs across people. Finally, this method permits the partitioning of within- and between-subjects (dyad, target, etc.) variance, allowing better tests of between-subjects variables of interest (such as motivation level), and more precise estimates of overall accuracy and the reliability of the measure within subjects. 177 participants watched one of two target videos and answered questions about their motivation to be accurate, their similarity to the targets, and their comfort and anxiety about the task. At the level of inference, difficulty ratings predicted accuracy across both videos. For the target who was "easier" to read, greater motivation, similarity, and comfort predicted higher accuracy. Across

both videos, anxiety interacted with sex to predict slopes of difficulty on accuracy. We conclude that multi-level modeling is a potentially important technique that can answer new questions about empathic accuracy.

**F178****OBJECTIVE EMPATHIC ACCURACY AND SUBJECTIVE PERCEPTIONS OF UNDERSTANDING: THE PERFECT RECIPE FOR RAPPORT**

Michael W. Myers<sup>1</sup>, Sara D. Hodges<sup>1</sup>; <sup>1</sup>University of Oregon – The ability to accurately infer the thoughts and feelings of others (i.e., empathic accuracy) has long been considered an integral component of positive social interactions. However, previous research on empathic accuracy using a paradigm developed by Ickes (2003) has primarily examined factors that predict who is accurate and when. In contrast, this study reverses this focus by examining empathic accuracy as a predictor rather than an outcome – specifically as a predictor of rapport in social interactions. We hypothesized that smooth interactions are the result of being able to accurately infer other people's thoughts, but only when those other people feel understood (perceived empathy). College students (n = 74) participated in dyads and were instructed to talk with each other about the topic of parental divorce. At the end of the conversation, in order to measure perceived empathy, participants provided ratings of how well their conversation partner understood them. Later, separate observers rated the dyads' rapport. A different set of coders rated how accurately participants inferred their conversation partner's thoughts. Consistent with our hypothesis, hierarchical linear regression revealed that the interaction of empathic accuracy and perceived empathy significantly predicted rapport, whereas neither main effect did. Furthermore, this effect remained significant even after accounting for whether or not both participants in the dyad had experienced parental divorce. Thus, empathic accuracy between two people does contribute to social harmony, but only when it is accompanied by those people's subjective perceptions of being understood.

**F179****THE INFLUENCE OF SOCIAL STATUS ON THE NEURAL SUBSTRATES OF PERSON PERCEPTION: IT'S NOT HOW MUCH YOU MAKE IT'S WHAT YOU DO.**

Jasmin Cloutier<sup>1,2</sup>, Nalini Ambady<sup>2</sup>, Tom Meagher<sup>1</sup>, John Gabrieli<sup>1</sup>; <sup>1</sup>MIT, <sup>2</sup>Tufts University – The ability to detect social status information about social targets can be extremely beneficial to perceivers navigating their social environment. Indeed, available social status information can guide the impression formed of conspecifics and provide valuable information on how to behave in relation to that social target. In non-human primates, it has been shown that high status social targets (i.e., dominant members of the social hierarchy) are perceived to be rewarding (Deaner, Khera, & Platt, 2005). In humans however, social status can be construed in many ways. Accordingly, the current study examines the effect of distinct social status information on the neural substrates of face perception. In an event-related fMRI experiment, subjects were presented with sentences describing either the salary or the professional occupation of a subsequently presented face. Subjects were asked to form an impression of the targets using the descriptive information available to them. Of interest was the contrast between faces described by high and low status information. The results reveal that, compared to targets paired with low status professional occupations, targets paired with high status professional occupations evoke preferential activation of ventral prefrontal brain regions (i.e., ventral medial prefrontal cortex). However, targets paired with high salaries did not evoke preferential activation of these brain regions compared to targets paired with low salaries. These results suggest that like non-human primates, humans might perceive high social status targets (defined by the social value ascribed to their professional occupation) as rewarding.

**F180****BEHAVIOR AND PERCEPTION ACROSS THE SOCIAL NETWORK: WHO YOU ARE DEPENDS ON WHO YOU'RE WITH AND WHO YOU ASK** Allan

Clifton<sup>1</sup>, <sup>1</sup>Vassar College – Although it is widely accepted that individuals behave differently in different situations, self-report measures of personality generally assess how one "usually" sees oneself. When asked to do so, individuals can identify different aspects of their personalities elicited by interactions with specific friends, family members, and acquaintances. I describe a method of using social network analysis to examine this cross-dyadic variability in personality. Participants (N= 135) provided standard self-report personality information, including the IPIP-NEO and IIP, then detailed relationships with and among 30 individuals in their personal social networks. Participants subsequently completed a brief FFM inventory (the TIPI) regarding their self-perceived personality when interacting with each of the members of their networks. As an external measure of the validity of participants' self-report, a subset of individuals from each social network (N= 784) completed an informant version IPIP-NEO of the target participant's personality. Using social network analysis and multilevel modelling, I compared informant reports with both global self-report and dyadic self-report when interacting with each informant. Self-report's convergence with informant reports is improved by including dyadic judgments of personality, suggesting we can reduce some of the blind spots in self-report through a more fine-grained assessment of the individual's personality. Blind spots in standard self-report research may be partially understood as a methodological limitation of the ways in which we assess personality.

**F181****THE ONTOGENY OF THE PERSON PERCEPTION DUAL ARCHITECTURE**

Sara Hagá<sup>1</sup>, Leonel Garcia-Marques<sup>2</sup>; <sup>1</sup>Lisbon University Institute (ISCTE-IUL), Portugal, <sup>2</sup>University of Lisbon, Portugal – In social psychology, dual process models have been proposed to account for much of adult behavior. Most of these models distinguish between a more efficient (automatic) and a corrective (controlled) way to process information. In this talk, I will illustrate how research conducted with children can validate and enrich such models. Taking the three-stage model of Person Perception proposed by Gilbert, Pelham and Krull (1988) as a starting point, and adapting their paradigms into three child studies, we found that dispositional characterization of an actor (in terms of traits – study 1; or attitudes – study 2) has an earlier ontogenetic onset than the situational correction operation. These results offer convergent evidence for greater automaticity of the characterization operation compared with the correction one. However, some other results (study 1 and particularly study 3, where prior expectations were manipulated) suggest that prior expectations play an important role in the characterization stage (mastered already by preschool aged children), rendering the link between behavior categorization and dispositional characterization less naturally correspondent than the model assumes. These results illustrate how adding a developmental approach can support and, critically, refine our social psychological theories as well as suggest a need for further research exploring the impact of prior expectations about traits and attitudes on dispositional inferences drawn both by children and adults.

**F182****DON'T ASK, DON'T TELL? NEUROPHYSIOLOGICAL EVIDENCE FOR GAYDAR IN EVERYDAY FACE PERCEPTION** Joshua A. Tabak<sup>1</sup>, Vivian

Zayas<sup>2</sup>, Warasinee "Jah" Chaisangmongkon<sup>3</sup>; <sup>1</sup>University of Washington, <sup>2</sup>Cornell University, <sup>3</sup>Yale University – Sexual orientation can be read from briefly presented faces of unknown women and men with above-chance accuracy in tasks that explicitly instruct participants to make gay-straight judgments (Tabak & Zayas, under review; Rule & Ambady, 2008). Do judgments of sexual orientation occur in the absence of instructions to do so? To address this question, we recorded Event-Related Potentials (ERPs) as participants performed a three-stimulus oddball task (Jeon & Polich, 2001). Participants were presented photographs of straight men (70% of targets), gay men (15%), and straight women (15%)

for 200 ms, and instructed to tap the spacebar in response to women's faces and to not respond to men's faces. Replicating past research showing that infrequent stimuli elicit greater P300 than frequent stimuli, straight women's faces elicited greater P300 "context-updating" ERP waveforms than did straight men's faces. Critically, even though participants were never asked to make a gay-straight judgment, gay men's faces also elicited larger P300s than did straight men's faces. To assess the ability to spontaneously and unintentionally infer women's sexual orientation, participants completed a mirror version of this task. Similarly, although participants were unaware of the gay vs. straight faces, divergent P300 ERP waveforms indicated that faces of gay women were differentiated from faces of straight women. These findings demonstrate that sexual orientation is inferred from faces even when individuals are not explicitly instructed to judge sexual orientation and raise questions about the common assumption that bias cannot occur if marginalized identities, such as sexual orientation, are not explicitly revealed.

**Prosocial Behavior****F183****PROSOCIAL REACTIONS TO TRAUMATIC EXPERIENCES** Renée El-

Gabalawy<sup>1</sup>, Katherine B. Starzyk<sup>1</sup>, Corey S. Mackenzie<sup>1</sup>; <sup>1</sup>University of Manitoba, Canada – When will people empathize with and help others? Prosocial behavior is important for positive interpersonal, group, and intergroup interactions. The goal of this research was to identify potential causes of prosocial behaviour. Most past research has emphasized the negative impact of trauma and suffering for a variety of psychosocial outcomes. However, recent research suggests there may be positive consequences to suffering. Under certain conditions, such as when people experience post-traumatic growth, past suffering can lead to increased prosocial orientation. Building on this past research, the specific aim of the current study was to investigate how people's interpretations of their suffering and current well-being predict post-traumatic growth, and whether the experience of post-traumatic growth predicts empathy and prosocial behavior (e.g., volunteerism). Participants were 93 undergraduate Psychology students who completed individual difference measures (e.g., empathy and helpfulness) and self-reported their personal histories of past and current suffering. Multiple regressions revealed that subjective interpretation of the duration of time an individual suffered positively predicted post-traumatic growth. Self-reports of current suffering mediated the link between duration of suffering and post-traumatic growth, with current suffering being negatively associated to post-traumatic growth. Finally, post-traumatic growth positively predicted empathy and helpfulness. The present findings have important social and clinical implications.

**F184****MORAL UNCERTAINTY MOTIVATES MORAL BEHAVIOR** Jason M Chin<sup>1</sup>, Jonathan W Schooler<sup>2</sup>; <sup>1</sup>University of British Columbia, <sup>2</sup>University of

California Santa Barbara – Previous research has described ways in which moral self judgments can affect one's motivation to behave prosocially. While doing so, this research has largely overlooked how one's confidence in these self judgments affect behavior in this most moral of manner. The present research sought to fill this gap, exploring the question of whether moral uncertainty motivates moral behavior. Three studies supported the central hypothesis regarding moral uncertainty's motivating properties. Study one used a correlational design to demonstrate that uncertainty about one's moral self worth independently predicted increased volunteerism. Studies two and three used an experimental approach, demonstrating that helping behaviors were increased by both positive and negative moral uncertainty.

**F185**

**THE GOOD OF GOSSIP? THE BENEFITS OF THIS UNLIKELY PROSOCIAL BEHAVIOR.** Matthew Feinberg<sup>1</sup>, Robb Willer<sup>1</sup>, <sup>1</sup>University of California, Berkeley – Although often perceived as undesirable and antisocial, gossip is a common part of human social life. The ubiquity of gossip suggests that important functional reasons underpin this behavior. Two experiments were conducted to examine the psychological causes of gossip. We hypothesized people are compelled to gossip because (1) it relieves negative, and promotes positive, emotions, and (2) it punishes transgressors and helps others. In study 1, participants witnessed a social transgression in an economic game. Their emotions were measured before and after gossiping with a future partner of the transgressor. In study 2, we added a third condition to examine the effects of gossiping to an uninvolved third party. In both studies, gossiping to the transgressor's future interaction partner decreased negative emotion and increased positive emotion, relative to a control condition. In study 2, gossiping to a third party had a similar effect on positive and negative emotions, but to a lesser extent. Self-reported motives and content analyses from both studies indicated that the primary motive behind gossiping was more prosocial than antisocial. Furthermore, the data suggest that those whose gossiping motives were highly prosocial were significantly more likely to feel an increase in positive emotions after gossiping. Gossip appears to be more about being prosocial than antisocial.

**F186**

**ANALYZING AND MANAGING THE MOTIVATIONAL CONFLICT PROVOKED BY PRESENTING THE INDIVIDUAL IN NEED AS ONE AMONG OTHERS.** Luis Oceja<sup>1</sup>, Tamara Ambrona<sup>1</sup>, Belén López-Pérez<sup>1</sup>, Eric Stocks<sup>2</sup>, <sup>1</sup>Universidad Autónoma de Madrid, <sup>2</sup>University of Texas at Tyler – According to the one-among-others effect, presenting an individual in need together with other individuals with similar needs does not reduce the empathy-induced altruism but it introduces other prosocial motives that may conflict with it. In two experiments the manipulation of the target in need (i.e., presenting her as either one-individual or one-among-others) did not reduce the empathy felt for the individual. However, results also revealed that the one-among-others presentation (a) increased the conflict between wanting to help the individual and being fair with the others (Experiment 1), and (b) decreased the offered aid when the beneficiary of help was the individual but increased it when the beneficiary was a group of individuals. It is concluded that one-among-others presentation produces a motivational conflict, and that the occurrence of prosocial behavior depends on whether the situation allows to solve such conflict.

**F187**

**BROKEN CITY: URBANIZATION'S IMPACT ON ATTENTION TO PERIPHERAL INFORMATION** Daniel Rempala<sup>3</sup>, <sup>1</sup>University of Hawaii at Manoa, <sup>2</sup>University of Rochester, <sup>3</sup>Keimyung University – Urbanization shows a reliable, negative correlation with prosocial behavior (Stebly, 1986). Most research of this phenomenon has focused on situational factors. However, Rempala (submitted) recently showed that greater urbanization predicts poorer recall of peripheral information about needy targets. Rempala proposed that consistent exposure to a high-input environment leads one to disregard peripheral information, ultimately leading to a failure to notice needy targets. The current study sought to (1) replicate the results of the Rempala study, (2) examine peripheral information unrelated to targets in need, and (3) examine whether exposure to urban environments at a particular age is especially predictive of ignoring peripheral information. To calculate urbanization, participants listed every location that they lived up to eighteen-years-old. For each location, we calculated an Urbanization Index score using the location's population, population density, and participants' classifications of their neighborhoods (i.e., urban, suburban, or rural). We also calculated each participant's urbanization for six three-year intervals (birth-to-three, four-to-six, etc.). Participants then engaged in a distractor task while watching video clips featuring needy targets. After the final clip, partici-

pants completed two memory tests: one pertaining to the needy targets, the other pertaining to peripheral information unrelated to the needy targets. Urbanization showed a significant, inverse relationship to both sets of scores. When examining different age ranges, urbanization in middle adolescence (i.e., ages thirteen-to-fifteen) showed the strongest negative relationship with memory test scores. These results provide the first indication that development in urban environments, especially during middle adolescence, leads to poorer recall of peripheral information.

**F188**

**THE EFFECTS OF FUTURE INTERACTION ON DISTRIBUTION TO A THIRD PARTY** Makoto Nakajima<sup>1</sup>, Toshikazu Yoshida<sup>2</sup>, <sup>1</sup>Mie University, <sup>2</sup>Nagoya University – Several researchers have pointed out that under-rewarded people often redressed inequities from third parties. However, previous researches on this tendency have not completely assessed the importance of their recognition to future interaction. This study examined whether an individual who has been treated inequitably would redress the balance. A total of 373 undergraduates completed a questionnaire that contained two hypothetical exchange situations. The respondents were initially either over-rewarded or under-rewarded, and then they were given a chance to distribute the rewards between themselves and their partners. In each situation, the respondents worked with different partners. In addition, respondents were informed that their partners worked with someone at another time. Two-way ANOVAs revealed a significant main effect of experience ( $F(5,368) = 2.74, p < .01$ ); this result suggests that over-rewarded people redressed those inequities from third parties by contributing reward excessively. Those effects were confirmed only on the condition with clear information on the possibility of the future interaction. In addition, an analysis of their emotions revealed that those participants who were treated inequitably by partner were likely to give up redress inequity on the condition with unclear information on the possibility of the future interaction. The results indicate that over-rewarded people redressed those inequities from third parties only when they knew that their first and second partner worked together. Finally, the influence of recognition on future interpersonal interaction was discussed.

**F189**

**ACTIVATING THE MOTIVE OF QUIXOTEISM: THE TRANSCENDENT-CHANGE ORIENTATION** Sergio Salgado<sup>1</sup>, Luis Oceja<sup>2</sup>, <sup>1</sup>Programa Capital Humano Avanzado (Conicyt, Chile), <sup>2</sup>Universidad Autónoma de Madrid (España) – We use the term Quixoteism to label a social motive which has the ultimate goal of increasing the welfare of the world. It is proposed that this motive is activated by the transcendental-change orientation: a disposition toward provoking changes that go beyond a specific individual or group. Three studies were conducted to test this proposal. In Study 1, we developed a scale to measure such transcendental-change orientation. Subsequently, in two other studies participants were asked to read an article that described the actual case of a person in need. Results of Study 2 showed that the centrality of the transcendental-change orientation (measured two months earlier) predicted the extent to which the article was interpreted consistently with the ultimate goal of Quixoteism. Results of Study 3 showed that increasing the salience of such orientation increased the likelihood of performing a high cost prosocial behaviour.

**F190**

**DETERMINED TO FORGIVE?: FREE-WILL, DETERMINISM, FATALISM, AND FORGIVENESS** Seth Gitter<sup>1</sup>, Kathleen Vohs<sup>2</sup>, Roy Baumeister<sup>3</sup>, <sup>1</sup>University of Alabama, <sup>2</sup>University of Minnesota, <sup>3</sup>Florida State University – Recent research has found some negative consequences of belief in determinism including increases in cheating (Vohs & Schooler, 2008) and decreases in prosocial behavior (Baumeister, Masicampo, & DeWall, 2009). Bargh (2009), however, suggested that determinist beliefs might lead to some positive behaviors – specifically forgiveness. We sought to test this hypothesis and extend the research to include issues of trust. Determinists might find trust difficult as it is likely hard to trust others who are

believed to lack true control of their behavior. 47 undergraduates completed measures of belief in determinism/free-will/fatalism, forgiveness, and trust. Findings were partially consistent with Bargh's hypothesis. Although the determinism and free-will subscales of the measure did not correlate with forgiveness or trust, individuals who more strongly believed in fatalism (that outcomes are predetermined but not necessarily due to genetic or environmental predispositions) indicated a greater desire to forgive and less desire to seek revenge and/or avoid those that harmed them. Contrary to our original hypothesis, those endorsing fatalism were more likely to say they trusted others than those who indicated a disbelief in fate. These findings suggest that a belief in predetermination, but not necessarily causal inevitability, leads to a greater likelihood of forgiving after transgressions. The finding showing a relationship between trust and a belief in predetermination is somewhat counter-intuitive. Future research should examine the potential self-protective benefits of trust to alleviate anxiety about the "inevitable" transgressions of others.

#### F191

##### THE EFFECTS OF POWER ON FORGIVENESS, REVENGE, AND GRUDGE

Careen Khoury<sup>1</sup>, Curtis Phillips<sup>1</sup>, Kyle Nash<sup>1</sup>, Alexander G. Santelli<sup>2</sup>, C. Ward Struthers<sup>1</sup>; <sup>1</sup>York University, <sup>2</sup>Columbia University – Victims' responses following a transgression have been shown to be influenced by intrapersonal factors such as neuroticism and agreeableness (Walker & Gorsuch, 2002; McCullough & Hoyt, 2000), Right Wing Authoritarianism (Khoury et al., 2009), and empathy (Zechmeister et al., 2004). One intrapersonal factor that might also influence how victims respond after they experience a transgression is whether or not they feel powerful. Specifically, would individuals who feel more or less powerful be inclined to forgive the transgressor, seek revenge against the transgressor, or hold a grudge against the transgressor? Using an experimental design, the purpose of Study 1 was to investigate the effects of power on forgiveness and revenge. As predicted, the results revealed a non-significant effect of power on forgiveness and a positive significant effect of power on revenge. Individuals who felt more powerful following a real life transgression were more likely to seek revenge against the transgressor compared to their counterparts. The purpose of Study 2 was to extend the research by investigating the relation between power and holding a grudge. As predicted, a significant negative relation between power and grudge was found. Individuals who felt more powerful were less likely to hold a grudge against the transgressor compared to their counterparts. In addition, a replication of the non-meaningful relation between power and forgiveness and the positive relation between power and revenge was found. These results shed light on the effect of victims' power on the social motives to forgive, seek revenge, and hold a grudge.

#### F192

##### THANKFUL FEELINGS, THOUGHTS & BEHAVIOR: A TRIPARTITE MODEL OF EVALUATING BENEFACTORS AND BENEFITS

Maureen Mathews<sup>1,2</sup>, Linda E. Zyzanski<sup>1</sup>; <sup>1</sup>Virginia Commonwealth University, <sup>2</sup>St. Mary's College of Maryland – Gratitude and indebtedness are treated as similar social exchange constructs, though little work has examined how these constructs are independent from each other. Additionally, how a person evaluates components of a social exchange – benefactor and benefit – may also vary. Two studies examined affective, cognitive and behavioral measurement during a social exchange to assess their associations with gratitude and indebtedness. Participants completed a distribution game for which they gave and received tickets for a raffle with a fictitious partner. Study 1 findings indicated that gratitude was associated with positive affect, but positive affect was a better predictor of exchange behavior. Indebtedness was more closely associated with cognition and was not a significant predictor of exchange behavior. Positive affect and positive thought were associated with a positive attitude toward the benefactor, whereas positive thought alone was associated with a positive attitude toward the benefit (i.e., raffle tickets). Study 2 added a between-subjects variable (gratitude, indebtedness, or control) to see if a manipulation involving the benefit affected responses. Participants in

the gratitude and indebtedness conditions evaluated the partner and the tickets more positively compared to those in the control condition. Gratitude was directly associated with positive affect and inversely associated with negative cognition, whereas indebtedness was directly associated with positive affect across the three conditions. Three components of attitude were associated with attitude toward the benefactor across conditions; affect and cognition alone provided the best model for predicting attitude toward the benefit.

#### F193

##### DO GREEN PRODUCTS MAKE US BETTER PEOPLE? Nina Mazar<sup>1</sup>, Chen-

Bo Zhong<sup>1</sup>; <sup>1</sup>University of Toronto – In the past few decades, consumers have become increasingly attentive to ethical considerations as witnessed in the remarkable growth in the global market for organic and environment-friendly products. At the heart of this trend, which is often referred to as green consumption, lies the assumption that purchasing choices not only reflect price and quality preferences but also social values. What has not been sufficiently understood is how green consumption fits into our global sense of morality and affects behaviors outside of the consumption domain. Based on recent theories in behavioral priming and moral regulation, we argue that exposure to green products versus purchasing them will have markedly different effects on subsequent behaviors. Across three lab studies we found that in line with the ethical halo associated with green consumerism, a mere exposure to green products increased altruistic sharing in an anonymous dictator game compared to an exposure to conventional products, whereas the purchase of green products (versus conventional products) reduced altruistic sharing and even licensed cheating and stealing. These results suggest that although green consumerism is perceived as taking the moral high ground, the purchase of green products may establish "moral credentials," ironically licensing subsequent morally questionable behavior. We feel this study has important theoretical and practical implications for research on moral regulation and consumer behavior and will inspire future studies on the interconnectedness of our everyday behaviors and the conditions under which they affect ethical decisions.

#### F194

##### PROSOCIAL RESPONSES TO RANDOMNESS: COMPENSATORY CONTROL AND HELPFUL INTENTIONS

Daniel, A. Nadelny<sup>1</sup>, Jillian, C. Banfield<sup>1</sup>, Aaron, C. Kay<sup>1</sup>; <sup>1</sup>University of Waterloo – The aim of the present research was to examine the possibility that increased prosocial intentions can result from attempts to compensate for threats to perceptions of order. Previous research has found that people compensate order threats by increasing perceptions of control in external sources (Kay et al, 2008). Several competing theories on the origins of prosocial behaviour exist, such as the debate between Daniel Batson, advocating altruism, and Robert Cialdini, advocating an egoistic explanation. However, thus far no research has been published concerning the possibility of prosocial intentions acting as a compensatory mechanism to restore a sense of order in the world. In the current studies, perceptions of order were manipulated through writing about a time when participants did or did not have control over a positive outcome, or by reading a fake news story suggesting that the world was orderly or random. Prosocial intentions were then measured. These studies supported our hypothesis, showing that presenting participants with an order threat led to increased prosocial intentions in those contexts in which prosocial behavior was directly related to restoring order, but not when it was only related to general helpfulness.

#### F195

##### ALTRUISM, TRUST, AND COOPERATION: EMOTIONAL AND ATTITUDINAL CORRELATES OF THREE DISTINCT PRO-SOCIAL BEHAVIORS

Gregg Sparkman<sup>1</sup>, Christopher Oveis<sup>2</sup>, Dacher Keltner<sup>1</sup>; <sup>1</sup>University of California, Berkeley, <sup>2</sup>Harvard University – Recent economic and sociological research on pro-social behavior has yielded insight into three distinct types of pro-social behaviors--altruism, trust, and cooperation--that are represented in three different economic games: the dictator game, the trust

game, and the commons dilemma. The constructs measured by these economic games are becoming increasingly important in social psychological research; however, while the three games are thought to tap into distinct facets of pro-sociality, little research has systematically studied their social cognitive correlates. In the present research, undergraduate participants' social attitudes and emotions were assessed after playing the dictator game, trust game, and an adapted single-turn version of the commons game. All three games were associated with similar amounts of positive affectivity and affection-based emotion. Trusting and altruistic behaviors, but not cooperative behaviors, were assessed with increased feelings of compassion, gratitude and appreciation. Altruistic and cooperative behavior, but not trust, was associated with increased belief that others are caring. Altruistic behaviors were associated with heightened beliefs that others are altruistic, compassionate and trustworthy, and increased feelings of being cared about and loved by others. Finally, participants who behaved more cooperatively felt less angry, sad, and resentful toward others. These results lend insight into three distinct facets of pro-sociality.

### F196

#### **THOSE WHO SAVE FOR A RAINY DAY GIVE THEIR MONEY AWAY: EVIDENCE THAT PATIENCE AND ALTRUISM ARE POSITIVELY CORRELATED**

Bethany Burum<sup>1</sup>, Daniel Gilbert<sup>1</sup>; <sup>1</sup>Harvard University – People have the unique capacity to make sacrifices—both for other people and for the people they will become. While financial considerations support a negative correlation between these two kinds of sacrifice, recent research indicates that in many ways we view our future selves as other people, suggesting that altruism and patience may share a common mechanism and be positively correlated. To explore this relationship, we conducted an internet survey that included two series of hypothetical choices: one in which participants chose between receiving \$5 now or receiving a greater amount in the future, and another in which they chose between receiving \$5 now or giving a greater amount to another participant. Operationalizing patience as the minimum amount required to compel participants to wait, and altruism as the minimum required to compel them to give, we found a reliable positive correlation between patience and altruism ( $N=85$ ,  $r=.300$ ,  $p=.005$ ). A second survey replicated this correlation ( $N=53$ ,  $r=.273$ ,  $p=.048$ ) and verified that it was not due to differences in participants' tendency to provide socially desirable responses. We also corroborated this correlation between patience and altruism by finding a positive correlation ( $N=110$ ,  $r=.384$ ,  $p<.001$ ) between the Self-Report Altruism Scale and the Elaboration on Potential Outcomes Scale (which correlates with indices of patience such as procrastination and compulsive buying; Nenkov, Inman, and Hulland, 2008). These findings suggest the value of further investigating the relationship between patience and altruism and whether a common mechanism underlies these two distinguishing human capacities.

### F197

#### **PERCEIVED MOTIVATIONS FOR CHARITABLE INVOLVEMENT**

Karl Dach-Gruschow<sup>1</sup>; <sup>1</sup>University of Illinois at Urbana-Champaign – Given the history of the debate over whether people behave altruistically, it is of interest what the lay explanations of prosocial behavior are. A survey of 257 students was collected, asking for short explanation of why participants thought people participated in charity and what they felt people gained from that experience. Results were not as far from academic theory as might be expected. Results indicated that participants only see altruism or "wanting to help others" as part of the larger picture. A qualitative analysis of participants responses indicated that motivations fit largely into three categories: 1) desire to help/support an issue, 2) self-affirmation or mood enhancement 3)reputation or resume enhancement. Overall participants attributed the behavior more to internal psychological motives than external utilitarian motives, with self-affirmation being nearly as strong as the desire to help for helping's sake. However, participants frequently attributed multiple causes for involvement for a single individual, and felt that some individuals may begin for selfish reason, but continue for less self motivated reasons.

### F198

#### **THE BYSTANDER EFFECT IN A MULTI-PLAYER DICTATOR GAME**

Karthik Panchanathan<sup>1,2</sup>, Willem Frankenhuis<sup>1,2</sup>, Joan Silk<sup>1,2</sup>; <sup>1</sup>UCLA Department of Anthropology, <sup>2</sup>Center for Behavior, Evolution, and Culture – The Bystander Effect states that the likelihood that someone helps a victim decreases as the number of potential helpers increases. Most such studies assume that the decision to help is dichotomous (e.g., to call the police or not) and that the victim's welfare saturates with one dose of help (e.g., one phone call is sufficient). Here, we modify the Dictator Game from behavioral economics, used to study pro-social behavior, in order to extend the Bystander Effect to cases of continuous help. In Study One, we vary the number of dictators simultaneously transferring money to a single recipient. We find a strong Bystander Effect: with one dictator, recipients earn nearly twice as much as with two or three dictators. In Study Two, an online replication eliciting hypothetical transfers, we observe no such Bystander Effect. In Study Three, in order to evaluate whether this observed Bystander Effect is due to a diffusion of responsibility or uncertainty over other dictators' transfers, we implement a "strategy method" version of Study One: the first dictator makes a transfer proposal to the recipient; simultaneously, the second dictator makes a series of transfer proposals, each corresponding to a possible transfer proposal from the first dictator. The results support a diffusion of responsibility interpretation: second dictators make low transfer proposals, which are not contingent on first dictator transfers. In Study Four, another online replication eliciting hypothetical behavior, second dictators transfer the most when first dictators transfer very little or very much, and match first dictators for intermediate transfers.

### F199

#### **MIMICRY AND THE NORMAL SOCIAL BRAIN: EVIDENCE FROM THIRDPARTY OBSERVATION OF DYADIC INTERACTIONS**

Liam Kavanagh<sup>1</sup>, Patricia Churchland<sup>1</sup>, Chris Suhler<sup>1</sup>, Piotr Winkielman<sup>1</sup>; <sup>1</sup>UCSD – Though mimicry seems likely to have grown out of our capacity for imitative learning, its function in human social interaction is unclear. This research tests the hypothesis, forwarded by P.S. Churchland, that mimicry is acts as a signal to potential interaction partners of one's general pro-social tendencies ("a normal social brain"). Subjects viewed two videotaped interviews and rated both mimicking and non-mimicking interviewees on several dimensions of social judgment. Subjects rated mimicking interviewees as less trustworthy and competent than non-mimicking interviewees, but this effect was dissipated when favorable information about the interviewer was presented. This offers preliminary evidence that third parties (who are neither the subject nor performer of mimicry) judge mimics more by their choice of models than by their general imitative capacity.

### F200

#### **EMPATHY AND THE EFFECTS OF NUMBER AND TYPE OF IDENTIFIABLE VICTIMS**

Kathleen Schmidt<sup>1</sup>, Timothy D. Wilson<sup>1</sup>; <sup>1</sup>University of Virginia – When faced with the suffering of others, people are often flooded with feelings of empathy. Individuals overwhelmed with these feelings may employ strategies to regulate their reactions. Such strategies may include distancing oneself from the empathy target, justifying the target's situation or finding ways to help the target. In a series of studies, we looked at the relationship between number of empathy targets and participant judgment of the targets, participant mood and trait ratings, and helping behavior. Participants saw pictures and read stories about needy children or criminal offenders recently released from prison. Number of targets ranged from one to fifteen. Measures included participant ratings of their current mood, the targets' moods, and trait judgments about themselves and the target. Participants exposed to three child profiles were more likely to sign up to receive information concerning children's charities than participants who saw one child – an effect moderated by moral disengagement. Participants who saw three recent offenders judged them more harshly on measures such as likelihood of reoffending than participants who saw one offender. Individual difference measures such

as system justification, belief in a just world, moral disengagement and political identification interacted with number of targets profiled to predict participant traits related to empathy. The relationship between empathy and number of victims is complicated and can vary based on participant and victim characteristics.

**F201**

**THE EFFECTS OF RACE AND RACIAL ATTITUDES ON THE RELATIONSHIP BETWEEN EMPATHY AND HELPING BEHAVIOR** Stephanie Echols<sup>1</sup>, Joshua Correll<sup>1</sup>, Jean Decety<sup>1</sup>, <sup>1</sup>The University of Chicago – The present investigation explored the effect of race and racial attitudes on the relationship between empathic understanding and helping behavior. Participants viewed a series of 2.2 second video clips of Black and White individuals displaying facial expressions of pain. After each video, participants reported their empathic understanding and inclination to help each target. Perceptions of pain intensity were used as a measure of empathic understanding. A composite measure of helping behavior was computed by summing ratings of how much medication and the percentage of the insurance claim awarded to each target. Implicit racial prejudice and explicit motivation to control prejudice were assessed to determine whether racial attitudes moderated the relationship between empathic understanding and helping as a function of target race. Data was analyzed using a multi-level multiple regression procedure. First level regressions explored the relationship between empathic understanding and helping by target race within participant, and second level regressions explored how the within-subject relationships were moderated by individual differences in racial attitudes. Key results showed that implicitly measured racial prejudice differentially moderated the relationship between empathic understanding and helping for Black and White targets. Increases in implicitly measured racial prejudice were significantly associated with decreases in the relationship between empathic understanding and helping for Black targets and increases for White targets. Understanding how racial group membership and racial attitudes impact the ability to perceive and respond with care to others in distress is crucial to understanding the conditions in which empathy and helping behavior are expressed.

## Stereotyping/Prejudice

**F202**

**COUNTER-STEREOTYPICAL IMPLEMENTATION INTENTIONS REDUCED AUTOMATIC STEREOTYPING, BUT TASK-IRRELEVANT, STEREOTYPE-IRRELEVANT IMPLEMENTATION INTENTIONS DID NOT.** Brandon Stewart<sup>1</sup>; <sup>1</sup>University of Queensland – Our previous research has demonstrated that a conscious counter-stereotypical implementation intention (e.g., when I see a Black face, I will think "safe") does reduce automatic stereotyping (Stewart & Payne, 2006). However, there is a question as to whether this implementation intention was effective because participants interpreted the think "safe" intention as a recommendation to be cautious or because they were distracted from the task. In this experiment, participants were asked to identify an object (e.g., gun or tool) after being primed with either an African American or a Caucasian face. Half of the participants formed a counter-stereotypical implementation intention to think the word, "safe", when they saw Black faces. Other participants received an intention to think "table", a task-irrelevant, stereotype-irrelevant thought. Results showed that participants in the table condition showed a stereotypical race bias, while participants in the counter-stereotypical condition showed a reduction in race bias. Process dissociation analyses confirmed that counter-stereotypical intentions influenced stereotyping only through an automatic process. Interestingly, the think "accurate" instructions actually increased the PDP estimate of control, but this increase in control did not counteract the increase in automatic bias. These findings rule out the explanation that counter-stereotypical participants were responding by being more cautious or more distracted.

**F203**

**ANOTHER THREAT IN THE AIR: MACROECONOMIC THREAT HEIGHTENS ANTI-ASIAN AMERICAN ATTITUDES** David Butz<sup>1</sup>, Kumar Yogeewaran<sup>2</sup>; <sup>1</sup>Morehead State University, <sup>2</sup>University of Massachusetts, Amherst – Macroeconomic conditions have a range of consequences for psychological responding and have long been suspected to contribute to aggression and hostility toward racial and ethnic outgroups. The current work employs an experimental approach to examine the implications of economic threat for attitudes toward ethnic outgroups. Integrating prior work on macroeconomic threat with recent threat-based models of prejudice, we predicted that reminders of economic threat would elicit negative attitudes toward outgroups perceived as a threat to the economic interests of one's group. Supporting this prediction, in Study 1 United States residents who were primed with economic threat relative to a non-threatening control topic subsequently reported more negative attitudes toward Asian Americans, a group stereotyped as high achieving and, therefore, a threat to scarce employment opportunities. In Study 2, U.S. residents who were primed with economic threat reported more negative attitudes toward Asian Americans than participants primed with a non-economic relevant threat and a non threatening control topic. In addition, participants in the economic threat condition reported higher levels of threatened affect (anxiety) than participants in the no threat control condition and marginally higher levels of anxiety than participants in the non-economic threat condition. Subsequent analyses indicated that anxiety mediated the effect of economic threat on Asian American attitudes. The work will be discussed in terms of its importance for understanding the interplay between environmental conditions and intraindividual psychological responses in fomenting antisocial responses to ethnic outgroup members.

**F204**

**EVIDENTIARY STANDARDS OF RACISM** Amanda K. Sesko<sup>1</sup>, Monica Biernat<sup>1</sup>, Patricia G. Devine<sup>2</sup>; <sup>1</sup>University of Kansas, <sup>2</sup>University of Wisconsin-Madison – Is any given behavior (e.g., laughs at a racist joke) unambiguously racist or does information about the targets engaged in such behaviors affect such judgments? How do perceivers make such inferences? To explore these questions, we applied an "evidentiary standards" approach (Biernat & Ma, 2005; Biernat, Ma, & Nario-Redmond, 2008) to examine how many racist behaviors are required before perceivers suspect (minimal standard) or confirm (confirmatory standard) that a target is racist as a function of whether the target is known to be stereotypically racist, stereotypically non-racist, or neutral in content. White participants read background information about a target and then were presented with a series of racist behaviors engaged in by the target. As the computer displayed each behavior, participants indicated the point at which they first suspected racism and then when they were confident that the target was racist. As predicted (Biernat, et al., 2008), the evidence required to suspect vs. confirm racism in the target varied as a function target's background information. Although similar number of behaviors was required to suspect racism for all targets, more behaviors were required to confirm racism for targets with no prior history of racism (i.e., nonstereotypical and neutral targets). Further, while it took fewer behaviors to suspect and more to then confirm racism for the stereotypical non-racist target, there were no differences in the required number of behaviors to suspect or confirm racism for the stereotypical racist. Implications for perceptions of racism based on category membership of the target are discussed.

**F205**

**THE RELATION BETWEEN AMBIVALENT SEXISM, SELF-STIGMA, AND ATTITUDES ABOUT MARRIAGE EQUALITY IN SEXUAL MINORITIES** Kevin A. McLemore<sup>1</sup>, Matt L. Miller<sup>1</sup>, Gregory M. Herek<sup>1</sup>; <sup>1</sup>University of California, Davis – Ambivalent sexism has been described as an ideological system that justifies and maintains gender inequality in society by establishing both benevolent and hostile evaluations of men and women (Glick & Fiske, 1996, 1999). As stereotypes about sexual minorities are often tied

to gender belief systems (e.g., Kite & Deaux, 1987), ambivalent sexism may uniquely impact sexual minorities (in this case, gay men and lesbian women). To what extent do sexual minorities endorse ambivalent sexism? What effect does this have on their self-evaluations as sexual minorities (i.e., self-stigma) and their support for marriage equality? We hypothesize that the degree to which sexual minorities endorse ambivalent sexism positively influences their level of self-stigma and negatively influences their support for marriage equality. To examine these hypotheses, we collected data from a community sample of 92 sexual minorities (45 self-identified gay men and 47 self-identified lesbians). Most predictions were supported by regression analysis. In gay men, complementary stereotypes and hostile sexism influenced both self-stigma ( $\beta = 0.54$ ,  $p < 0.001$  and  $\beta = 0.44$ ,  $p = 0.003$ , respectively) and support for marriage equality ( $\beta = -0.38$ ,  $p = 0.01$  and  $\beta = -0.36$ ,  $p = 0.02$ , respectively). In lesbians, however, only resentment of paternalism influenced self-stigma ( $\beta = 0.47$ ,  $p = 0.01$ ) and support for marriage equality ( $\beta = -0.55$ ,  $p < 0.001$ ). Thus, the results suggest that ambivalent sexism may predispose sexual minorities to psychological harm via self-stigma leading to support for public policy that is contrary to their own interests.

#### F206

**JUDGMENTS OF CLAIMANTS OF DISCRIMINATION: THE ROLE OF AMBIGUITY, TIMING OF CLAIMS, AND MODERN RACISM** Norann T. Richard<sup>1</sup>, Stephen C. Wright<sup>1</sup>, <sup>1</sup>Simon Fraser University – Individuals who attribute negative outcomes to discrimination, no matter the likelihood that discrimination actually occurred, are often judged more negatively than those who make other attributions (Kaiser & Miller, 2001). The current study sought to further investigate the conditions under which discrimination claimants are perceived most negatively. Specifically, we examined whether evaluations were harsher when discrimination was subtle rather than blatant and when the targets responses were immediate, delayed or absent. Participants read a vignette about a well-educated Aboriginal male job applicant who was not hired due to either obvious or subtle discrimination, and who chose not to make a discrimination claim, made a claim immediately after being told he was not hired, or waited several days before lodging a claim. The protagonist was evaluated more negatively, described as more of a complainer, and as a less desirable employee when the discrimination was subtle compared to blatant. Participants' modern racism against Aboriginals was a significant covariate on this effect. In addition, an interaction emerged whereby the timing of the complaint had no effect on ratings in the subtle discrimination condition, but the obvious discrimination scenario was rated less discriminatory when the claimant waited several days to complain than when his claim was made immediately. These findings are especially disconcerting for discrimination claimants as they will be perceived more negatively when responding to the now more common subtle forms of discrimination, and the legitimacy of their claims may be questioned if they take even a few days to consider their decision.

#### F207

**PLACEBO AFFIRMATIONS: MERE AWARENESS OF SELF-AFFIRMATION THEORY IMPROVES ACADEMIC PERFORMANCE** Courtney Bearn<sup>1</sup>, Suzanne Taborsky-Barba<sup>2</sup>, Sarah Tomassetti<sup>2</sup>, Rachel Sumner<sup>1</sup>, Natalie Golaszewski<sup>2</sup>, Eden Davis<sup>2</sup>, Nancy H. Apfel<sup>1</sup>, Jonathan Cook<sup>2</sup>, Valerie Purdie-Vaughns<sup>1</sup>, Julio Garcia<sup>2</sup>, Geoffrey Cohen<sup>2</sup>, <sup>1</sup>Columbia University, <sup>2</sup>University of Colorado, Boulder – Research finds that affirmations of self-integrity counteract stress, reduce defensiveness, and improve people's performance in threatening situations. For instance, such self-affirmations, in which students reflect on a personally important value such as relationships with friends, were found to improve the grades of at-risk ethnic minority students (Cohen, Garcia, Apfel, & Master, 2006). A key question is the impact of people's awareness of the affirmation process. Widespread application of affirmation interventions will give rise to awareness among people of their rationale and intended impact. Accordingly, we conducted an experiment with college students to test the effect of awareness of the affirmation mechanism on academic perfor-

mance. Participants were randomly assigned to experimental condition. In the treatment condition, they read a scientific report about self-affirmation—they learned that such affirmations involve writing about values and that this reduces stress and improves performance. By contrast, in the control condition, they read a report about a neutral topic (paper manufacturing). A significant main effect was found. Participants who read about self-affirmation reported better adjustment in college and received better grades the next semester (as indicated by official college transcripts). This positive effect was found regardless of whether the report portrayed self-affirmation accurately (as writing about important personal values) or inaccurately (as writing about how personally unimportant values might be important to others). Mere awareness of a self-affirmation mechanism, it seems, provides a stress-reducing placebo that enables better performance. Discussion addresses how the consequences of self-affirmation mechanisms may be enhanced or undermined by awareness of them.

#### F208

**ASPECTS OF RELIGIOUS BELIEFS AS PREDICTORS OF EXPLICIT AND IMPLICIT ATTITUDES TOWARD AFRICAN-AMERICANS AND HOMOSEXUALS** Luke Fiedorowicz<sup>1</sup>, John Edwards<sup>1</sup>, <sup>1</sup>Loyola University Chicago – Many theorists propose a link between religiosity and prejudice; however, many studies show contradictory results. Recently, there has also been a growing interest in the differences between implicit and explicit prejudices. Current literature suggests that explicit and implicit attitudes are linked and one can influence the other. However, it is possible there are different sets of predictors of each attitude type. African-Americans have historically been the most openly targeted minority in America. Recently, gay men and lesbians have also faced increased prejudice. The purpose of this project was to examine several aspects of religiosity (involvement, intrinsic/extrinsic, fundamentalism, quest, history, and maturity) and their relationship to explicit and implicit attitudes. 288 undergraduate students completed an online questionnaire measuring aspects of religiosity and computer based measures of explicit and implicit attitudes. We found that very few aspects of religious beliefs predicted explicit attitudes toward African-Americans but almost all aspects were related to explicit attitudes toward gay men and lesbians. Religiosity did not predict implicit attitudes toward African-Americans or gay men, however; some aspects of religiosity were related to implicit prejudice toward lesbians. Furthermore, there were moderating and mediating effects for the implicit attitudes toward lesbians but not any other target group. This study demonstrates that relationships with religiosity and prejudice vary across aspects of religiosity and type or prejudice. These results suggest reasons for the diversity of previous findings and set directions for more comprehensive future research.

#### F209

**SOCIAL EXCLUSION AND RACIAL BIAS: THE IMPACT OF TESTOSTERONE CHANGE** Robert Hitlan<sup>1</sup>, Derrick McAdams<sup>1</sup>, Rory Deol<sup>1</sup>, Catherine DeSoto<sup>1</sup>, <sup>1</sup>University of Northern Iowa – The current study examined the relation between testosterone change levels and attitudes toward immigrants. Eighty-one males (Mage=19.54) provided saliva samples 20 minutes prior to a chat-room interaction with three other "group members" (actually study confederates) where participants were either excluded or included during a group discussion. Following the interaction participants completed questionnaires lasting approximately 20 minutes including a scale measuring different aspects of bias, after which saliva samples were again collected. Data indicated that testosterone changes were related to self-reported attitudes towards immigrants. For participants showing increased testosterone levels, exclusion increased bias against immigrant groups.

**F210****THE POWER OF EXPECTATIONS: HOW STEREOTYPE THREAT AFFECTS ATHLETES IN ACADEMICS**

Glenn Wong<sup>1</sup>, Catherine Sanderson<sup>1</sup>, <sup>1</sup>Amherst College – This study examined the effects of athlete status, task order, feedback, and personality on stereotype threat for student-athletes on both academic and athletic performance. Male athletes and non-athletes each performed a short, 20-multiple choice question math task and a lab-room basketball-shooting task (order was randomly assigned) and received positive or neutral feedback (randomly assigned) for their performance on the first task. Results showed that athletes performed significantly worse on the math test when they did the basketball task first, suggesting that the basketball task triggered the negative stereotype of athlete intelligence, which may have led to the decline in academic performance. In addition, athletes performed significantly worse on the math task when they did the basketball task first and received positive feedback for their basketball task performance. We hypothesize that athletes who received positive feedback for their basketball performance identify with their athlete status more than if they received negative feedback, and, in turn, the triggered athlete identity may lead to the decline in math performance. Furthermore, athletes with low self-esteem and/or high fear of negative evaluation performed worse on the math task after receiving positive feedback on the basketball task than did all other participants in all other conditions. In sum, this research reveals that simply performing an athletic task may lead student-athletes to underperform on an academic task, especially if they received positive feedback on the athletic task, and that student-athletes who are low in self-esteem/high in fear of negative evaluation are particularly likely to experience underperformance.

**F211****CLAIMING PREJUDICE ON OTHERS' BEHALF: REDUCING SOCIAL COSTS FOR TARGETS OF SEXISM**

Benjamin J. Drury<sup>1</sup>, S. Brooke Vick<sup>2</sup>, Cheryl R. Kaiser<sup>1</sup>, <sup>1</sup>University of Washington, <sup>2</sup>Whitman College – Individuals who attribute negative outcomes to prejudice can incur social costs, such as being viewed as complainers (Kaiser & Miller, 2001, 2003). Might it be that these social costs can be avoided if, instead of the target making her own attribution, an observer makes the attribution on her behalf? Two studies examined reactions to a target when a fellow ingroup member – an advocate – made a discrimination claim on the target's behalf. We hypothesized that the advocate's attribution to prejudice would reduce social costs for the target. In study 1, participants read vignettes in which a female target was denied a promotion and either the target or a female advocate verbally attributed this outcome to sexism. Targets were perceived as complaining less and made a more positive impression when the advocate claimed prejudice than when the target herself made the claim. Study 2 used the same vignettes, but also manipulated the target's verbal agreement or disagreement with the claim. Targets were viewed equally as positively when they agreed with an advocate's claim of sexism as when they denied this claim. These studies suggest that advocates' attributions to prejudice may deflect potential negative social costs for the target of prejudice, while also allowing the target the freedom to agree with the attribution without incurring such negative costs.

**F212****THE ROLES OF PERCEIVED INCLUSIVENESS AND DESERVINGNESS IN PREDICTING PROACTIVE BEHAVIORAL RESPONSES TO PRIDE DISPLAYS**

Jennifer J. Ratcliff<sup>1</sup>, Justine Jaskier<sup>1</sup>, Kimberly Gawron<sup>1</sup>, <sup>1</sup>The College at Brockport, SUNY – Marginalized groups can benefit from feeling and expressing pride in their group membership (Pickett, et al., 2008). However, little work has examined the consequences of pride displays for the attitudes and behaviors of majority group members. Research has begun to address this issue by exploring majority group members' perceptions of pride in outgroups, and the implications of such perceptions for subsequent behavior (Ratcliff & Pittinsky, 2008). Results demonstrated that perceived pride has two dimensions: a) authentic pride, or genuine pride; and b) hubristic pride, or arrogant

pride (cf. Tracy & Robbins, 2007). Additionally, these data show that perceptions of authentic pride are particularly important in predicting positive proactive behaviors toward outgroups (e.g., putting a pro-gay marriage sticker on one's car). Nevertheless, this research does not elucidate the mechanism whereby perceived authenticity influences such support. The current work therefore attempted to address this gap in the literature. We specifically manipulated the perceived deservingness and inclusiveness (i.e., how welcome individuals believed they would feel at the gathering) of a pride display in a novel group, and examined how each impacted perceptions of authenticity and willingness to engage in proactive support for the group. Results revealed that believing the group deserved to feel pride predicted both perceptions of authenticity and proactive support for the group, whereas perceived inclusiveness did not. Furthermore, perceived deservingness partially mediated the relationship between perceived authenticity and proactive support. Thus, pride displays that include messages of deservingness may be particularly effective in evoking support from majority group members.

**F213****IT'S NOT YOU, IT'S ME: THE IMPACT OF ATTRIBUTIONS TO SELF AND DISCRIMINATION ON PSYCHOLOGICAL WELL-BEING**

Stefanie Simon<sup>1</sup>, Brenda Major<sup>1</sup>, <sup>1</sup>University of California, Santa Barbara – The goal of the present research was to investigate the relationship between attributions to discrimination, attributions to the self, and psychological well-being. Attributions to discrimination can be self-protective for low status groups. According to Crocker and Major (1989), attributions to discrimination allow for external attributions for negative life events and, thus, place the blame for the failure outside of the self. This perspective assumes that when external attributions are made to discrimination, internal attributions to the self are discounted. However, McClure (1998) argues that individuals may be aware of multiple causes that influence an event. Therefore, making an attribution to discrimination does not necessarily discount an attribution to the self. The present research investigated the possibility of multiple attributions of negative life events by examining the distinct effects that attributions to discrimination and attributions to the self have on various well-being outcomes for women and ethnic minorities. Results from Study 1 revealed that for both women (N = 326) and ethnic minorities (N = 222), attributions to discrimination were negatively related to self-esteem. However, when attributions to self were controlled for statistically, attributions to discrimination were no longer significant and attributions to self were negatively related to self-esteem. Study 2 replicated the self-esteem results from Study 1. Additionally, Study 2 revealed the same pattern on anxiety and depression for ethnic minorities (N = 161), but not for women (N = 249). This research reveals a more complex explanation of the attribution process and suggests differences across low status groups.

**F214****WORKING HARD OR HARDLY WORKING? PERCEPTIONS OF EFFORT AND EVALUATIONS OF POSITIVELY STEREOTYPED GROUPS**

Amy Walzer<sup>1</sup>, Alexander M. Czopp<sup>2</sup>, <sup>1</sup>University of Nebraska Omaha, <sup>2</sup>Western Washington University – The shifting standards model (Biernat, Manis, & Nelson, 1991) has demonstrated how different groups may be held to different standards of ability based on stereotypes. Because positively stereotyped group members are often perceived as having natural ability (i.e., Black people are perceived as being naturally athletic) we believed positively stereotyped group members would be perceived as putting less effort into stereotyped tasks than non-stereotyped group members. Furthermore, according to expectancy violation theory (Jussim, Coleman, & Lerch, 1987) we believed positively stereotyped group members would be blamed more for failure and credited less for success on stereotyped tasks, compared to non-stereotyped group members. Participants read about an athlete who was either Black or White and who either succeeded or failed at an athletic task. The participants rated the target on scales of perceived natural ability, perceived effort, and blame/credit and decided whether they would give the target an effort based scholarship. The hypothesis that the Black athlete would be rated as more natu-

rally athletic and as putting less effort into athletics than the White athlete was supported. Additionally, the Black target was rated lower on the blame/credit scale than the White target (indicating more blame and less credit). However, inconsistent with our hypothesis the Black athlete was evaluated more positively and was awarded the scholarship more than the White athlete. Finally, effort was found to mediator between target race and target evaluation, in the success condition.

### F215

#### **SOCIAL COGNITIVE MEDIATORS OF THE RELIGIOUS FUNDAMENTALISM- PREJUDICE RELATIONSHIP**

Eric D. Hill<sup>1</sup>, Heather K. Terrell<sup>2</sup>, Adam B. Cohen<sup>1</sup>, Craig T. Nagoshi<sup>1</sup>; <sup>1</sup>Arizona State University, <sup>2</sup>University of North Dakota – This study was designed to investigate the extent to which cognitive style accounts for the relationship between religious fundamentalism (RF) and prejudice. This study also examines the degree to which threat response tendency moderates the relationship between cognitive style and prejudice. A total of 199 undergraduates completed survey measures of religious fundamentalism, homophobia, modern racism, and hostile and benevolent sexism. Need for cognition (NFC), personal need for structure (PNS), and preference for consistency (PFC) served as measures of cognitive style, and personal fear of invalidity (PFI) served as a measure of threat response tendency. Multiple mediator path analysis models were estimated for each prejudice outcome, and the significance of mediated effects was assessed using bias-corrected bootstrapping of confidence limits. Interactions between PFI and the three cognitive style variables were included in each model to assess whether the effect of cognitive style on prejudice is moderated by threat response tendency. NFC partially mediated the relationship between RF and both homophobia and benevolent sexism. PFC partially mediated the relationship between RF and both modern racism and hostile sexism. The PNS X PFI interaction partially mediated the relationship between RF and both homophobia and hostile sexism. The effect of this interaction was driven by the tendency for individuals with high PNS and low PFI to have higher RF and prejudice. Consistent findings across types of prejudice suggest that religious fundamentalism is associated with lower need for cognition and greater preference for consistency, which, in turn, predict greater prejudice.

### F216

#### **SOCIAL STIGMA OF SEVERE MENTAL ILLNESS & ITS EFFECTS ON HIRING DECISIONS**

Christopher Fowler<sup>1</sup>, Jason Faker<sup>1</sup>, Melody Sadler<sup>1</sup>; <sup>1</sup>San Diego State University – An experiment investigated effects of symptoms and label on social stigma of severe mental illness (SMI), specifically schizophrenia (SZ) and depression (DP), and whether presence of the SMI label precipitates stigma or whether stigma is a function of symptoms stereotypic of SMI. A 5 (Condition: SZ symptoms with label/no label, DP symptoms with label/no label, No symptoms/no label) x 2 (Applicant Gender: female, male) between-participants factorial design was utilized. Participants (N=180) read a job advertisement and were exposed to a fictitious job applicant. Applicant qualifications were held constant. Symptoms were conveyed in notes from a telephone interview with the applicant's former employer. Labels were included in a background check with brief medical history. Stigma was assessed via likelihood of hiring applicant, starting salary assigned, expected job performance, etc. A manipulation check revealed participants in the symptoms conditions recalled more condition-specific details than participants in the control condition. Additionally, participants in the label conditions recalled the label more often than not, suggesting both manipulations were successful. Results revealed participants were significantly more likely to hire an applicant not displaying symptoms. Participants were also more likely to hire an applicant displaying DP than SZ symptoms. The (negative) impact of being labeled was especially large for the SZ than DP applicant. Thus, participants appear to stigmatize based on both label and symptoms. It appears that "leakage" of symptoms has ramifications for chances of being hired and performance expectations. Understanding such processes may have ramifications for reduction of SMI-related stigma.

### F217

#### **DEPERSONALIZATION AS A NEGATIVE CONSEQUENCE OF POSITIVE STEREOTYPES**

John Oliver Siy<sup>1</sup>, Sapna Cheryan<sup>1</sup>; <sup>1</sup>University of Washington – Negatively-valenced stereotypes have been the focus of most prejudice research (Fiske, 1998). As a result, less is known about the potential consequences of positively-valenced stereotypes. The present research examines the deleterious effects of positive stereotypes. Specifically, we examine depersonalization, being viewed as an interchangeable exemplar of one's social group, as a potential negative consequence of being positively stereotyped. To the extent that targets of positive stereotypes subscribe to U.S. cultural ideals of individualism, depersonalization may be a negative consequence. In this study, Asian/Asian American participants (n = 116) imagined a scenario in which they received a positive comment that either targeted the self ('You are so good at math') or their racial group ('You Asians are so good at math'). Asian Americans reacted more negatively to a positive comment directed at their racial group than to a positive comment directed at the self. This difference in evaluations of the two comments was mediated by a greater feeling of depersonalization in response to the group-directed comment than the self-directed comment. Although Asians (non-U.S. citizens) also reported feeling more depersonalized by the group-directed comment, they responded equally positively to the group-directed and self-directed comments. These data provide evidence that evaluations of positive stereotypes are culturally-specific. In addition, they are not always interpreted as compliments, suggesting that traditional definitions of prejudice (Allport, 1954) should be expanded to include positive stereotypes.

### F218

#### **CAN PRIMING THOUGHTS OF WHITE PRIVILEGE LEAD TO BEHAVIORS THAT PROMOTE RACIAL EQUALITY?**

Colleen Carpinella<sup>1</sup>, Jonathan Iuzzini<sup>2</sup>; <sup>1</sup>University of California, Los Angeles, <sup>2</sup>Hobart and William Smith Colleges – The current study investigated the impact of priming thoughts about one's racial privilege on one's engagement in behaviors promoting racial equality. Participants were randomly assigned to one of three priming conditions: white privilege, white disadvantage, or control (neutral prime). Participants completed three tasks, each of which was designed to enable participants to make decisions that would either promote racial equality or enhance status hierarchies between groups. Specifically, the tasks required participants to: (a) redraw school district boundaries in a fictional city with great diversity of race and class, (b) allocate student activity funds to a range of organizations (Classics Club, Black Student Union), and (c) select books for a literature course from a list containing white authors and authors of color. Additionally, participants completed a measure of symbolic racism and provided information about their prior contact with people of diverse backgrounds. Contrary to our predictions, the results demonstrate that priming thoughts of white privilege more frequently led to participants engaging in behaviors that would enhance status hierarchies, as opposed to behaviors that would promote racial equality. We suggest that this is a self-protective reaction, particularly given that this pattern is especially strong among individuals with stronger symbolic racist attitudes. It is important to note, however, that frequent engagement with people of diverse backgrounds (through extracurricular activities) was associated with greater promotion of racial equality on the three tasks. These results have implications for the manner in which an examination of white privilege should be employed in addressing racial inequality.

### F219

#### **TO CONFRONT OR NOT TO CONFRONT: NON-TARGETS' RESPONSES TO RACIST, SEXIST, AND HETEROSEXIST COMMENTS**

Cheryl L. Dickter<sup>1</sup>, Virginia A. Newton<sup>1</sup>; <sup>1</sup>College of William & Mary – The current study was designed to examine the behavior of individuals in situations in which a prejudicial comment is made about a social group to which the perceiver does not belong. The goal of this research was to develop a model predicting verbal and non-verbal responses from relevant situational and

individual variables. Undergraduate students were asked to report on a recent situation in which they overheard an individual making a derogatory comment about a social group based on race, gender, or sexual orientation. Although many participants indicated that they were upset or offended by the comment, only a small number of participants directly confronted the individual about the prejudicial remark (9.5%) or indirectly expressed disagreement through non-verbal behavior (15.5%) at the time the comment was said. Behaviors ranged from endorsing the comment to condemning the remark; these responses were predicted by participants' ratings of the offensiveness of the comments, their individual emotional responses, and their perception of the costs and rewards that might result from confronting the individual. Multiple regression analyses indicated that a model predicting confronting behavior from perceived offensiveness of the comment, type of setting, emotional response, perceived costs of confronting, and self-reported prejudice accounted for a significant amount of variance. This study demonstrates that although individuals might be upset by a biased comment made about an outgroup, there are a variety of behaviors and reactions that result from this situation; these responses can be better understood by investigating specific situational and individual variables.

#### F220

##### **ARE YOU STEREOTYPING ME? A PRELIMINARY LOOK AT CONSTRUCTS UNDERLYING THE DESIRE FOR IMPRESSION FORMATION ACCURACY**

Anna Berlin<sup>1</sup>, Steven L. Neuberg<sup>1</sup>; <sup>1</sup>Arizona State University – What is it about being stereotyped that has the potential to be so bothersome? Even beyond the content of the particular stereotypes applied to oneself (which, in some cases, may be favorable), the very perception that one is being stereotyped suggests that one is not being perceived accurately or as an individual. This investigation focuses on individual differences in motivation, beliefs, and commitments that influence the goal of having others form an accurate impression of oneself. To achieve this goal, individuals must, logically, (1) desire that one be individuated, (2) believe that one can identify when one is being misperceived, (3) believe that one has the ability to motivate others to be accurate, (4) believe that one's individuating characteristics are indeed perceivable to others, and (5) be willing to persist in changing others' inaccurate impressions. We present the development of an integrative set of scales designed to measure individual differences along these dimensions. Based on data gathered from a sample of undergraduate students, we report a range of psychometric analyses and their implications for item selection, scale reliability and dimensionality, and relationships among scales. We view this set of scales as facilitating an understanding of if, when, and how individuals successfully initiate the process of altering others' stereotype-based and/or inaccurate impressions.

#### F221

##### **DIFFERENT PREJUDICES TOWARD DIFFERENT TYPES OF INTERRACIAL COUPLES: EXAMINING ALTERNATIVE EXPLANATIONS**

Stephen A. Mistler<sup>1</sup>, Angela G. Pirlott<sup>1</sup>, Steven L. Neuberg<sup>1</sup>; <sup>1</sup>Arizona State University – Between 1992 and 2000, the prevalence of interracial marriage in the United States more than doubled, increasing from 2.2% to 4.9%. How do people feel about such relationships, and what accounts for these feelings? Undergraduate students rated relationships of Asian, Black, and White men with Asian, Black, and White women; each participant answered the same questions for all nine possible heterosexual pairings of the above groups, as well as items designed to assess, for each race-gender type (e.g., Asian female), beliefs about their long-term mate value, short-term mate value, and scarcity as potential mates. Given issues of sample size, we report only findings from White participants. In general, White participants expressed more prejudice against interracial couples than same-race couples, even for couplings not involving members of their own race. This apparently simple bias, however, masks a more complex psychology based on interactions of specific race-gender pairings with perceiver gender. As one example, White participants were less accepting of White women with minority men than of White men with minority women, and reacted particularly negatively to the

pairing of White women with Black men than to the pairing of White women with Asian men; these patterns of antipathy were especially strong for White male participants. We assess the broader range of findings in light of frameworks suggesting that negative reactions toward interracial couples arise from concerns with "race-mixing," from concerns about potential lost resources for one's group, and from assessments of valuable reproductive opportunities potentially gained and lost.

#### F222

##### **RACISM, AGEISM, AND IDEOLOGY IN VOTE CHOICE DURING THE 2008**

**PRESIDENTIAL ELECTION** Lee Jussim<sup>1</sup>, Elizabeth R. Salibi<sup>1</sup>, Sean T. Stevens<sup>1</sup>, Florette Cohen<sup>2</sup>, Sheldon Solomon<sup>3</sup>; <sup>1</sup>Rutgers University - New Brunswick, <sup>2</sup>CUNY - Staten Island, <sup>3</sup>Skidmore University – The historic 2008

Presidential Election offered social psychologists a unique opportunity to investigate the impact of race in American politics. Barack Obama, the Democratic nominee, was the first African-American to secure a major political party's nomination for president. Symbolic racism argues that American politics are primarily divided along racial lines and that African-American candidates are at a significant disadvantage. Yet, other research suggests that political ideology is the main source of division in American politics and consistently the best predictor of candidate evaluation and vote choice, particularly in Presidential elections. The current study was designed to test these competing hypotheses and investigate whether symbolic racism or ideology had a greater impact in the 2008 General Election. In the week prior to the Presidential Election participants completed measures of symbolic racism, sexism, ageism, ideology, and party affiliation. They were then randomly placed in one of three conditions (Obama caricature, McCain caricature, Nader caricature) and presented with imagery that exaggerated rumored negative characteristics of the candidate. This imagery was followed by questions evaluating the imagery, the candidate, and likelihood of vote measure. Ideology emerged as the best predictor of candidate evaluation and vote choice in both conditions. Ageism did not significantly impact McCain, while consistent with symbolic racism theories, racism did indeed reduce support for Obama. Much of this influence, however, occurred indirectly; conservative ideology mediated much of the effect of racism on lower support for Obama.

#### F223

##### **PARTICIPANTS' RESPONSES TO COMPLETING THE RACE IMPLICIT**

**ASSOCIATION TEST** Rebecca S. Frazier<sup>1</sup>, Brian A. Nosek<sup>1</sup>, Mahzarin R. Banaji<sup>2</sup>, Anthony G. Greenwald<sup>3</sup>; <sup>1</sup>The University of Virginia, <sup>2</sup>Harvard University, <sup>3</sup>University of Washington – Completing the race-based Implicit

Association Test (IAT) can provide a palpable experience of one's own evaluative associations with race, and thus might serve an educational purpose. Over the past four years, 497,128 visitors to a public website (<https://implicit.harvard.edu/>) completed the "Race IAT" and received feedback on their performance. Following feedback, participants answered questions about their experience and interpretation of the task. Most participants found the IAT experience to be interesting (83.3%), enjoyable (69.2%), and eyeopening (63.4%). When asked to endorse explanations for their test performance, a majority said that culture (54.7%), and the order in which responses were presented (49.1%) were influential. Fewer endorsed explanations such as conscious knowledge about the topic (28.9%), unconscious knowledge (27.6%), and greater familiarity with one group or the other (24.6%). Among those showing a pro-White implicit bias, participants who had also self-reported a pro-White bias were more likely to cite contextual causes for their pro-White bias (e.g., news/media, how others perceive the group, their unconscious knowledge). However, participants with explicitly egalitarian or pro-Black beliefs were more likely to cite procedural causes (task order/handedness) as the source of their bias.

**F224**

**ILLUSORY CORRELATIONS EXTENDED** Florian Kutzner<sup>1</sup>, Tobias Vogel<sup>1</sup>,  
<sup>1</sup>University of Heidelberg – Under the notion of illusory correlations (ICs, Hamilton & Gifford, 1976), learning paradigms have been used to study stereotype formation in majority-minority settings. Empirical evidence and theoretical accounts suggests that ICs are confined to learning with relatively few observations, postponing impression formation and no need to accurately use impressions. In the present research we show that ICs generalize to a broader, more ecologically valid set of conditions. In three experiments (N=117) we found majority evaluations to reflect the frequent valence, positive or negative, more strongly than minority evaluations. Crucially, this was the case (a) after extended experience with the groups (320 trials, Experiment 1), (b) after continuously using the group impression during the learning phase (Experiment 2) and (c) after making the correct usage personally relevant by means of monetary reinforcement (Experiment 3). Additionally, for the first time we provide evidence that ICs are used to discriminate. Paralleling the evaluations, participants approached (avoided) the majority more than the minority when positive (negative) behaviors prevailed. This effect was reliable when the usage was personally relevant and, intriguingly, stronger and more persistent for positive, as compared to negative, discrimination of the minority.

**F225**

**THE RELATIONS BETWEEN COGNITIVE APPRAISALS AND EMOTIONAL RESPONSES TO AMBIGUOUS DISCRIMINATION WITH DEPRESSIVE SYMPTOMS** Amy Bombay<sup>1</sup>, Kim Matheson<sup>1</sup>, Hymie Anisman<sup>1</sup>,<sup>1</sup>Carleton University – The impacts of perceiving blatant discriminatory events on emotional responses and depressive symptoms may be influenced by cognitive appraisals. It is uncertain whether similar processes are involved when ambiguous forms of discrimination are encountered. In response to scenarios depicting ambiguous discriminatory events in First Nations adults (N=151), the degree to which events were attributed to discrimination were related to emotional responses (shame, anxiety, sadness and anger). Multiple mediation analyses revealed that shame and anxiety were unique mediators of the relation between appraisals of discrimination and depressive symptoms. Further, the roles of these emotions in accounting for this relationship were stronger when events were appraised as threatening, uncontrollable, global, stable, and when similar past events had been experienced. It seems that when discriminatory events are ambiguous, shame and anxiety are fundamentally related to the presence of depressive symptoms, which contrasts with the anger and sadness that is elicited by blatant discrimination.

**F226**

**A THREAT-BASED APPROACH TO SUBGROUPS: DO DIFFERENT SUBGROUPS OF GAY MEN ELICIT DIFFERENT PREJUDICES?** Corey L. Cook<sup>1</sup>, Catherine A. Cottrell<sup>1</sup>,<sup>1</sup>University of Florida – How do people react toward different subgroups of gay men? Previous research has suggested that the process of subgrouping can lead people to more readily recognize different characteristics among members of a stereotyped superordinate group (e.g., gay men). In particular, an evolutionary, threat-based approach to prejudice suggests that different subgroups of gay men (e.g., those perceived to be politically active, feminine, masculine, or promiscuous) should evoke different patterns of tangible threat perceptions. These perceptions of threat should then result in distinct adaptive emotional and behavioral reactions focused on minimizing the perceived threat. In the current research, we hypothesized that gay male targets in general will be perceived as posing greater health and values threats than will straight targets, resulting in greater feelings of moral and physical disgust. These threat patterns were predicted to differ among the various subgroups of gay men, as were emotional and behavioral reactions to these groups. Students at a large university in the southeastern U.S. (n = 376) reported threat perceptions and behavioral and emotional reactions to the different subgroups in question. Differences in threat perception and behavioral and emotional reactions to

subgroups were observed as a function of subgroup status and sexual orientation of targets, thus supporting the overall hypothesis that subgroup recognition can cue different threat perceptions. In all, this work illustrates the importance of investigating reactions to subgroups, which may be viewed differently from each other and the superordinate group.

**F227**

**RELATIONAL MOTIVATION IN PREJUDICE AND DISCRIMINATION: THE CASE OF SOCIAL EXCLUSION** Steven Noel<sup>1,2</sup>, Rick M. Cheung<sup>1,2</sup>, Curtis D. Hardin<sup>1,2</sup>,<sup>1</sup>Graduate Center, City University of New York, <sup>2</sup>Brooklyn College, City University of New York – Although research to date shows that people cope with social exclusion from unimportant others by rejecting them (Maner et al., 2007) and their attitudes (Bourgeois & Leary, 2001), many relationships are not so easily abandoned. From the perspective of shared reality theory (Hardin & Higgins, 1996), each interpersonal connection requires the maintenance of corresponding "shared reality," including tuning one's attitudes toward the perceived relationship-relevant attitudes of others (e.g., Sinclair et al., 2006). Two experiments demonstrate that even minimal motivation to maintain interpersonal relationships with ostensibly prejudiced people is sufficient to reverse standard effects of social exclusion. In both experiments, behavior and attitudes were assessed after manipulations of social exclusion in a computer-mediated ball-tossing game and relational motivation—shared birthday and favorite food (or not) and expecting further interaction (or not) with game partners. In Experiment 1, heterosexuals played a second game with ostensible homosexuals less and were more explicitly anti-gay when excluded than included in a previous game by ostensibly anti-gay partners, but only when they were motivated to get along with the anti-gay partners. In Experiment 2, whites sat further from belongings of an African American and were more explicitly anti-black when excluded than included in a previous game by ostensibly anti-black partners, but only when they were motivated to get along with the anti-black partners. Taken together, these findings suggest that even minimal relational motivation elicits attempts to maintain relationships with rejectors through social tuning, despite the fact that doing so entails increased homophobia and racism.

**F228**

**SUPERSTARS CLOSE TO ME: THE EFFECT OF ROLE MODEL CLOSENESS ON PERFORMANCE UNDER THREAT** Christopher E. Cole<sup>1</sup>, Allyce H. Monroe<sup>1</sup>, Patricia N. Gilbert<sup>2</sup>, David M. Marx<sup>1</sup>,<sup>1</sup>San Diego State University, <sup>2</sup>Tulane University – Research has shown that concerns about confirming a negative group-relevant stereotype leads to under-performance in threatening testing situations (Steele & Aronson, 1995). However, current research has shown that exposure to counter-stereotypic role models alleviates the negative effects of stereotype threat (e.g., Marx, Stapel, & Muller, 2005). The present experiments extend role model research by examining a characteristic that may make role models particularly effective, namely closeness (i.e., shared experiences with a role model). Accordingly, two experiments were conducted to examine the moderating effects of role model closeness on participants' performance. Experiment 1 investigated the effects of closeness by manipulating whether a female role model was from the same (close) or different school (distant) as the female participants. Results showed that participants' performance was enhanced after exposure to a close, compared to a distant, female role model. To explore role model closeness further, Experiment 2 exposed female participants to a role model from their school who either struggled with negative perceptions about her math ability (i.e., a female stereotypic experience) or did not struggle with such perceptions (i.e., a male stereotypic experience). Results showed that although female participants felt closer to the role model who struggled, their performance was enhanced after exposure to a role model who did not struggle relative to one who did. Taken together, these results suggest that closeness is an important moderating factor of the role model effect as long as exposure to role models does not likewise remind participants about their own struggles in math.

**F229****BE CAREFUL WHO YOU STAND NEXT TO: EFFECTS OF SURROUNDING INDIVIDUALS ON IMPLICIT BIAS** Courtney Soderberg<sup>1</sup>, Jeffrey W. Sherman<sup>1</sup>; <sup>1</sup>University of California, Davis

— A large amount of research has investigated the malleability of implicit attitudes. In these studies, a single face is presented on any given trial. In real life though, we rarely encounter individuals in isolation; there is normally at least one other person present. These surrounding individuals may provide a direct point of comparison for the target of our attention – leading to contrast effects – or information about whom the person associates with – leading to assimilation. While both contrast and assimilation effects are possible, due to the particular stimuli and arrangement used in the study, we predicted that surrounding targets with other individuals would lead to assimilation effects. To test this, we employed a combination flanker – IAT task. Participants were administered IATs with two of three types of trials: words and faces appearing alone, with race-matched flankers, or with race-mismatched flankers. IAT scores for the three different types of trials were compared to a normal IAT. Consistent with predictions, targets assimilated toward the flankers: matched flankers increased IAT scores, while mismatched flankers decreased IAT scores. Interestingly, the mismatched flanker effect influenced other trial types; faces that had previously been seen with mismatched flankers elicited less bias even when they were seen without any flankers or with matching flankers. Quad modeling showed that the variation in IAT scores was due to changes in the association strengths of both the black-bad and white-good associations. Further implication of the research, particularly of the unexpected bleed-over effect, are discussed.

Poster withdrawn.

**F231****RACIAL BIAS REDUCTION IN THE SHOOTING TASK: THE EFFECTS OF COUNTERSTEREOTYPES AND MOOD** Ioana Latu<sup>1</sup>, Heather Kleider<sup>1</sup>; <sup>1</sup>Georgia State University

— Research from the shooter bias paradigm (Correll, Park, Judd, & Wittenbrink, 2002) shows systematic racial bias in shooting decisions: participants are faster to shoot Black compared to White armed targets and more likely to shoot Black compared to White unarmed targets. The current study designed a method of reducing this racial bias, while disentangling the role of counterstereotypes and affective states in bias reduction. White undergraduates were asked to recall and report in writing one of four personal experiences: a positive or a negative experience with a Black person, a positive experience during a family vacation, or a negative experience during a family fight. Afterwards they played the shooting videogame. Results showed support for affective-based bias reduction perspectives. Compared to participants who recalled a negative experience, those who recalled a positive experience, regardless of whether it was race-related or not, showed decreased racial bias. These participants were equally as fast to shoot armed Black compared to White targets. Participants who did not suspect a connection between the recall task and the shooting game also showed a reduction for racially-biased false alarm rates, such that they were less likely to mistakenly shoot unarmed Black compared to a White targets after recalling a positive experience. This finding is consistent with the mood-as-information model (Schwarz, 1990), which posits that good moods signal the absence of threat, which is an underlying factor of the shooter bias. Theoretical implications, as well as applied implications for police-officers' in-field shooting decisions, are discussed.

**F232****DIRECTIONAL STEREOTYPING: DOES THE GROUP CALL FORTH THE STEREOTYPE, OR DOES THE STEREOTYPE CALL FORTH THE GROUP?** William T.L. Cox<sup>1</sup>, Patricia G. Devine<sup>1</sup>; <sup>1</sup>University of Wisconsin - Madison

— Stereotyping research typically examines associations between social groups and their stereotypic attributes in a deductive manner, by explicitly providing the group label and studying the attributes participants associate with it. This is ideal for readily visible groups; one may assume

a Black person is Athletic, but not that an Athletic person is Black. However, when group membership is not readily visible, individuals may stereotype inductively, relying on stereotypes to infer group membership (e.g., inferring that a well-dressed man is gay). Furthermore, associations uniquely tied to a social group (e.g., Black-Rapper) may operate strongly in both an inductive and deductive manner. The present study tests the directional stereotyping hypothesis, which states that associations can either be stronger in the attribute-group direction (inductive stereotypes), the group-attribute direction (deductive stereotypes), or be bidirectional. Participants completed thought-listing tasks in which they were provided either a social group (e.g., Black, Gay) or attribute (e.g., Athletic, Well-dressed) and asked to list the first five words that came to mind. Responses were coded to reflect the directional strength of each association, and their analysis supported the directional stereotyping hypothesis, such that associations were differentially inductive, deductive, or bidirectional, dependent in part on whether membership in the group is readily visible. These findings have implications for theories and research on stereotype formation and maintenance. In addition, these results could inform stereotype reduction interventions that are better adapted to the directionality of stereotyped groups whose stereotypes are reinforced by their use as identifiers of group membership.

**F233****SEEING IS BELIEVING: GENDER DIFFERENCES IN PREDICTIVE VALIDITY OF PRE-TEST MENTAL IMAGES** Diana E. Betz<sup>1</sup>, Denise Sekaquaptewa<sup>1</sup>; <sup>1</sup>University of Michigan

— Negative thinking can impede women's math performance, and imagining positive outcomes can improve task performance. The present work asks whether positive mental images are predictive for stereotype-relevant tasks, and whether this depends on how clearly they are envisioned. Thirty-nine male and 48 female undergraduates took a math test after first reporting their mental images of the predicted test outcome. Negative statement agreement (e.g., "I had a mental image of myself doing poorly") was subtracted from positive ("I had a mental image of myself doing well") to create a valence difference score. Image clarity was assessed with 2 items ("I could (visualize/verbalize) the possible outcome clearly in my mind") that were strongly correlated ( $r = .5, p < .0005$ ) and averaged into a clarity composite score. Regression analyses identified gender ( $B = 3.4, t = 2.34, p = .02$ ) and image valence ( $B = 2.06, t = 2.19, p = .03$ ) as significant predictors of math scores,  $F(14,68) = 3.56, p < .0005$ , such that men outscored women and positive mental imagery predicted higher math scores. However, these effects were qualified by a marginal three-way interaction among image clarity, imagery valence, and gender ( $B = 2.72, t = 1.67, p = .10$ ) such that for men, clear images of positive outcomes predicted higher scores ( $B = 3.04, p = .04$ ), but for women, image clarity and valence did not significantly predict test scores ( $B = -.72, p = .3$ ). The implications of mental images of possible outcomes for math-gender stereotype threat are discussed.

**F234****OF PRIDE AND DISCRIMINATION: DISPLAYING RELIGIOUS INTOLERANCE WHILE WAITING** Don Mauss<sup>1</sup>, Chuck Tate<sup>2</sup>; <sup>1</sup>California State University, Bakersfield, <sup>2</sup>San Francisco State University

— The purpose of this study was to see whether religious intolerance could be demonstrated behaviorally in a controlled environment. Participants reported their tolerance for other religious systems a month before arriving at the study session. Upon arrival to the study, we primed participants' religious identities by asking them to provide their religious affiliation (along with other demographic information). We provided a cover story that necessitated participants waiting in a separate room while we prepared another room for the study. However, we actually observed participants' behavior in the waiting room via a hidden camera closed-circuit video feed. We randomly assigned participants to either a control or an experimental condition before entering the waiting room. The control condition featured a plain denim jacket while the experimental condition featured a denim jacket with the logo "Pagan and Proud." The jacket was always placed in the same position on a file cabinet next to three identical chairs. Participants were asked to take a seat and were

told they would wait approximately 6 minutes. After 4 minutes of observation via the hidden camera, the researcher retrieved the participant and debriefed them. Results showed that individuals who identified as monotheistic (i.e., Christian, Muslim, Jewish) in the experimental condition sat farther from the stimulus than monotheists in the control condition. Non-theists (no religion/atheist) did not differ by condition. These findings held across reported tolerance and suggest that encountering pride over an identity not shared by the participant produces discriminatory behavior for monotheists.

### F235

**"MY PRESIDENT AND I?": EFFECTS OF THE INAUGURATION OF THE FIRST AFRICAN AMERICAN PRESIDENT ON PERCEIVED STEREOTYPE THREAT AMONG 6TH GRADERS** Rachel Sumner<sup>1</sup>, Courtney Beams<sup>1</sup>, Natalie Golaszewski<sup>2</sup>, Nancy H. Apfel<sup>1</sup>, Jonathan Cook<sup>2</sup>, Valerie Purdie-Vaughns<sup>1</sup>, Geoffrey Cohen<sup>2</sup>, Julio Garcia<sup>2</sup>; <sup>1</sup>Columbia University, <sup>2</sup>University of Colorado, Boulder – Since the inauguration of America's first African American president, numerous media reports have asked African American and Latino students, who are often academically at-risk, to assess the impact of Obama's achievement on their own motivation and achievement. In spite of these students' endorsement of Obama's "Yes, we can" rallying cry, research suggests that the impact of his achievements on them is unclear. The present research examines the effect of temporarily increasing the psychological salience of Obama in the classroom on perceptions of stereotype threat – that is, concerns about being negatively stereotyped in school. Participants were African-American, Latino, and White 6th grade middle school students. A random half of students completed probes asking about their attitudes about Obama (Obama prime condition). The remaining students instead completed filler probes related to health behavior (health prime condition). All students then completed measures assessing their concerns about being negatively stereotyped in school. Results reveal that among White students, no differences by condition emerged. By contrast, Black and Latino students in the Obama prime condition reported significantly less concern about being negatively stereotyped in school relative to those in the health prime condition. Discussion addresses the affirming nature of social-political events and the consequences that they can have for student motivation and achievement.

### F236

**CULTURAL INERTIA: U.S. CULTURE AND CURRENT EVENTS** Stephanie A. Quezada<sup>1</sup>, Moira P. Shaw<sup>1</sup>, Michael A. Zárate<sup>1</sup>; <sup>1</sup>University of Texas at El Paso – The growing presence of different cultural groups in the United States has resulted in prejudice and conflict between ethnic groups. Some research supports the idea that groups should merge to form one common ingroup. Other research highlights the need for groups to maintain their group distinctiveness. These contradictory findings are explained by cultural inertia, which is defined as the resistance to cultural change, unless the change is already occurring. The present study investigated cultural inertia by testing the extent to which perceived cultural change influences whether minority groups express heightened prejudice towards White Americans when minorities are made to believe they will have to change to accommodate White Americans. Latinos were randomly assigned to one of three conditions where they were biased to believe that U.S. culture is changing to accommodate Latinos or Latinos are changing to assimilate to U.S. culture. Explicit attitudes towards White Americans, degree of support for pro-minority legislation, levels of collective self esteem, and attitudes and openness to change were measured. Results indicated that Latinos responded with less prejudice towards White Americans when they were led to believe that U.S. culture is changing to accommodate Latinos. Furthermore, Latinos were more likely to support pro-minority legislation when they felt threatened (believed they will have to change to accommodate White Americans). Higher collective self esteem was also found to predict sup-

port for pro-minority legislation. These findings support cultural inertia and help explain how perceptions of cultural change can cause conflict and prejudice between different ethnic groups.

### F237

**LATINO STEREOTYPES AND SUBTYPES IN THE UNITED STATES** Holen, E. Katz<sup>1</sup>, Irene, V. Blair<sup>1</sup>, Natalie, M. Wheeler<sup>1</sup>; <sup>1</sup>University of Colorado at Boulder – Despite a vast literature concerning the content, structure, and function of stereotypes, there has been very little research about the stereotypes associated with Latinos. Latinos are the largest and fastest growing minority group in the U.S. and are disadvantaged in many important social domains, including education, employment, healthcare, and criminal justice. One avenue for understanding these disadvantages is to identify the stereotypes and subtypes that are held about Latinos. Our prior research found that when people consider the group Latinos/Hispanics, the stereotype that emerges is well defined but complex. For example, the strongest aspects of the stereotype include very negative traits (e.g., criminal, poor, dirty, and uneducated) but also some very positive traits (e.g., family-oriented, cultured, generous, and humble). The present study was conducted to better understand the perceived subtypes that may exist within the larger group. Free response data from an earlier study were distilled into 125 distinct characteristics and printed on individual cards. Fifty one participants were asked to sort the cards to represent meaningful subtypes of Latinos, using as many or as few groups as made sense to them ("leftover" cards permitted). Once they had sorted the cards, the participants were asked to provide labels for each subtype created. Participants' responses were subjected to a cluster analysis, the results of which reveal four consensually agreed-upon subtypes. These subtypes can be characterized as (1) family and culturally oriented, (2) working to make a better life, (3) ignorant and a drain on society, and (4) disrespectful, violent, and criminal.

### F238

**THE WEIGHT OF STIGMA: THE AFFECT OF COMPENSATION ON WORKING MEMORY** Heather Rieck<sup>1</sup>, Brenda Major<sup>1</sup>, Cheryl R. Kaiser<sup>2</sup>; <sup>1</sup>University of California, Santa Barbara, <sup>2</sup>University of Washington – Overweight individuals, particularly women, are targets of negative stereotypes, prejudice, and discrimination. Past research has shown that overweight women can overcome some of the negative consequences of weight-based prejudice by compensating, e.g., exerting extra effort to make a positive impression (Miller, Rothblum, Felicio, & Brand, 1995). We hypothesize, however, that compensation may have some drawbacks. Specifically, we predict that any extra effort involved in compensating for stigma can deplete self-regulatory resources, leading to impairments in working memory (Richeson & Trawalter, 2005). Eighty-one women (33 average weight, 24 overweight, and 24 obese) were asked to give an audio (weight not salient) or video (weight salient) speech about why they would make a good dating partner. As we hypothesized, overweight and obese individuals in the video condition performed worse on a stroop task following the speech whereas average weight individuals experienced no decrements in performance by condition. The self-reports of the overweight women mirror their performance on the stroop task: they reported trying harder during their speech and emphasizing positive qualities more than obese and average weight women in the video condition. Obese women, however, reported trying less and emphasizing positive qualities less than overweight and average weight women in the video condition. This study expands research on coping by examining the psychological consequences of compensating for weight stigma.

### F239

**RACIAL PHENOTYPICALITY BIAS: EXAMINING THE ROLE OF SKIN TONE IN IMPLICIT AND EXPLICIT ASSOCIATIONS** Keith Maddox<sup>1</sup>, Thomas Mann<sup>1</sup>, Joseph Charbonneau<sup>2</sup>, Michael Slepian<sup>1</sup>; <sup>1</sup>Tufts University, <sup>2</sup>University of Massachusetts, Lowell – Racial phenotypicality bias (Maddox, 2004) is the extent to which individuals rely on within-category variability in facial cues in forming impressions of others. One feature in particular – skin

tone – has been focal in explanations of this bias. In this study, we further explored the role of skin tone, hypothesizing that manipulations of skin tone are sufficient to elicit both implicit and explicit bias toward Black male targets. Toward this end, we developed two implicit measures of skin tone bias toward Black males and examined their relationship with one another, and with several explicit individual difference measures of racial and phenotypic bias. Participants completed skin tone versions of both the Implicit Association Test (IAT) and a primed (non-conscious) Lexical Decision Task (LDT) and several attitudinal scales. Participants also completed a face rating task assessing aspects of racial phenotypicity, facial affect and attractiveness. Consistent with predictions, participants revealed significantly more negative implicit associations with dark skin tone than light skin tone on the IAT. However, the LDT was not sensitive to any potential bias. Furthermore, while there were some correlations among explicit measures, none showed a relationship with the IAT. Results also revealed that manipulations of skin tone significantly influenced explicit judgments of faces. Notably, darker skinned targets were rated as having a more negative affective expression. This difference was only predicted by the Reliance on Perceptual Cues scale (Livingston, 2001). The results suggest an important role for skin tone in phenotypicity bias toward Black males at both implicit and explicit levels.

#### F240

**TARGET EMPOWERMENT: CAN TARGETS USE PERSPECTIVE TAKING TO REDUCE BIAS?** Elizabeth Focella<sup>1</sup>, Jessica Whitehead<sup>1</sup>, Jeff Stone<sup>1</sup>, Toni Schmader<sup>2</sup>; <sup>1</sup>University of Arizona, <sup>2</sup>University of British Columbia – The current research tested specific strategies stigmatized targets could use to reduce bias directed against them during a one-on-one interaction with a prejudiced individual. According to the Target Empowerment Model (TEM, Whitehead et al., 2009), blatant strategies, such as perspective taking, could cause backlash directed against the target, but a more subtle strategy, such as asking self-affirming questions (Stone et al., 2009), may be used prior to perspective taking to decrease prejudice against the target. Using a social networking paradigm, three experiments examined if an Arab American target could reduce bias by employing a combination of affirmation and perspective taking. Study 1 showed that when the target prompted them to take his perspective, highly prejudiced participants showed increased bias relative to control conditions. Study 2 demonstrated that, contrary to previous research, (Crocker, Niiya, Mischkowski, 2008), when highly prejudiced participants were affirmed on values related to "love" prior to perspective taking, they displayed increased bias against the target, but that perspective taking reduced bias against the target when participants were first affirmed on values related to "fairness." Study 3 replicated these findings by showing that perspective taking alone increased bias against the target, but affirming participants on values related to fairness prior to perspective taking significantly reduced bias compared to the control. Taken together, these results suggest that, when employed by a stigmatized target, perspective taking alone can backfire, but asking self-affirming questions about fairness prior to inducing perspective taking can be a successful strategy for reducing bias in highly prejudiced individuals.

**HIGH-STATUS GROUPS ARE "PROTECTED", LOW-STATUS GROUPS ARE "FAIR GAME": THE ANTI-EGALITARIAN NATURE OF ANTI-PREJUDICE NORMS.** Karen Douglas<sup>1</sup>, Robbie Sutton<sup>1</sup>, Leigh McClellan<sup>1</sup>, Bonny Hartley<sup>1</sup>; <sup>1</sup>University of Kent – Changing social norms appear to have brought about welcome reductions in prejudice and discrimination toward certain - if not all - social groups (Crandall, Eshleman, & O'Brien, 2002). The present studies investigate whether low status tends to protect or leave groups open to prejudice. In Study 1, 98 British participants indicated that prejudice and discrimination are more acceptable to society and to themselves if directed at lower rather than higher status groups (e.g., scoring below midpoint on scales anchored 1 = low status to 8 = high status). In Study 2, 214 participants each rated one unique, named social group. The lower the social status of the group, the more

participants indicated that prejudice and discrimination were tolerated by society, and tolerated and expressed by themselves ( $r_s > .50$ ,  $p_s < .001$ ). Mediation analyses revealed two sources of these anti-egalitarian effects. First, low status signifies that prejudice is descriptively normative and thus not strongly proscribed, liberating the expression of prejudice. Second, people independently are more prejudiced toward low-status groups, and tend to see their own prejudices as relatively acceptable. In Study 3 ( $n = 104$ ), the status of a group in a fictional society was manipulated. When the group was described as low (versus high) in status, prejudice was rated as more acceptable in the fictional society, but less acceptable to participants themselves. As a result, participants did not express any more prejudice toward lower status groups. Participants are egalitarian in principle, but follow norms that are anti-egalitarian in practice.

#### F242

**FOREWARNED IS FOREARMED: THE PALLIATIVE ROLE OF MERITOCRACY IN WOMEN'S REACTIONS TO IMPENDING DISCRIMINATION** Ellen E. Newell<sup>1</sup>, Shannon K. McCoy<sup>1</sup>, Joseph D. Wellman<sup>1</sup>, Brandon Cosley<sup>1</sup>, Ryan Pickering<sup>1</sup>; <sup>1</sup>University of Maine – Women who strongly endorse meritocracy may fare better in the face of impending sexism than women who do not. Women forewarned about the potential for a sexist evaluation of their work compensate by distancing themselves from feminine stereotypes (Kaiser & Miller, 2001). Because meritocracy is positively associated with perceived control over one's outcomes (McCoy, Cosley, & Major, 2010), we propose that the more women endorse meritocracy the more they will compensate for impending sexism. We examined compensation via linguistic analysis of women's speeches to a sexist or non-sexist man. In language use, women are more likely to use pronouns and mention psychological and social processes whereas men are more likely to use longer words, more articles, prepositions, and mention their current concerns (Newman, et al., 2008). The more women endorsed meritocracy the less they talked like a woman ( $r = -.491$ ,  $p < .05$ ) and the lower their blood pressure ( $r = -.529$ ,  $p < .05$ ) during a speech delivered to a man they believed held sexist attitudes. Further, the less women talked like a woman, the lower their BP in the sexist condition ( $r = .587$ ,  $p < .05$ ). These relationships were not observed when the male evaluator did not hold sexist attitudes. Our data suggest that women high in meritocracy compensated for impending sexism by distancing themselves linguistically from women and consequently had lower blood pressure during the speech. These data provide further evidence that meritocracy may indeed be palliative for members of low status groups.

#### F243

**GROUP-ORIENTED STATES, DISPOSITIONS, AND PREJUDICE** Hyeyoung Shin<sup>1</sup>, Charles Stangor<sup>1</sup>, James Uleman<sup>2</sup>, John Dovidio<sup>3</sup>; <sup>1</sup>University of Maryland - College Park, <sup>2</sup>New York University, <sup>3</sup>Yale University – Social cognitive and dispositional conditions that activate prejudice were investigated. Because prejudice is, in general, based on group membership, group-oriented states and group-oriented dispositions were proposed to explain conditions that activate prejudice. A group-oriented state is a temporary social cognitive state in which an individual perceives him- or herself as a member of a social group. A group-oriented disposition is an internalized dispositional tendency to be cognitively or emotionally interdependent with or dependent on a group. As hypothesized, in both U.S. and South Korea, college students who are in group-oriented states or with higher group-oriented dispositions showed higher tendency to support group-based hierarchy and hierarchy-based stereotypes and prejudice. In addition, group-oriented state and group-oriented disposition mediated the relation between culture (Korea as compared to U.S.) and prevalence of support for hierarchy-based stereotypes and prejudice. This suggests that the effects of group-oriented states and dispositions on support for hierarchy-based stereotypes and prejudice may account for differences found between the two cultures in perceptions of social groups. When one is oriented towards group memberships or

interdependent with/ dependent on groups, the likelihood of categorizing others in terms of group labels and supporting hierarchy among social groups is higher.

#### F244

##### **STEREOTYPE THREAT CONCERNS AMONG BLACK AND WHITE MEN EXPERIENCING HOMELESSNESS** Carolyn Weisz<sup>1</sup>, Renee Houston<sup>1</sup>;

<sup>1</sup>University of Puget Sound – For individuals experiencing homelessness, concerns about racial stereotyping may exacerbate the stigma of homelessness. This study examined concerns of self-identified Black (n = 31) and White (n = 32) homeless men about racial stereotyping by service providers. Survey data were collected during a one-day service fair, Project Homeless Connect, in Tacoma, Washington. We predicted and found that agreement with two items measuring stereotype concerns (1 = not at all, 5 = extremely) was higher for Black than White men: "When interacting with a service provider of a different race than myself, I think about stereotypes they may have about me,"  $t(61) = 2.83, p < .01$ , and "I worry that service providers may hold stereotypes about me because of my race,"  $t(61) = 2.03, p < .05$ . An index of these two items was significantly correlated with a preference for "interacting with a service provider of my same race" for White participants,  $r = .75, p < .001$ , but not Black participants,  $r = .25, p = .17$ . In contrast, the index was significantly correlated with agreement with the statement, "I put off making appointments for services," for Black participants,  $r = .49, p < .01$ , but not White participants,  $r = .29, p = .11$ . These findings suggest that Black men, relative to White men, may experience concerns about racial stereotyping that interfere with their use of services, and that for White men, concerns about racial stereotyping may impact their relationship with service providers from racial outgroups.

#### F245

##### **THE EFFECTS OF FAMILIARITY AND TIME ON SOCIAL PERCEPTION** Clarissa Chavez<sup>1</sup>, Michael Zárate<sup>2</sup>; <sup>1</sup>Auburn University-Montgomery,

<sup>2</sup>University of Texas at El Paso – The presented research explored the impact of familiarity and time on social perception within a lexical decision task. Prior to test, familiarity was manipulated with an exposure task where participants learned individuating information about targets. Time was manipulated by testing participants both 2-6 hr and 48 hr after the exposure task. It was predicted that participants would respond to the unique traits associated with the learned targets faster when the exposure was 48 hr earlier than when the exposure was 2-6 hr earlier. Also, participants would respond to the stereotypic and unique traits with equal speed when tested 48 hr after exposure. As predicted, participants responded significantly faster to the unique traits 48 hr after exposure ( $M=535, SD=73$ ) than 2-6 hr after exposure ( $M=589, SD=100$ ) when associated with the learned targets,  $F(1,50)=16.02, p=.0002$ . This was not found for the stereotypes 48 hr ( $M=573, SD=100$ ) and 2-6 hr ( $M=557, SD=85$ ) after exposure,  $F(1,50)=.70, ns$ . Furthermore, participants responded to the unique traits significantly faster ( $M=535, SD=73$ ) than to the stereotypes ( $M=557, SD=85$ ) when associated with the learned targets 48 hr after exposure,  $F(1,50)=8.03, p=.0066$ . In contrast, when associated with the novel targets, participants responded to the stereotypic traits ( $M=547, SD=83$ ) significantly faster than to the unique traits ( $M=570, SD=83$ ),  $F(1,50)=10.52, p=.0021$ . The current research will be discussed for its relevance to models of social perception.

#### F246

##### **"I SUCK, THEREFORE I HATE": TESTING AUTOMATIC BIAS ACTIVATION VERSUS SELF-REGULATORY ACCOUNTS OF EGO-THREAT INDUCED OUTGROUP BIAS** Thomas J. Allen<sup>1</sup>, Jeffrey W. Sherman<sup>1</sup>; <sup>1</sup>University of

California, Davis – Previous research has shown that ego threat can increase outgroup bias. The conventional explanation is that increased outgroup bias is motivated by the need to restore self-esteem (Fein & Spencer, 1997). Furthermore, it is argued that ego threat increases the activation of negative associations about the outgroup (Spencer et al., 1998). However, a plausible alternative hypothesis is that ego threat results in self-regulatory failure (Baumeister et al., 1993), which could

lead to an increased influence (rather than increased activation) of automatically negative associations. We sought to test these competing hypotheses using the Quadruple Process Model of implicit task performance (Sherman et al., 2008). The Quad model is a multinomial model that can dissociate the contribution of automatically activated associations versus self-regulation to performance on measures of implicit bias (e.g. Implicit Association Test). In the present study, Non-Black participants experienced or did not experience an ego threat prior to performing a Black-White Implicit Association Test (IAT). IAT scores reflected more bias in the ego threat than in the control condition. Modeling revealed that associations between negativity and African-Americans increased in the ego threat condition compared to the control condition. There were no differences in the degree to which participants attempted to regulate their associations. The results largely support the view that ego threat leads to increased activation of negative associations rather than diminished self-regulation.

#### F247

##### **SENTENCE SEVERITY, DEFENDANT RACE AND CONCERNS OVER WRONGFUL CONVICTIONS AND ACQUITTALS** Karin Martin<sup>1</sup>, Kimberly Kahn<sup>2</sup>, Jack Glaser<sup>1</sup>; <sup>1</sup>Goldman School of Public Policy, University of

California, Berkeley, <sup>2</sup>University of California, Los Angeles – The present study hypothesizes that sentence severity and defendant race have an effect on concern for wrongful convictions and acquittals (Type I and Type II errors, respectively) and that racial attitudes are predictive of this effect. A survey-embedded experiment with a nationally representative sample presented respondents with a triple murder trial summary, manipulating the maximum penalty (death penalty vs. life without the possibility of parole) and the race of the defendant (Black vs. White). Glaser, Martin, & Kahn (2009) found that Black defendants are more likely to be convicted in a capital case. The present analysis examines respondents' expressed concern with General and Specific Type I error (wrongful conviction) and Type II error (wrongful acquittal) -- where "General" refers to concerns about errors in the abstract and "Specific" refers to concern in terms of the case summary about which a decision was made. Items on the Symbolic Racism 2000 Scale (Henry & Sears 2002) were used to measure racial attitudes. Those expressing more negative attitudes toward Black people were more likely to express significant concern with Type I Specific and Type II Specific Error in the "white defendant/life sentence without the possibility of parole" condition than in the other three experimental conditions. Taken together with the previous finding, these results suggest that racial attitudes and willingness to convict may be more indicative of the exercise of increased caution with White defendants than of increased punitiveness toward Black defendants.

#### F248

##### **MUST BE ONE OF THE GOOD ONES: IMAGES OF SMILING BLACK MALES ELIMINATE PRIMING EFFECTS FOR GUN RECOGNITION** Kareem

Johnson<sup>1</sup>, Amy Pavill<sup>1</sup>; <sup>1</sup>Temple University – Priming stereotypes of African-Americans has been shown to facilitate recognition of objects that are associated with the stereotypes. For instance, Payne (2001) found that Caucasian participants were faster to recognize guns after being primed with African-American male faces relative to faces of Caucasian males. However, exposure to African-American male faces has also been shown to activate brain areas linked to fear and vigilance. At this point it is unclear whether the facilitated recognition of guns is due to the cognitive associations or due to the negative emotional responses. The purpose of the current study was to examine the effects of cognitive associations and emotional responses by using facial stimuli varying in race and emotional expression. Sixty Caucasian and African-American participants completed two object recognition tasks. One task tested recognition of guns versus tools, and the other tested recognition of sports equipment versus office equipment. Before each stimulus object, a face (Black or White) was briefly presented that displayed either a happy, neutral, or an angry facial expression. Both Caucasian and African-American participants were faster and more accurate to recognize guns following expo-

sure to a Black male face displaying a neutral or angry facial expression. However, no differences in recognition were found between happy Black and happy White faces. Results suggest that weapon-identification priming effects involve an interaction of cognitive associations and emotional responses. Moreover, results also suggest that weapon-identification priming effects due to negative stereotypes can be overcome by the presentation of counter-stereotypic images (i.e. Black males who are smiling).

**F249****SEXUAL ORIENTATION AND PERCEIVED ATTRACTIVENESS: GAY MEN (BUT NOT WOMEN) GET A BOOST.**

Kristin Puhl<sup>1</sup>, Kristi Lemm<sup>1</sup>, <sup>1</sup>Western Washington University – Stereotypes about sexual orientation permeate popular culture, from television to coverage of Lindsay Lohan and Adam Lambert. These stereotypes are often linked to physical attractiveness, particularly the stereotypes of the "metrosexual" man and masculinized lesbians. Does perception of sexual orientation influence perception of attractiveness? It depends on the gender of the target. Photographs of men and women were pre-rated as either more attractive or less attractive. Three hundred and fourteen undergraduate participants of both genders viewed the more or less attractive photos along with brief scenarios that included subtle reference to the target's sexual orientation being gay or straight. Participants rated the targets on physical attractiveness and social desirability. As expected, ratings of physical attractiveness and social desirability showed a strong main effect of pre-rated attractiveness, with more attractive male and female targets receiving higher ratings (all  $p$ s < .05). For male targets, these main effects were qualified by an interaction with presented sexual orientation such that the rated difference between the more and less attractive targets was greater in the gay condition than in the straight condition ( $p$ s < .05). In contrast, for female targets, sexual orientation did not interact with attractiveness. Attractive gay men may receive a boost in their perceived attractiveness and social desirability relative to straight men and less attractive gay men. For female targets, physical attractiveness appears to be a more salient characteristic than sexual orientation, perhaps because of a fundamental difference in the nature of (or the perception of) male and female sexual orientation.

**F250****RACIALLY BIASED JURY DECISION MAKING PROCESS: THE IMPACT OF VICTIM RACE, DEFENDANT RACE, ATTORNEY RACE, AND SES ON CULPABILITY**

Libier Isas<sup>1</sup>, Leslie Martinez<sup>1</sup>, Cynthia Willis-Esqueda<sup>1</sup>, Claudia Escandon<sup>1</sup>; <sup>1</sup>University of Nebraska-Lincoln – Studies have indicated bias against Hispanic defendants (Bodenhausen & Lichtenstein, 1987; Lipton, 1983). Willis-Esqueda, Espinoza, and Culhane (2008) demonstrated that low SES Mexican American defendants were thought more culpable than low SES White defendants or high SES ones. Also, a Mexican American attorney who represented a low SES Mexican American client was believed less professional, as part of the bias against the low SES Mexican American defendant (Espinoza & Willis-Esqueda, 2008). We examined the perceived culpability for involuntary manslaughter and extended the examination of bias against Mexican Americans by varying the victim's race. We hypothesized that culpability would exist for the Mexican American defendant of low SES who was represented by a Mexican American attorney with a White victim. European American participants were ( $N = 258$ ,  $Mage=19.88$ ) from a mid-western university volunteered for a study titled "Perceptions of Crime and Legal Actors" (web-based site). Crime materials and questionnaires were presented on-line with electronic data collection. Results indicated for responsibility ( $p < .05$ ), confidence in decision ( $p < .05$ ), and blame ( $p = .06$ ; marginal) there was an interaction of defendant race and SES. MA defendants of low SES were given higher culpability ratings than WA, or those of high SES. Specifically, MA defendants were held more responsible than WA defendants were ( $p < .05$ ). When the victim was WA and the defendant had a MA attorney, the defendant was more responsible for crime than when the victim was MA and the defendant had a WA attorney ( $p = .061$ ; marginal).

**F251****DO LGB INDIVIDUALS DISTANCE THEMSELVES FROM THE MAJORITY COMMUNITY FOLLOWING THE PASSAGE OF ANTI-GAY REFERENDA? A QUANTITATIVE AND QUALITATIVE LOOK.**

Nickolas M. Jones<sup>1</sup>, Melissa Warstadt<sup>1</sup>, Rhonda M. Schultz<sup>1</sup>, Daniel L. McKinnis<sup>1</sup>, Kristin P. Beals<sup>1</sup>; <sup>1</sup>California State University, Fullerton – Gay men, lesbians and bisexuals are stigmatized in our society. Stigma can be realized in many ways including sanctioned discrimination through the governmental provision of rights and responsibilities. This study aimed to examine the association between the LGB community and the majority (straight) community following the passage of Proposition 8 in California, an initiative to ban same-sex marriage. It is hypothesized that LGB Californians will distance themselves from heterosexual individuals following the identity devaluation of losing Prop 8. A total of 388 participants were recruited to complete an online survey that was available for the two weeks prior to the election, and one week following the election. In order to participate, individuals had to identify as LGB, be California residents, and be at least 18 years of age. As expected, the research revealed that LGB affiliation with their straight counterparts was significantly diminished ( $t = 4.824$ ,  $p < .001$ ), which highlighted a marked distancing of the LGB community from the mainstream. Wanting a deeper understanding of this process of community distancing, 250 participants answered the question, "Did the outcome of Proposition 8 change your view of heterosexual people with whom you interact?" as part of a larger follow-up study examining the LGB communities reaction to the court decision to uphold Prop 8. These qualitative data support what was found in the first study and add depth and insight to our understanding of the community's reaction to identity devaluation. Limitations and future directions will be discussed.

**F252****CAUTION! THERE'S A POLITICIAN AMONG US: STEREOTYPES ABOUT POLITICIANS AFFECT JUDGMENTS ABOUT THE BELIEVABILITY OF THEIR ACCOUNTS OF PAST EVENTS**

Kerra Bui<sup>1</sup>, Valerie Purdie-Vaughns<sup>1</sup>, Marcia K. Johnson<sup>1</sup>; <sup>1</sup>Yale University – The amount of detail contained in another individual's account of an event influences our evaluation of whether the account reflects an experienced event (interpersonal reality monitoring [IRM], Johnson, Bush, & Mitchell, 1998). In the present research, we apply findings from cognitive studies of IRM to advance understanding of how stereotypes influence people's judgments of the believability of events. Previous research on IRM shows that, generally, increased detail in verbal accounts increases people's believability, except when participants are given cues that increase their suspicion about a speaker. Given the recent heightened interest in politicians and the stereotype that they are not trustworthy, we examined IRM in the context of stereotypes about politicians. In Study 1, participants rated believability of accounts in a 2 (occupation: politician, teacher)  $\times$  4 (account type: no detail, emotional detail, perceptual detail, emotional + perceptual details) design, with occupation varying between subjects and account type varying within subjects. As expected, accounts containing maximum detail increased believability of teachers, but not politicians. Study 2 was similar in design, and, in addition, obtained response times for believability ratings. Judged believability of teachers and politicians did not differ; however, participants were slower in rating statements by politicians than teachers. Taken together, these studies are consistent with the idea that suspicion moderates interpersonal reality monitoring. Implications for theories of stereotyping are discussed.

**F253****THE INFLUENCE OF SKIN COLOR AND SOCIAL CLASS ON PERCEIVED MERIT-BASED ACHIEVEMENT**

Jacque-Corey Cormier<sup>1</sup>, Sylvia Perry<sup>2</sup>, Mary Murphy<sup>2</sup>; <sup>1</sup>Morehouse College, <sup>2</sup>University of Illinois at Chicago – Previous researchers have investigated the effect of skin color on socioeconomic opportunities, social judgment, levels of depression, perceptions of beauty and threat, self-esteem, and racial identity. To date, no one has investigated how people's attitudes about affirmative action are affected

by targets' skin color. The present study examined this question. In addition, we examined how target's social class affected perceivers' attitudes about merit, support for affirmative action, and perceived reverse discrimination. Participants read a vignette describing prospective African American college applicants' socioeconomic status and viewed a photo of the applicant (manipulating target's skin color). As hypothesized, skin color and social class significantly affected the degree to which perceivers felt targets were the recipients of affirmative action assistance, their attitudes towards affirmative action and perceived reverse discrimination. Participants supported affirmative action more and perceived less reverse discrimination when evaluating medium-skinned applicants compared to lighter- and darker-skinned applicants. Interestingly, social class had an effect on people's perception of merit. Specifically, people were more likely to believe that the applicants was awarded admission and scholarship based on merit if they had higher SES. Potential mediators, such as perceived stereotypicality, likeability, and stereotyping of the target were also investigated. This data suggests that Whites' views of affirmative action policies are shaped not only by group membership, but also by target's skin color and SES. Implications for understanding support of affirmative action policies and for intergroup attitudes are discussed.

#### F254

**BIAS IN COURT AND HIRING DECISION MAKING: THE EFFECTS OF SOCIAL NORMS AND ATTITUDES ON PRIMARY AND PERIPHERAL TARGETS** William Huggon<sup>1</sup>, Jonathan L. Freedman<sup>1</sup>; <sup>1</sup>University of Toronto – Prejudice is judged less acceptable today, resulting in efforts to avoid being (or appearing) biased; there is a conscious effort to be fair to a black target. It is hypothesized that while bias might not affect a target, it might affect opinions about a witness for the target, inadvertently affecting the target's outcome. Using Fazio's MODE model, it is thought bias against the target is reduced due to deliberation and motivation (including anti-prejudice norms). But when considering the witness, motivation and ability are reduced (due ironically to target focus) and decision making becomes more spontaneous- affected mainly by personal values and prejudices. In a series of studies examining this effect in criminal trials and hiring practices, congruency of race of target (defendant or applicant) and key witness (alibi or job reference) was varied. Participants read a court trial or résumé and decided the fate of the target (verdict or hiring decision). Bias could be predicted using internal and external motivation to respond without prejudice (IMS & EMS) and social dominance orientation (SDO). The main predictor was external motivation to respond without prejudice. When low in EMS (social norms were unimportant) bias against the target was based on personal values. When high in EMS, race of primary target did not effect decision, but when the race of the target and their key witness were incongruent, there was greater bias dependent on higher SDO.

#### F255

**ACCUSATIONS OF BIAS: HOW R-IAT FEEDBACK AFFECTS WHITES' COGNITION, AFFECT, AND BEHAVIOR** Sylvia Perry<sup>1</sup>, Mary Murphy<sup>1</sup>; <sup>1</sup>University of Illinois at Chicago – What are the psychological and behavioral implications of being accused of prejudice? Although people today are unlikely to be called "racist" unless they commit a blatant act of racism, to date millions of Americans have been told they hold racial bias against Blacks through an online implicit measure of prejudice—the Race-Implicit Associations Test (R-IAT). Nearly 70% of the people who complete the IAT receive feedback that they have some form of bias toward Blacks (Greenwald, Nosek, & Banaji, 2003). Because many Whites fear just this type of accusation (Richeson & Shelton, 2003), it is important to investigate how prejudice feedback on the R-IAT affects people psychologically and interpersonally. To date, no one has examined the consequences of this prejudice feedback. To examine these questions, we randomly assigned participants to receive prejudice or no prejudice R-IAT feedback. We hypothesized that the prejudice feedback would significantly affect people's subsequent emotions (e.g., guilt and anxiety) and behaviors toward Blacks. Consistent with this hypothesis,

we found that participants who received prejudice (vs. no prejudice) feedback experienced more negative affect, less positive affect, and showed more avoidant behaviors toward Blacks. These results suggest that prejudice feedback from the R-IAT may unintentionally lead to negative consequences for diversity efforts, and subsequent interracial interactions.

#### F256

**A SPECIAL CASE OF STEREOTYPE THREAT IMPROVING MATHEMATICAL PERFORMANCE IN WOMEN AND IMPAIRING IT IN MEN** Robert Spunt<sup>1</sup>, Kimberly Kahn<sup>1</sup>, Shane Frederick<sup>2</sup>, Matthew Lieberman<sup>1</sup>; <sup>1</sup>University of California, Los Angeles, <sup>2</sup>Yale University – The effect of social context on mathematical performance has been studied through the phenomenon of stereotype threat, in which knowledge of stereotypes regarding the mathematical ability of one's own group affects performance in a direction consistent with the valence of the stereotype. That is, stereotype knowledge (e.g. men outperform women) impairs performance in the negatively stereotyped group (women) and improves it in the positively stereotyped group (men). This research, however, has largely used standardized math problems that primarily rely on the presence of sufficient mathematical knowledge. In the present study, we investigated how knowledge of sex differences in mathematical abilities affects performance on the Cognitive Reflection Test (CRT). Each problem on the CRT induces incorrect first responses that must be caught and corrected in order to solve each problem. These erroneous intuitions are typically reported with high confidence, suggesting that any contextual factor that reduces confidence in intuitions should improve performance on the CRT. In support of this hypothesis, we observed that describing the CRT as a confirmation of sex differences in mathematical ability improved performance in women and impaired it in men. Additionally, this induction of stereotype threat reduced overconfidence in women and increased it in men. That is, stereotype threat improved mathematical performance in women and impaired it in men. Although this effect is atypical in the stereotype threat literature, we present it as a special case that is easily reconciled with existing accounts of the mechanisms via which stereotype threat impairs mathematical performance in women.

#### F257

**BLACK OR WHITE? THE BLACK-APE ASSOCIATION AND RACIAL CATEGORIZATION** Rebecca Hetey<sup>1</sup>, Jennifer L. Eberhardt<sup>1</sup>; <sup>1</sup>Stanford University – Can activating an implicit association between Blacks and apes influence how faces are perceived and racially categorized? A bidirectional mental link between Blacks and apes has been documented, such that 1) priming people with Black faces makes them more attuned to apes and 2) priming people with apes leads to an attentional bias toward Black faces (Goff, Eberhardt, Williams, & Jackson, 2008). We examined whether this Black-ape association would also affect how faces are perceived and racially categorized. We predicted that exposing participants to ape-related words would increase the likelihood that a biracial target would be categorized as Black as opposed to White. Participants were primed with either apes or big cats (control) by completing one of two word search puzzles. They were then presented with a color photograph of a Black-White biracial male and asked to make a forced choice as to whether he was Black or White. Participants primed with apes were more likely to categorize the face as Black compared to those in the control condition. This effect appears robust; the majority of participants in the ape condition indicated that the face was Black, whereas the majority of participants in the control condition indicated that the face was White. As predicted, our findings suggest that the Black-ape association can indeed affect the process of racial categorization. Additional results and their implications are discussed.

**F258****DOES STEREOTYPE THREAT REQUIRE STEREOTYPE REMINDERS AND BIASED EVALUATION POTENTIAL? LIVE BUT NOT VIDEO OUT-GROUP PRESENCE MAY BE REQUIRED.**

Lloyd Sloan<sup>1</sup>, Grady Wilburn<sup>1</sup>, Deborah Van Camp<sup>1</sup>, Jamie Barden<sup>1</sup>, Kristin Jones<sup>1</sup>, Daniel Martin<sup>2</sup>; <sup>1</sup>Howard University, <sup>2</sup>California State University, Hayward – Diagnostic, stereotype-related testing in minority settings doesn't damage performance (Sloan, 2000; Marx, 2006), but does with White test-givers, qualifying Steele and Aronson's (1995) theory. Can stereotype threat be aroused in minority settings (where it's usually absent) simply by out-group presence, or by threatened outgroup evaluation, or is White presence and substantial White control of one's evaluation necessary? Would displaying a video presence of a White co-experimenter lead to Stereotype Threat when only a Black experimenter was physically present? 264 African-American university students took challenging verbal (SAT) tests described as individually Diagnostic or Nondiagnostic by White or Black experimenters or by Black experimenters with a White Participant present. In a fourth condition, the Black experimenter presented a projected video of a White male test-giver presenting the SAT instructions. The still video of the White test-giver remained projected throughout the test session in order to maximize reminders of out-group presence and potential evaluation. The White experimenter produced stereotype threat performance decrements while the African American experimenter didn't, except when a White test taking participant was present in the test group, suggesting that some out-group presence is required for Stereotype Threat effects. The Black experimenter's projection of the White tester's instructions and image had no impact on Black participants' performance in contrast to the performance damaging impact of the continuously present and evaluating White tester. These findings suggest that biased evaluation concerns, possibly involved in arousing stereotype threat, may require live White presence coupled with the unrestrained potential for biased evaluation.

**F259****RACISM SCALES: PSYCHOMETRIC ISSUES AND THE MISINTERPRETATION OF RESULTS**

Rupert Klein<sup>1</sup>, Adam Montroy<sup>1</sup>, Jennifer Newby<sup>1</sup>; <sup>1</sup>Lakehead University – Several studies have validated that altering the numerical labels on attitudinal Likert-type scales changes the responses of participants. Specifically, replacing a bipolar scale (-5 to +5) with a unipolar scale (0 to 10) often results in different distributions of responses. Many racism studies seem arbitrarily to use unipolar/bipolar labels. An additional problem is the abundant use of median splits when analyzing data often resulting in labeling similar participants into different groups. This is particularly problematic if erroneously labeling someone a racist. This study hypothesized that (1) using bipolar scales, rather than unipolar scales, will result in different participant response distributions and (2) conducting median splits will overestimate the number of racists in a sample. Three popular racism scales (i.e. Attitudes Toward Blacks, Modified Racism, Color Blind Racial Attitudes) were selected. Participants were undergraduate students randomly assigned to complete the original, unipolar, racism scales (n = 93) or the modified, bipolar, racism scales (n = 89). To analyze the data skewness and kurtosis were calculated for each racism scale and then converted into z scores for comparison. Results indicated statistically different skews between the modified and original scales. Responses to modified items were generally less racist. Median splits were then conducted on all three scales dividing them into the 'racist' and 'non-racist' groups. The 'racism' group mean for all three scales was at or below the midpoint of the summed scales suggesting that the majority of students labeled as 'racist' were in fact expressing predominantly non-racist attitudes or indifference.

**F260****THE MALLEABILITY OF IMPLICIT RACE MEASURES: A META-ANALYSIS**

Jaclyn Ronquillo<sup>1</sup>, Brian Lickel<sup>2</sup>; <sup>1</sup>University of Southern California, <sup>2</sup>University of Massachusetts Amherst – The present meta-analysis provides a quantitative review of studies concerning the malleability of implicit stereotypes and prejudice. Using Blair's (2002) taxonomy of conditions that moderate implicit racial biases as a theoretical framework, it was demonstrated that experimental manipulations intended to produce a change (regardless of direction) have a small to moderate effect on implicit stereotypes and prejudice. Furthermore, it was shown that conditions that manipulate a perceiver's social goals and intentions yield stronger effect sizes than conditions that manipulate an aspect of the external environment. Finally, inferential judgments of emotions and appraisals likely to be experienced in the original studies demonstrated that stress due to experimental manipulations in the literature predict the magnitude of implicit racial biases. The theoretical and practical implications of these findings are discussed.

**F261****EFFECTS OF STEREOTYPE THREAT ON GIRLS' MATH EDUCATION**

Bettina J. Casad<sup>1</sup>, Faye L. Wachs<sup>1</sup>, Patricia Hale<sup>1</sup>, Bren M. Chasse<sup>2</sup>, Jessica Didway<sup>1</sup>, Sara Chapman<sup>1</sup>, Kayla Wells<sup>1</sup>, Erika Estrada<sup>1</sup>, Carolina Nuno<sup>1</sup>, Adamina Camacho<sup>2</sup>, Elizabeth Sill<sup>1</sup>; <sup>1</sup>California State Polytechnic University, Pomona, <sup>2</sup>California State University, Fullerton – This study examined the effects of stereotype threat on adolescent girls' math performance, attitudes, and behavioral intentions. Research on stereotype threat regarding women and math has largely been conducted with college women and effects on adolescents are less clear. Eighth-grade students (N = 617) from four middle schools in southern California participated in the study. Participants completed a pre-questionnaire, a pre-algebra test under stereotype threat or no threat conditions, and a post-questionnaire. It was predicted that girls under stereotype threat would have lower math performance, more negative attitudes toward math, and fewer behavioral intentions to pursue further math education compared to girls in the identity safety condition. Further, this effect will be moderated by math or gender identity such that girls who have stronger identities will be more negatively affected by stereotype threat than girls who have weaker identities. Results supported the hypotheses; however, only girls in honors math were affected by stereotype threat. Females highly identified with math had more negative attitudes in the threat than the control condition. Females highly identified with gender had lower math performance in the threat condition than the control. Results for behavioral intentions showed a marginal effect indicating reactance. That is, girls highly identified with math reported greater behavioral intentions in the threat than control condition. The role of gender and math identity in moderating girls' reactions to stereotype threat will be discussed further in the context of the larger body of stereotype threat literature.

**F262****MEDICAL DOCTOR IMPLICIT DIAGNOSIS (MDID)**

Gordon Moskowitz<sup>1</sup>; <sup>1</sup>Lehigh University – Stereotypes commonly influence people's cognition and behavior even when they are unaware that the stereotype has been activated or used. This influence has been identified in professional settings such as law enforcement, teaching and limited illustrations in the medical field. Two experiments examine whether stereotypes are implicitly activated in medical doctors. Implicit affect in doctors has previously been evidenced (using an IAT), but are specific negative "medical" stereotypes associated with African Americans? Experiment one assessed what diseases and treatments medical doctors associate with African American patients. Experiment two presented these stereotypic (and control) terms to medical doctors as part of a computerized task. Subliminal images of Black and White men were shown to doctors prior to each word and reaction times to the words were recorded. When primed with a Black Face reaction time was faster for stereotypic diseases. Thus, a bias was found in which doctors implicitly associate a set of diseases with African Americans. This implicit stereotype includes diseases to

which African Americans are genetically predisposed, but it also includes social behavior for which no biological basis exists on which to base the association (such as AIDS and drug use). Thus, although doctors correctly associate cardiac arrest with African Americans, they also associate drug use, crack addiction, and AIDS.

### F263

**ANTI-ATHEIST PREJUDICE IN THE INTERPERSONAL REGULATION OF RELIGIOUS BELIEF: A SHARED REALITY PERSPECTIVE** Michael W. Magee<sup>1</sup>, Curtis D. Hardin<sup>2</sup>; <sup>1</sup>CUNY Graduate Center, <sup>2</sup>Brooklyn College of CUNY – Despite a growing tolerance for religious diversity in America, the increase in religious pluralism in post-war America has not coincided with a proportionate increase in tolerance for non-believers. In fact, Americans are less accepting of atheists than any other cultural minority. Why? From the perspective of shared reality theory, threats to religious faith like atheism also threaten the relationships in which religious faith is shared. Because religious beliefs are typically established and maintained in the context of parental relationships, shared reality theory implies that religious beliefs and attitudes associated with them will be psychologically defended to the degree to which parental relationships are stable and vital, including the exacerbation of anti-atheist prejudice (AAP). Three experiments provide converging evidence for the role of parental shared reality in the regulation of religiosity and AAP. The first two experiments demonstrate how AAP is implicated in the interpersonal regulation of religiosity in response to the unconscious threat of evolution; the unconscious threat posed by evolution resulted in reduced AAP (and reduced religiosity), but only if participants did not perceive shared religious realities with fathers (exp 1) or if participants reported an insecure attachment style (exp 2). In another experiment the unconscious threat posed by atheists resulted in lower levels of religiosity, but only for those participants who did not perceive shared religious realities with their mothers. Interpretations of these findings in the context of shared reality theory are discussed and offer a possible explanation as to why many Americans are hostile to atheism.

### F264

**MOVING BEYOND RACE: THE EFFECT OF TARGET STEREOTYPICALITY ON SHOOT/DON'T SHOOT DECISIONS** Debbie Ma<sup>1</sup>, Jessica J. Sim<sup>1</sup>, Joshua Correll<sup>1</sup>; <sup>1</sup>The University of Chicago – Previous research has exclusively studied mean-level differences in shoot/don't shoot decisions between Black and White targets. However, members within racial groups vary in terms of how stereotypic they are, which impacts the degree to which targets are held to stereotypes about the group at large. The current studies investigated whether target stereotypicality moderated the decision to shoot above and beyond the effect of racial category alone. Study 1 showed that on trials in which targets were of average stereotypicality, participants exhibited racial bias (i.e., faster shoot responses to armed Blacks versus Whites), but that this effect was amplified on trials featuring targets rated as highly stereotypic. Moreover, racial bias reversed when targets were viewed as unsterotypical (i.e., faster shoot responses to armed Whites versus Blacks). Study 2 sought to examine whether training reduced the impact of stereotypicality on errors in shoot responses. Although training eliminated participants' use of race in shoot/don't shoot decisions, such that they made fewer errors, target stereotypicality continued to have an influence on these judgments.

### F265

**I AM A MAN: THE GENDERED CONSEQUENCES OF RACIAL DISCRIMINATION** Brooke Allison Lewis Di Leone<sup>1</sup>, Phillip Atiba Goff<sup>2</sup>; <sup>1</sup>The Pennsylvania State University, <sup>2</sup>University of California, Los Angeles – Is racial discrimination gendered? A series of four studies suggests that it is. In Study 1, participants generated examples of racial discrimination directed at Black men, Black women, or gender-unspecified targets. The incidents mentioned in response to Black male and gender-unspecified targets were similar to each other, but different from most incidents mentioned in response to Black female targets. In Study 2, the gender-neutral examples generated in Study 1 were subsequently rated as more

likely to happen to Black men than Black women. More importantly, the more severe an individual rated an act of discrimination, the more it was rated as likely to happen to a Black man, but not a Black woman. In Study 3, participants perceived racial discrimination directed at Black male targets, but not White male targets, to be emasculating. These studies suggest both that perceptions of racial discrimination depend on target gender and that observers may conceptualize of racial discrimination as a masculine domain. Extending this finding to the target's perspective, Study 4 tested the hypothesis that Black men would experience racial discrimination as a threat to their masculinity. Black men who experienced racial discrimination in a laboratory setting responded with compensatory masculine behavior—doing more pushups—in proportion to their level of masculinity threat. Taken together, this research suggests that both the conceptualization of racial discrimination and the harms it causes may be gendered and that research must consider intersectional identity in order to capture the context and consequences of racism.

### F266

**THE SHARP END OF SATIRE: RACIAL SATIRE INCREASES RACIAL PREJUDICE** Chuck Tate<sup>1</sup>; <sup>1</sup>San Francisco State University – Racial satire is controversial because of conflicting claims that it can reduce prejudice by hyperbolizing stereotypes or that its reliance on stereotypes increases racial prejudice. This set of experiments explored attitude change resulting from exposure to racial satire. In Experiment 1 participants were randomly assigned to view either racial satire about the target group African-Americans by a self-identified Black comedian or gender satire about the target group women by the same comedian. Results showed that, accounting for regression to the mean and offensiveness of the satire, those exposed to racial satire had a significant increase (pretest to posttest) in negative attitudes toward African-American targets as compared to those exposed to gender satire. There was no change in egalitarian attitudes toward African-Americans by condition. There was also no change in prejudice toward White targets by condition. Experiment 2 examined whether the foregoing results depend on the racial identity of the comedian. Participants were randomly assigned to view either racial satire about the target group African-Americans by a self-identified White comedian or religious satire about the target group Catholics by the same comedian. Results showed an increase in egalitarian attitudes toward African-Americans, but no change in negative attitudes. However, there was a significant increase in negative attitudes toward Whites for those exposed to racial satire. These results suggest that racial satire has the ironic effect of increasing racial prejudice, and that this increase in prejudice depends on the match between the comedian's racial identity and the target group of the satire.

### F267

**THE NATURE OF WEIGHT BIAS AMONG MEDICAL STUDENTS IN A VIRTUAL CLINICAL INTERACTION** Susan Persky<sup>1</sup>, Collette P. Eccleston<sup>2</sup>; <sup>1</sup>Social and Behavioral Research Branch, National Human Genome Research Institute, <sup>2</sup>Syracuse University – Stigma and bias negatively affect interactions between health care providers and patients who are overweight. This can lead to outcomes like disparities in preventive health services (i.e., cancer screening). Given the great complexity of the clinical communication context and the interconnectedness between the roles of patient and provider, it is difficult to ascertain what elicits provider biases. Biases may be triggered automatically by mere presence of overweight patients; whether this activation is sufficient for causing differential clinical outcomes is unexplored. We explored whether mere presence of an overweight patient was sufficient to trigger bias and differential clinical recommendations in a group of medical students. In real-world contexts overweight patients can differ from non-overweight patients on multiple characteristics (e.g., health conditions). Therefore, we conducted clinical encounters in a virtual reality environment, which allowed us to hold all patient factors (non-weight-related appearance, non-verbal behavior, symptoms, information provision, etc.) constant between an overweight and non-overweight virtual patient while pre-

servicing naturalistic elements of the clinical encounter. Interpersonal and clinical care-related variables were assessed during and after the interaction. Results indicate that, mere size of the patient does produce consistent differences in post-encounter care recommendations, attitudes toward the patient, interpersonal judgments of the patient, and blaming of the patient for causing her symptoms. Findings suggest that overweight patients may trigger bias and differential treatment based on their size alone in the absence of particular health characteristics, interaction styles, or other variables.

### F268

**N170 RESPONSES TO FACES PREDICT IMPLICIT INGROUP FAVORITISM: EVIDENCE FROM A MINIMAL GROUP STUDY** Kyle G. Ratner<sup>1</sup>, David M. Amodio<sup>1</sup>; <sup>1</sup>New York University – People typically favor members of their own group in evaluations and behavior. This "ingroup favoritism" even occurs for novel and arbitrary group distinctions, and it leads to implicit positive evaluations of ingroup members. To understand the mechanisms underlying this effect, we examined the association between implicit evaluative bias and differences in basic-level face perception of novel ingroup vs. outgroup members. Using the minimal group paradigm, we assigned participants to one of two arbitrarily-defined groups. We then recorded event-related potentials (ERPs) while participants viewed and categorized faces of people identified as members of their novel ingroup vs. outgroup. Next, participants completed a behavioral measure of implicit evaluative bias toward the ingroup vs. outgroup. Our analysis focused on the N170 component of the ERP, which peaks in occipitotemporal scalp regions at approximately 170 ms following face onset and is believed to reflect the earliest stages of face perception. Larger N170 amplitudes to outgroup vs. ingroup faces predicted stronger implicit ingroup favoritism on the behavioral measure of implicit evaluation. These results suggest that mere group membership affect face perception, which may then contribute to the expression of positive ingroup bias in behavior. By linking face perception to implicit evaluative responses, these findings begin to provide new insight into how group categorizations can shape social perceptions and behaviors.

### F269

**FINDING THE FAITHLESS: PERCEIVED ATHEIST PREVALENCE REDUCES ANTI-ATHEIST PREJUDICE** Will Gervais<sup>1</sup>; <sup>1</sup>University of British Columbia – Historical sources and contemporary polls reveal persistent negative attitudes towards atheists. Three studies investigated the relationship between anti-atheist prejudice and perceptions of atheist prevalence. Atheists do not have a particularly visible collective presence, despite being quite numerous. In recent years, some atheist groups have made concerted efforts to "come out" and publicize their numbers. How might this trend affect anti-atheist prejudice? Decades of research suggest that prejudice increases with relative outgroup size. However, a functional approach to prejudice suggests that different types of outgroups elicit different types of reactions, raising the possibility that this positive prejudice-outgroup size effect might be eliminated or reversed for some groups. Three studies found converging evidence of a negative relationship between atheist prevalence and anti-atheist prejudice. Study 1 demonstrated that anti-atheist prejudice among religious believers is reduced in countries in which atheists are prevalent. Study 2 demonstrated that perceived atheist prevalence is negatively associated with anti-atheist prejudice, especially among deeply religious individuals. Study 3 demonstrated a causal relationship: reminders of atheist prevalence reduced anti-atheist prejudice. This effect was not attributable to either intergroup contact effects or to mere familiarity with atheist beliefs. These findings suggest both novel directions for future prejudice research and potential interventions that could reduce a variety of prejudices.

### F270

**I'M NOT OLD: ACCOUNTING FOR PERSISTENT PRO-YOUNG PREFERENCES ACROSS THE AGE SPAN** Nicole M. Lindner<sup>1</sup>, Brian A. Nosek<sup>1</sup>; <sup>1</sup>University of Virginia – Age differs from other social groups like gender and race—age group membership is impermanent (aging is inevitable) and the group boundaries are flexible, allowing individuals to resist self-categorization as old. Attitudes toward old versus young are remarkably resistant to ingroup preferences among older adults, particularly implicitly—adults over 60 have similarly strong implicit pro-young biases (Cohen's  $d = 1.23$ ) as adults under 25. We investigated factors that may explain why adults of all ages prefer the young so strongly ( $N > 280000$ ; age range = 18-89). Social identity theories anticipate that individuals derive self-esteem from identifying with their groups, even low-status groups. Because of the ambiguity of age group memberships, it appears that individuals resist self-identifying as 'old' by redefining the boundary between young and old to be older than whatever age they are presently. Further, the more that individuals felt younger than their chronological age, the stronger their implicit and explicit pro-young preferences were. At the same time, participants' own chronological age and their internal motivation to respond without prejudice predicted weaker pro-young preferences, whether measured implicitly or explicitly, while external motivation simultaneously predicted stronger pro-young preferences. This suggests that internal motivations to avoid negativity toward old people are a counterweight to other sources of persistent negativity toward the elderly and aging. These findings can inform the application of social identity theories to other social groups whose membership is impermanent or subjective.

### F271

**FAIR OR FOUL? RACIAL PHENOTYPICALITY PREDICTS FOULS CALLED BY NATIONAL BASKETBALL ASSOCIATION OFFICIALS** Michael Sargent<sup>1</sup>, Keith Maddox<sup>2</sup>, Michael Murray<sup>1</sup>; <sup>1</sup>Bates College, <sup>2</sup>Tufts University – Previous work has established variants of racial phenotypicality bias within categories. For example, darker-skinned Blacks and those with other, more phenotypically Black, facial features tend to be judged more negatively and more in line with Black stereotypes than category members with less typical features. Motivated by recent work documenting positive own-race biases in fouls called by National Basketball Association (NBA) officials, the present study's purpose was to assess the role of Black players' racial phenotypicality in NBA foul rates. Several coders rated photographs of current Black NBA players, rating each face on 9-point scales in terms of skin tone and also how "Afrocentric" its features were. The photos were also coded on a set of control variables, including babyfacedness, attractiveness, and hair style. Regression analyses indicated that at the low end on the phenotypicality continuum, increases in phenotypicality were associated with higher foul rates, but for most of the range, the relationship was actually negative. In addition to reporting these data in detail, this poster will examine possible explanations for these relationships, and will explore features of the officiating context that might suggest ways to reconcile these effects with those of previous studies of skin tone and phenotypicality bias.

### F272

**COLORBLIND CONSTRUCTIONS OF AMERICAN IDENTITY AS IDEOLOGIES OF OPPRESSION** Nia L. Phillips<sup>1</sup>, Glenn Adams<sup>1</sup>; <sup>1</sup>University of Kansas – Two studies examined the relationship between different constructions of American identity (colorblind or multicultural) and perception of racism in ambiguous events. In Study 1, we measure participants' endorsement of colorblind or multicultural constructions of American identity, strength of American identification, perceptions of racism in ambiguous events, and support for anti-racist social policies. In Study 2, we imposed a construction of American identity as either colorblind or multicultural and then assessed strength of American identification and perception of racism. Results provide evidence for the hypothesized effect of identity constructions on racism perception. Multicultural constructions of American identity afforded racism perception; colorblind constructions

of American identity promoted racism denial. Discussion focuses on colorblind constructions of American identity as intentional worlds of oppression. In one direction, colorblind constructions of American identity reflect particular beliefs and desires associated with American glorification and cultivated ignorance of racial injustice. In the other direction, colorblind constructions of American identity promote "desired" ends by leading people—regardless of individual intention or awareness—to perceive less racism in ambiguous events and express less endorsement for antiracist policy.

### F273

**LOOKING THE PART: THE INFLUENCE OF GENDER, AGE, AND WEIGHT ON PERSONNEL DECISIONS** Enrica N. Ruggs<sup>1</sup>, Michelle R. Hebl<sup>1</sup>, Daniel J. Beal<sup>1</sup>; <sup>1</sup>Rice University—Past research has consistently documented the negative relation between weight and personnel decisions (i.e., interview evaluations, promotions, salary; Roehling, 1999; Roehling, Roehling, & Pichler, 2007). Past research also has documented the negative relation between aging and personnel decisions (i.e., evaluations, training; Duncan & Loretto, 2004; Gordon & Arvey, 2004). Almost no research, however, has joined these two fields of study. In the current paper, we examine how weight and age (as well as gender) work together to influence personnel decisions. A total of 327 men and women (varying in age and size) rated targets of varying weight (heavy, medium, thin), age (20, 40, and 60 years of age), and gender on a number of job-related dimensions (i.e., professional success, hireability, trainability, interpersonal skills). Additionally, they rated targets on a number of dimensions that might be influenced by weight and age stereotypes (i.e., whether one should work with technology, be in the front office and visible, work in a sedentary environment). Results revealed a number of predicted main effects and interactions for target age, weight, and gender on personnel ratings as well as effects of participant characteristics (for participant age and gender, but not weight). Furthermore, several of the effects of target characteristics on personnel ratings were mediated by stigma-relevant stereotypes (e.g., whether the person should work in a face-to-face job accounted for the negative effect of target weight on personnel ratings). We discuss the theoretical and applied implications of these results.

### F274

**DIFFERENTIALLY DANGEROUS? RACIAL STEREOTYPICALITY IMPACTS SHOOTER BIAS AMONG BLACKS** Kimberly Kahn<sup>1</sup>, Paul G. Davies<sup>2</sup>; <sup>1</sup>University of California, Los Angeles, <sup>2</sup>University of British Columbia, Okanagan—The current study investigates whether within-group differences in phenotypic racial stereotypicality exacerbate racial stereotyping among individuals' own racial group in split-second shoot/don't shoot decisions. Prior research has shown that group members who are high on phenotypic Black stereotypicality (i.e., those with darker skin, broader noses, and fuller lips) encounter more bias than low stereotypic group members (e.g., Eberhardt et al., 2004). In this experiment, we test whether Black participants display stereotypicality-biased decision-making against Black targets in the shooter paradigm (see Correll et al., 2002). Because of their greater association with stereotypes linking Blacks with danger, it is hypothesized that high stereotypic (HS) Blacks will experience more racial bias than low stereotypic (LS) Black or White targets. Forty five Black participants completed a quick shoot/don't shoot videogame, in which target stereotypicality (HS Black, LS Black, White) and object type (neutral, gun) were manipulated. Errors (incorrectly shooting an unarmed target and incorrectly not shooting an armed target) were measured. Results confirmed that HS Black targets elicited stronger racial bias than LS Black targets or Whites targets. Specifically, a lower shooting criterion was adopted for HS Black targets, such that less certainty was required to shoot those targets. Results suggest that phenotypic stereotypicality of potentially hostile targets can increase the accessibility of stereotypes linking Blacks with danger, intensifying racial bias in decisions to shoot. Further, stereotypicality biases among Blacks may operate at implicit levels against their own group members. Implications for policing are discussed.

### F275

**GENDER DIFFERENCES IN THE DISCLOSURE OF FEAR: WHEN SELF-PRESENTATION = STEREOTYPE COMMUNICATION.** Robbie Sutton<sup>1</sup>, Karen Douglas<sup>1</sup>, Amy-Jo Lynch<sup>1</sup>; <sup>1</sup>University of Kent, Canterbury, UK—Stereotypes may be perpetuated by biases in the way that people talk about themselves. The present studies investigate this mode of stereotype communication in the context of much-studied gender differences in the fear of crime. An English field survey revealed that men and women attribute much higher levels of fear to "the average female" than to "the average male" (Study 1). This gender stereotype is not only descriptive: in scenario studies involving community (Study 2) and student (Study 3) samples, women (but not men) who expressed low levels of fear were evaluated negatively. This prescription appears to be ideological: ambivalent sexism is related to perceptions that fearless women are foolish (Study 4). These gender stereotypes appear to affect, and to be fuelled by, self-presentational tactics. In a Scottish door-to-door survey, a "lie scale" was inversely related to men's but not women's reported levels of fear (Study 5). Men in an experimental field survey reported lower levels of fear if instructed to "fake good" rather than to be open and honest. Conversely, the instruction to fake good increased women's reported fear levels (Study 6). Taken together the studies illustrate a stereotype communication process that might be dubbed "faking gender". Individuals are reluctant to disclose emotional states that diverge from stereotypical expectations, for fear of incurring a backlash. As a result, they provide distorted self-presentations that tend to confirm those expectations. This positive feedback loop helps lend a self-perpetuating capacity to gender stereotypes.

### F276

**FALLING FROM GRACE: INFRAHUMANIZING THE INGROUP FOLLOWING VALUE VIOLATION** Christine Reyna<sup>1</sup>, Mark Brandt<sup>1</sup>, G.Tendayi Viki<sup>2</sup>; <sup>1</sup>DePaul University, <sup>2</sup>University of Kent, U.K.—Research on infrahumanization suggests that people often attribute fewer human qualities to members of outgroups than to members of their own group (e.g. Leyens et al., 2001). This tendency has been used to explain a host of anti-social outcomes. In two studies, we show that even ingroup members may lose a degree of their human status by violating important social values and morals, and thus "fall from grace." We predict that ingroup members will be perceived as symbolically threatening, less human, and thus less deserving of prosocial emotions and behaviors. Study 1 surveyed members of the community about perceptions of race and economics. White participants infrahumanized Whites living in poverty more than Blacks in the same economic circumstances (controlling for participant income). The tendency for White participants to infrahumanize poor Whites was fully mediated by judgments of responsibility and blame. Study 2 surveyed university students about students in their ingroup and students at a rival school. We found that human status was not determined by group membership, but rather by whether or not a group upheld important values. Ingroup members who violated these values were infrahumanized as much as outgroup members who violated values. In addition, the relationships between infrahumanization and greater social rejection and punishment were fully explained by perceptions of value violation. These findings are discussed in terms of the importance of expanding infrahumanization research to look at moral judgments and symbolic threat when evaluating the human status of both ingroup and outgroup members.

### F277

**THE MAKING AND UNMAKING OF AMERICANS: ETHNIC IDENTITY AND CONTRIBUTIONS TO THE NATIONAL GOOD DETERMINE WHETHER ETHNIC MINORITIES ARE SEEN AS AMERICAN** Kumar Yogeeswaran<sup>1</sup>, Nilanjana Dasgupta<sup>1</sup>, Cristian Gomez<sup>1</sup>; <sup>1</sup>University of Massachusetts, Amherst—Despite the prevalence of contemporary multicultural ideals, are ethnic minorities perceived to be less authentically American when they embrace their ethnic identity? However, are they perceived to be more American when their work benefits the national good? Do these

factors interact to predict when Americans will include vs. exclude ethnic minorities from the national fold? Study 1 demonstrated that exposure to accomplished Asian-Americans increased inclusion of this ethnic group as American, but only when these individuals appeared ethnically assimilated, not when they were ethnically identified. However, making equivalent Whites (e.g., Irish-Americans) appear ethnically identified vs. assimilated did not affect the degree to which they were seen as American. Studies 2-3 manipulated minority individuals' ethnic identity and their professional work (i.e., work that emphasized vs. did not emphasize the national good). Results showed that exposure to Hispanic-Americans who were ethnically assimilated increased the inclusion of this ethnic group as American, but only when their accomplishments emphasized the national good. Moreover, greater inclusion occurred because these individuals enhanced the perceived distinctiveness of America as an international beacon of progress. However, exposure to identical individuals who were ethnically identified increased exclusion of Hispanic-Americans when their work did not emphasize the national good. This effect was mediated by fears that non-European cultural practices would contaminate American society. Collectively, these studies demonstrate that people's willingness to include or exclude ethnic minorities from their national group is driven by two factors: the fear of cultural contamination and the motivation to bolster America's distinctiveness in the world.

## Well-Being

### F278

**GETTING USED TO THE GOOD THINGS IN LIFE: HEDONIC ADAPTATION TO POSITIVE LIFE EVENTS** Katherine M. Jacobs<sup>1</sup>, Julia K. Boehm<sup>1</sup>, Sonja Lyubomirsky<sup>1</sup>; <sup>1</sup>University of California, Riverside – Positive life events like getting married, purchasing a new home, or graduating from college are associated with boosts to an individual's sense of well-being. With time, however, those positive feelings begin to subside through a process known as hedonic adaptation. This research examines the course of hedonic adaptation and, specifically, the predictors that can prolong gains in well-being stemming from a pleasant life event. To this end, a 15-day study tracked participants' well-being before, during, and after receiving five days of complimentary, self-relevant feedback. Multi-level modeling analyses revealed that participants experienced increases in well-being immediately on receiving the feedback, but that well-being diminished in subsequent days, suggesting that hedonic adaptation was occurring. However, those who reported a greater number of positive emotions and pleasant experiences subsequent to the feedback were better able to maintain their well-being gains and to delay hedonic adaptation. The findings are interpreted in the context of Lyubomirsky and Sheldon's (2009) model of hedonic adaptation to positive life changes, and their implications for achieving ever-greater happiness are discussed.

### F279

**ASSESSING NEED THEORY: FINANCIAL SECURITY MEDIATES THE MONEY-HAPPINESS LINK** Mark Kurai<sup>1</sup>, Ryan Howell<sup>1</sup>; <sup>1</sup>San Francisco State University – Previous studies have indicated a diminishing effect of increased money on happiness or subjective well-being when examining across countries. The most prominent theory to explain these findings is need theory, which proposes that increasing income and wealth can correspondingly increase well-being for impoverished individuals only because the money is used to satisfy basic physiological needs. The present study assesses the underlying assumptions of need theory by advocating that money can buy happiness beyond poverty if the money satisfies higher-order psychological needs. Method. Three diverse samples (N=359) of unemployed college students, older adult students, and older employed adults completed an online survey assessing life satisfaction, financial security, and economic standing. Results. Across the two older adult samples, results show that as economic standing rises so does individual perceptions of financial security (a safety need), which

in turn increases a cognitive component of happiness, life satisfaction. Conclusion. Our study is one of the first to use a mediational model in testing the accuracy of need theory. We provide evidence that the relationship between money and well-being is mediated by financial security in samples above poverty, thus extending need theory to include a more advanced level of Maslow's hierarchy. Furthermore, we extend support for the use of multiple indicators of economic standing when examining economic theory over the traditional use of absolute income.

### F280

**WHAT PREDICTS LIFE SATISFACTION? DOES IT DIFFER FOR MEN AND WOMEN?** Shimon Saphire-Bernstein<sup>1</sup>, Shelley E. Taylor<sup>1</sup>, Amy N. Moore<sup>1</sup>, Suman Lam<sup>1</sup>, Teresa E. Seeman<sup>1</sup>; <sup>1</sup>University of California, Los Angeles – Researchers have recently suggested that relationships may not be central to life satisfaction, but gender differences in the association between these variables have not been explored. The tend-and-befriend model of coping with stress suggests that the quality of social relationships may be more important for women than for men, which suggests that the importance of relationship quality to life satisfaction depends on gender. Such an effect has yet to be demonstrated, and whether there are gender differences in the importance of other factors related to well-being remains an open question. In this study, a sample of young adults (n = 186) completed measures of psychological resources, mental and physical health symptoms, and quality of a broad array of relationships, and these measures were then related to overall life satisfaction separately by participant gender. Results largely replicated the importance of psychological resources and mental and physical health for life satisfaction, and there were few differences between men and women in the effect sizes of these variables. However, relationship quality across a broad array of relationships strongly predicted life satisfaction for women, whereas for men, only the relationship quality of close friends was a significant influence on life satisfaction. Results are discussed in terms of the forces that have shaped similarities and differences in how men and women construe satisfaction from their lives.

### F281

**JAPANESE VERSION OF GMI AND WELL-BEING** Hiroko Kamide<sup>1</sup>, Ikuro Daibo<sup>1</sup>; <sup>1</sup>Graduate School of Human Sciences, Osaka University – The aim of this study is to develop Japanese version of Growth Motivation Index (GMI; Bauer et al., 2008) and to investigate the relationship between the scale and well-being in Japan. Growth motivation is examined as an individual's motivation toward personal growth and personality development. Two forms of growth motivation are proposed to correspond to two broad paths of personality development -- one more cognitive, the other more experiential (Bauer et al., 2008). These motivations contributed to well-being (Bauer et al., 2008). Bauer et al. (2008) developed GMI (Growth Motivation Index) and we aimed to develop the Japanese version of GMI (JGMI) and investigate the relationships between J-GMI and well-being in Japan. We translated GMI into Japanese and 295 Japanese students evaluated JGMI (20 items, 7 point) and PWB (43 items, 6 point; Ryff & Keyes, 1995). PWB are composed of 6 dimension of well-being (Self-Acceptance, Environmental Mastery, Positive Relationship with Others, Personal Growth, Purpose in Life, and Autonomy). The result of factor analysis showed that JGMI differentiated into cognitive and experiential growth that corresponded to GMI and also a specific factor that reflected motivation to contribute to the society. Regression analyses demonstrated that the JGMI-experiential subscale predicted measures of well-being across 6 dimensions stronger than the JGMI-cognitive subscale. This finding was similar to Bauer et al. (2008). However, the dimension of Positive Relationship with Others was predicted by the JGMI-contribution subscale characteristically. The role of growth motivation in well-being was discussed from the perspective of cultural background.

**F282****THE RELATION OF ATTITUDINAL BALANCE TO WELL-BEING** Paul

Fuglestad<sup>1</sup>; <sup>1</sup>University of Minnesota, Twin Cities – Drawing on balance theory (Heider, 1958), the present investigation examined the relation of attitudinal (dis)agreements with close others to well-being and the moderating influence of self-monitoring (Snyder, 1974). It was hypothesized that disagreements with close others (e.g., romantic partners) about important attitudes (e.g., core values) would have negative effects on relational and personal well-being and that self-monitoring would moderate the relation of disagreement to well-being (i.e., low self-monitors would be more affected by disagreement). Participants completed the Self-Monitoring Scale, an assessment of core values from the standpoint of self and close others (e.g., friends, family, romantic partner), and measures of relational (e.g., closeness, communication quality) and personal well-being (e.g., self-esteem, depression, life satisfaction). Disagreement with close others regarding the favorability of core values was consistently related to less relational and personal well-being. This pattern was particularly true of romantic relationships and friendships. For romantic relationships, the relation of value disagreement to well-being was moderated by self-monitoring. For low self-monitors, greater value disagreement with romantic partners predicted less relational and personal well-being, and the relation of disagreement to personal well-being was partially mediated by relational well-being. For high self-monitors, greater value disagreement with romantic partners predicted less relational well-being, but did not predict personal well-being. Independent of value disagreement, for high self-monitors, greater relational well-being predicted greater personal well-being. Results suggest that balance processes are important for close relationships and psychological well-being. Furthermore, it appears that individual differences in self-monitoring moderate these processes.

**F283****DO EXTRAVERTS ALWAYS HAVE GREATER WELL-BEING THAN INTROVERTS? IT DEPENDS ON HOW ONE MEASURES EXTRAVERSION, INTROVERSION, AND WELL-BEING.** Veronika Huta<sup>1</sup>; <sup>1</sup>University of Ottawa

– It is widely accepted that extraverts have greater well-being than introverts. However, this conclusion is based on research that a) only studied high/moderate arousal well-being, b) usually confounded extraversion with positive affectivity, c) largely operationalized introversion as a deficit in extraversion. Our aim was to determine whether there are important well-being outcomes that do not relate to extraversion, whether some of these relate positively to introversion, and whether it may be more realistic to say that the most fulfilled individuals are those who can exercise both extraversion and introversion. In Study 1 (N = 99 undergraduates), we studied the most commonly used measures of extraversion, and these related to high and moderate arousal well-being, life satisfaction, well-being with friends, and well-being in the city; however, extraversion was consistently unrelated to low arousal well-being, well-being when alone, and well-being in nature. Furthermore, when the facets of extraversion were studied separately, and thus not confounded with positive affectivity, only friendliness related quite consistently to well-being, while gregariousness, excitement-seeking, and assertiveness were unrelated to certain outcomes, most notably life satisfaction. Study 2 (N = 228 undergraduates) replicated Study 1, and introduced a psychometrically sound scale to assess introversion as a set of active interests in its own right, including inward-orientation, subjectivity, and introspection. Introversion related positively to low arousal well-being, well-being when alone, and well-being in nature. Finally, individuals who were high in both extraversion and introversion scored higher on the majority of well-being outcomes than people who were only extraverted or introverted.

**F284****EFFECT OF SELF-PERSPECTIVE ON ACHIEVEMENT SATISFACTION**

**JUDGMENT** Nangyeon Lim<sup>1</sup>, Eunkook M. Suh<sup>1</sup>; <sup>1</sup>Yonsei University – Taking a third-person perspective relative to a first-person perspective, makes people perceive objective, visible information and others' existence more saliently. Therefore, 3rd-person perspective makes oneself to expect more judgment from others about one's own behaviors. The present research examined, if perceiving oneself through a 1st-person or a 3rd-person perspective affects the relative emphasis on affect balance and social appraisals, when assessing one's satisfaction with achievement. Forty-two undergraduate students participated in this study. Participants were randomly assigned to one of two experimental conditions: first-person perspective, and third-person perspective conditions. After either 1st-person or 3rd-person perspectives are primed, respectively, all of the participants were asked to write briefly about their most important achievements within recent three years. Then, achievement satisfaction was assessed by asking participants to report how much they are satisfied about what they achieved. Affect balance score was calculated by asking participants how frequently they felt positive affect and negative affect about the achievement, and then subtracting negative affect score from the positive affect score. Social appraisal score was obtained by asking participants to rate how their significant others (parents and their close friends) would evaluate their recent achievement. The results show that those who view themselves through 1st-person perspective evaluate their achievement satisfaction based on their affect balance toward their achievements, whereas those who view themselves through 3rd-person perspective evaluate their achievement satisfaction based both on their own affect balance and social appraisals about their achievement.

**F285****THE WAY TO BE HAPPY IN A CONSUMER SOCIETY: MEDIATORS OF PURCHASE PREFERENCES ON SUBJECTIVE WELL-BEING** Naoko

Chaimowitz<sup>1</sup>, Ryan Howell<sup>1</sup>; <sup>1</sup>San Francisco State University – Previous research shows that material wealth is not necessary in order to increase one's sense of well-being. However, there have not yet been enough studies to provide a clear understanding of the relationship between materialism, financial aspiration, and well-being. Many studies are focused on materialism as personal traits, values, or goals; and thus, there is a need for understanding how buying behavior and decision-making affects well-being. The present study examines the hypothesis that experiential purchase preferences increased psychological need satisfaction which in turn increased subjective well-being. Participants (n = 145) were asked to respond to a series of survey questions regarding their use of money and overall level of well-being as well as their current psychological need satisfaction. We test a mediation model with a hierarchical regression and predicted that experiential purchase preferences increased psychological need satisfaction which in turn increased subjective well-being. As predicted, almost all of the reduction in the direct path from experiential purchase preference to subjective well-being was due to the increased psychological need satisfaction that was experienced with increases in experiential purchasing. We then replicated this result with a diverse sample (n = 349) recruited through social network sites. Our results suggest that spending money on experiences, rather than merchandise, may have the benefit of increasing psychological need satisfaction which in turn increased a sense of well-being.

**F286****UNDERSTANDING DISPARITIES IN HEALTH: AN EXAMINATION OF THE RELATIONSHIPS BETWEEN COMMUNITY ESTEEM, EMPOWERMENT, AND WELL-BEING** Lisa Molix<sup>1</sup>, Caitlin Ward<sup>1</sup>, Shaina Spector<sup>1</sup>; <sup>1</sup>Tulane

University – The physical and psychological health statistics of Louisiana residents are traditionally among the worst in the United States. In New Orleans, longstanding health disparities have been exacerbated by recent disasters such as Hurricane Katrina, which devastated many of the city's communities. Bringing together theory and research on community

esteem, empowerment, and disparities in overall health, the present research is part of a program of research examining the role of a variety of psychosocial variables in predicting physical and psychological well-being. Specifically, this study examined the ways in which community esteem and empowerment relate to physical and psychological well-being in a sample of New Orleans citizens. A sample of New Orleans residents were recruited at public locations (e.g., festivals, farmer's markets, parks) to participate in exchange for monetary compensation. The results suggested that higher levels of community esteem were associated with more positive psychological and physical well-being. In addition, community esteem was also associated with higher levels of empowerment. Although empowerment did not significantly influence the relationship between community esteem and physical well-being, it mediated the relationship between community esteem and psychological well-being among members of low status groups. In accord with our past work, the results suggest those with the lowest social status (e.g., those living in the areas with the highest levels of blight) seem to benefit the most from empowerment.

### F287

#### RELIGIOSITY/SPIRITUALITY AND ABSTINENCE SELF-EFFICACY DURING TREATMENT FOR ADDICTION: THE MEDIATING EFFECTS OF SUBJECTIVE MEANING IN LIFE

Amanda E. R. Robinson<sup>1</sup>, Kenneth E. Hart<sup>1</sup>, <sup>1</sup>University of Windsor – The recent surge of psychological research on religiosity/spirituality (R/S) is particularly strong amongst scholars interested in understanding the onset and remediation of alcohol and other drug (AOD) disorders. Despite this recent increased scrutiny, little is known about the psychological mechanisms that might help explain how and why R/S factors contribute to improved long-term abstinence in persons striving to overcome their AOD dependence. To fill this void, we conducted a process study of abstinence self-efficacy (ASE) in a sample of inpatients in early stage recovery who were receiving spiritually-oriented treatment. We tested the hypothesis that greater levels of involvement in prayer and meditation (ie., R/S) would contribute to increased confidence in the ability to resist temptations to drink. Furthermore, based on research suggesting the salubrious consequences of R/S factors are mediated by concomitant increases in the sense of meaning in (one's) life (Steger & Frazier, 2005; Krause, 2008), we expected the effects of R/S on ASE would diminish or disappear after controlling for perceived meaning. 40 inpatients attending 12-Step oriented alcoholism programs in the UK completed questionnaires assessing the constructs of interest. Regression analyses revealed: (1) R/S and perceived meaning were both predictive of higher levels ASE, and (2) levels of subjective meaning in life fully mediated the relationship between R/S and ASE. These findings suggest a psychological model of early stage recovery in which treatment impacts R/S involvement, which helps clients feel their life in recovery has meaning and significance, which bolsters resilience to relapse via ASE.

### F288

#### DAILY RHYTHM OF AFFECT AND ITS DETERMINANTS: YOUNG AND OLD MARCH TO THE BEAT OF DIFFERENT DRUMS

Susanne Scheibe<sup>1</sup>, Jutta Mata<sup>1</sup>, Laura L. Carstensen<sup>1</sup>, <sup>1</sup>Stanford University – Do people feel better in the morning or evening? Previous research with young adults suggests that affect varies throughout the day, with positive affect being lower in the morning and rising towards the evening and negative affect being stable. We examined factors associated with such daily fluctuations in affect, including activity, physical condition, and motivational-emotional conflict. Because these factors change across the lifespan we further tested age differences in daily affect fluctuations as well as their determinants. A sample of 178 adults aged 19-94 years completed five daily measurements over seven consecutive days. Using three-level hierarchical linear models, we found that in younger adults positive affect increased and negative affect decreased over the day. Younger adults also reported better physical functioning and lower motivational and emotional conflict in evenings than mornings, and these factors were strongly coupled with affect. In contrast, older adults' well-being did not

consistently improve over the day. Although they, too, reported reduced negative affect, their positive affect remained high throughout the day, despite their physical condition worsening towards the evening. Physical problems and motivational conflict did not compromise older adults' affect as much as young adults'. Age differences in daily affect slopes could not be explained by time allocation to work versus leisure. Findings suggest that emotion- and self-regulatory processes, rather than type of activity, are responsible for daily fluctuations in affect. Moreover, older adults' improved emotion-regulatory abilities appear to help them maintain high levels of positive affect throughout the day.

### F289

#### SATISFACTION WITH EXPERIENTIAL VERSUS MATERIAL PURCHASING

Amy R. Harrison<sup>1</sup>, Grant Donnelly<sup>1</sup>, Ryan T. Howell<sup>1</sup>, <sup>1</sup>San Francisco State University – Research has shown that experiential purchases, as opposed to material purchases, are perceived as money well-spent, as increasing feelings of vitality, as increasing relatedness, and are less subject to social comparison. The current study seeks to support these finding by utilizing a repeated-measures design and assessing various types of experiential and material purchases based on their fulfillment of psychological needs. Method: Participants (n = 67) completed an online survey, which prompted them to think of their most recent purchases across six different categories, qualified as either experiential purchases (dining experience, live event, and traveling) or material purchases (books or music purchase, clothing or jewelry, and electronics). Participants then rated the purchases for the degree to which they satisfied psychological needs. Results: As predicted, the experiential purchases were associated with more happiness directly after the purchase, more relatedness satisfaction, more vitality, and a decreased social comparison. Surprisingly, as a category, experiential purchasing was rated as contributing less to current happiness than material purchasing. When analyzed individually, the dining experience and live event purchases had the lowest ratings of current happiness – perhaps due to a susceptibility to hedonic adaptation. However, the travel experience had the highest rating of current happiness, and indeed, the highest well-being ratings of all the purchasing categories. Conclusion: These results supported the previous findings on the experience recommendation and extend past work by more precisely indicating that traveling might be the experiential purchase that most maximizes well-being.

### F290

#### OVERSPENDING: A DEBT TO HAPPINESS

Grant Donnelly<sup>1</sup>, Amy Harrison<sup>1</sup>, Ryan T. Howell<sup>1</sup>, <sup>1</sup>San Francisco State University – Past research suggests that individuals with a higher level of subjective debt also experience increased levels of stress (Norvilitis et al., 2006) and psychological distress (Brown, Taylor & Price, 2005). However, past research has mostly ignored a possible relationship between overspending (a behavior that often leads to debt) and purchasing decisions. The main goals of this study were to corroborate the relation between overspending and decreased happiness- and to determine if increases in debt were due to impulsive buying behaviors, materialism, or decreased saving behavior. Method. A diverse sample (N=158) of unemployed college students, part-time employed students, full-time employed students and employed adults completed an online survey which measured their spending and saving behavior, purchasing preferences and behaviors, and personality traits. Results. Data suggest that overspending is not correlated with life satisfaction, but is associated with lower happiness and mental health as well as higher materialistic values. Additionally, the results suggest that over-spenders buy more impulsively and less experiential, have lower savings behavior, lower financial security, and lower socioeconomic status. Conclusion. Our study demonstrates the multiple negative outcomes, both psychologically and financially produced by over-spending.

**F291**

**THE FUNCTIONS OF LIFE NARRATIVE SCENES FROM CHILDHOOD, ADOLESCENCE, AND ADULTHOOD** Joshua Wilt<sup>1</sup>, Dan P. McAdams<sup>1</sup>, <sup>1</sup>Northwestern University – People draw on their life stories for a variety of purposes, such as nurturing relationships, teaching others, and developing a clear sense of self (Webster, 1993). In turn, many of the reasons that people use their stories are related to well-being (McLean & Pals, 2008). A limitation of this research to date is that it has focused almost exclusively on the uses of remembering stories and storytelling in general. Research has not yet examined whether different scenes in the story (such as scenes from childhood, adolescence, and adulthood) are used for different functions. This study examined 1) whether scenes occurring at different stages of life are used for different functions, and 2) whether the functions of different scenes are differentially related to well-being. Participants completed one written narrative each for memories from childhood, adolescence, and adulthood. Questionnaires designed to assess the functions of life stories in general (Bluck, Alea, Habermas, & Rubin, 2005; Webster, 1993; 1997) were modified to assess how participants use each specific life story scene. Well-being was assessed with measures of life-satisfaction (Diener, 1985) and social health (Keyes, 1998). Results showed that people use scenes in their life stories for different functions, and also that the relationships between the functions of stories and well-being differed across scenes. These findings support the utility of delineating the functions of life stories by discrete scenes and suggest that the ways people use discrete scenes in their life stories may be uniquely relevant to psychosocial adaptation.

**F292**

**COLLEGE STUDENTS' SMILES IN THEIR FIRST SEMESTER FACEBOOK PHOTOS PREDICT LONG-TERM WELL-BEING AND PLANS TO DONATE MONEY TO THE UNIVERSITY AS ALUMNI** J. Patrick Seder<sup>1</sup>, Shigehiro Oishi<sup>1</sup>, <sup>1</sup>University of Virginia – In the classic study by Harker & Keltner (2001), the degree to which participants smiled in their high school yearbook photos was shown to predict well-being three decades later. We conducted a four-year-long study in which we coded the degree to which participants were smiling in their main Facebook photo when it was retrieved during their first semester at college. In addition, we counted the number of words posted by the participants in their Facebook profiles at that time. We used both variables to predict well-being, satisfaction with the university, future plans to donate money to the university, and GPA as measured four years later. Participants (n = 49) completed a battery of well-being measures during their first semester at college (Fall 2005), and gave us permission to retrieve and code their Facebook profiles. At the end of their final semester at college (Spring 2009), participants completed a follow-up web study. Results show that the degree to which participants were smiling in their main Facebook photo during their first semester at college (four years earlier) predicts Satisfaction With Life, Felt Understanding, overall satisfaction with the university, and intentions to donate money to the university as an alumnus. Amount of personal information posted in the Facebook profiles during the first semester at college predicts lower GPA (overall and major-specific) four years later, as well as greater amounts of self-reported illness and stress. Amount of profile content, however, is not correlated with participants' self-reports about how often they update their Facebook pages.

**F293**

**MODEL CONSTRUCTION FOR THE PSYCHOLOGY OF MEANING OF LIFE: TOWARD INTEGRATIVE APPROACH TO THE VIEW OF LIFE** Yu Urata<sup>1</sup>, <sup>1</sup>Meijo University – In psychology, a number of studies have examined ideas of the meaning of life, but no comprehensive model has been developed that integrates philosophical foundations and empirical research. This study constructed an integral model for concepts of the meaning of life using a model construction methodology based on qualitative data. Three models were constructed: Framework (Model I), Element (Model II), and Composition (Model III). Model I was a theoretical

framework model based on philosophical, anthropological, and psychological theories. Model II was constructed using categorization data on the meaning of life drawn from various sources in previous studies. Model III was constructed by integrating Models I and II. These models proposed four fundamental principles underlying concepts of the meaning of life: Personal, Relational, Social/universal, and Religious/spiritual. These principles formed a "nested" structure that unfolds from Personal to Relational to Social/universal to Religious/spiritual. In addition, some typical cases were analyzed by assessing structural properties of meaning systems. The model may provide a comprehensive framework for understanding concepts such as "depth" and "breadth" as associated with concepts of the meaning of life.

**F294**

**THE IMPORTANCE OF NATURE IN PROMOTING PERSONAL AND ENVIRONMENTAL WELL-BEING** Elizabeth K. L. Nisbet<sup>1</sup>, John M. Zelenski<sup>1</sup>, <sup>1</sup>Carleton University – Social and personality psychologists, as experts in human behavior, have important roles to play in helping to overcome environmental problems. Disconnection from the environment and a lack of contact with nature may contribute to environmentally destructive behaviour as well as to human unhappiness. Fostering a subjective sense of connectedness to nature (nature relatedness or 'NR') may be a promising way to promote sustainable attitudes and behavior, as well as improving psychological well-being. Our previous research suggests that people who have a strong connection to nature (are highly 'nature related') are happier, hold more pro environmental attitudes, and behave in more sustainable ways. In this study, we test the idea that spending time in nature promotes positive emotions, and fosters sustainable attitudes and behavior. An online, month-long, longitudinal experience sampling method was used to investigate if trait connectedness (NR) predicts nature contact and in turn contributes to both happiness and sustainable behavior. We assessed trait NR, happiness, time spent in nature, and sustainable behavior over five weeks. Initial trait connectedness (NR) was associated with positive emotions and vitality at the end of the study, and this was, in part, due to time spent in nature over a month. Time spent in nature also mediated the relationship between NR and self-reported sustainable behavior. We suggest that, in contrast to environmental messages that evoke unpleasant emotions, emphasizing the positive aspects of connectedness with nature (such as increased happiness) may provide an effective tool in motivating environmental behavior and promoting psychological well-being.

**F295**

**HOW NEED SATISFYING AND DEPRIVING EXPERIENCES OF VIDEO GAME PLAY SHAPE AGGRESSION AND WELL-BEING** Andrew Przybylski<sup>1</sup>, <sup>1</sup>University of Rochester – Most research has focused on the graphic and narrative contents of video games in understanding and evaluating how video game engagement influences short and long-term well-being. Taken together, this research suggest that video games can exert different kinds of influence as a function of their contents; health narratives have been shown to enhance health behavior (Baranowski et al., 2008), whereas violent content has been identified as a contributor to aggression (Anderson, 2004) Little research to date has examined how game structure might also shape short-term shifts in well-being and aggression through motivational processes. Our talk will review a number of survey-based, experimental, and experience-sampling studies that explore the relations between motivational factors rooted in the structure of games and short-term shifts in player well-being. Based on cognitive evaluation theory, we hypothesized that: (1) game engagement that satisfied the basic needs for competence and autonomy would serve to increase well-being and intrinsic motivation, and (2) game engagement that undermined need satisfaction would contribute to increased anxiety, aggression, and disengagement. Further, we expected that (3) these motivational processes would shape short-term shifts in well-being over and above differences in game content. Results derived from between- and within-person analyses revealed that psychologically need satisfying experiences of play were linked with increased well-being and

intrinsic motivation, whereas game engagement that thwarted needs lead to increased anxiety and aggression. Importantly, these results remained in evidence within and between both nonviolent and highly violent games.

#### **SPSP GSC SURVEY: WHAT GRADUATE STUDENTS WANT FACULTY TO KNOW**

Jennifer Pattershall<sup>1</sup>, Helen Lee Lin<sup>2</sup>, Austin Lee Nichols<sup>3</sup>, Kathleen Fortune<sup>4</sup>, Marina Milyavskaya<sup>5</sup>, Nicole Noll<sup>6</sup>; <sup>1</sup>University of Arkansas, <sup>2</sup>University of Houston, <sup>3</sup>University of Florida, <sup>4</sup>University of Manitoba, <sup>5</sup>McGill University, <sup>6</sup>Temple University – Graduate students are constantly evaluated on their course work, teaching, and research productivity. However, they rarely have the opportunity to give formal evaluations of their training programs or advisors. The SPSP GSC decided to give graduate students the chance to conduct this evaluation, to let faculty know how students feel about their education. Approximately 250 graduate student participants (61% female, M age = 28) were recruited over the SPSP listservs. Participants had completed an average of 3.7 years of graduate school. They represented 36 U.S. states, 4 Canadian provinces, and 9 other countries outside of North America. A variety of Likert-type questions assessed students' opinions about training programs (e.g., "I feel as though my training program is preparing me for the job I want when I finish my degree") and advisors (e.g., "I feel as though my advisor understands my goals and is helping me achieve them"). In addition, participants responded to open-ended questions about training programs and advisors (e.g., "What do you wish you could tell your advisor about your graduate school experience?"). These questions provided students the opportunity to share their experiences in an anonymous forum. The responses will be summarized to show where graduate students feel their programs and advisors excel, and where there could potentially be improvement.

### G2

#### **PSYCHOSOCIAL BELIEFS AND IMPLICIT ATTITUDES AS DETERMINANTS OF SUNSCREEN INTENTIONS AND SUNSCREEN USAGE AND THE MODERATING EFFECTS OF RACE**

Abby B. Harvey<sup>1</sup>, Andrew Karpinski<sup>1</sup>; <sup>1</sup>Temple University – Researchers have been aware of the impact that sun-related knowledge and psychosocial beliefs have on sunscreen practices, however, much of the existing research is more than a decade old and largely ignores race. In the current study 119 Caucasian and 44 African American participants completed a series of questions regarding their psychosocial beliefs toward sunscreen, a set of implicit measures about sunscreen-relevant attitudes, and indicators of their past sunscreen use and intentions to use sunscreen in the future. Across all participants, we found that photoaging beliefs, knowledge about skin cancer, beliefs about the effectiveness of sunscreen, and implicit attitudes toward sunscreen predicted intentions to use sunscreen. Additionally knowledge about skin cancer, beliefs about the effectiveness of sunscreen, and implicit attitudes toward sunscreen significantly predicted past sunscreen use, while perceived drawbacks to using sunscreen and implicit attitudes toward skin cancer marginally predicted past sunscreen use. Next we examined whether the relationship between any of the psychosocial beliefs in the models and sunscreen use and intentions to use sunscreen were moderated by race. Drawbacks to using sunscreen did not affect African Americans with regards to their intentions to use sunscreen, however, it was an important factor Caucasian participants considered in conjunction with their intentions to use sunscreen. Furthermore, implicit attitudes toward skin cancer predicted use and intentions to use sunscreen for African Americans but not for Caucasians. This research raises awareness to the necessity to consider the impact of race with regards to skin cancer and associated beliefs and behaviors.

### G3

#### **WHAT ABOUT AFTER THEY CONFORM?: EXAMINING THE CONFORMITY AND ATTITUDE CHANGE IN A POLITICAL DISCUSSION**

William Mauldin<sup>1</sup>, H. Colleen Sinclair<sup>1</sup>; <sup>1</sup>Mississippi State University – The present experiment examined the extent to which participants went against their own political beliefs by publicly conforming to the majority in a political discussion. Further, we measured the amount of attitude change participants expressed privately post-discussion. 390 participants completed a screening survey to gauge their political positions. Approximately 2 weeks later participants returned for an alleged "political discussion" either via instant messenger or face-to-face (determined by random assignment.) At the outset of the discussion, 6 votes were taken on 1 of 2 issues (either gay rights [n=201] or environmental policy [n=189]). Voting in turn, 3 confederates preceded the participant (1 confederate following the participant), and voted the opposite of what the participant's position was known to be. Conformity was assessed by the degree to which participants voted with the group (and against their own beliefs). Attitude change was assessed by computing a difference score between screening survey items and post-discussion measures. Participants in the gay rights condition were significantly more likely to conform (71-74%) and change their attitude if they went into the experiment anti-gay rights, attitude change was especially likely in face-to-face contexts rather than on-line contexts. In contrast, pro-gay rights individuals were significantly less likely to conform (30-33%) and showed attitude polarization. In the environmental condition, pro and anti participants had the same amount of conformity (60-64%) but attitude change was rare. Further discussion addresses why patterns vary between social justice issues (e.g., gay rights) and not for other types of political issues (e.g., environmental policy).

### G4

#### **ON THE ALERT: INFORMATION SEARCH DURING DECEPTIVE COMMUNICATION**

Naoya Tabata<sup>1</sup>; <sup>1</sup>Toyo University – A number of studies have investigated deceptive communication behavior and cues to deception have been identified (e.g. Zuckerman, DePaulo & Rosenthal, 1981). However, few studies have focused on information processing during deceptive communication. Therefore, characteristics of information search during deceptive communication were investigated. Facial expressions provide information about emotions (McCrosky & Richmond, 1996). The gaze in particular is often used to read the intentions of others (Endo, 2005). Therefore, it was hypothesized that facial expressions and the gaze of the self and that of the partner would be the focus of attention during deceptive communication. Two participants played a board game called "Ciao Ciao". In order to win this game, a player must hold the cards close to a partner's chest. Moreover, players can lie about a dice throw, because they throw the dice secretly and then announce the number. The degree of intimacy between two participants was manipulated, such that 28 participants played with a friend, and 16 played with a stranger. Attention to movements by the self and by the partner, such as facial expressions, gaze, body and hand movements, speech style and timing of announcements during the game were investigated. Results indicated that participants focused more attention on facial expressions and gaze of the self, compared to other movements by the self. Conversely, participants focused more attention on facial expressions and gaze of the partner when the partner was a friend. No significant attention to movements was observed with a stranger.

**G5****COLLEGE BINGE DRINKING FROM THE NATURAL DRINKING GROUP PERSPECTIVE**

James Lange<sup>1</sup>, Loraine Devos-Comby<sup>1</sup>, Jason Daniel<sup>1</sup>, <sup>1</sup>San Diego State University – College student binge drinking has been estimated to contribute to over 1,800 student deaths per year. Because it has become such a widely acknowledged public health problem, research has advanced on identifying factors that predict its occurrence. Personality, environmental, parental, cognitive, and even genetic variables have explained at least a portion of the variance in binge drinking. However, very little attention has been paid to the immediate social environment in which this drinking tends to occur. College students tend to drink within small groups of people who are bonded by friendship or other personal relationship. These natural drinking groups (NDGs) may be a substantial influential force on the individuals within it; perhaps even a more substantial influence than the more the more thoroughly studied generic "peer" influence. The study we report upon was conducted at a large public university in the southwestern United States. It was conducted with the goal of exploring the role of relationships within and social identity to NDGs on college student drinking. 414 students – who had been randomly selected – participated in a web-based survey with questions pertaining to their last drinking occasion. Two statistical interactions were found on the dependent variable, drinking quantity: (1) presence of a romantic interest within the NDG and being in a committed relationship, and (2) conformity to perceived NDG drinking norms was moderated by participants' level of social identity with the group. Both findings demonstrate that relationships within NDGs may play an important role in the drinking behavior of college students.

Poster G6 moved to B295.

**G7****THE ROLE OF LEADERS AS ATTACHMENT FIGURES: RE-EXAMINING THE LEADER-FOLLOWER RELATIONSHIP**

Daniel J McAllister<sup>1</sup>, Kelvin Pang<sup>1</sup>; <sup>1</sup>National University of Singapore – We examine the role of leaders as attachment figures in organizational settings. Drawing theoretical foundations for our work from adult attachment theory, we argue that followers can form context-specific attachment bonds with their leaders, and the nature of these specific attachment bonds is largely influenced by follower attachment style. We contend that through the mechanism of transference, followers' general beliefs of significant others affect the way they choose to rely on specific leaders and/or whether they see themselves as worthy of leader acceptance. Furthermore, we hypothesize that followers who are securely attached to their leaders experience a heightened sense of thriving (sense of learning and vitality) at the workplace. We developed new scales to measure a follower's specific attachment avoidance and anxiety towards his or her leader, and empirically tested this model with a sample of 270 matched supervisor-subordinate dyads. Results demonstrated strong support for the transference hypothesis, that individual differences in follower attachment styles (anxiety and avoidance) predicted follower attachment to a specific leader. In turn, specific attachment avoidance to the leader was a strong predictor of follower-reported thriving at work, while specific attachment anxiety was not. Taken together the findings bring into focus the relevance of attachment theory for understanding the dynamics of leader-follower relationships.

**G8****THE EFFECT OF RED ON PHYSICAL PERFORMANCE**

Wilbert Law<sup>1</sup>, Stefanie Putter<sup>2</sup>, Andrew Elliot<sup>1</sup>, Roger Feltman<sup>1</sup>; <sup>1</sup>University of Rochester, <sup>2</sup>Colorado State University – In previous research, the effects of seeing the color red on physical performance have been shown to be inconclusive. These inconsistencies were due to a lack of proper control measures, no control for color saturation and brightness, inconsistent time presentation of the color manipulation, and experimenter biases. The present study aimed to test the effect of seeing the color red on physical performance (measured by handgrip strength) using a more methodologically

vigorous experimental design. Participants, recruited from a subject pool, were randomly assigned to one of the three conditions (red, green, and gray). Participants' handgrip strength was measured before and after the manipulation. Participants were asked to look at a colored sheet according to the condition that was assigned in between the two strength measurements. Results showed that seeing the color red enhanced physical performance compared to seeing the color grey but no significant difference was found between red and green. Future directions and implications of these results are discussed.

**G9****PASSION FOR WORK: THE ROLE OF RECOVERY STRATEGIES AND RUMINATION IN BURNOUT**

Laurence Crevier-Braud<sup>1</sup>, Jacques Forest<sup>1</sup>, Eliane Bergeron<sup>1</sup>; <sup>1</sup>Universite du Quebec a Montreal – Vallerand and colleagues (2003) proposed a Dualistic Model of Passion wherein two types of passion are proposed: harmonious passion (HP) and obsessive passion (OP), which predict adaptive and less adaptive outcomes respectively. Previous research (Vallerand et al., in press) has shown the role of the DMP in burnout. To further extend previous results, the present study investigated the role of recovery strategies outside the work place and rumination about work in the relationship between passion and burnout. It was hypothesized that HP would lead to more recovery strategies, whereas OP would lead to more rumination about work. In turn, those strategies will subsequently influence the level of burnout. Participants (n=173) were nurses and completed an online survey. Results from structural equation modeling indicated that HP positively predicted recovery strategies and negatively predicted rumination about work, while OP was negatively associated to recovery and positively to rumination. Moreover, recovery from work predicted lower level of burnout whereas rumination predicted higher level of burnout; fit indices supported our model. Overall, these results suggest that it would be valuable to promote the development of HP and to prevent OP in the realm of work in order to attain and maintain psychological health at work. Directions for future research are proposed.

**G10****THE INFLUENCE OF DIVERSITY CLIMATE PERCEPTIONS ON TRUST IN LEADERSHIP: THE MEDIATING ROLE OF PROCEDURAL JUSTICE**

Benjamin Liberman<sup>1</sup>; <sup>1</sup>Columbia University – Organizational diversity climate is an individual assessment of how well an employee perceives his or her organization maintains an inclusive environment committed to embracing diversity and providing equal opportunity to all employees (Pugh, Dietz, Brief, & Wiley, 2008). This study investigated whether employees who perceive their organization's climate as pro-diversity have higher perceived trust in leadership than employees who perceive their organization's diversity climate as negative. Results were taken from the 2002 Federal Human Capital Survey in which over 100,000 Federal government employees were surveyed regarding their agency's policies, practices, and procedures. Hierarchical moderated multiple regressions assessed the moderating effect of minority group membership on the relationship between diversity climate perceptions and trust in leadership. Results show that diversity climate perceptions are positively related to trust in leadership evaluations. The findings of this study also support the hypotheses that minority group membership does moderate the relationship between diversity climate perceptions and trust in leadership. Regardless of whether they perceived their diversity climates as positive or negative, minority workers had higher trust in leadership evaluations than Whites. In addition, procedural justice did mediate the moderating effects of minority group membership on the relationship between diversity climate perceptions and trust in leadership. These research findings show that diversity climates do impact trust in leadership perceptions, supporting Cox's (1993) Interactional Model of Cultural Diversity which states that either positive or negative affective and performance-related outcomes for the employee are dependent upon the organization's diversity climate.

**G11****PLANNING RESEARCH-RELATED CAREERS: HOW STEREOTYPES ABOUT RESEARCHERS AMONG ENGINEERING, LIFE SCIENCE, AND PSYCHOLOGY MAJORS CONTRIBUTE** Sara Branch<sup>1</sup>, Ida Ngambeki<sup>1</sup>, Anna Woodcock<sup>1</sup>, William Graziano<sup>1</sup>, Demetra Evangelou<sup>1</sup>; <sup>1</sup>Purdue University –

The study examined research-related beliefs and expectations among students in Engineering, Life Science, and Psychology. Students (N=534) were surveyed regarding their stereotypes of researchers in their major area and the degree to which others (e.g., faculty, advisors) either encouraged or discouraged them to pursue research both as a student and as a career. Factor analysis of the items tapping students' researcher stereotypes revealed three factors: "precision scientist" (i.e. detailed, systematic;  $\alpha=.80$ ), "loner" (i.e. solitary, disorganized;  $\alpha = .71$ ) and "artist-engineer" (i.e. natural talent, artistic;  $\alpha =.55$ ). Regarding the precision scientist stereotype, engineering majors reported the highest level (M =11.33), followed by Psychology majors (M = 10.82) and then Life Science majors (M = 9.92). Regarding the artist engineer, engineering majors were significantly lower (M =9.71) than either Psychology (M = 10.51) or Life Science majors (M = 10.04). Regarding encouragement to pursue research, the overall pattern suggested that majors in Engineering and Psychology reported (and expected) more support for involvement in research than did Life Science majors. Regarding sex differences, women reported less encouragement than men, a notable exception being that women reported greater encouragement from advisors. These results suggest that faculty are actively influencing the perception students have of researchers in their field. These perceptions combined with the degree to which faculty encourage or discourage participation in research were also related to students' expectations and plans to pursue research-related careers.

**G12****WINNING THE VOTING 'RACE': SDO PREDICTS PARTY MEMBERSHIP**

Camilla S. Overup<sup>1</sup>, Brandee E. Marion<sup>2</sup>, Stefanie Teran<sup>1</sup>, Paige Muellerleile<sup>1</sup>, Jamie Warner<sup>1</sup>; <sup>1</sup>Marshall University, <sup>2</sup>University of Alabama – In the 2008 Presidential election, the Democratic nominee was Black. Talking about the role of race in the election, the Republican nominee said he thought voters would vote for "best of reasons, not the worst of reasons." Several theories may explain race in voting behavior, including social dominance orientation (SDO), symbolic racism (SR) and need for cognition (NC). SDO could predict voting patterns in two different ways: people who identify as Republicans or Democrats may only be willing to vote their parties. Alternatively, White voters may be unwilling to vote for a Black candidate. SR would make a more straightforward interpretation: People who obtain high SR scores should be less likely to vote for a Black candidate. Finally, NC's predictions about voting behavior indicate that voters who crossed parties to vote for a different candidate may not have done so because of some racial motivation, but rather, they may have voted across parties for other reasons related to issues or ideas that could be predicted by their need to think in more depth about the issues. Participants were 155 Democratic or Republican voters who completed a series of questionnaires prior to the election and who responded to a second survey after the election. Using DA and MANOVA, we classified party-consistent and inconsistent voters, using SDO, SR, and NFC as predictors of party membership and the reverse. This strategy indicated that only SDO predicted party membership. Focused comparisons of cross-party voters indicated no differences between groups on these variables.

**G13****LINGUISTIC CHANGE IN RESPONSE TO SWINE FLU (H1N1) Y. R.**

Tausczik<sup>1</sup>, J. W. Pennebaker<sup>1</sup>, K. J. Petrie<sup>2</sup>; <sup>1</sup>The University of Texas at Austin, <sup>2</sup>The University of Auckland – The language used in personal blogs following the first confirmed swine flu infections in Mexico was examined. Perceptions of a disease outbreak, particularly perceived threat, are related to the behavioral measures individuals take to protect themselves from infection (Rubin, Amlôt, Page, & Wessely, 2009). Language use might

inform perceptions of swine flu and reactions that motivate protective behavior. Thus, blogs were collected during the 17 days following the World Health Organization's (WHO) announcement. All blogs mentioning swine flu (N = 9,698) and a matched sample of control blogs (N = 9,698) were collected using the spinn3r blog aggregating service. As expected, use of health, anxiety and death words were higher in blogs discussing swine flu. Despite increased warnings by WHO and geographic spread of the disease, focus on the disease and perceived anxiety in blogs discussing swine flu was highest initially and then linearly declined (health words:  $r = -0.947$ ,  $p < 0.001$ ; anxiety:  $r = -0.928$ ,  $p < 0.001$ ; death:  $r = -0.671$ ,  $p = 0.003$ ). These results and other changes in language suggest that novelty and uncertainty of the outbreak at the beginning may be more important than the severity of the outbreak in influencing perceptions of risk. Sustaining public vigilance throughout the epidemic may be difficult particularly when public announcements may be causing the novelty to wear off.

**G14****MOOD AND LABELING IN THE UNDERDOG EFFECT: ARE X AND Y TEAMS DIFFERENT FROM FRONT-RUNNER AND CHALLENGER TEAMS?**

JongHan Kim<sup>1</sup>, Maureen O'Callaghan<sup>2</sup>; <sup>1</sup>Coastal Carolina University, <sup>2</sup>University of Alaska – Individuals have a tendency to associate with successful people and teams and distance themselves from unsuccessful people and teams. However, this tendency is contradictory to the underdog effect: Rooting for an underdog who is weaker and has a lower chance of winning. In this study, we investigated how spectators' mood and the labeling of teams affect underdog effect. The top dog was defined as having won 6 out of the last 7 games against the underdog. Labels of team were manipulated by changing the labels of the top dog and the underdog to either Team X and Team Y or Front-Runner and Challenger. Participants wrote about a particular incident where they were great (or awful) compared to others and then read a scenario of a sports game and indicated how much they would like to see each team win, how exciting it would be for each team to win, and how much money they would bet on each team. Scores of liking and excitement were combined to get a composite score of rooting for a team. When participants felt great, the underdog effect was magnified when the teams were described as X and Y than Front-Runner and Challenger. When participants felt awful, however, the underdog effect was disappeared when the teams were described as Front-Runner and Challenger but the underdog effect was occurred when the teams were described as X and Y. In terms of money betting, all participants bet more money to the top dog over the underdog.

**G15****EMOTIONAL AND COGNITIVE REACTION TO FEEDFORWARD INTERVENTION** Eyal Rechter<sup>1</sup>; <sup>1</sup>Hebrew University of Jerusalem –

Feedforward Intervention (FFI; Kluger & Nir, in press), is an organizational intervention based on the principles of Appreciative Inquiry (Cooperider & Srivastva, 1987) and positive psychology (Seligman, Steen, Park & Peterson, 2005). Through analyzing peak experience in a constructed interview, FFI aims to enhance motivation and performance through recognizing personal strengths and virtues and , necessary conditions for top performance. It is hypothesized that FFI heightens self-efficacy, facilitate learning and have positive effect on mood and bonding between interviewee and interviewer. It is further hypothesized that individuals' Attachment Style (Bowlby, 1987) moderates these effects. Two studies were conducted to assess FFI's influence: In Study 1 (N=262) a one-way ANOVA showed that participants in FFI condition (interviewed by trained research assistants) reported higher positive emotions than participants in a control interview and no-treatment participants, who reported the lowest level of positive emotions. This effect interacted with attachment style, so that Avoidant individuals did not show the positive effect on emotions. Participants in the FFI condition also reported higher perception of learning. In study 2 (N=132), participants in FFI condition (interviewed by fellow-participants) expressed higher liking and appreciation for their interviewers; reported higher level of satisfaction with

the process; indicated more personal strengths; listed more possible actions they can perform in order to achieve a personal goal and higher self-efficacy regarding their belief in their ability to achieve their goals – compared with participants in a Feedback condition. Practical implications of the finding will be discussed.

#### G16

**THE PARADOX OF THE HPV VACCINE: HOW TO TARGET SEXUALLY INACTIVE WOMEN FOR PROTECTION AGAINST AN STI** Claire Baxter<sup>1</sup>, Paula Barata<sup>1</sup>; <sup>1</sup>University of Guelph – Since the introduction of the HPV vaccine, uptake has been lower than expected and has met significant barriers. Lack of sexual experience predicts resistance to the vaccine; however, the vaccine is most efficacious before the onset of sexual activity. It is possible that sexually inactive women do not perceive HPV vaccination messages to be directed at them. The purpose of this study was to measure the effect of a targeted educational message on the intentions of sexually inactive women. Participants were 109 undergraduates who completed an online survey; each participant was randomly assigned to one of three conditions. The experimental conditions manipulated the type of information provided on HPV and the vaccine: general (minimal information), detailed (emphasized sexual transmission of HPV), or targeted (emphasized the benefit to sexually inactive women). Experimental conditions were successful in increasing predicted components of HPV knowledge. Overall, an increase in information was related to an increase in intention to receive the HPV vaccine. Comparisons between the general and targeted information conditions revealed a significant interaction, such that sexually inactive women intended to receive the vaccine more in the targeted information condition than the general information condition, whereas intentions of sexually active women were not affected. Most importantly, intentions of sexually inactive women rose from not intending to intending to receive the vaccine in the targeted condition ( $p < .05$ ). These results suggest that targeted educational material may help to increase the number of inoculations in sexually inactive women, while not decreasing the intentions of sexually active women.

#### G17

**UNCERTAINTY IN EYEWITNESSES' MEMORY JUDGMENTS: VARIATIONS OF TASK DIFFICULTY** Jens Hinrich Hellmann<sup>1</sup>, Jonas H. Rees<sup>2</sup>; <sup>1</sup>Jacobs University Bremen, Germany, <sup>2</sup>Bielefeld University, Germany – Observers often judge the reliability of eyewitness testimony based on the eyewitnesses' apparent certainty (vs. uncertainty) in the accuracy of their memory. One potential source of uncertainty can be the perceived difficulty of a task. For eyewitnesses, it is often difficult to answer specific questions about a witnessed incident. We investigated whether the difficulty of questions in eyewitness interviews can profoundly affect eyewitnesses' mnemonic certainty, and whether this difficulty can even have an impact on more general judgments. We asked German participants questions about a video that was extensively covered by the German media and a topic of much public debate at that time. We pilot tested our questions regarding their difficulty. Participants rated the vividness of their memory for a witnessed event as worse after answering more difficult (as compared to easy) questions. Importantly, those participants who answered only difficult (vs. easy) questions reported less interest in current political events, probably using this explanation to justify their subjectively incomplete memory. Participants who were asked a mix of easy and difficult questions reported to have more vivid and complete memories for the witnessed event than participants who were asked the difficult questions only. These findings have implications for interrogation procedures: They suggest that interrogators should add easy questions (even when the answers to these are not of interest) to the list if difficult questions have to be asked. Thus, uncertainty in eyewitnesses could be elicited to a lesser extent in an already uncomfortable situation.

#### G18

**DISCERNING PROCESSES IN COLLEGE DRINKING: THE NORM-BEHAVIOR ASSOCIATION OVER TIME USING RETROSPECTIVE & DAILY DIARY MEASURES** Jerry Cullum<sup>1</sup>, Steve Armeli<sup>2</sup>, Tennen Howard<sup>1</sup>; <sup>1</sup>University of Connecticut, <sup>2</sup>Farleigh Dickenson University – Social-norm based interventions in college drinking are common, but show mixed efficacy. Although such interventions assume a passive social influence process, past research and theory suggest several alternative processes that may also contribute to the norm perception-drinking association over time (dissonance reduction, heuristic recall bias, selective affiliation). The goal of the present study was to examine the evidence for these various processes that may contribute to the norm perception-drinking behavior association, while also beginning to distinguish among some of these alternatives. Over a 3 year period, students ( $N = 574$ ) reported yearly on their drinking levels and perceptions of drinking norms, using conventional retrospective reports over a month period, and daily diary reports for 30 days. We investigated cross-lag longitudinal models using Structural Equation Modeling to test for evidence of social influence/alternative processes, and compared cross-lag effects across retrospective and daily aggregate models to determine the extent to which heuristic recall biases contribute to the norm-drinking association. Past drinking behavior consistently shaped changing perceptions of drinking norms across years. This effect was not attributable to heuristic biases during retrospection. Perceptions of social norms had a smaller and inconsistent affect on changing drinking behavior across years, although models ignoring this effect provided a less adequate fit of the data. These results suggest that much of the norm perception-drinking behavior association is driven by a dissonance reduction and/or selective affiliation process, and that social influence processes contribute less to this long-term association. Implications for interventions designed to reduce college drinking are discussed.

#### G19

**PERCEPTION OF COMMUNAL GOALS AND STEM CAREER INTEREST** Emily K. Clark<sup>1</sup>, Amanda B. Diekman<sup>1</sup>; <sup>1</sup>Miami University – Despite women's increasing presence in traditionally male-dominated careers such as law and medicine, women continue to be underrepresented in science, technology, engineering, and mathematics (STEM; US Department of Labor, 2007). An important distinction may be that STEM is perceived to inhibit communal goals, such as working with or helping others. Communion remains a central aspect of the female gender role (Diekman & Eagly, 2008), and thus to the extent that STEM is perceived as inhibiting communal goals, women will continue to opt out of these careers. The current research examines the consequences of the perception that STEM careers inhibit communal goals. Participants read about a typical day for a scientist in which the scientist's tasks were framed either agentically or communally. They then reported their endorsement of agentic and communal goals, and provided their attitudes toward and perceptions of the career. Among participants who read about an agentically-framed career (representing the stereotypical perception of STEM), endorsement of communal goals was negatively related to positivity toward the career, interest in the career, and predicted personal success and enjoyment. However, in the communally-framed career condition, communal goal endorsement was unrelated to these outcomes. Additionally, participants predicted that women would enjoy the communally-framed career more than the agentically-framed career, while there was no effect of framing on predicted enjoyment for men. This research suggests that to encourage women's presence in STEM careers, it may be important to consider congruity between goals important to women and perceptions of career goal fulfillment.

**G20**

**THE INFLUENCE OF POLITICAL IDEOLOGY, VOTER AND CANDIDATE CHARACTERISTICS ON POLITICAL PERCEPTIONS** Jennifer Ma<sup>1</sup>, Shari Silver<sup>1</sup>, Larissa Lasko<sup>1</sup>, Michele Tugade<sup>1</sup>; <sup>1</sup>Vassar College – The 2008 Presidential election was exciting in part because of the possibility of electing an historic first (African-American or woman). Some political strategists suggested that Sarah Palin was selected to attract voters unhappy that Hillary Clinton was out of the race. The current study explored factors that may influence perceptions of political candidates. Eighty-three undergraduates rated Barack Obama, Joe Biden, John McCain, Palin, Clinton, and eight fictional candidates varying in gender, race, and policy stances on a series of characteristics. They also completed various individual difference measures. For the real candidates, participants rated Democrats and presidential candidates more positively than Republicans and vice-presidential candidates, with Palin rated least positively. For the hypothetical candidates, those with liberal policy stances were perceived more positively than those with conservative stances. Significant gender x party and gender x race interactions were also found. As expected, participants' own political orientation influenced perceptions of both the real and hypothetical candidates. And while participants' gender and expressed sexism and racism influenced these perceptions, most effects disappeared when participants' ideology was controlled, demonstrating the dominant role of ideology. However, women perceived Palin less positively than men did, even when participants' ideology was controlled. With the exception of Palin, the real candidates were perceived more positively than their hypothetical counterparts. Palin was perceived less positively than her counterpart (who among conservative candidates was perceived the most positively). These data suggest that one female candidate cannot be substituted for another without regard for other factors such as her political ideology.

**G21**

**SUPPORT FOR GOVERNMENTAL SPENDING ON ENVIRONMENTAL ISSUES DEPENDS ON SOCIAL NORMS, SELF-EFFICACY, AND THE WILLINGNESS TO MAKE TRADE-OFFS** Amanda Mahaffey<sup>1</sup>; <sup>1</sup>Lisbon University Institute, Center for Social Research and Intervention – According to polls conducted by the Yale Center of Environmental Law and Policy, 63% of Americans believe that the U.S. "is in as much danger from environmental hazards, such as air pollution and global warming, as it is from terrorists." In fact, 83% now believe that global warming is a serious problem. If this is so, then why don't we, as citizens, do more to protect ourselves and our environment from such dangers? Using archival methods with both the panel and time-series survey data collected by the American National Election Study during the 2008 election season, we find that the answer may lie in social norms for community and political involvement, self-efficacy for influencing the government, and the willingness to prioritize the environment over and above general standard of living. These nation-wide data show that those who believe that others are socially and politically involved are more likely to become involved themselves. And those who have greater self-efficacy for their role in government and its processes are more likely to support increased governmental spending on environmental issues, even if this means trade-offs in standard of living. These findings help us to understand determinants of involvement in issues of environmental sustainability so that we may further study ways of influencing those determinants with the goal of promoting social change.

**G22**

**SOCIO-INTERACTIVE PRACTICES AND PERSONALITY IN ADULT LEARNERS OF ENGLISH WITH LITTLE FORMAL EDUCATION** Nairan Ramirez-Esparza<sup>1</sup>, Kathryn Harris<sup>2</sup>, John Hellermann<sup>2</sup>, Clemence Richards<sup>2</sup>, Patricia Kuhl<sup>1</sup>, Steve Reder<sup>2</sup>; <sup>1</sup>Labs, University of Washington, <sup>2</sup>Portland State University – Previous research has shown that the amount of education immigrant adults receive in their native languages is associated with learning English as a second language in a formal setting. Drawing on a

large corpus of video recorded classroom data, the goal of this study was to understand the processes and mechanisms associated with learning in individuals who have little or no formal education in their home countries. In order to accomplish this goal we a) observed the socio-interactive behaviors and the expression of personality in learners who attended classes to learn English as a second language, b) measured how individuals who had little formal education in their home countries (low education learners) differ from individuals who had formal education (high education learners), and c) analyzed the relation between socio-interactive behaviors and personality with literacy test scores. The results showed that low education learners behaved differently in the classroom than high education learners (e.g., low education learners were more introverted than high education learners). Socio-interactive behaviors and personality were related to literacy test scores (e.g., the more introverted learners expressed the lower their test scores). Implications of educational background on learning are discussed, as well as the limitations from this study.

**G23**

**THE EFFECTS OF POSITIVE MOOD AND SHAME ON DRINKING IN A JAPANESE SAMPLE** Staci Wendt<sup>1</sup>, Cynthia Mohr<sup>1</sup>, Mo Wang<sup>2</sup>, Songqi Liu<sup>2</sup>; <sup>1</sup>Portland State University, <sup>2</sup>University of Maryland – Recent research has documented a dramatic increase in alcohol consumption among the Japanese (e.g. Milne, 2003; WHO, 2004). Specifically, there is a greater increase of alcohol use among women, compared to men (Osaki et al., 2005). A recent study showed that Japanese college students were reporting drinking to cope behavior (DTC; Yeh et al., 2001) which has been linked to the development of alcohol-related problems (Cooper, 1994). Furthermore, college students are at a unique developmental time period where habits developed in college, such as DTC, become increasingly difficult to alter (Frone, 2003). Despite the increase in consumption and preliminary reports of DTC behavior, research investigating the antecedents of drinking is still somewhat limited. Of specific interest to this population may be drinking in response to shame, as Japanese culture has been characterized as shame-based, compared to guilt-based Western cultures (Benedict, 1946). The current study investigated the buffering effects of positive mood on shame-related drinking in multiple contexts, building upon the Mohr et al. (2008) finding demonstrating a positive mood buffer on shame-related drinking in solitary contexts among U.S. college students. Current results showed that positive mood significantly buffered the effect of shame when drinking away from home ( $b = -.48, p < .001$ ), but not in the solitary, or at home, context ( $b = .08, p > .05$ ). Further, gender was a significant between-person moderator for the positive mood buffer on shame when drinking away ( $b = -.39, p < .001$ ). Findings will be discussed in view of Hull's self-awareness model (1981), the buffering hypothesis (Fredrickson et al., 2000) and shame literature.

**G24**

**EXPLORING THE FACTORS STIMULATING THE REPORT OF RELIGIOUS, RACIAL OR ETHNIC DISCRIMINATION** Alejandra Alarcon Henriquez<sup>1</sup>; <sup>1</sup>Université Libre de Bruxelles – Ethnic discrimination against immigrants and their descendants is a major problem on the field of employment. The consequences are higher unemployment rates, precarious employments and lower wages, which contribute greatly to the existing inequalities between "nationals" and "non nationals" (International Labour Organization, 2007). The elaboration of antidiscrimination laws by several European governments is an important step in the struggle against inequalities. Laws could be considered as voice opportunities provided by the institutions for those who feel unsatisfied with the system (Hirschman, 1970). Recent reports show that these voice strategies in an attempt to improve the system from within are underused by minority group members and encourage EU governments to tackle the situation (European Union Agency for Fundamental Rights, 2009). In the following study, we investigate under which conditions minority group members do report discrimination and/ or decide to use legal tools to fight against religious, ethnic or racial discrimination. We interviewed 33 minority group members that actually did report the discrimination they

have experienced to organisms challenging discrimination in Belgium (semi-directing interviews). One of the discussed results show that high status minority group members with high levels of identification with the superordinate group are more inclined to use legal and normative strategies to struggle against discrimination than low status minority group members with low levels of identification with the superordinate group. We interpret these findings *inter alia* in the framework of Simon and Klandermans' Politicised Collective Identity model (2001).

### G25

**INTERPERSONAL CONFLICTS ON THE JOB AND NURSES' ALCOHOL CONSUMPTION** Laurie M. Jacobs<sup>1</sup>, Cynthia D. Mohr<sup>1</sup>, Robert R. Sinclair<sup>2</sup>, Robert R. Wright<sup>1</sup>, Debi Brannan<sup>1</sup>; <sup>1</sup>Portland State University, <sup>2</sup>Clemson University – In response to stressful situations, in which events or experiences may provoke negative emotion, alcohol consumption may serve to reduce distress in accordance with the tension-reduction hypothesis. In addition to the potential effects of other stressors, negative interpersonal experiences seem to have a particularly strong impact on the individuals who experience them (e.g. Rook, 1998). As a group, nurses may experience high levels of stress because of the nature of nursing work, and may therefore be a good population in which to study this phenomenon. Nurses are exposed to patients and patients' families who may be under stress because of their health situations. This provides nurses with many opportunities to experience negative interpersonal interactions or conflicts with patients, patients' families, or coworkers during their work lives, which may lead to potentially unhealthy consequences such as drinking to cope. Each week for 12 weeks, 142 registered nurses (94% female) completed a web-based survey that included questions about the most negative interpersonal interaction or conflict at work that week and about their drinking behavior. HLM analyses revealed that nurses' ratings of the stressfulness and undesirability of the week's most negative at-work interpersonal interaction were both positively associated with the maximum number of drinks they consumed on any one occasion during that week. In other words, in weeks when nurses experienced a more undesirable or stressful conflict, their maximum level of alcohol consumption tended to be higher. Results are contextualized in the literature on interpersonal conflicts and tension-reduction drinking.

### G26

**URBAN DISTRICT IDENTITY AS A COMMON INGROUP IDENTITY AND THE DIFFERENT ROLE OF INGROUP PROTOTYPICALITY FOR MINORITY AND MAJORITY SUBGROUPS.** Elze Ufkes<sup>1</sup>, Sabine Otten<sup>1</sup>, Karen van der Zee<sup>1</sup>, Ellen Giebels<sup>2</sup>; <sup>1</sup>University of Groningen, <sup>2</sup>University of Twente – In a multi-cultural neighborhood context, this study examines how identification with a superordinate identity (urban districts) influences residents' attitudes towards other ethnic groups. Identification with a superordinate identity can lead to more positive attitudes towards members of other subgroups (Common Ingroup Identity Model; Gaertner & Dovidio, 2000). Additional research shows that when members of a subgroup perceive their group as highly prototypical for the common ingroup identity, the benefits of identification with a superordinate group are hampered (Mummendey & Wenzel, 2004). Past research mainly focused on situations with same sized groups and not on minority versus majority groups. However, in many real-life settings, subgroups within superordinate identities do not have the same size. And, as recently suggested but not investigated, members of minority groups may especially have difficulties in perceiving their subgroup as prototypical for the superordinate identity (Dovidio, Gaertner, & Saguy, 2008; Wenzel, Mummendey, & Waldzus, 2008). In the current study we hypothesize and show that for minority group members, perceived ingroup prototypicality may actually be beneficial. Forty-two residents with an ethnic minority and 52 residents with an ethnic majority (N=94) background completed our questionnaire. The hypothesized 3-way interaction effect of minority vs. majority status, identification and ingroup prototypicality on outgroup attitudes was confirmed. Indeed, for majority members there was a positive relation between identification and outgroup attitudes, when they perceive their ingroup as less prototypical. Conversely,

for minority members there was a positive relation between identification and outgroup attitudes, when they perceive their ingroup as more prototypical.

### G27

**DAILY MOOD-DRINKING SLOPES PREDICTING ONE YEAR ALCOHOL-RELATED OUTCOMES** Cynthia Mohr<sup>1</sup>, Debi Brannan<sup>1</sup>, Staci Wendt<sup>1</sup>, Laurie Jacobs<sup>1</sup>, Robert Wright<sup>1</sup>; <sup>1</sup>Portland State University – Individuals drink to enhance positive experiences as well as cope with negative experiences, and these patterns have been associated with distinct contexts (social vs. solitary; Cooper et al., 1995). Those who drink to enhance positive experiences demonstrate greater alcohol use, similar to those who drink to cope. However, unlike those who drink to enhance, those who drink to cope are more likely to have drinking problems. Recent research using daily process methodology has afforded the opportunity to examine how everyday experiences predict subsequent increases in consumption. The current study employed a daily electronic interviewer with three daily assessments of drinking and mood to examine within-person positive and negative mood-drinking relationships. Individual mood-drinking slopes were then examined as predictors of 12-month follow-up interview data showing drinking-related problems and drinking-to-cope motives. Forty-nine moderate-to-heavy drinking adults (24 women) from the local community rated their positive and negative moods and alcohol consumption thrice daily (morning, afternoon, and evening) on a handheld electronic interviewer for 30 days. Twelve months later, participants completed an additional phone interview. Solitary, negative mood-related drinking was significantly correlated with drinking-to-cope motives ( $r = .50, p < .01$ ) and alcohol problems ( $r = .37, p < .05$ ) at the 12-month follow-up. The positive mood, solitary drinking association was inversely related to drinking to cope motives 12 months later ( $r = -.33, p < .05$ ). These results support motivational models of alcohol consumption that specify drinking in response to positive or negative experiences as psychologically distinct behaviors.

### G28

**THE DIFFERENTIAL EFFECT OF INTERVIEW-INTERVIEWEE CULTURE ON NONVERBAL CORRELATES OF DECEPTION** Ruth Miles<sup>1</sup>, Paul Taylor<sup>1</sup>, John Dixon<sup>1</sup>; <sup>1</sup>University of Lancaster – Existing studies of non-verbal correlates of deception tend to rely on manual coding of suspects' behavior and treat this behavior as independent from the behavior of the interviewer. In this study we examined the head, arm and body movements of interviewers and mock suspects under conditions of intra- and inter-cultural backgrounds. Our measures were taken in real time using attached sensors, which enabled an analysis of both overall movement and mimicry in movement over time. Participants (N = 22) of South Asian and White British origin experienced a structured (negotiation task) or unstructured (coffee shop chat) dyadic interaction before being interviewed by a confederate of the same or different cultural background. At interview participants told the truth about the interaction they experienced, and fabricated an account of the interaction that they did not experience. A series of mixed ANOVAs revealed: i) a main effect of head movement, with more movement occurring in fabricated accounts; and, ii) an interaction effect for arm movement, with more movement associated with deception but only within the intra-culture interactions. Analyses using dynamic time warping methods revealed sharp changes in the extent of mimicry across genuine and fabricated accounts, but these differences were not uniform across participants. Our results have implications for understanding cultural differences in nonverbal behavior and the potential misunderstandings that may arise from such differences.

### G29

**WHAT IS THEIR MOTIVATION? EXAMINING THE CHILDREN'S ENVIRONMENTAL MOTIVES SCALE** Coral M. Bruni<sup>1</sup>, Randie C. Chance<sup>1</sup>, P. Wesley Schultz<sup>1</sup>; <sup>1</sup>California State University, San Marcos – Presently, few scales have been created looking at children and their natural connections. The previously established Environmental Motives Scale (EMS;

Schultz, 2001) is currently being adapted for use with children. Preliminary research has found the new Children's Environmental Motives Scale (CEMS) is a valid and reliable measure for use with children (Chance, Bruni, & Schultz, 2008). Yet, little is known about the validity and reliability of established models. This current study examines data from the last two waves of a longitudinal study on the development of children's environmental attitudes. Specifically, this study examines the convergent validity using the Children's New Environmental Paradigm (Manoli, Johnson, & Dunlap, 2007) and the Inclusion of Self and Nature scale (Schultz, 2001), as well as the test-retest reliability of the CEMS. Results from this study provide strong support for the appropriateness of the CEMS for use with children. Reliability was assessed using Cronbach's alpha for the total scale, and scores ranged from .79 to .85. Test-retest analysis was assessed over a period of one year and was significant for the total scale. In addition, correlations between the CEMS and other measures of environmental concepts were examined. This research not only supports that this scale is appropriate for use by children, but also supplies future researchers with an instrument that can be administered across a larger population.

### G30

#### THE SOCIAL CONTAGION OF NEGATIVE AND POSITIVE WORK-HOME PERCEPTIONS AMONG EMPLOYEES, THEIR SPOUSES AND THEIR MANAGERS

E. Layne Paddock<sup>1</sup>, Gregory D. Webster<sup>2</sup>; <sup>1</sup>Singapore Management University, <sup>2</sup>University of Florida – A recent avenue of research on work and family domains relates to the contagion – termed crossover – of both negative (conflict) and positive (enrichment) perceptions among closely related individuals in the same domain. Existing research focuses on crossover of negative perceptions between spouses (e.g., Westman, Vinokur, Hamilton, & Roziner, 2004). However, given the increasing amount of time individuals are spending at work, work associates' perceptions may also impact employees' delicate balance of work and home domains. Here we include others from work (employees' managers) and home (employees' spouses), using triadic data to better understand how, over time, crossover effects occur. Specifically, we explore how employees' managers' home→work perceptions impact the relationships between employees' and their spouses' work-family perceptions. We use a longitudinal design that includes negative and positive crossover, adding to the scant research on positive crossover. Employed sets of spouses (n = 44) participated by each completing two surveys spaced two weeks apart and by each having their supervisors complete a one-time survey. Results from a series of multi-level random coefficient models suggest managers' positive and negative work-family perceptions moderated employees' positive and negative work-family perceptions, albeit in structurally different ways. Specifically, for positive spillover the extent of within-couple relationships are moderated by managers' positive perceptions, and for negative spillover managers' negative perceptions moderate employees' mean negative perceptions. As expected, results show crossover occurs between close others at work (manager-employee) and at home (employee-spouse) and provide initial evidence of the role of positive crossover in fostering inter-domain well-being.

### G31

#### DOES CORRESPONDENCE BETWEEN PARENTS' AND CHILDREN'S WEIGHT-RELATED ATTITUDES AND BEHAVIORS CONTINUE INTO THE COLLEGE YEARS?

Sarah Novak<sup>1</sup>, C. Veronica Smith<sup>2</sup>; <sup>1</sup>Hofstra University, <sup>2</sup>University of Delaware – Research examining parents' role in shaping children's weight-based attitudes and behaviors is mixed. Most of this work has focused on very young children in order to capture emergent beliefs and behaviors (e.g., Davison, Francis & Birch, 2005; Keery, Eisenberg, Boutelle, Neumark-Sztainer, & Story, 2006). Though a few studies have incorporated fathers' perspectives, most have focused on transmission from mother to child. Our investigation sought to determine whether correspondence with either parent continued to be evident among college-aged children. Participants were 294 students and their biological parents. Each member of the triad individually completed a

survey of weight-related attitudes and behaviors, including weight status, body dissatisfaction, appearance esteem, symptoms of eating disorders, beliefs about the controllability of weight, as well as diet and exercise habits. The results underscore the importance of including both parents' attitudes and examining same-sex parent and opposite-sex parent similarities. Though parents and children generally resembled one another on weight status, the strongest links were unexpectedly found between mothers and sons. Results also indicated that parent-child resemblance is clear for some weight-related habits, including exercise and unhealthy dieting practices, and the general perceptions that weight is controllable. However, correspondence was not found for some of the more internally focused attitudes, like appearance esteem. Given the unfortunate, though common, tendency to blame parents for children's weight concerns, examining the continued associations between parents and children can help researchers learn more about the causes and effects of these problems as children make the transition into independence and adulthood.

### G32

#### THE IMPACT OF QUALITY OF VIEW ON THE CALIBRATION OF CONFIDENCE AND IDENTIFICATION ACCURACY FOR SIMULTANEOUS AND SEQUENTIAL LINEUPS

Jamal K. Mansour<sup>1</sup>, Jennifer B. Beaudry<sup>2</sup>, Rod C. L. Lindsay<sup>1</sup>, Jennifer Wood<sup>1</sup>, Teresa Mateus<sup>1</sup>, Kate MacLennan<sup>1</sup>, Michelle I. Bertrand<sup>1</sup>, Natalie Kalmet<sup>1</sup>, Elisabeth Whaley<sup>1</sup>; <sup>1</sup>Queen's University, <sup>2</sup>University of South Carolina at Beaufort – An eyewitness' confidence in their lineup identification is used in court to evaluate the credibility of the identification. However, the correlation between confidence and accuracy is only moderate ( $r = \sim .30$ ). Calibration is the correspondence between confidence in a lineup decision and the probability that the decision is correct. Brewer and Wells (2006) showed calibration better represents variability in confidence across decisions than a confidence-accuracy correlation and that under variable situational conditions, calibration can be good even while the confidence-accuracy correlation is modest. To expand this research, we examined calibration and the confidence-accuracy correlation with variable quality views of the "criminal" and different lineups. Participants in four studies (Ns = 20 - 38) completed 24 trials; they watched a staged crime video, indicated whether and where the "criminal" was in a simultaneous or sequential lineup, and rated their decision confidence. In two studies, quality of face view was manipulated via a stocking on the "criminal's" face and in two studies, hat and sunglasses presence was manipulated. Participants viewed 25s/large videos (good video view) or 3s/small videos (poor video view) of the "crimes". Calibration was excellent across and within viewing conditions, though the confidence-accuracy correlation ranged from .34 to .42. Calibration was equivalent for the hat/sunglasses manipulations but for the stocking disguise, calibration was better when video exposure was good than poor. Participants were overconfident when they viewed simultaneous lineups but well calibrated with sequential lineups. The results support calibration for representing the confidence-accuracy relationship across different conditions.

### G33

#### FREQUENCY OF SOCIAL COMPARISON AS A PREDICTOR OF WORK-FAMILY CONFLICT

Elizabeth Poposki<sup>1</sup>, Alyssa Friede Westring<sup>2</sup>, Jessica Keeney<sup>1</sup>, Ruchi Sinha<sup>1</sup>, Ann Marie Ryan<sup>1</sup>; <sup>1</sup>Michigan State University, <sup>2</sup>DePaul University – Social comparison is the process by which individuals desire, seek out, and interpret information about others in relation to the self when objective information with which to form self-appraisals is lacking (Festinger, 1954; Wood, 1996). In this paper we proposed that social comparison would play a role in individuals' perceptions of work-family conflict (WFC) due to the socially constructed nature of both work and family and the fact that work-family conflict represents a stressor and therefore makes individuals more likely to desire comparison information (Katz & Kahn, 1966; Taylor, Buunk, & Aspinwall, 1990). WFC is a type of role conflict wherein participation in one role makes participation in another role more difficult, and has been shown to affect impor-

tant outcomes for individuals, families, and organizations (e.g., depression, alcoholism, and turnover; Eby et al., 2005). Because work represents a competitive environment (Greenberg et al., 2007), others are likely to be self-presenting and individuals attempting to socially compare are more likely to encounter unrealistically positive information about others' WFC status. Additionally, the desire for self-evaluation may result in upward comparisons (Wood, Michela, & Giordano, 2000). Thus, we hypothesized that individuals making more frequent social comparisons with respect to WFC would perceive higher levels of WFC, controlling for typical predictors of WFC (hours spent at work and number of children). In a sample of 1275 working adults, we found support for this hypothesis,  $\beta = .09$ ,  $F(3,1273) = 66.76$ ,  $p < .01$ ,  $R^2 = .14$ ,  $\Delta R^2 = .02$ ,  $p < .01$ .

### G34

#### THE EARLY DETECTION OF DEPRESSION FROM SOCIAL NETWORKING SITES: A WORD-USE ANALYSIS

Shannon E. Holleran<sup>1</sup>, Matthias R. Mehl<sup>1</sup>; <sup>1</sup>University of Arizona – Depression has a high prevalence among college students. Because it is a highly private (i.e. experiential) and socially stigmatized mental illness, it often goes undetected in daily life. The basic research question behind this line of research is how students' textual postings on their social networking websites can be used for the early detection of depression. We present findings from three studies linking aspects of participants' natural online word use to their reported (sub-clinical) levels of depression. In Study 1, a lab experiment, 57 participants wrote about themselves in a simulated blog. In Study 2, a real-world extension of Study 1, 204 participants provided their actual Myspace profiles. Study 3, finally, sought to replicate Study 2 using the Facebook profiles of 126 participants. Participants' natural language use was analyzed using Linguistic Inquiry and Word Count (LIWC) program. Across all three studies, aspects of participants' word use were related to their reported levels of depression (i.e. scores on the Beck Depression Inventory). Using less positive emotion words (e.g. happy, good), more fatigue-related words (e.g. tired, sleepy), and more swear words were related to increased levels of depression. Together, the results suggest that the language people use online in social networking sites provides a window into their emotional well-being and can potentially be used for the early detection of depression.

### G35

#### THE PEAK/END RULE IN PROSPECTIVE JUDGMENTS OF LIFE QUALITY

Neil Lutsky<sup>1</sup>, Annelise M. Lawson<sup>1</sup>; <sup>1</sup>Carleton College – Do prospective judgments of the quality of a life undervalue the addition of positive but relatively less pleasant years to that life? This question is important in light of the use of proxy advance directives, where individuals are called upon to make medical decisions for patients unable to do so themselves. Diener, Wirtz, and Oishi (2001) demonstrated that adding positive but relatively less pleasant years to a pleasant life resulted in lower life quality evaluations when lives were assessed retrospectively. But is this also true of the prospective judgments proxy decision-makers may be called upon to make? To assess this, 46 participants evaluated a fictitious character's happy life ending either at age 30 or at age 35 with 5 additional but relatively less happy years (using materials similar to those of Diener, Wirtz, & Oishi). Results documented the same retrospective effect reported by Diener, Wirtz, and Oishi. In addition, the mean quality rating of the shorter life was significantly higher than that of the longer life in the prospective condition,  $F(1, 44) = 24.47$ ,  $p < .05$ . This finding generalizes the effect to the substituted prospective judgments proxies may be called upon to make in a medical context.

### G36

#### DISHONEST DEED, CLEAR CONSCIENCE: SELF-PRESERVATION THROUGH MORAL DISENGAGEMENT AND MOTIVATED FORGETTING

Lisa L. Shu<sup>1</sup>, Francesca Gino<sup>2</sup>, Max H. Bazerman<sup>1</sup>; <sup>1</sup>Harvard Business School, Harvard University, <sup>2</sup>Kenan-Flagler Business School, University of North Carolina at Chapel Hill – People routinely engage in dishonest acts without feeling guilty about their behavior. When and why does this occur? Across four studies, people justified their dishonest deeds through moral disengagement and exhibited motivated forgetting of information that might otherwise limit their dishonesty. Using hypothetical scenarios (Studies 1 and 2) and real tasks involving the opportunity to cheat (Studies 3 and 4), we find that dishonest behavior increased moral disengagement and motivated forgetting of moral rules. Such changes did not occur in the case of honest behavior or consideration of the behavior of others. In addition, increasing moral saliency by having participants read or sign an honor code significantly reduced or eliminated unethical behavior. While dishonest behavior motivated moral leniency and led to strategic forgetting of moral rules, honest behavior motivated moral stringency and diligent recollection of moral rules.

## Attitudes/Persuasion

### G37

#### THE EFFECT OF EMBODIED SOCIAL COGNITION, MESSAGE STRENGTH, AND MESSAGE FRAMING ON COUNTER-ATTITUDINAL PERSUASION

Bryan D. Poole<sup>1</sup>, William E. Langston<sup>1</sup>, Greg W. Schmidt<sup>1</sup>; <sup>1</sup>Middle Tennessee State University – Previous research has shown how receptivity of persuasive messages is affected when message strength (strong vs. weak) and framing (positive vs. negative) are controlled, and when embodied cognition (e.g., overt head movement) is manipulated. The present study was designed to entwine these three variables for the first time to further examine what role embodied cognition plays in the persuasion literature. We tested the hypothesis that head movement interacts with strength and framing by selectively influencing the effects of one or more, but not all, levels of these variables. While nodding, shaking, or not moving their heads, 82 participants listened to four counterattitudinal messages, each being composed of a different combination of strength and framing, and then rated the degree to which they agreed or disagreed with each message. Nodding participants experienced attitude change when they heard strong, negatively-framed messages, whereas participants who shook their heads while listening to the messages experienced attitude change when they heard strong, positively-framed messages. Our results suggest that head movement creates an expectation for message framing, and that when expectation and framing are inconsistent, increased attention toward and elaboration of the messages and subsequent attitude change occur. Therefore, embodied cognition may merely be a mechanism of expectancy change rather than a separate, novel route to understanding behavior.

### G38

#### EFFECTS OF GENDER-TARGETING IN PERSUASION: A MALE-TARGETED INVITATION LETTER TO A COLLEGE SUICIDE PREVENTION SCREENING

Kate Bentley<sup>1,2,3</sup>, Catherine A. Sanderson<sup>1</sup>, Ann P. Haas<sup>3</sup>; <sup>1</sup>Amherst College, <sup>2</sup>Massachusetts General Hospital Depression Clinical and Research Program, <sup>3</sup>American Foundation for Suicide Prevention – This research examines the effects of message targeting as a function of gender on individuals' responsiveness to persuasive messages. Specifically, this study compares response rate and characteristics of respondents in college students who receive a male-targeted invitation letter versus a generic invitation letter into a suicide prevention screening at two distinct institutions (Pittsburgh School of Medicine and Massachusetts Institute of Technology Graduate School). First, analyses revealed that when the generic invitation letter was used during two years at MIT, overall participation increased from 6.6% to 15.6%, but when the generic letter was changed to the male-targeted letter at Pittsburgh, participation decreased from

19.2% to 7.8%. Second, findings revealed that at Pittsburgh, respondents to the male-targeted invitation letter revealed lower depression scores than respondents to the generic letter, and male respondents to the male-targeted letter revealed higher eating behaviors scores than male respondents to the generic letter. At MIT, second-year respondents to the generic letter revealed higher depression scores than first-year respondents to the generic letter, and second-year male respondents revealed lower eating behaviors scores than first-year male respondents. Finally, only when the generic letter was used during both years at MIT, results revealed a significant increase in the overall number of students and the percentage of male students who began counseling. This study provides valuable information for future research on maximizing the persuasiveness of health messages by framing according to characteristics of the target audience.

### G39

**THE DYADIC AND INTERACTIVE NATURES OF CONDOM NEGOTIATION: COUNTERATTACKS TOWARD CONDOM USE PERSUASION AND RESISTANCE AGAINST THE COUNTERATTACKS** Dongha Yi<sup>1</sup>, Inkyoung Ryo<sup>1</sup>, Taekyun Hur<sup>1</sup>; <sup>1</sup>Korea University – Condom use has been mainly investigated in terms of intra-personal factors, such as attitudes, intention, control, etc. Even though some studies of condom negotiation recently focused on interpersonal processes inevitable involved in condom use, the interpersonal processes did not include the nature of dyadic interaction. The present research proposed and investigated the dyadic and interactive responses in condom negotiation, such as one's reactions (counterattacks) toward the partner's condom use persuasion (Study 1) and the partner's resistance against the counterattacks (Study 2). In Study 1, 91 college students answered to open-ended questionnaires asking counterattack strategies toward the partner's condom use persuasion in order to nullify each of condom negotiation strategies such as responsibility, sex-rejection, etc. Through a content analysis, the counterattacks were categorized into several strategies: sex-rejection, responsibility, confidence, etc. Study 2 examined the secondary condom negotiation strategies when the first condom negotiation attempt was counterattacked (implying resistance against the counterattacks of Study 1). In a computer administrated experiment, 215 college students first selected a preferred condom negotiation strategy in a romantic relationship scenario, and then given the partner's reaction to nullify their first persuasion attempts, they were asked to write their response against it. The results found that strategy change, strategy resist and strategy give up were most frequently revealed at disease, sex-rejection, sexual satisfaction strategy. The analyses implicate that each condom negotiation strategy with partner has different effect on condom use behavior. These findings were discussed with regard to their implications in cultural variations and safe sex education.

### G40

**ONCE GUILTY, ALWAYS GUILTY? HOW ASSOCIATIVE STRENGTH MODERATES NEGATION EFFECTS** Lieke D.J. Curfs<sup>1</sup>, Rob W. Holland<sup>1</sup>, José H. Kerstholt<sup>2</sup>, Daniël H.J. Wigboldus<sup>1</sup>; <sup>1</sup>Behavioural Science Institute, Radboud University Nijmegen, The Netherlands, <sup>2</sup>TNO Human Factors, The Netherlands – What happens to an attitude when part of the information it is based on appears to be untrue? Previous research has shown that explicit attitudes can apply truth values whereas implicit attitudes cannot (Gawronski & Bodenhausen, 2006). This would thus result in a discrepancy between implicit and explicit attitudes. We predicted that associative strength moderates negation effects for implicit attitudes but not for explicit attitudes. That is, implicit attitudes are expected to be particularly immune to negation when they are based on strong mental representations. We tested this by presenting participants with a murder case in which a suspect is identified. Part of the incriminating information (i.e., the motive) was later withdrawn. Associative strength was manipulated by presenting the motive for the suspect either at the start or the end of the murder case. When information is presented at the start of attitude formation it will occupy a central position in the associative

network. Contrarily, when the information is presented at the end it will occupy a peripheral role in the associative network (e.g., Sedikes & Sowronski, 1993). On an explicit measure we found that attitudes changed in the direction of the negation; i.e., participants found the suspect less guilty after negation, independent of when the incriminating motive was presented. However, implicit attitudes only changed in the direction of the negation when the motive was presented at the end of the murder case. We conclude that the strength of the associative network moderates the effects of negation on implicit attitudes.

### G41

**PREDICTING EMOTIONAL REACTIVITY FROM THE NEGATIVITY BIAS** Pietri Evava<sup>1</sup>, Natalie Shook<sup>1</sup>, Russell Fazio<sup>2</sup>; <sup>1</sup>The Ohio State University, <sup>2</sup>Virginia Commonwealth University – When judging novel objects, people generally weigh resemblance to a negative more heavily than resemblance to a positive. However, there is variability in the extent to which individuals exhibit this negativity bias. The current study examined whether this individual difference relates to the emotional reactivity experienced in response to a stressful event. Participants first played the BeanFest game, in which they were presented with novel stimuli (beans varying in shape and speckles) and learned which were good versus bad on the basis of whether the beans increased or decreased their points when chosen. The participants then classified the game beans, and novel ones that varied in their resemblance to the game beans. The weighting bias was indexed by averaging the response to novel beans that were similar to both positive and negative beans and thus, shared positive and negative characteristics. Participants then completed a stressful anagram task, in which they had very limited time to solve difficult and insoluble anagrams. Participants' mood was measured before and after the task. Initial mood interacted with the weighting bias to predict final mood. Participants who began in a bad mood experienced little mood change, presumably because they were not affected by the task experience. For participants who initially were in a relatively good mood, however, the anagram task was impactful and the weighting bias predicted their final worsened mood state. Those with a stronger negativity bias demonstrated more emotional reactivity than those with a weaker bias.

### G42

**ON THE STRENGTHENING OF IMPLICITLY-FORMED ATTITUDES: WHEN USAGE INCREASES ACCESSIBILITY.** Richard V. Kendrick<sup>1</sup>, Michael A. Olson<sup>1</sup>; <sup>1</sup>University of Tennessee – Attitudes have been shown to form via non-conscious detection of covariations between novel objects and affectively laden stimuli (Olson & Fazio, 2001). Because individuals remain largely unaware of both their origins and influence, we argue that implicit attitudes resemble "gut intuitions" that can result in automatic albeit less consciously detectable activation upon exposure to the attitude object. But what effects do implicit attitudes have on subsequent processing of information concerning the attitude object, and how might these effects impact the implicitly formed attitude? We argue that implicitly formed attitudes affect the way that individuals perceive and make sense of novel, otherwise neutral pieces of information about the object in the same way that explicit attitudes have been shown to do. Moreover, we argue that the disambiguation process results in stronger, more accessible attitudes. After completing a well-established implicit learning procedure designed to create attitudes towards novel objects in the absence of awareness, participants were presented with ambiguous attribute information regarding the objects they were conditioned to like and dislike. Participants were then asked to rate the ambiguous information as to its quality and meaning. As evidence of a subsequent attitude-consistent processing bias, participants tended to disambiguate the information such that it conformed to the conditioned valence. What is more, participants who demonstrated disambiguation of information in an attitude consistent manner evidenced increased accessibility of the evaluatively-conditioned attitudes. Thus, experimentally-formed attitudes about which participants were unaware become stronger when used to disambiguate object-relevant information.

**G43****THE TIGHT-KNIT FAMILY (METAPHOR) AND POLITICAL ATTITUDE**

**CONSTRAINT** Brad Lippmann<sup>1</sup>, Grace Deason<sup>1</sup>, Jennifer Filson Moses<sup>1</sup>, Marti Hope Gonzales<sup>1</sup>, <sup>1</sup>University of Minnesota – Recent work on political attitude constraint (i.e., inter-attitudinal consistency) underscores the need to examine bottom-up psychological process in addition to top-down, elite-driven effects (Federico & Schneider, 2007; Jost, Federico, & Napier, 2008). Citizens' beliefs about the ideal family – likely derived through social learning and temperament – constitute an under-explored determinant of political preference. Extant research supports the contention (Lakoff, 2002) that conceptions of the family are related to policy preferences (Barker & Tinnick, 2006; Hartman, 2007; Deason, et al., 2008), that individuals spontaneously describe government-citizen relations using family metaphors (Deason, et al., 2008), and that this relationship is partially mediated by general views of morality (Deason, et al., 2008). The current analyses extend this line of research by elucidating the role of constraint in the relationship between notions of family, morality, and political issues. Specifically, holding constrained notions of the ideal family – as indicated by low standard deviations across items within respondents – is associated with greater value constraint, which in turn is associated with greater issue constraint. Importantly, a) the family-morality and morality-issue constraint relationships are obtained over and above the impact of indicators of participants' ability (political knowledge) and motivation (partisan extremity) to hold highly constrained issue preferences, b) neither relationship is moderated by political knowledge, and c) morality constraint only partially mediates the impact of family constraint on issue constraint, all of which suggest that notions of the family are more supplement than substitute for knowledge in political decision-making.

**G44****DISCREPANT IMPLICIT AND EXPLICIT MATERIALISM ATTITUDES ARE ASSOCIATED WITH BEHAVIORAL INHIBITION**

Jun Fukukura<sup>1</sup>, Melissa Ferguson<sup>1</sup>, Vivian Zayas<sup>1</sup>, <sup>1</sup>Cornell University – Attitudes toward material goods have traditionally been measured by using explicit scales such as the Material Values Scale (Richins & Dawson, 1992) and the Belk Materialism Scale (Belk, 1985). As with many explicit measures, these scales are somewhat transparent and responses may be influenced by social desirability pressures. We designed an implicit measure of materialism by creating a Single Category Implicit Association Test (SC-IAT, Karpinski & Steinman, 2006) using words associated with materialism (e.g., buy, luxury, shop). In Study 1, participants completed our SC-IAT in addition to the Material Values Scale and various well-being indices. We found that discrepant implicit and explicit attitudes toward materialism were correlated with higher behavioral inhibition and depression scores. In Study 2, we manipulated behavioral inhibition by having participants approach concepts that people high on behavioral inhibition avoid. We found that having participants approach these concepts led to less positive implicit attitudes toward materialism. Results are discussed in terms of the implications of discrepancies between implicit and explicit materialism attitudes and how behavioral inhibition may lead to embracing materialistic values.

**G45****IT'S SO EASY TO FALL IN LINE: A TWO-STAGE MODEL OF REACTANCE**

Randy Stein<sup>1</sup>, John Bargh<sup>1</sup>, Margaret Clark<sup>1</sup>, Patricia Chen<sup>2</sup>, <sup>1</sup>Yale University, <sup>2</sup>University of Michigan – We propose a two-stage model of influence in which acquiescence is the default response tendency to social influence attempts, and reactance is a secondary, effortful step. Experiment 1 replicated the classic reactance finding in which participants tend to disagree with an author who is too forceful in expressing his attitudes, even though they initially held the same attitude position as the author. However, as predicted by the model, this reactance effect was eliminated when participants were under a high cognitive load. Similarly, in Experiment 2, we conceptually replicated this effect by showing that, when asked to be contacted about a follow up study, participants are less likely

to comply when the request contains coercive language. When cognitively loaded, though, this reduction in compliance is eliminated. We review theoretical reasons for the primacy of compliance and conformity and discuss possible exceptions to the rule.

**G46****MORE IS BETTER THAN LESS: PEOPLE PREFER (X > Y) TO (Y < X) INTERGROUP COMPARISONS**

Vera Hoorens<sup>1</sup>, Eddy Van Avermaet<sup>1</sup>, <sup>1</sup>Katholieke Universiteit Leuven, Belgium – When people say that two groups (X and Y) differ, they may say that group X possesses a characteristic more than group Y or that group Y possesses the characteristic less than group X. These descriptions are logically equivalent: If that X possesses a characteristic more than Y, Y possesses it less than X. We examined whether (X > Y) and (Y < X) are also psychologically equivalent. In Study 1 (N = 302), participants filled out a survey consisting of comparative statements about men and women. They agreed more with (X > Y) statements than with (Y < X) statements, regardless of the valence of the characteristics being described or the stereotype-consistency of the statements. In Study 2 (N = 100), participants responded more favorably to a newspaper article comparing younger and older employees and including (X > Y) statements than to a newspaper article including (Y < X) statements. Participants in Study 3 (N = 216) freely listed gender differences. They listed more desirable characteristics when thinking of traits that one gender possessed more than the other than when thinking of traits that one gender possessed less than the other. Finally, Study 4 (N = 104) suggests that the relatively unfavorable responses to (Y < X) statements may be due to the particularly unfavorable view of at least one of the groups being compared than these statements communicate. Implications of the 'more is better than less' phenomenon for effective verbal communication, impression management and questionnaire design are discussed.

**G47****SOURCE EXPERTISE AND PERSUASION: THE EFFECTS OF PERCEIVED OPPOSITION OR SUPPORT ON MESSAGE SCRUTINY**

Jason K. Clark<sup>1</sup>, Abigail T. Evans<sup>1</sup>, Duane T. Wegener<sup>2</sup>, <sup>1</sup>University of Iowa, <sup>2</sup>Purdue University – The perceived expertise of a message source has been one of the most widely studied factors in the persuasion literature. Although source expertise has been shown to influence persuasion in a variety of different ways (see Briñol & Petty, 2009), relatively little research has explored how such perceptions might influence the amount of scrutiny given to persuasive messages. In the present research, we examined how the potential link between expertise and processing may be determined by whether a source opposes or supports the views of the message recipient. When messages are counterattitudinal, an expert source should motivate people to attend to information more carefully than an inexpert because of heightened concern that he/she will have success bringing about an unwanted policy. However, the relation between source expertise and source-related concern should be the opposite for proattitudinal appeals. In these situations, people should feel more concerned when an inexpert source is providing an appeal because he/she should be viewed as less likely to effectively argue this position and consequently, have less success than a source with more expertise. The findings of two studies supported these predictions. When messages were counterattitudinal, greater message scrutiny was observed when sources were high rather than low in expertise. However, when messages were proattitudinal, increased processing was found when source expertise was low as opposed to high. Furthermore, greater concern about the source's support or opposition of the message recipient was associated with increases in processing.

**G48****STRUCTURAL ATTITUDE WEAKNESS AND MOTIVATIONAL ATTITUDE STRENGTH: THE ROLE OF DOUBT IN SELECTIVE EXPOSURE**

Vanessa Sawicki<sup>1</sup>, Jason K. Clark<sup>2</sup>, Duane T. Wegener<sup>1</sup>, Leandre R. Fabrigar<sup>3</sup>; <sup>1</sup>Purdue University, <sup>2</sup>University of Iowa, <sup>3</sup>Queen's University – Strong attitudes are more predictive of behavior and information processing (Petty & Krosnick, 1995). In selective exposure to information, attitudes associated with strength-related features (e.g., importance, confidence) create preferences for proattitudinal information (Brannon, Tagler, & Eagly, 2007). However, when attitudes are weak (uncertain), people are predicted to seek out ways to increase attitude confidence (Chaiken, Liberman, & Eagly, 1989), and uncertainty leads people to seek out information only when that information is expected to increase confidence (Bohner, Rank, Reinhard, Einwiller, & Erb, 1998). This presents a paradox, because information perceived as most likely to increase confidence should be information that agrees with the existing attitude. Thus, under at least some circumstances, uncertainty rather than certainty should lead to greater selection of proattitudinal over counterattitudinal information. Participants reported their attitude, reported attitude confidence (Study 1) or completed a doubt priming manipulation (Study 2), and selected and read information supporting or opposing nuclear power. In both studies, centered regression analyses yielded a significant interaction between attitude and confidence. When relatively uncertain (1 SD below the mean of the confidence measure or in the doubt prime condition) people selected more pro- rather than counter-attitudinal information (a significant positive relation between attitude and information chosen). When relatively confident (1 SD above the mean of the confidence measure or in the confidence prime condition), the relation between attitude and information chosen was nonsignificant. At least in some cases, attitudes traditionally associated with weakness are capable of producing the effects typically associated with strong attitudes.

**G49****GENDER AND COMMUNICATION MODE EFFECTS ON PERSUASION**

Bradley M. Okdie<sup>1</sup>, Rosanna E. Guadagno<sup>1</sup>, Petia K. Petrova<sup>2</sup>; <sup>1</sup>The University of Alabama, <sup>2</sup>Dartmouth College – Men and women respond differently to persuasive attempts depending on whether the attempt occurs via computer-mediated communication (CMC) or face-to-face (FTF) (Guadagno & Cialdini, 2002; 2007). The present study investigated the extent to which communication mode and type of influence tactic affected participants' support for one of two charities in a 2 (communication mode: CMC vs. FTF) X 3 (influence condition: authority vs. consistency vs. control) between subjects design. Participants engaged in a discussion with a same-sex confederate to determine where the Psychology Department should donate funds. In the consistency condition, participants were asked to address envelopes for one of the two local charities under consideration for the donation. In this condition, the confederate presented arguments in favor of this same charity. In the authority condition, the confederate purported to be a graduate student. Participants then engaged in an interaction (FTF or CMC) with the confederate to decide which charity would receive the donation. Results indicated that there was an interaction between communication mode and influence condition such that the participants in the consistency condition reported greater willingness to volunteer for the charity advocated by the confederate but only when the interaction occurred FTF. Moreover, males in the authority condition were more confident in their decision when they interacted via CMC as opposed to FTF. This is consistent with past research demonstrating that social cues of the communicator are less influential in CMC and that gender and communication mode also impact persuasion.

**G50****THE RELATIONSHIP BETWEEN IMPLICIT & EXPLICIT ATTITUDES AND NON-VERBAL BEHAVIOR TOWARD LESBIANS AND STRAIGHT WOMEN**

Amanda Breen<sup>1</sup>, Andrew Karpinski<sup>1</sup>; <sup>1</sup>Temple University – We investigated the relationship between implicit and explicit attitudes and non-verbal behavior. One of the main goals of this study was to conceptually replicate McConnell & Leibold (2005) using the target group of lesbians and straight. We hypothesized that the implicit attitudes toward lesbians would predict non-verbal behavior during an interaction better than explicit attitudes toward lesbians. Forty-two heterosexual undergraduate women interacted with a confederate whom they were led to believe was either heterosexual or lesbian. This interaction was subsequently coded for various non-verbal behaviors including body openness and tension, facial and body expressiveness, and number of smiles and nods. Following this interaction, participants completed the Single Category Implicit Association Test (SC-IAT; Karpinski & Steinman, 2006) and the Implicit Association Test (IAT; Greenwald, McGhee, & Schwartz, 1998) to assess implicit associations with straight women and lesbians. In addition, participants also completed several explicit attitude measures including the Attitudes toward Lesbians Scale (ATLS; Herek, 1994) and the Index of Homophobia (IHP; Hudson & Ricketts, 1981). We found that participants had more positive implicit associations with straight women as compared to lesbians. However, using explicit attitude measures, we found that participants reported favorable attitudes toward lesbians. Surprisingly, we also found that participants' non-verbal behavior tended to be more positive during the interaction with the lesbian confederate than with the straight confederate. Finally, none of the implicit or explicit measures predicted non-verbal behavior during the interactions. Implications and directions for future research will also be discussed.

**G51****THE ENDORSEMENT OF ANTI-IMMIGRATION ATTITUDES AMONG IMMIGRANTS: SOCIAL TUNING FROM A SYSTEM JUSTIFICATION PERSPECTIVE**

Adam Johnson<sup>1</sup>; <sup>1</sup>CUNY Graduate Center & Brooklyn College – Affiliative social tuning effects indicate that individuals tend to "tune" their attitudes toward those of others to affirm interpersonal affiliations (Sinclair, Huntsinger, Skorinko & Hardin, 2005). However, when the attitudes of two salient close others are discrepant, tuning toward one individual may threaten affiliations with another. What factors influence social tuning outcomes when close others' attitudes are discrepant? Two experiments manipulated the salience of close others' discrepant immigration attitudes in order to examine the influence of system justification motives on the social tuning of immigration attitudes. In Experiment 1, participants wrote about two close others with discrepant immigration attitudes or the national debate on immigration and were then experimentally required to attack one of the attitude positions before filling out an immigration attitude scale. A significant three-way interaction indicated that compared to native-born citizens (n = 52), non-native immigrants (n = 36) were more likely to endorse Anti-Immigration attitudes when a close other's (vs. national) anti-immigration attitude was salient, especially if this Anti-Immigration position had been attacked. In Experiment 2, participants with salient Pro-Immigration close others completed measures of system justification (ESJ) and social dominance (SDO) while expecting to interact with a high (vs. low) affiliated Anti-Immigration confederate. Compared to citizens (n = 37), immigrants (n = 30) endorsed ideologically more conservative attitudes when the Anti-Immigration confederate was affiliated. Overall, when discrepant immigration attitudes were salient, immigrants (but not citizens) were more likely to tune toward (vs. away from) system-justifying anti-immigration attitudes if these attitudes were associated with affiliated others.

**G52****PRIMING CONSTRUAL LEVELS IMPACTS ATTITUDE ESTIMATES ON THE IAT**

**H. Anna Han** – Past research has demonstrated that estimates of attitude provided by Implicit Association Test (IAT; Greenwald et al., 1998) can be malleable depending on the context or perspective mindset (see Han et al., 2009). The current set of experiments extend this work by exploring how one's subjective construals, or mental representations, of events can impact the attitude estimates obtained on the IAT. The present work draws from construal level theory, which suggests that how people construe objects systematically impacts judgment and decision-making (e.g., Trope & Liberman, 2003). High- and low-levels can be primed in prior irrelevant contexts (e.g., Freitas et al., 2004; Fujita et al., 2006), and more abstract, higher level construals have been shown to enhance self-control (Fujita et al., 2006). Two experiments tested the hypothesis that people's subjective construal of an event/object can systematically impact self-control relevant attitude estimates on the IAT. Female participants first completed one of two construal level manipulations validated in previous research. Then, they completed the apples vs. candy bars IAT (e.g., Karpinski & Hilton, 2001) as an ostensibly unrelated task. As predicted, in both experiments, higher level construals promoted associating candy bars with negativity. These findings indicate that, although primed in an unrelated context, how abstractly or concretely people construe events can play a critical role in attitude estimates on the IAT. Moreover, even when the objective features of the testing situation remain constant, the IAT can manifest apparent attitude change as a function of people's subjective construals.

**G53****DOES MINDFULNESS REDUCE NEGATIVITY BIAS?**

**Laura G. Kiken<sup>1</sup>, Natalie J. Shook<sup>1</sup>**, <sup>1</sup>Virginia Commonwealth University – Mindfulness has been conceptualized as a nonjudgmental awareness of and attention to current experiences, suggesting a lack of bias toward positive or negative information. However, a causal link between mindfulness and reduced bias has not been demonstrated empirically. The present research addressed this gap by examining if mindfulness reduced bias on an objective measure of attitude formation and a subjective measure of optimism and pessimism. Study One was correlational. Participants played a computer game, BeanFest, that required learning whether novel stimuli produced positive or negative outcomes in order to succeed. Participants then completed measures of trait mindfulness, as well as an optimism and pessimism scale. The results indicated that dispositional mindfulness was positively correlated with the formation of positive attitudes and optimism, while negatively correlated with pessimism, hinting at a potential positivity bias. Study Two extended these findings using a randomized experiment comparing a brief mindfulness induction to an unfocused attention control condition. The mindfulness condition demonstrated a positivity bias in attitude formation as well as increased optimism compared to the control condition. Also, those in the control condition exhibited a negativity bias in attitude generalization, whereas those in the mindfulness condition did not demonstrate any bias in attitude generalization. The findings from both studies suggest that mindfulness is associated with reduced negativity bias and in some cases is associated with positivity bias. These findings suggest important implications for the benefits of mindfulness on individual and collective well-being.

**G54****NATIONALISM AND ATTITUDES TOWARDS IMMIGRANTS: EMOTIONAL AND MORAL PREDICTORS**

**Damla Ergun<sup>1</sup>, Corrie V. Hunt<sup>1</sup>**, <sup>1</sup>University of Minnesota-Twin Cities – Since 9/11, Americans reported higher levels of nationalism and negative attitudes towards progressive immigration policies and immigrants. We investigated the predictors of nationalism and attitudes towards immigrants. Recent research in social psychology suggests that liberals and conservatives rely differentially on different moral considerations (Haidt & Graham, 2007). We examined the extent to which these moral considerations can explain variation in these attitudes. Specifically, we were interested in the "ingroup" foundation, or

upholding values of loyalty, and the "fairness" foundation, or concerns with individual rights and justice. In line with research (Haidt, 2001) suggesting that people's reactions to moral issues may stem from their emotional responses, we asked participants how they have been feeling lately with respect to the political climate. Analyses revealed specific emotion by moral foundation interactions. Conservative participants that felt most positively and reported habitually relying on the ingroup foundation, reported stronger anti-immigration attitudes. That is, positive affect seemed to strengthen the relationship between the ingroup foundation and anti-immigration attitudes. Liberals, who habitually rely less on this foundation, did not show this pattern. We observed, however, that when liberals that endorsed the fairness foundation highly also felt angry about the political climate, they were less nationalistic. But when liberals endorsed the purity foundation highly (a foundation that has to do with avoidance of "unclean" people) and were fearful about the political climate, they reported more nationalistic attitudes. We argue that emotional reactions can interact with moral considerations in specific ways, and contribute to our understanding of political attitudes.

**G55****THE INDEPENDENT EFFECT OF MORAL CONVICTION ON ATTITUDE ACCESSIBILITY AND ATTITUDE KNOWLEDGE**

**Daniel Wisneski<sup>1</sup>, Linda Skitka<sup>1</sup>**, <sup>1</sup>University of Illinois at Chicago – The current study had two goals. First, we examined whether feelings of strong moral conviction exerted an independent effect on attitude accessibility. On the one hand, attitudes held with strong moral conviction are also likely to be high in other aspects of attitudes strength related to accessibility. On the other hand, moral conviction does not boil down to other measures of attitude strength and likely exerts an independent effect of accessibility (Skitka, Bauman, & Sargis, 2005). The second goal of the current study was to examine how moral conviction related to attitude knowledge. Different theories from literature on morality, values, and attitudes make different predictions about whether moral conviction should be related to more or less knowledge. Competing hypotheses were proposed related to each of these three literatures. The current study measured (1) participants' levels of attitude accessibility using response latencies and (2) attitude knowledge using both self report and knowledge listing measures. Participants then reported their levels of attitude strength and attitude related moral conviction in reaction to one of two political issues. Finally, they reported how often they expressed their attitude, how often they followed news related to the attitude, and how often they followed the news overall. Results showed that stronger moral conviction predicted greater accessibility and greater knowledge even when controlling for attitude strength, frequency of attitude expression, and measures of news exposure. Results are discussed in terms of how moral conviction relates to the constructs of attitude strength, values, and other theories of morality.

**G56****EVIDENCE THAT UNCONSCIOUS THINKING INFLUENCES PERSUASION BASED ON ARGUMENT QUALITY**

**Ian M. Handley<sup>1</sup>, Brett M. Rynnion<sup>1</sup>, C. Mark Sollars<sup>1</sup>, Laura Cichosz<sup>1</sup>, Jarrett Twamley<sup>1</sup>**, <sup>1</sup>Montana State University – Some evidence suggests that individuals can think unconsciously about previously presented information and form judgments that are normatively better than those made by individuals who can think consciously or who are prevented from thinking whatsoever. However, an alternative explanation suggests that unconscious thinking might not product this effect. Rather, individuals may form an impression of incoming information and use this impression when reporting their judgments after a period of distraction. The goal of the current experiment was to test for the influence of unconscious thinking even when participants are prevented from forming an impression of incoming information, circumventing the alternative explanation. Participants listened to a personally-relevant persuasive message containing either strong or weak arguments supporting senior comprehensive exams. This message was played at a 220 words per minute, which is comprehensible but prevents elaboration. Next, participants either immediately reported their attitudes about

the exams, were distracted for 3 minutes then reported their attitudes (unconscious-thought condition), or were given 3 minutes to think about the message then reported their attitudes. Consistent with an unconscious-thought explanation, analyses indicated that participants in the unconscious-thought condition reported significantly more favorable attitudes toward the exams if they heard strong versus weak arguments, whereas participants in the other conditions did not. These results indicate that when participants are unlikely to form impressions of persuasive information as they hear it, they still form better judgments (attitudes) from that information when they can think unconsciously versus consciously or not at all. Implications for persuasion are also discussed.

**G57**

**PROMOTING HEALTHY BEHAVIOR: HOW PROCESS- AND OUTCOME-FOCUSED APPEALS CAN INFLUENCE THE PERSUASIVENESS OF FRAMED HEALTH MESSAGES** Yun Lee<sup>1</sup>; <sup>1</sup>University of Iowa – What types of appeals are effective to increase the persuasiveness of loss- versus gain-framed health-related messages? Two experiments address this question by examining the influence of process-focused versus outcome-focused appeals on evaluations of loss- versus gain-framed health-related messages. The results reveal that when the message is loss-framed, participants with high (vs. low) perceived risk prefer process-focused appeals—an effect that is driven by the negative consequences anticipated from increased uncertainty—than outcome-focused appeals. When the message is gain-framed, however, outcome-focused messages become more appealing for participants with low (vs. high) perceived risk—an effect that is driven by the positive consequences anticipated from decreased uncertainty.

Poster withdrawn.

**G59**

**THE RESPONSE MAPPING MODEL: WHY PRIMING EFFECTS DO NOT ALWAYS REFLECT PARTICIPANTS' AUTOMATIC ASSOCIATIONS WITH PRIMES** Laura Scherer<sup>1</sup>, Alan Lambert<sup>1</sup>; <sup>1</sup>Washington University in St. Louis – For years, evaluative priming tasks have been used as a way of accessing participants' automatic evaluations, or "implicit attitudes". However, there is still much that we do not understand about the psychological processes involved in these tasks. In this poster, we present a Response Mapping Model that can explain certain types of counterintuitive priming effects. One of the most important implications of this model is that primes can sometimes elicit strong effects that have little or no relation to participants' actual associations with those primes. This model stands in stark contrast to older models of evaluative priming (e.g. those assuming a spreading activation process), which assume that primes exert their effect by activating participants' evaluative associations. In Experiment 1, we show that evaluatively neutral primes can sometimes elicit strong positive responses, or strong negative responses, depending on the task context in which they are presented. In Experiments 2 and 3, we demonstrate that these context effects do not represent a change in participants' feelings toward, or perceptions of, the neutral primes. Instead, such effects reveal a particular way in which participants perform the priming task; namely, by categorizing the primes and mapping them onto the available responses. Hence, we will argue that priming effects for any given prime can be independent of an actual association, and instead are dependent on two factors: a) the responses that are required by the task (e.g. "good" vs. "bad"), and b) the combination of prime types that are presented in the task.

**G60**

**THE PROCESS OF SELECTIVE EXPOSURE: THE PROCESS OF SELECTIVE EXPOSURE: WHY CONFIRMATORY INFORMATION PROCESSING WEAKENS OVER TIME.** Peter Fischer<sup>1</sup>, Steven Lea<sup>2</sup>, Andreas Kastenmüller<sup>3</sup>, Tobias Greitemeyer<sup>4</sup>, Julia Koeppi<sup>5</sup>, Dieter Frey<sup>5</sup>; <sup>1</sup>University of Graz, Austria, <sup>2</sup>University of Exeter, UK, <sup>3</sup>Liverpool John Moores University, UK, <sup>4</sup>University of Sussex, UK, <sup>5</sup>Ludwig-Maximilians-Universitaet Munich, Germany – The present studies investigated whether the tendency to prefer decision-consistent over decision-inconsistent information after preliminary decisions varies during the sequential process of seeking additional decision-relevant information. Specifically, we tested whether decision makers would be more confirmatory in their information evaluation and information search at the beginning (immediately after the preliminary decision) rather than at the end of an information search process. The results of five studies suggest that this expectation was justified: participants exhibited stronger confirmatory tendencies in information evaluation and search right after making a decision than they did during later stages of an information search process. Results revealed that motivational (dissonance) processes are not likely to account for this effect. Rather, the results are more in line with a cognitive account: people appear to be more motivated to detect the best decision alternative at the beginning (as opposed to the end) of an information search process, which consequently leads to increases in confirmatory information processing during the initial stages of an information search process.

**G61**

**THE EFFECTS OF POWER ON CONFIRMATORY INFORMATION PROCESSING** Julia Koeppi<sup>1</sup>, Peter Fischer<sup>2</sup>, Birte Englich<sup>3</sup>, Dieter Frey<sup>1</sup>; <sup>1</sup>Ludwig-Maximilians-Universitaet Munich, Germany, <sup>2</sup>University of Graz, Austria, <sup>3</sup>University of Cologne, Germany – People tend to systematically prefer decision-consistent to decision-inconsistent information (selective exposure, biased assimilation). The present studies investigated the impact of subjectively perceived power on confirmatory information processing after decision making. Consistently, in three studies we found that embodiment power inductions (induced by making a fist) lead to greater confirmatory tendencies in the evaluation and search of decision-relevant information (Studies 1-3). This tendency is unlikely to be due to mere physical strain (Study 3), and was mediated by differences in experienced decision certainty (Studies 2 and 3). That is, high power inductions make people more confident about the validity of their decision preference, and thus they systematically prefer information that is consistent with their decision preference.

**G62**

**POLITICAL MAGNETISM IN SOCIAL TUNING: POLARITY SHIFTS IN LIBERALISM AND CONSERVATISM AFTER THE ELECTION OF OBAMA** Rick M. Cheung<sup>1</sup>, Steven Noel<sup>1</sup>, Curtis D. Hardin<sup>1</sup>; <sup>1</sup>Brooklyn College and Graduate Center, City University of New York – Parallel social-tuning experiments conducted before and after the 2008 presidential election show that a rapid change in the political zeitgeist can transform the normative influence of the perceived politics of others from repulsion to attraction. In the presence of an experimenter who was ostensibly either "extremely liberal" or "mildly liberal", participants completed measures of political ideology and interpersonal perception. Before the election, participants anti-tuned away from the extremely liberal experimenter by exhibiting (a) less liking for the experimenter, (b) increased self-declared political rigidity, and (c) increased endorsement of the protestant work ethic, to the degree that they perceived close others to be politically conservative. In contrast, after the election of Barack Obama, participants tuned toward the extremely liberal experimenter by exhibiting (a) decreased self-declared political rigidity, (b) decreased endorsement of protestant work ethic, and (c) increased endorsement of liberal public policies, to the degree that they perceived close others to be politically conservative. Post-election social-tuning effects were especially pronounced when the experimenter was interpersonally likable. Hence, the election of Obama switched polarity of liberalism from repulsion to attraction and conser-

vatism from attraction to repulsion among people attached to conservative close others, suggesting that political ideology is expressed in a kind of magnetic field of interpersonal relationships and political climate.

### G63

#### WHO CARES IF PRESIDENTIAL CANDIDATES LIE? PREDICTING MORAL JUDGMENTS OF DECEPTIVE CLAIMS

Anne L. Zell<sup>1</sup>, Stephanie Sorensen<sup>1</sup>; <sup>1</sup>Augustana College – What predicts people's moral judgments of presidential candidates' deceptive statements? 113 participants completed a questionnaire about their reactions to six deceptive claims made by Barack Obama and John McCain during the presidential campaign. After reading each claim, participants read a refutation from Factcheck.org, then rated their moral judgments and other perceptions of the claim. Participants also completed measures of religiosity, Machiavellianism, and their attitudes about deception in politics. Religiosity was associated with lower Machiavellianism scores and with greater agreement that the use of deception in politics is unacceptable and deserves moral rebuke. However, religiosity was not associated with judging the claims as more morally wrong when responses to Obama's and McCain's claims were averaged. As expected, highly religious participants were more likely to vote for McCain, and religiosity was associated with more negative judgments of Obama's claims, but not of McCain's claims. Women rated the claims as more morally wrong than men did. Judging the claims as morally wrong was associated with perceiving that the claims were untrue, that the claims would be damaging for the other candidate if true, that the claims were motivated by a desire to win, that the claims would have convinced the participant if they hadn't read Factcheck.org's analysis, and that the discrepancy between the candidates' claims and Factcheck.org's claims was large. Significant predictors were entered in a simultaneous regression. Results indicate that both perceiving claims to be untrue and perceiving claims to be potentially damaging account for unique variance in people's moral judgments.

### G64

#### PUTTING LIKE A PRO: THE ROLE OF POSITIVE CONTAGION IN GOLF

Jennifer Joy-Gaba<sup>1</sup>, Charles Lee<sup>1</sup>, Sally Linkenauger<sup>1</sup>, Jonathan Bakdash<sup>1</sup>, Dennis Proffitt<sup>1</sup>; <sup>1</sup>University of Virginia – Previous work has shown that properties from one object can readily transfer to another – a law called contagion (Rozin, Millman, & Nemeroff, 1986). We investigated whether a putter with a positive contagion affects both performance and perception. To test these effects, half of participants were told they would use a putter that belonged to a professional golfer (positive contagion), while the remaining participants were not told anything about the putter. Afterwards, all participants drew a circle corresponding to the size of the golf hole and then took 10 test putts. Results revealed that the professional group putted better than the control group, making 38% more putts,  $t(38) = 2.11, p = .04, d = .67$ . In addition, the professional group perceived the hole as larger prior to putting compared to the control group, drawing the hole 10% larger,  $t(38) = 2.49, p = .02, d = .79$ . One possible explanation is that participants' experienced an increase in self-confidence after being told that they would use the professional's putter, making putting seem easier and the hole appear larger. This study suggests the powerful impact that belief has on performative and perceptual outcomes.

### G65

#### ANTHROPOMORPHISM MEDIATES THE EFFECT OF SPIRITUALITY ON ABORTION ATTITUDES

Kathryn Johnson<sup>1</sup>, Anna Berlin<sup>1</sup>, Sara Brimhall<sup>1</sup>, Adam Cohen<sup>1</sup>; <sup>1</sup>Arizona State University – Abortion remains a controversial issue capable of influencing voters, and eliciting emotional arguments and protest behaviors. Religious people are more likely to be pro-life than the non-religious, and one possible explanation may be variability in the classification of fetuses as persons. Although, a fetus is not a legal person in the U.S., we theorized that religious people may continue to personify fetuses which, in turn, may predict a pro-life stance. We surveyed 496 university students about the personhood of various entities; the mental, emotional, spiritual, moral, kinship, and humanness

attributes of each entity; and participants' attitudes toward various public policies including abortion. As expected, both highly religious Christians ( $M = 5.97$ ) and Catholics ( $M = 5.96$ ) were significantly more likely ( $p < .001$ ) than secularists ( $M = 4.17$ ) to rate fetuses as persons on a Likert-scale of 1 to 7. Moreover, people who considered fetuses to be persons were more opposed to abortion. A Sobel test confirmed that personification of fetuses partially and significantly mediated the relationship between spirituality and abortion attitudes ( $z = 3.04, p = .002$ ). Next we explored on what basis religious people consider fetuses to be persons. A regression analysis showed that, in contrast to secularists, Christians ascribed emotional, spiritual, and kinship attributes, even over and above ascriptions of humanness, when rating the personhood of fetuses. We suggest that some people may oppose abortion, in part, because they think of the fetus as a person (a baby) rather than as a potential human (a fetus).

### G66

#### IS OBAMA THE ANTI-CHRIST? RACIAL PRIMING AND EXTREMIST CRITICISMS ON SUPPORT FOR BARACK OBAMA

Kris Gerow<sup>1</sup>, Matt Motyl<sup>2</sup>, Tom Pyszczynski<sup>1</sup>; <sup>1</sup>University of Colorado at Colorado Springs, <sup>2</sup>University of Virginia – Early in Senator Barack Obama's successful bid to be the first African American President of the United States many extremist claims were leveled at him in attempts to undermine his candidacy. Among the more extreme claims were that he is the "Anti-Christ". Proponents of these views took information from the Bible and attempted to apply it to President Obama. For example, the zip code of his Chicago residence is 60606, which is the Biblical "mark of the beast," or "666," if the zeros are omitted. Similar claims are discussed in detail on over 800,000 websites according to a recent Google search. Claims like these are rarely made about Caucasian Presidential candidates. The present study hypothesized that believers of these claims may be using religious justification for their aversion to the first African American Presidential candidate as a way to mask their socially unacceptable racism. Ninety participants were randomly assigned to be primed with race or not and then read one of three editorials proclaiming Obama to be the Anti-Christ, a poor choice for President, or an excellent choice for President before completing a measure of support for Obama. The results demonstrate that participants displayed a decreased preference for Obama after reading the Anti-Christ editorial and being primed with race. Among participants not primed with race, the Anti-Christ editorial led to an ironic increased preference for Obama. These results support the hypothesis that racism played an important role in determining reactions to extremist claims against Obama.

### G67

#### UNPACKING SYSTEM JUSTIFICATION: PERCEPTIONS OF SYSTEM EQUALITY AND FAIRNESS

Nicole E. Noll<sup>1</sup>, Andrew Karpinski<sup>1</sup>; <sup>1</sup>Temple University – An implicit assumption of system justification theory is that individuals recognize the general inequality of a social system. Measures of system justification assess the extent to which individuals legitimize an unequal system by indicating that it is fair. Awareness of inequality is a key, yet undemonstrated, premise in the argument that members of disadvantaged groups justify the social systems that oppress them. In this study, we assessed perceptions of the (in)equality and (un)fairness of gender relations and examined their relation to gender-specific system justification. Two hundred eighty-nine college students (192 female) completed scales we developed to measure the equality (7 items) and fairness (6 items) of the general social relations between women and men in United States. They also completed an 8-item scale measuring gender-specific system justification (GSJ; Jost & Kay, 2005). Men showed significantly greater GSJ than did women. Although both men and women believed gender relations to be unequal and unfair, women rated them as significantly less equal and less fair than did men. Interestingly, equality and fairness were differentially related to GSJ between women and men. Among women, equality and fairness were unique positive predictors of GSJ. Among men, the interaction of these predictors showed that men who believed gender relations to be more equal and

less fair showed the most GSJ, whereas those who believed gender relations to be more equal and more fair showed the least GSJ. Our results suggest that the meaning of system justification varies by social status or group membership.

### G68

**RELIGIOSITY AND BELIEFS ABOUT SCIENTIFIC QUESTIONS** Judith Danovitch<sup>1</sup>, Nicholaus Noles<sup>2</sup>; <sup>1</sup>Michigan State University, <sup>2</sup>University of Michigan – Religious and scientific communities commonly argue over complex topics, such as the origin of life. It is clear that religiosity influences opinions about scientific findings in some specific cases, but it is less clear whether religiosity influences broader attitudes towards scientific questions that are not typically discussed in a religious context. Thus, we examine the relationship between religiosity and judgments about scientific questions that are unrelated to any specific religious belief. Participants (n=81) rated the likelihood that humans will find an answer to each of 15 questions using a 7-point scale. Five items involved questions that already have clear answers (e.g., why do volcanoes erupt?) and 10 items involved open scientific questions that are not overtly related to religious beliefs (e.g., what causes black holes to form?). Participants also completed scales measuring religiosity and belief in God. We found a significant negative correlation between question ratings for open scientific questions and religiosity,  $r = -.244$ ,  $p = .028$ , as well as belief in God,  $r = -.276$ ,  $p = .013$ , suggesting that individuals who are more religious and believe more strongly in God think that humans are less likely to solve scientific problems. Results will be discussed in the context of follow-ups examining whether religious individuals are generally less confident in human problem solving capabilities, or whether they are more strongly drawn to alternative explanations of natural phenomena, such as those provided by religious sources.

### G69

**THE NEWLYWED GAME: RELATIONAL POWER PREDICTS PHYSIOLOGICAL STRESS REACTIVITY AND MARITAL SATISFACTION** Mattitiyahu S. Zimler<sup>1</sup>, Paula R. Pietromonaco<sup>1</sup>, Sally I. Powers<sup>1</sup>; <sup>1</sup>University of Massachusetts, Amherst – This study examined the connection between perceived marital power and both relationship satisfaction and physiological stress reactivity. One of the few studies investigating these connections has shown that having less power predicts greater physiological stress, although the patterns vary somewhat for husbands and wives (Loving et al., 2004). On this basis, it was hypothesized that lower power would predict higher cortisol levels and less relationship satisfaction. We also examined whether gender would moderate these links. Forty-eight newlywed couples discussed a major unresolved area of conflict for 15 minutes and provided 5 saliva samples to assess cortisol before, during, and after the discussion. Spouses completed questionnaires assessing power in their relationship, influence in the discussion, and overall marital satisfaction (Dyadic Adjustment Scale). When husbands reported more power, control, and influence in the discussion, wives expressed significantly more general relationship satisfaction and more positive evaluations of the conflict discussion. Wives' greater relationship influence predicted husbands' higher marital satisfaction and wives' lower levels of cortisol. Furthermore, when wives believed they had greater influence in more traditionally feminine domains (e.g., family-related decisions), they showed significantly less cortisol reactivity; in contrast, when they believed they had more influence in traditionally masculine domains (e.g., money), they showed significantly increased cortisol reactivity. These findings suggest that the connection between marital power and satisfaction, and the physiological stress responses they elicit, may vary depending on the domain of power. Additionally, these findings underscore the need for marital power dynamics to be considered within the context of gender.

### G70

**THE EFFECTS OF RELATIONSHIP THREAT AND SELF-ESTEEM ON COMPARISONS TO OTHER ROMANTIC RELATIONSHIPS** Brianna Harris<sup>1</sup>, Sandra L. Murray<sup>1</sup>; <sup>1</sup>University at Buffalo, The State University of New York – The current study was designed to examine how social comparisons to the romantic relationships of others are used strategically to meet the differing relationship goals of low and high self-esteem individuals. According to the risk regulation model of romantic relationships, a relationship specific threat differentially elicits the competing goals of self-protection and relationship-promotion for low and high self-esteem individuals. It was thus hypothesized that LSE's would engage in social comparisons that allowed them to meet self-protection goals. The current study employed two different measures of social comparison tendencies following a relationship-specific threat (writing about a time one's partner had hurt or disappointed him). One of these measures offered participants the chance to engage in or to avoid making a social comparison, while the other allowed participants to engage in a comparison with very certain outcomes. Results revealed that threatened low self-esteem individuals avoided making social comparisons when the outcomes of the social comparison were unclear. When given the opportunity to compare to a friend (a comparison with more certain outcomes), threatened LSE's engaged in downward comparison, indicating that they felt that their relationship was better than their friend's relationship on a variety of dimensions. Findings from the current study are consistent with evidence suggesting that low self-esteem individuals' automatic inclination is to connect to their partner and protect their relationship (i.e., Murray, Derrick, Leder, & Holmes, 2008), as well as with previous evidence on social comparison that suggests that low self-esteem individuals take safe opportunities for comparisons.

### G71

**EMPATHIC ACCURACY AND DEPRESSION IN NEWLYWED COUPLES** Holly Laws<sup>1</sup>, Paula R. Pietromonaco<sup>1</sup>, Sally I. Powers<sup>1</sup>; <sup>1</sup>University of Massachusetts Amherst – The empathic accuracy hypothesis was tested in a sample of newlywed couples from the Growth in Early Marriage project. Prior research (Simpson, Oriña, & Ickes, 2003) has shown that accurate appraisals of a partner's feelings relate to increased closeness for non-relationship-threatening information, while accurately understanding relationship-threatening feelings predicts decreased closeness. Less is known about the potentially moderating role of depression. The depressive realism hypothesis suggests that depressed individuals are less biased in appraisals of negative information. This study examined the empathic accuracy hypothesis in appraisals of spousal behaviors and explored whether depression moderates this relationship. 48 couples engaged in a 15-minute conflict discussion, following which spouses rated aspects of their own and their partner's behaviors during the conflict. Discrepancy scores between appraisal of the spouse's behavior and that spouse's self-rating were correlated with a measure of relationship closeness. Initial findings provide partial support for the hypotheses. For husbands, but not wives, higher closeness was related to more accurate appraisal of wives' support behaviors ( $r = .295$ ,  $p < .05$ ), but was negatively associated with wives' criticism ( $r = -.443$ ,  $p < .05$ ). Follow-up analyses indicated that accurate appraisal of criticism was not significantly associated with relationship closeness in more depressed husbands. This pattern suggests that the empathic accuracy model may not adequately account for the nature of relational processes for depressed individuals. Further analyses will be conducted using the Actor-Partner Interdependence Model (APIM; Cook & Kashy, 2005) with hierarchical linear modeling (HLM) to account for the dependency between spouses' outcomes.

**G72****UNCERTAINTY INCREASES SENSITIVITY FOR RELATIONSHIP-RELEVANT INFORMATION, BUT DECREASES SENSITIVITY FOR RELATIONSHIP-IRRELEVANT INFORMATION**

Jana Janssen<sup>1</sup>, Patrick Müller<sup>2</sup>; <sup>1</sup>University of Mannheim, <sup>2</sup>SHL Group – Research has shown that uncertainty increases individuals' sensitivity for fairness information when evaluating the quality of social relationships. The underlying reasoning is that fairness provides important information about relationships and thereby helps to cope with uncertainty. The present research hypothesizes that the sensitizing effect of uncertainty is not specific for fairness, but also applies to other types of relationship-relevant information, such as trust. Moreover, it is proposed that uncertainty increases sensitivity for relationship-relevant information, but decreases sensitivity for relationship-irrelevant information. Three studies were conducted to test these predictions. In a field study (1), job applicants rated a company's trustworthiness (relationship-relevant information). Uncertain individuals relied more strongly on trust judgments than certain individuals to evaluate the company's attractiveness as employer. In a scenario study (2), individuals' uncertainty, the company's trustworthiness (relationship-relevant information), and the attractiveness of the company location (relationship-irrelevant information) were manipulated. Uncertainty sensitized individuals for trust information, but not for information about the company location. Study 3 was conducted to rule out the possibility that the latter result of study 2 was due to a dominant impact of trust information. Individuals' uncertainty and the attractiveness of the company location (relationship-irrelevant information) were manipulated. Uncertain individuals relied less strongly on information about the company location than certain individuals. Results show that (a) uncertainty sensitizes individuals not merely for fairness information, but more general for relationship-relevant information (e.g., trust), and (b) uncertainty specifically sensitizes individuals for relationship-relevant information, but desensitizes individuals for relationship-irrelevant information. Implications for uncertainty management research are discussed.

**G73****HOW WE THINK ABOUT TEASING: EXAMINING THE GAP IN PERCEPTIONS OF TEASING IN GENERAL AND TEASING IN CLOSE RELATIONSHIPS**

Glen Gorman<sup>1</sup>, Christian Jordan<sup>1</sup>; <sup>1</sup>Wilfrid Laurier University – Although the targets of teasing often view teasing more negatively than do teasers (Kruger et al., 2006), in close relationships perceptions of teasing may be relatively positive and the reasons for teasing may be more prosocial. We compared perceptions of teasing with a close other (both when the participant was the teaser and the target) to general perceptions of teasing. We also explored the specific reasons for teasing. Participants answered questions about teasing in three different situations: teasing in general, the participant as a teaser, and the participant as the target of teasing. Participants also rated the frequency with which teasing occurs for particular reasons (e.g., to be mean) both in general and between themselves and a close other. Our results replicate the finding that teasers view an episode of teasing more positively than do targets. However, teasing in both of these cases was viewed much more positively than in the general case. These results held for perceptions of teasers' intentions and the overall negativity of the tease itself. With respect to the reasons for teasing, participants believed that teasing as a joke or to communicate caring occurred more often in close relationships than in the general case, and that teasing to be mean was more common in the general case. These results suggest that, although a rift exists between the perceived intentions of the teaser and the target, people are motivated to soften the blow of a tease in order to protect important relationships.

**G74****PERCEPTIONS OF IRREPLACEABILITY: HOW SATIATING THE GOAL OF FEELING IRREPLACEABLE IN ONE'S DATING RELATIONSHIP INCREASES PERCEIVED TRUST FOR LOW SELF-ESTEEM INDIVIDUALS**

Sadie Leder<sup>1</sup>, Sandra L. Murray<sup>1</sup>, Jennifer C. D. McClellan<sup>2</sup>, John G. Holmes<sup>2</sup>, Rebecca T. Pinkus<sup>1</sup>, Brianna Harris<sup>1</sup>; <sup>1</sup>University at Buffalo, State University of New York, <sup>2</sup>University of Waterloo – The current work examined the hypothesis that feeling hard to replace within one's romantic relationship fosters a sense of trust in the partner's continued responsiveness. We posited that the goal of feeling uniquely valuable is likely to be thwarted for those with low self-esteem. Accordingly, we wanted to investigate how experimentally increasing feelings of irreplaceability affected perceptions of trust in the dating relationships of low self-esteem individuals. Participants were 77 undergraduate couples involved in exclusive dating relationships. For individuals in the experimental condition, we satiated the goal of feeling irreplaceable by leading participants to believe that their partner (who was physically present) perceived a number of qualities in them that they could not imagine finding in alternative partners. All participants then completed measures tapping perceived trust. A hierarchical linear regression analysis revealed a significant condition by self-esteem interaction. Breaking down the interaction revealed that low self-esteem participants felt significantly more trust for their partners in the experimental condition as compared to the control condition. Thus, for individuals with insecurities about self-worth, making salient the ways that their partner uniquely valued them lead to increased trust in their partner's continued responsiveness. No such simple effect was anticipated or obtained for participants higher in self-esteem, as these individuals are believed to chronically feel more irreplaceable, as well as trusting of their romantic partners.

**G75****BLISSFUL ROMANTIC RELATIONSHIPS: I'D SURE DATE MYSELF**

Carlie M. Allison<sup>1,4</sup>, Amy C. Moors<sup>2,4</sup>, Amber Farrington<sup>3,4</sup>, Patrick Markey<sup>4</sup>; <sup>1</sup>University of Wisconsin- Madison, <sup>2</sup>University of Michigan- Ann Arbor, <sup>3</sup>Florida State University, <sup>4</sup>Villanova University – Relationship research suggests that people are attracted to partners similar to themselves. Though individuals may seek similarity in partners they may not be able to obtain such individuals. Also, similarity, while desirable, is no guarantee of happiness. The current study adds to the literature by exploring how discrepancies between ideal and current partner personality traits affect relationship satisfaction and propensity for cheating. In addition, the current study includes a population often ignored in relationship research: gay, lesbian, and bisexual couples. Participants consisted of 365 individuals in a monogamous relationship. Participants completed measures assessing Big Five personality traits for the participant, their ideal partner, and their perceptions of their current partner's personality, as well as measures of relationship satisfaction and propensity for cheating.

Results indicated across gender and sexual orientation, partner/ideal partner similarity was related to higher relationship satisfaction ( $p < .01$ ). Furthermore, partner/ideal partner dissimilarity was related to higher propensity for cheating ( $p < .01$ ). Significant gender differences were found in relation to self/partner dissimilarity and relationship satisfaction and propensity for infidelity. For females, dissimilarity on agreeableness ( $p < .01$ ), conscientiousness ( $p < .01$ ) and openness to experience ( $p < .01$ ) was significantly related to lower relationship satisfaction. For males, openness to experience was significantly related to relationship satisfaction ( $p < .05$ ). Furthermore, dissimilarity on neuroticism was significantly related to propensity for infidelity ( $p < .05$ ) for females, while for males, dissimilarity on conscientiousness ( $p < .05$ ) and openness to experience ( $p = .01$ ) was significantly related to propensity for infidelity.

**G76**

**ATTACHMENT STYLE AS A PREDICTOR OF SYSTEMIC STRESS REACTIVITY TO MARITAL CONFLICT** Casey DeBuse<sup>1</sup>, Paula Pietromonaco<sup>1</sup>, Sally Powers<sup>1</sup>, <sup>1</sup>University of Massachusetts, Amherst – Dating partners' attachment styles predict their physiological stress responses to conflict; a link that may be important in predicting the outcomes of such conflict (Powers et al., 2006). Research on relational conflict has focused primarily on understanding responses of the hypothalamic-pituitary-adrenal (HPA) axis, using its end product, cortisol, as a biomarker of stress reactivity. However, research on responses to other psychological stressors has begun to place greater emphasis on examining stress response systems in concert. This work has focused on the HPA axis and the sympathetic branch (SNS) of the autonomic nervous system (e.g., Gordis et al., 2006), using cortisol as an indicator of HPA activation and  $\alpha$ -amylase (A-A) as a putative biomarker of SNS activation. The current research applied this systemic approach to examine whether more insecurely attached spouses would show greater systemic physiological stress reactivity. Forty one newlywed couples completed an adult attachment measure (the Experiences in Close Relationships questionnaire), privately discussed a major, unresolved area of conflict for 15 min, and provided saliva samples (to index cortisol and A-A) at several points before and after the discussion. As expected, more anxiously attached husbands showed higher levels of both cortisol ( $r = .35, p = .03$ ) and A-A ( $r = .34, p = .04$ ) post conflict; wives, however, did not show this association. These findings suggest that anxiously attached husbands may be especially physiologically reactive to conflict discussions. The next step will be to determine why husbands, but not wives, show this effect.

**G77**

**BETTER OFF ALONE: SOCIAL DETACHMENT FOLLOWING PEER REJECTION** Daniel L. Benkendorf<sup>1</sup>, Stefanie Bruno<sup>2</sup>, Michael J. Kern<sup>2</sup>, Kristin L. Sommer<sup>2</sup>, <sup>1</sup>Fashion Institute of Technology, State University of New York, <sup>2</sup>Baruch College and the Graduate Center, City University of New York – Contemporary attachment frameworks assert that threats to felt security initially lead people to seek physical or mental representations of attachment figures (Shaver & Mikulincer, 2002; Mikulincer & Shaver, 2003). When attachment figures are perceived as unavailable or unlikely to provide support, however, individuals engage in deactivation strategies that include the suppression of attachment anxiety and avoidance of emotional connections with others. Three studies were conducted to solicit support for deactivation strategies among rejected individuals. In each of the studies, social rejection was manipulated by randomly pairing unacquainted participants and asking them to talk freely for three minutes. Participants then rated each other in terms of likability and desire for friendship, with knowledge that the partner would soon view these ratings. Actual ratings were replaced with false feedback. Half of the participants were randomly chosen to receive negative ratings, suggesting that the other person did not like them very much or want to be friends with them. The remaining half received positive ratings. Across studies, results revealed that rejected (compared to accepted) participants reported lower attachment anxiety (Study 1); generated fewer allocentric self-descriptors (e.g., "sensitive," "caring," "friendly") on the Twenty Statements Test and scored lower on empathy (Study 2); and reported reduced desire for emotional closeness with others (Study 3). Consistent with attachment theory (Mikulincer & Shaver, 2003), we suggest that deactivation behaviors assist in protecting individuals from the pain of future rejection.

**G78**

**INHIBITED AND DISTANT: WHY SOCIAL SUPPORT IS SOMETIMES ELUSIVE** Lisa B. Reddoch<sup>1</sup>, Kelley J. Robinson<sup>1</sup>, Jessica J. Cameron<sup>1</sup>, <sup>1</sup>University of Manitoba – The social support provided in intimate relationships is an important contributor to physical, psychological, and relational well-being (e.g., Collins & Feeney, 2000; Schachner et al., 2005; Reblin & Uchino, 2008). Unfortunately, some people do not feel supported by their partners. Inhibition to convey needs to a potentially

rejecting partner may impede support communications. Inhibitions influence overt communications (Vorauer et al., 2002) and may also play a role in nonverbal support behaviours such as physical closeness— a strategy that is used in both seeking and providing support (Robinson & Cameron, 2007; Simpson et al., 1992). The current study tested the influence of inhibitions to convey support needs on partners' physical closeness and subsequent reports of felt support during a laboratory-induced support-interaction. Heterosexual dating partners were unknowingly assigned to support-seeker and caregiver roles. Support-seekers were then exposed to a stressor to motivate support-seeking behavior. Subsequent to the exposure, all couples experienced an unstructured, unobtrusively videotaped support-interaction. Afterwards, support-seekers indicated the extent to which they had felt inhibited to convey their needs during the interaction, and reported on how supported they felt from their partners' responses. Results revealed that inhibited support-seekers felt less supported by their partners following the interaction. This link was mediated by dyadic physical closeness as it was coded from the videotapes. Thus, when support-seekers are more inhibited, the couple exhibits less physical closeness which ultimately impedes support-seekers' feeling adequate support. Implications for social support-seeking and caregiving will be discussed.

**G79**

**THE FORBIDDEN FRUIT EFFECT: THE COSTS OF LOOKING AWAY FROM ATTRACTIVE OTHERS** Timothy Deckman<sup>1</sup>, C. Nathan DeWall<sup>1</sup>, Jon K. Maner<sup>2</sup>, D. Aaron Rouby<sup>2</sup>, <sup>1</sup>University of Kentucky, <sup>2</sup>Florida State University – This study investigates the effects of an attention retraining task on different attitudes and behaviors of those involved in romantic relationships. The attention retraining task consisted of seeing two pictures of one attractive and one average member of the opposite sex followed by a letter. Participants were then forced to look away from the attractive picture 80% of the time (experimental condition) or had their attention forced away from both pictures in equal amounts (control condition). The first study found that participants in the attention retraining condition were significantly less satisfied with their relationship and held significantly more positive feelings towards infidelity than those in the control condition. Study 2 found that participants in the attention retraining condition had significantly better memory for attractive faces they had seen during the attention retraining task than did participants in the control condition. Study 3 found that participants in the attention retraining condition were significantly faster to attend to attractive targets in a subsequent dot probe task than those in the control condition. These results indicate that training attention away from attractive alternatives makes people less satisfied in their current relationship, have more positive feelings towards cheating on their partner, have better memory for attractive faces, and faster to attend to attractive alternatives.

**G80**

**(DYS)FUNCTIONAL ATTITUDES? SOCIAL REJECTION, LONELINESS, AND ADVERTISEMENT PREFERENCES** Elizabeth A. Majka<sup>1</sup>, David E. Levari<sup>1</sup>, Penny S. Visser<sup>1</sup>, <sup>1</sup>University of Chicago – In this study we sought to examine how individuals use their attitudes to assist in regulating their belonging needs. Functional theories of attitudes (e.g., Katz, 1960; Smith et al., 1956) argue that individuals often hold and express attitudes that reflect their active goals and needs. In particular, when belonging needs are heightened (e.g., via social rejection), functional theories argue that individuals should prefer attitude objects that target a social adjustive (vs. utilitarian) function—i.e., the 'functional matching effect'. However, the belonging regulation system can also go awry, such as in the case of chronically lonely individuals (Gardner et al., 2005). According to skills deficit models of loneliness, these individuals may be less likely to demonstrate the functional matching effect. To examine these predictions, 44 undergraduates were first rejected or accepted while playing the virtual ball tossing game Cyberball (Williams et al., 2000). Following Cyberball, they indicated their preferences for advertisements with slogans targeting a social adjustive or utilitarian attitude function. Finally, participants

completed a number of auxiliary measures including measures of loneliness (Hughes et al., 2004). Contrary to an attitude functions perspective, rejected (vs. accepted) participants did not prefer advertisements that targeted the social adjustive function. However, increased levels of loneliness did bias participants' preferences toward utilitarian (vs. social adjustive) slogans. Taken together, these data provide some support for skills deficit models of loneliness while challenging functional theories of attitudes. Findings will be discussed in light of recent models of belonging regulation and ongoing research in our lab.

### G81

**NOT GONNA WRITE YOU A LOVE SONG: BUT I WILL ANALYZE IT FOR YOU** Melanie Canterberry<sup>1</sup>, Omri Gillath<sup>1</sup>, Jennifer A. Hamilton<sup>1</sup>; <sup>1</sup>University of Kansas – The wide variety of love songs suggests that there should be differences in people's preferences for which love songs they like and how they perceive love through songs. Previous research has highlighted cross-cultural differences in the content of love songs, but to date, there have been few studies investigating how individual characteristics relate to preferences of love songs. In the current study, we examined participants' thoughts and feelings regarding love songs. Analysis revealed associations between attachment styles and sexual mating strategies, and preferences and perceptions of love songs. For example, people high in attachment anxiety seem to prefer love songs with a sad theme. These songs, in turn, lead them to long for more in their relationships and feel angry and wishful. People high in attachment avoidance (or those indicating lower preference for a long-term mating strategy) tend to feel unfulfilled when listening to love songs and believe that true love exists only in the songs. Conversely, participants reporting an idealistic view of love and those low on attachment avoidance feel more in love with their partners when listening to love songs. A content analysis of the songs chosen by people as their favorite revealed that not being currently in a relationship was associated with a higher number of security-related words in these songs, suggesting a desire for what they do not have. These findings begin to shed light on how love songs are associated with romantic relationship experience and views of love.

### G82

**SEEKING CERTAINTY: THE COMPENSATORY ROLE OF POSITIVE ILLUSIONS IN CLOSE RELATIONSHIPS** Maya Aloni<sup>1</sup>, Sandra Murray<sup>1</sup>; <sup>1</sup>University at Buffalo, The State University of New York – Considerable research has shown that people are motivated to perceive their partner and relationship in the most positive light possible (Murray, Holmes & Griffin, 1996a; 1996b). We hypothesized that situations of uncertainty, even if experienced outside the context of one's relationship, trigger compensatory cognitions designed to attach greater value to one's relationship. In addition, given that people with high (Highs) and low (Lows) self-esteem prioritize different relationship goals, we expected positive illusions to be particularly exacerbated for high self-esteem individuals (Murray, Holmes & Collins, 2006). One hundred and twenty six people in dating relationships participated. Participants first completed the Rosenberg (1965) self-esteem scale. Participants in the uncertainty salient condition were asked to describe their thoughts and feelings about being uncertain outside the context of their relationship. Participants in the control condition wrote about their thoughts and feelings when watching television (Van den Bos, 2001). We manipulated relationship threat by asking participants to describe their partner's most negative (threat) or most positive (no threat) qualities. We then measured people's perceptions of their partner and their relationship (Murray & Holmes, 1997). We obtained a significant self-esteem by uncertainty salience interaction. Highs in the uncertainty salient condition viewed their partner and relationship more positively than Highs in the control condition. In contrast, Lows in the uncertainty salient condition viewed their partner and relationship less positively than Lows in the control condition. These findings suggest that situations of uncertainty do trigger positive illusions for people with high self-esteem.

### G83

**THE RELATIONSHIP BETWEEN CAUSAL UNCERTAINTY AND NONCONSCIOUS MIMICRY** Rachel Ruttan<sup>1</sup>, Jill A. Jacobson<sup>1</sup>, Jennifer Passey<sup>1</sup>; <sup>1</sup>Queen's University – Causal uncertainty pertains to doubts about one's ability to understand the causes of social events (Weary & Edwards, 1994), and previous research has found that higher levels of causal uncertainty are associated with greater interpersonal problems such as rejection (e.g., Rytwinski & Jacobson, 2005; Passey, 2006). However, the attempts to determine the reasons for the causally uncertain people's social difficulties have thus far been inconclusive. We hypothesized that causally uncertain people's more effortful and vigilant processing of social information may impair their ability to engage in nonverbal behaviors that facilitate social exchanges (cf. Edwards et al., 2000). Thus in the the current study, we investigated the failure to engage in mimicry, a specific nonverbal behavior that can lead to greater liking, as a possible explanation for causally uncertain individuals' social difficulties. A sample of 133 women interacted with a female confederate who shook her foot or touched her face throughout the session. Three judges (blind to experimental condition) recorded the participants' frequency and duration of face touching or foot shaking during the baseline period before interacting with the confederate and during the five-minute interaction period. Following the interaction, participants completed the Causal Uncertainty Scale (Weary & Edwards, 1994) and a liking measure. When given an accuracy goal, which should increase the importance of their chronic goal of accurate understanding, higher levels of causal uncertainty were significantly associated with lower levels of mimicry. However, in the no goal condition, no significant differences existed between high and low causally uncertain participants.

### G84

**UNCERTAINTY MAY BE HARMFUL TO RELATIONSHIPS** Linda K. Acitelli<sup>1</sup>, Robert E. Wickham<sup>1</sup>, Stephanie J. Tobin<sup>1</sup>; <sup>1</sup>University of Houston – Individuals who are chronically uncertain about things are more depressed and anxious (Edwards, Weary, & Reich, 1998) than those who are certain. With these findings in mind, we expected that uncertainty in relationships (UR) would be related to unhappiness in relationships. To assess uncertainty in relationships, both partners of 238 couples were asked how much they thought they knew about personal relationships. As expected, UR was negatively related to relationship satisfaction. However, because close partners are interdependent, we expected that one partner's UR would be associated with the other partner's UR to predict relationship satisfaction. To test this interaction, we estimated the Actor-Partner Interaction Model (APIM; Kenny, Kashy & Cook, 2006) which labels the participant as 'actor' and the relationship partner as 'partner.' Results revealed a significant interaction between actor UR and partner UR. If the actor is low on UR, the partner's level of UR has a strong negative association with the actor's relationship satisfaction. That means that if both members of the couple are low on UR, the actor is highly satisfied with the relationship. In addition, if the actor is low on UR and the partner is high, the actor is much less satisfied. If the actor is high on UR, the actor is relatively dissatisfied with the relationship regardless of the partner's level of UR. Thus, if at least one partner is high on UR, the relationship is less satisfying. These findings may indicate that an individual's level of uncertainty can have unintended interpersonal consequences.

### G85

**THE INFLUENCE OF RELATIONAL-INTERDEPENDENT SELF-CONSTRUAL ON SELF-REGULATION AND ACCOMMODATION IN ROMANTIC RELATIONSHIPS.** Simmi Mann<sup>1</sup>, Marian, M Morry<sup>1</sup>; <sup>1</sup>University of Manitoba – Relational-interdependent self-construal (RISC) is a cognitive-personality pattern in which positive feelings regarding the self are derived from developing and maintaining close personal relationships with others (Cross et al., 2000). We hypothesized that higher RISC provides individuals with a greater motivation for self-control and accommodation in romantic relationships. One hundred and fifty-five undergraduate students (105 women, 50 men), in ongoing relationships

described instances of both accommodation and non-accommodation in response to a partner transgression. Subsequently, participants completed measures assessing relationship quality, dispositional self-control, and reported depletion levels. Partial correlations revealed that in comparison to Low RISC, High RISC was significantly associated with three of the four accommodation subscales: voice,  $r(78) = .31, p < .01$ , neglect  $r(78) = -.27, p < .01$ , and exit,  $r(78) = .21, p < .01$ . To examine regulatory depletion levels a 2(construal type: High RISC vs. Low RISC)  $\times$  2(Incident Type: Accommodation vs. Non-Accommodation) repeated measures ANOVA was conducted on depletion. High, compared to Low, RISC individuals significantly reported greater depletion after describing instances of non-accommodation. There was no difference between groups after descriptions of accommodation. Finally, hierarchical linear regressions examined whether RISC moderated the relationship between accommodation and depletion. For High RISC individuals, total depletion was a significant predictor of accommodation. In contrast, for Low RISC individuals, total depletion was not a significant predictor. In sum, the present research suggests that the presence of RISC is a motivating influence on accommodative and self-regulatory tendencies within a relationship context.

### G86

**MINDFULNESS, WILLINGNESS TO EXPERIENCE AFFECT, AND RELATIONSHIP SATISFACTION** Kathryn C. Adair<sup>1,2</sup>, Steffany J. Fredman<sup>1,2</sup>, Candice M. Monson<sup>3</sup>; <sup>1</sup>National Center for Posttraumatic Stress Disorder, <sup>2</sup>Boston University School of Medicine, <sup>3</sup>Ryerson University – Mindfulness and willingness to experience emotional affect have been associated with higher relationship satisfaction (Barnes et al., 2007; Wachs & Cordova, 2007). The purpose of the current study was to understand the relationships among mindfulness, willingness to experience emotions, and relationship satisfaction in a clinical sample of couples in which one member of the couple was diagnosed with Posttraumatic Stress Disorder (PTSD). Twenty individuals (10 couples) enrolled in a study of couple therapy for PTSD completed baseline self-report questionnaires including the Mindfulness Attention Awareness Scale (MAAS), the Affect Control Scale (ACS), and the Dyadic Adjustment Scale (DAS). Independent *t*-tests revealed that those with PTSD had significantly lower mindfulness scores than partners ( $t = -2.7, p < .05$ ), but did not find any other differences for these constructs. For partners with PTSD, mindfulness and affect control were negatively related ( $r = -.81, p < .01$ ). Though not significant, there was a moderately strong association between affect control and relationship satisfaction ( $r = -.46, p = .18$ ). Mindfulness was not associated with relationship satisfaction. For partners without PTSD, there were significant associations between all constructs in expected directions (MAAS and ACS  $r = -.74, p < .05$ , MAAS and DAS  $r = .85, p < .01$ , ACS and DAS  $r = -.81, p < .01$ ). Differences in the associations based on PTSD status suggest that those with PTSD may derive relationship satisfaction from aspects unrelated to mindfulness (e.g., instrumental support). Implications for treatment and future research directions will be discussed.

### G87

**HELPING TO FEEL CONNECTED: PROSOCIAL BEHAVIOR AFTER EXCLUDING OTHERS** Jennifer R. Daniels<sup>1</sup>, Kerry L. Marsh<sup>1</sup>; <sup>1</sup>University of Connecticut – Much of the research on the effects of social exclusion on subsequent prosocial behavior has focused on the target's reduction in helping (e.g., Twenge, Baumeister, et al, 2007). It has also been predicted that participants under demand for additional cognitive resources, they may be less likely to be prosocially oriented in the face of social disconnection (Williams & Govan, 2005). This experiment tested the possibility that being the ostracizer would actually yield increased prosocial behavior as a means to reconnect with other people after the breaking of social bonds. The addition of increased cognitive load may decrease the likelihood of prosocial behaviors. It was predicted that participants would be motivated to be prosocial because of a desire to reconnect but this might be more difficult if such purposeful behaviors require cognitive resources. Participants in a computer controlled online chat were placed

in conditions in which they were included positively or rejected another participant. In addition, participants were in either a high or low cognitive load condition. After an inclusion or exclusion experience, participants were offered opportunities to be prosocial. Although there were no differences in volunteering for additional tasks or for picking up fallen paperclips, there was a marginal effect of cognitive load with low load participants donating more money. Participants in the ostracizer condition did donate more money to a charity. However, when the donation target was the person they had just rejected, ostracizers donated the least. Results are discussed in terms of reconnecting with others after purposeful disconnection.

### G88

**SIMILARITIES AND DIFFERENCES IN VIEWS ON ROMANTIC RELATIONSHIPS ACROSS 16 COUNTRIES** Erina Lee<sup>1</sup>, Gian C. Gonzaga<sup>1</sup>; <sup>1</sup>eHarmony Labs – Researchers have long been interested in cross cultural aspects of romantic relationships. To explore this topic, 2246 individuals in married or cohabiting relationships participated in a world-wide online survey. There were between 112-173 participants in each of the following 16 countries: China, Germany, France, India, Italy, Japan, Korea, Poland, Brazil, Russia, Argentina, Spain, Mexico, Turkey, England, and the United States. In each country's official language, participants responded to a series of qualitative questions asking about important partner and relationship characteristics, as well as quantitative questions on relationship satisfaction and demographic variables. Responses were translated back into English and coded. Results showed many notable cross cultural similarities and differences. For example, among the most commonly shared responses to "what things are important for a couple to share in a good long-term relationship" were honesty, trust, and respect. Less commonly shared qualities included communication, love, and religious faith. There were also notable differences in relationship satisfaction across countries, with Eastern European and Asian countries rating relatively lower in relationship satisfaction compared to the geographically western countries. Chinese women and Japanese men, for example, had the lowest relationship satisfaction overall. Implications of this research include understanding how people of different countries and cultures think about relationships and how these perspectives impact relationship quality which will inform future cross-cultural research on romantic relationships.

### G89

**REJECTION SENSITIVITY PREDICTS INGRATIATION BY WOMEN FOLLOWING HARSH REJECTION IN A DYADIC INTERACTION** Rainer Romero-Canyas<sup>1</sup>, Kavita S. Reddy<sup>1</sup>, Sylvia Rodriguez<sup>1</sup>, Geraldine Downey<sup>1</sup>, Marissa Smith<sup>1</sup>, Charles L. Burton<sup>1</sup>; <sup>1</sup>Columbia University – Men, but not women, high in rejection sensitivity (RS) ingratiate toward those who reject them harshly. The circumstances (rejection by a group) and the form of ingratiation (spending money on the rejecters) are linked to men's self-concepts. This suggests that, in situations that define aspects of the social self, rejection will motivate high RS people to ingratiate. This experimental study tests the rejection-ingratiation link in a self-defining situation for women: the formation of close dyadic relationships. The study also tests the hypothesis that ingratiation will align with sociocultural beliefs about what makes a person attractive in that self-defining situation. Participants enrolled in an online dating study to meet a potential romantic partner and wrote a biographical sketch for their match. Days later, participants returned to the lab to meet their date, but all were rejected, though in ways that varied by condition. In the harsh rejection conditions, participants were told that the match had chosen not to meet them. In a control condition, participants were told that due to technical errors, the match had not arrived. Participants then reported how much money they would spend on a date with the match, and also picked a gift for the match, a gesture of nurturance. RS scores did not predict any of men's choices or women's use of money. However, following harsh rejection, high RS women chose more valuable gifts for the match than did low RS women. The implications for the study of ingratiation and rejection are discussed.

**G90****ADULT ATTACHMENT AND THE USE OF COMPASSIONATE STRATEGIES DURING RELATIONSHIP DISSOLUTION** Tara Collins<sup>1</sup>, Omri Gillath<sup>1</sup>;

<sup>1</sup>University of Kansas – Adult attachment researchers have found that the sense of attachment security is associated with healthy engagement in compassionate behavior (e.g., Gillath et al., 2005). One of the most difficult times to show compassion is when terminating a relationship. Two studies were conducted to assess the association between people's attachment style and the use of compassionate vs. non-compassionate breakup strategies. In the first study, attachment anxiety was found to be positively associated with using both compassionate and non-compassionate breakup strategies. Attachment avoidance, on the other hand, was positively associated with the use of only non-compassionate strategies when terminating a relationship. Moreover, avoidance was found to be negatively associated with using compassionate breakup strategies. In the second study, attachment related primes were used to invoke feelings of attachment anxiety, avoidance, or security in participants. Interestingly, security prime led individuals high in avoidance to use non-compassionate strategies less often than avoidant individuals who received the anxious or avoidant primes. These findings are among the first to explore compassion in the breakup context, showing that enhancing a person's sense of attachment can help not just him or her, but also his/her partner and make the dissolution process more tolerable.

**G91****THE INFLUENCE OF POSITIVE AND NEGATIVE COUPLE RITUALS ON COMMITMENT** Kelly Campbell<sup>1</sup>;

<sup>1</sup>California State University, San Bernardino – Couple rituals are defined as idiosyncratic behaviors that partners enact together. Examples of positive rituals include watching favorite television programs, having unique communication methods, and using special traditions to celebrate birthdays or anniversaries. Negative rituals include arguing in patterned ways, doing predictably mean things, and engaging in unhealthy couple activities together (e.g., smoking, drinking). The goal of this study was to examine the influence of positive and negative couple rituals on commitment. Six hundred and ninety six individuals involved in different types of couple relationships (e.g., dating, married) completed two online surveys. Compared to negative rituals, positive rituals were more strongly associated with commitment; however, for both positive and negative rituals, only certain dimensions predicted commitment. For positive rituals, the dimensions of ritual frequency, meaningfulness, equal participation, and idiosyncrasy were positively related to commitment. For negative rituals, the dimensions of frequency and continuation over time were negatively related to commitment, whereas ritual meaningfulness was positively associated with commitment. Therapists can use these findings to recommend that partners frequently engage in activities they both enjoy and that are idiosyncratic to the relationship in order to enhance commitment. It is also important for couple members to mutually participate in positive rituals. Couples should be discouraged from engaging in negative rituals and repeating destructive patterns across time. It is noteworthy that negative rituals were positively associated with commitment when individuals perceived them as meaningful to the relationship. This finding warrants further investigation and directions for future research are discussed.

**G92****TYPES OF DIVORCE AND THE RESULTANT IMPACT ON THE QUALITY OF REPARTNERED RELATIONSHIPS** Elizabeth Schoenfeld<sup>1</sup>, Ted Huston<sup>1</sup>;

<sup>1</sup>The University of Texas at Austin – Divorced individuals frequently encounter many of the same problems in their post-divorce relationships that were present in their prior marriages (Hetherington & Kelly, 2002). However, little is known about how the specific causes of divorce imputed by former spouses are associated with the quality of their post-divorce relationships. Using data from the Texas Baseline Survey on Marriage, we provided 355 divorced individuals with a list of 18 commonly identified reasons for divorce (e.g., Cleek & Pearson, 1985; Kitson,

1992) and asked them to indicate the extent to which each reason was implicated (if at all) in their divorce. Cluster analysis was performed on the responses, resulting in five types of divorce experiences: (1) both partners losing romantic interest in one another, (2) both partners lacking necessary marital skills, (3) having an abusive spouse, (4) having an unfaithful spouse, and (5) having a generally troubled marriage. The participants also responded to questions about their levels of satisfaction, commitment, positivity, and negativity in their current relationship, and we used MANOVA to compare the clusters in terms of quality of their relationships. Results indicated that clusters differed significantly in the quality of their repartnered relationships; specifically, marriages that ended because both partners exhibited a wide array of negative behaviors (Cluster 5 divorces) tend to result in the formation of new relationships that are also characterized by a greater number of negative behaviors. These new partnerships also tend to be characterized by a sense of obligation to continue the relationship.

**G93****SOCIAL EXCLUSION: A META-ANALYSIS** Charisse Corsbie-Massay<sup>1</sup>,

Stephen Read<sup>1</sup>;

**G94****A LONGITUDINAL STUDY OF HOSTILITY, RELATIONSHIP QUALITY, AND HEALTH OUTCOMES AMONG AFRICAN AMERICAN COUPLES** Max

Guyll<sup>1</sup>, Carolyn Cutrona<sup>1</sup>, Rebecca Burzette<sup>1</sup>, Daniel Russell<sup>1</sup>;

health among high hostile individuals. Additional analyses provided no indication that these relationships were moderated by gender. These findings resonate with the interpersonal perspective of personality, in which the expression and implications of personality characteristics such as hostility are dependent upon the social environment, including the quality of one's personal relationships. Moreover, high hostile individuals may enjoy better health outcomes if they are in relationships that do not exacerbate their pre-existing tendency for anger and suspicion.

**G95**

**USE OF SOCIAL MEDIA IN THE SERVICE OF BELONGING NEEDS** Megan L. Knowles<sup>1</sup>, <sup>1</sup>Franklin & Marshall College – Computer-mediated communication and social networking have become pervasive, and yet it is unclear whether these means of social contact actually bolster a sense of belonging among users or instead exacerbate feelings of isolation. To examine the extent to which social media serve belonging needs, one correlational study and two experiments were designed. A survey of undergraduates revealed that a chronically high need to belong predicts greater usage of social networking websites like Facebook. An experiment using a group exclusion/inclusion manipulation allowed for participant observation following acute social threat. Consistent with prior research on social snacking (Gardner, Pickett, & Knowles, 2005), excluded participants engaged in more "social" activities such as checking email and browsing their Facebook pages during a subsequent free period than included participants. As an initial examination of the protective value of online social networks, a second experiment included the Cyberball manipulation of social exclusion/inclusion, exposure to one's own Facebook page or a control activity, and a measure of aggression using the noise blast paradigm. Even though aggression is a typical response to social threat, excluded participants who had the opportunity to mitigate their social hunger by browsing Facebook engaged in no more aggression than included participants. In contrast, the comparably enjoyable control activity, reading online comics, did not protect excluded participants from this negative response to threat. Altogether, these studies suggest that heightened belonging needs may motivate the use of social media such as social networking websites, and their use may buffer individuals from the costs of exclusion.

**G96**

**PERCEPTION OF HONEST FEEDBACK AND HAPPINESS IN ROMANTIC RELATIONSHIPS** Jennifer L. Schwerer<sup>1,2</sup>, Kenzie Snyder<sup>1</sup>, Gertraud Stadler<sup>1</sup>, Niall Bolger<sup>1</sup>, Helen M. Newman<sup>2</sup>, <sup>1</sup>Columbia University, <sup>2</sup>City University of New York – According to Cole (2001) individuals are most satisfied by a romantic relationship when they are honest with their partner and believe that honesty is reciprocated. The objective of this analysis was to build on these findings by exploring the relationship among perceived honesty, frequency of confiding in one's partner, and the happiness in the relationship. Data were collected from a total of 108 heterosexual cohabitating couples. Each participant completed an online questionnaire that included Spanier's Dyadic Adjustment Scale (1976) and Pierce, Sarason, and Sarason's Quality of Relationships Inventory (QRI) (1991). Perceived honesty was measured using an item from the Support Scale of the QRI: "To what extent can you count on your partner to give you honest feedback, even if you might not want to hear it?" It was hypothesized that perceived honesty would be positively correlated with both confiding in one's partner and the level of happiness within the relationship. Pearson's correlations and linear regressions resulted in a significant weak positive relationship ( $r = .332, p < .001$ ) between perceived honesty and frequency of confiding in one's partner and a significant moderate positive relationship ( $r = .380, p < .001$ ) between perceived honesty and happiness. These findings suggest that honesty really is the best policy. Those who feel confident their partner gives honest feedback, even if it is something they might not want to hear, tend to confide in their partner more and feel happier in their relationship than those who are not confident their partner gives honest feedback.

**G97****LONG TERM SELF-PERCEIVED HEALTH, NEUROENDOCRINE, AND WELL-BEING CORRELATES OF EARLY ADULT SOCIAL ACTIVITY** Cheryl Carmichael<sup>1</sup>, Harry Reis<sup>1</sup>, <sup>1</sup>University of Rochester, Rochester NY – Early

adult social adjustment may connote a skill set that provides the ability to garner a litany of benefits into midlife that would enhance well-being and reduce health risk (e.g., stress-reducing benefits of social support, health promoting benefits of positive emotional experiences). A 30-year longitudinal study investigated the midlife benefits of social activity during college, a critical period for relationship development. Two hundred twenty-two college students (freshman and seniors, age 18-22) completed event-contingent social interaction records for 10-14 days during an academic year between 1974 and 1979. Measures of social interaction quantity (time per day interacting) and quality (perceived intimacy) were assessed. One hundred thirty-three (59.9%) participants (age 48-52) provided data on current self reported health, social life, and psychological adjustment via a web-based survey. Of those, 114 also provided salivary cortisol samples, a biomarker of neuroendocrine function. Greater overall college intimacy was marginally associated with lower (i.e., healthier) midlife cortisol levels ( $r = -.17, p = .08$ ); particularly for intimacy with opposite-sex ( $r = -.23, p < .05$ ), but not same-sex interaction partners ( $r = .03, ns$ ). Moreover, higher levels of college intimacy were associated with reduced self-reported midlife systolic blood pressure (SBP;  $r = -.27, p < .05$ ), reduced levels of midlife loneliness ( $r = .26, p < .05$ ), and increased midlife perceived support from friends ( $r = .25, p < .05$ ). Results for interaction quantity were weaker. The average amount of time per day spent interacting in college was unrelated to midlife cortisol, SBP, or loneliness (all  $r$ 's  $< .12, ns$ ), but was marginally associated with greater midlife perceived support from friends ( $r = .15, p = .07$ ).

**G98****THE EFFECTS OF PERSONAL CLOSENESS ON THE EXPERIENCE OF SOCIAL EXCLUSION** Laura Ashpole<sup>1</sup>, Lindsay Sharp<sup>1</sup>, Patricia Devine<sup>1</sup>; <sup>1</sup>University of Wisconsin-Madison – While the ostracism literature has

repeatedly demonstrated that being left out by strangers hurts, it has not explored the effects of exclusion in the context of enduring, important relationships (e.g., friendships). We developed competing hypotheses about whether exclusion by friends would be more or less threatening than exclusion by strangers. To test these hypotheses, participants played an online ball-tossing game in which they were excluded by mutually nominated close friends or by strangers. Prior to the game, we measured perceived closeness among the players and verified that friends were perceived as being closer than strangers. Following the game, we assessed basic needs, enjoyment of the game, ratings of the other players, perceived closeness among the players, and attributions for exclusion. Although all participants experienced the immediate social pain of exclusion (i.e. threat to basic needs), friendship precluded the more divisive effects of ostracism. Participants reported enjoying the game more and were less likely to derogate their friends than strangers. Further exclusion by strangers led to changes in perceived relationships among the players. Excluders came to be seen as closer to one another and more distant from the excluded individual. Friends, however, remained equally close following exclusion. Finally, whereas participants excluded by friends trivialized the experience, those excluded by strangers were embittered. This study suggests that pre-existing relationships can significantly affect both the subjective experience of exclusion and the ways in which individuals cope with exclusion. We discuss the immediate and enduring effects of exclusion in the context of social relationships.

**G99****THE HYDRAULIC NATURE OF SYSTEM JUSTIFICATION AND COMMITTED RELATIONSHIP IDEOLOGY** Martin Day<sup>1</sup>, John Holmes<sup>1</sup>, Aaron Kay<sup>1</sup>; <sup>1</sup>University of Waterloo – A consequential ideology in Western society

includes the uncontested belief that a committed relationship is the most important human relationship and almost all people want to marry or

seriously couple (DePaulo & Morris, 2005). Three studies investigated how system justification theory may explain the defense of such an ideology. In Study 1, we examined how a heightened motive to maintain the status quo affects the defense of committed relationship values. In Study 2, we investigated the reverse association, that is, how a threat to committed relationship ideology affects endorsement of the socio-political system. According to system justification theory, one reason people justify social systems is because of the control that they offer to their lives. Thus, in Study 3 we tested the possibility that people have biased beliefs about relationships because they act as a system that offers control. Results from all three studies reveal that men, but not women, defend relationship ideology consistent with predictions from a system justification framework.

### G100

#### ALL GOOD THINGS DON'T COME TO AN END: PERCEIVED RESPONSIVENESS AND CAPITALIZING ON POSITIVE EVENTS

Thery Prok<sup>1</sup>, Shelly L. Gable<sup>1</sup>, Natalya C. Maisel<sup>2</sup>; <sup>1</sup>University of California, Santa Barbara, <sup>2</sup>University of California, Los Angeles – This study examined whether perceived responsiveness to disclosures of positive events was associated with increases in personal well-being and relationship health. Sixty-seven cohabiting couples participated in a daily diary study for fourteen days. Participants were asked whether they shared a positive event with their partner each day of the study. Participants who shared a positive event then rated the responsiveness of their partner's reaction (Reis & Shaver, 1988) by indicating how understood, valued, and cared for the exchange made them feel. In addition, partners indicated how understood, valued, and cared for they attempted to make the participant feel when reactive to a positive event disclosure. Participants also completed measures on mood, relationship connectedness, and relationship security. Results indicated that compared to days when participants did not share a positive event, participants reported less sadness, anxiety, and more connection, positive affect, and relationship security on days when they shared a positive event and their partner was rated high on responsiveness (above their mean), controlling for the previous day's outcome. Low responsive days either did not differ from days with no positive events or participants had worse outcomes than days they had no positive events to share. Results showed the same pattern regardless of whether we examined participants' reports of their partners' responsiveness or partners' reports of their own behavior. These findings suggest that perceived responsiveness to positive events can amplify personal and relationship benefits beyond the positive event itself.

### G101

#### PERCEIVED PARTNER COMMITMENT, ROMANTIC ATTACHMENT, AND RELATIONSHIP OUTCOMES

Gwendolyn Seidman<sup>1</sup>; <sup>1</sup>Albright College – The relationship between attachment style and commitment has been widely studied (e.g., Birnie et al, 2009; Pistole et al, 1995). However, perceived partner commitment (PPC), the extent to which one believes one's partner is committed to the relationship, has received little attention, despite research suggesting that PPC is actually a better predictor of one's own commitment than the partner's self-reported commitment (Nock, 1995). In the current study, 251 individuals currently involved in romantic relationships completed an online survey assessing attachment-related intimacy avoidance and abandonment anxiety (Bartholomew & Shaver, 1998), commitment (Lund, 1995), PPC (rephrased Lund, 1995), attention to alternative partners (Miller, 1997), and relationship satisfaction (Hendrick, 1988). Two multiple regressions were conducted with PPC, own commitment, the attachment variables, and various interactions as independent variables, and a relationship outcome (attention to alternatives or satisfaction) as the dependent variable. Intimacy avoidance was associated with greater attention to alternatives, but this was qualified by an interaction with PPC, such that PPC was not related to interest in alternatives for avoidant participants; while more secure participants paid more attention to alternatives when they perceived their partners as less committed. For relationship satisfaction, abandonment anxiety predicted less satisfaction, but this was qualified

by an interaction with PPC, such that those high on abandonment anxiety were less satisfied if they perceived their partners as uncommitted, while more secure participants' relationship satisfaction was unrelated to PPC. Although participant's own commitment was correlated with PPC and both dependent variables, it did not interact with the attachment variables.

### G102

#### FOR MY EYES ONLY: GAZE CONTROL, ENMESHMENT AND RELATIONSHIP QUALITY

Raluca Petrican<sup>1</sup>, Christopher Burris<sup>2</sup>, Morris Moscovitch<sup>1,3</sup>; <sup>1</sup>University of Toronto, <sup>2</sup>St. Jerome's University, <sup>3</sup>Rotman Research Institute – Whereas perceived closeness that preserves the distinctness and autonomy of each partner can enhance the quality of intimate relationships, pseudo-closeness or enmeshment – reflecting an inability to distinguish one's own thoughts and emotions from a partner's and, thus, a loss of perceived distinctness and autonomy – may have more negative outcomes (Green & Werner, 1996). One hypothesized root of enmeshment is a partner's dispositional inability to differentiate self from other at the attentional level, or poor gaze control (Frischen, Bayliss & Tipper, 2007). To test this, 40 elderly married couples completed a gaze control task in which they had to inhibit following the gaze of a schematic face in order to make a correct response to a target letter. As an index of enmeshment, both partners gave independent oral accounts of the same two relationship events, and we assessed the percentage of "we"-focused (i.e., enmeshed) thoughts and emotions relative to "I" or partner-focused (i.e., differentiated) thoughts and emotions. Relationship quality measures tapped spouses' marital satisfaction and aversion to perceived loss of personal autonomy attributed to the other partner. As expected, spouses with poorer gaze control abilities were perceived by the partner as constricting the perceiving partner's autonomy, which in turn predicted lower marital satisfaction among the latter. Moreover, these links were mediated by enmeshment as evident in the event recollections of spouses with poorer gaze control. Thus, dispositional variations in fundamental social-perceptual processes may substantially affect both close relationship dynamics (i.e., differentiation versus identification) and long-term relationship quality.

### G103

#### EMPATHIC ACCURACY PREDICTS INCREASED SUPPORT PROVISION AND DECREASED CONFLICT IN ROMANTIC COUPLES

Jamil Zaki<sup>1</sup>, Sean P Lane<sup>2</sup>, Alexandra Suppes<sup>1</sup>, Niall Bolger<sup>1</sup>, Gertraud Stadler<sup>1</sup>, Kevin Ochsner<sup>1</sup>, Christine Paprocki<sup>1</sup>; <sup>1</sup>Columbia University, <sup>2</sup>New York University – Empathic accuracy (EA), one person's ability to understand another person's thoughts and feelings, has been a topic of study for decades. One guiding assumption of this work has been that understanding others should be beneficial for interpersonal interactions. There has been little direct evidence, however, that EA contributes to beneficial interpersonal outcomes, and some research has even demonstrated that EA concerning threatening information predicts negative relationship outcomes. The current study examined the real world relationship consequences of EA in romantic couples, under the hypothesis that EA would increase the likelihood of support provision, and decrease the likelihood of relationship conflict. We collected daily reports over a five-week period from 87 cohabiting romantic couples. Each day participants reported on 1) the emotions they experienced, 2) the emotions they believed their partner experienced, 3) the support they provided to or received from their partner, and 4) relationship conflict. Results indicated that participants' EA for their partner's anxiety predicted provision of both emotional and practical support the next day, but only if their partner's anxiety was elevated. Further, EA for a partner's anger predicted less conflict the next day, and that overestimation of a partner's anger predicted increased conflict. Overall, these data suggest that EA predicts beneficial relationship outcomes in couples in daily life. Moreover, the predictive results showed interesting specificity such that increased support and decreased conflict were predicted by EA for a partner's anxiety and anger, respectively.

**G104**

**PATTERNS OF INSECURE ATTACHMENT THAT DISTINGUISH FRIENDSHIPS FROM ROMANTIC RELATIONSHIPS** Robert Fuhrman<sup>1</sup>, Kimberly Smith<sup>1</sup>, Dorothy Flannagan<sup>1</sup>, Jarryd Willis<sup>1</sup>; <sup>1</sup>The University of Texas at San Antonio – The purpose of this study was to investigate how attachment styles varied across the relationship types of same-sex friends, cross-sex friends, and romantic partners. College-aged participants completed a questionnaire on one of the aforementioned relationships and were asked to select one of the four Bartholomew and Horowitz (1990) paragraphs that best described their attachments to that individual. Results indicated that the percentage of individuals who endorsed the secure paragraph was comparable to previous studies and similar across relationship types (57% to 60%). In contrast, the percentage of participants who endorsed the dismissive paragraph was significantly lower for romantic relationships (13%) than for either cross-sex friendships (27%) or same-sex friendships (31%). Alternately, the percentage of individuals who endorsed the preoccupied paragraph was higher for romantic partners (10%) and cross-sex friends (8%) than for same-sex friends (2%). Finally, the percentage of individuals who endorsed the fearful paragraph was considerably higher for romantic partners (17%) than cross-sex friends (8%), which in turn, was higher than same-sex friends (4%). Results also indicated that those in the friendship conditions who selected the preoccupied or fearful paragraphs were less likely to have a current romantic partner than those who selected the secure or dismissive paragraph. Higher levels of exclusivity and emotional investment in romantic relationships may contribute to the increase in the percentage of people who experience anxiety-based attachments with romantic partners. In addition, the lack of a romantic relationship may lead some people to experience more anxiety-based attachments in their friendships.

**G105**

**ROMANTIC RELATIONSHIP TYPES: A CLUSTER ANALYSIS OF PERSONAL, MORAL, AND STRUCTURAL COMMITMENT EXPERIENCES** Camille S. Brown<sup>1</sup>, Daniel J. Weigel<sup>1</sup>, Cailin Kulp O'Riordan<sup>2</sup>; <sup>1</sup>University of Nevada, Reno, <sup>2</sup>University of Hawaii – The present study aimed to extend the literature on commitment in romantic relationships by 1) identifying distinct types of relationships that vary based on experienced levels of personal, moral, and structural commitment, and 2) determining how these different types of relationships relate to other important relationship level variables. College students in romantic relationships (n=230) completed an initial questionnaire and a follow-up questionnaire four months later. A cluster analysis indicated three distinct types of relationships present in the sample: the first was medium on personal commitment, and high on moral and structural commitment; the second was high on personal and moral commitment, and low on structural commitment; and the third was low on personal, moral, and structural commitment. Analyses indicated that the different types of relationships varied significantly as expected on communication of commitment indicators, degree of relationship certainty, and measures of relationship length, type (i.e., level of intimacy), quality, and stability (i.e., still in relationship at follow-up); individuals in the first type of relationship reported the highest levels on these variables while those in the third type of relationship reported the lowest levels. This study is an important first step in identifying distinct types of romantic relationships and demonstrating how varying levels of personal, moral, and structural commitment may influence important relationship factors and outcomes. Future research on a more diverse sample may further illuminate this issue.

**G106**

**DENYING RESPONSIBILITY FOR PROBLEMS AND TRUST IN CLOSE RELATIONSHIPS** Jennifer Wieselquist<sup>1</sup>, Megan Scerra<sup>1</sup>, Kimberly Tymchyn<sup>1</sup>, Marisa Dzioba<sup>1</sup>; <sup>1</sup>University of New England – Past research has demonstrated that individuals trust their partners to the degree that their partners choose to behave in pro-relationship instead of self-interested ways in diagnostic situations (Wieselquist, Rusbult, Foster, & Agnew, 1999). Diagnostic situations sometimes arise when partners dis-

cuss problems in their relationship. For instance, a partner could completely deny responsibility for a problem in order to "save face" (a self-interested behavior) or the partner could accept some or all of the responsibility for causing the problem (a pro-relationship behavior). The present research explores the hypothesis that individuals trust their partners less when their partners deny responsibility for relationship problems. A correlational study was conducted in which participants described a negative incident that had occurred in their current dating relationships. In addition, they rated the degree to which they believed their partners were responsible for causing the problem and the degree to which their partners denied responsibility for it. Preliminary analyses suggest that individuals trust their partners significantly less when their partners deny responsibility for relationship problems. Furthermore, results suggest that whether or not a partner denies responsibility moderates the association between trust and perceptions of the partner's responsibility for the problem – trust was negatively associated with perceptions of the partner's responsibility only when the partner did not deny responsibility for the problem. These results are discussed in terms of the moderating role that a partner's denial of responsibility may play in trust-inspired benevolent memory for negative relationship incidents (Wieselquist, Rusbult, Finkel, & Kumashiro, 2009).

**G107**

**THE AUTOMATICITY OF DEROGATING ALTERNATIVES: EVIDENCE FROM BRAIN IMAGING** Meghan L Meyer<sup>1</sup>, Elliot T. Berkman<sup>1</sup>, Johan C. Karremans<sup>1</sup>, Matthew D. Lieberman<sup>2</sup>; <sup>1</sup>University of California Los Angeles, <sup>2</sup>Radboud University Nijmegen – It is well established that people in committed romantic relationships derogate the value of alternative partners as one strategy to maintain their current relationship. Interestingly, this 'derogation of alternatives' strategy disappears when romantically attached individuals are cognitively busy. Moreover, derogation of alternatives occurs even when participants have no instruction to deliberately regulate their responses in this way, and funneled debriefing suggests that they are unaware of doing so. To help clarify whether the derogation of alternatives may be an automatic relationship-protective strategy, we had romantically attached participants indicate whether they would consider each of a series of attractive (or unattractive) opposite-sex others as a hypothetical dating partner while undergoing fMRI scanning. This task was completed both without (and with) time pressure to allow participants to regulate their responses (or not). Behavioral results confirm the finding that attached participants consider attractive opposite-sex others as dating partners more frequently under time pressure than not. On trials when they successfully derogated attractive others (compared to when they did not), participants recruited several brain regions implicated in deliberative emotion regulation such as the ventral and dorsal lateral prefrontal cortices, and others that have been observed in other incidental processes such as the rostral ACC. These neural data offer further evidence that the derogation of alternatives by partners in committed relationships may be an automatic regulatory strategy.

**G108**

**LAUGHING TOGETHER: THE ROLE OF PERCEIVED AND ACTUAL SIMILARITY IN SENSE OF HUMOR IN RELATIONSHIPS** Michael R. Maniaci<sup>1</sup>, Harry T. Reis<sup>1</sup>; <sup>1</sup>University of Rochester – Although previous research has found that many forms of similarity are related to liking among strangers and relationship satisfaction among friends and romantic partners, little research has examined similarity in sense of humor, and existing research includes conflicting results. The present studies examined the role of similarity in sense of humor in interpersonal relationships. In study 1, 155 undergraduate participants received answer sheets ostensibly from a same-sex stranger that were manipulated so that the stranger's ratings of a series of jokes were either very similar, moderately similar, or very dissimilar to the participant's own ratings. There was a significant linear relationship between similarity condition and liking such that participants reported liking the stranger more when they shared a more similar sense of humor. Study 2 examined the role of perceived and actual similarity in sense of humor using dyadic data from

existing relationships. Both members of approximately 300 dyads (including friends, spouses, and dating couples) rated a series of jokes based on how funny they found them, how funny they thought their partners or friends would rate them, and how funny they thought their partners or friends would believe that they would rate them. Results indicated that participants perceived greater similarity in their sense of humor than actually existed. Participants also overestimated how well their partners could judge their sense of humor. Perceived similarity in sense of humor was significantly associated with relationship satisfaction for both friends and romantic partners, but actual similarity predicted relationship satisfaction only in dating couples.

#### G109

**I'VE MOVED ON: ROMANTIC RELATIONSHIP PREDICTORS OF NEW RELATIONSHIP FORMATION** Jana Hackathorn<sup>1</sup>, Daniel Weidler<sup>1</sup>, Melinda Bullock<sup>1</sup>, Eddie Clark<sup>1</sup>; <sup>1</sup>Saint Louis University – The present research expands the utilization of the Investment Model (Rusbult, 1980) by providing evidence of its predictive abilities in the transition from one romantic relationship to the next romantic relationship. The current study examined factors in the relationships of 168 adults (Mage = 36.95) that may predict whether an individual will begin a new romantic relationship after the dissolution of a past romantic relationship. Investment model variables (satisfaction, investments, and commitment) during both the past romantic relationship and the current relationship with the ex-partner, as well as other relationship variables such as self-expansion, and demographic variables (e.g. time since break-up) were examined. Participants' current relationship status was dichotomized into two groups: currently in a new romantic relationship (n=107) or currently not in a romantic relationship (n= 56). Logistic regressions indicated that higher investments (p<.05), higher satisfaction (p<.10), and higher commitment (p<.10), in the dissolved romantic relationships increased the likelihood of beginning a new romantic relationship with another person. Additionally, higher investment (p<.05), higher satisfaction (p<.05), and lower commitment (p<.05) in the current friendship with the ex-partner significantly increased the likelihood of engaging in a new romantic relationship. Results indicate that factors in the past romantic relationship and factors in the current friendship with an ex-partner may impact one's ability or desire to transition from a dissolved romantic relationship to a new romance.

#### G110

**MEASURING RELATIONSHIP NEED SATISFACTION: STEPS TOWARD THE CREATION OF AN IMPROVED QUESTIONNAIRE** Helen Lee Lin<sup>1</sup>, Ahmet Uysal<sup>1</sup>, Amber L. Bush<sup>1</sup>, C. Raymond Knee<sup>1</sup>; <sup>1</sup>University of Houston – Self-determination theory (SDT; Deci & Ryan, 1985, 2000), proposes that humans suffer poor well-being when their basic needs for autonomy, competence, and relatedness are not fulfilled. Within this area of research is literature on relationship need satisfaction, which suggests that if the same basic needs are not met in one's romantic relationship, one may see negative effects in the relationship. Critiques of the existing measure for relationship need satisfaction (La Guardia, Ryan, Couchman, and Deci, 2000) include flawed predictive validity and item wording. With the goal of creating an improved relationship need satisfaction scale, we generated 22 new items to measure autonomy, competence, and relatedness in romantic relationships. Sample items for autonomy include, "My partner is supportive of my desires and goals," and "Sometimes my partner pushes me to be someone I am not (reversed)." Items tapping competence included, "My partner conveys confidence in my ability to be a good romantic partner," and "My partner makes me feel like I do not measure up to other potential partners (reversed)." Finally, items measuring relatedness include, "I feel like my partner understands me," and "At times, I feel like my partner shuts me out (reversed)." Participants (N=194, 52% female) completed the new scale, the existing scale by La Guardia et al. (2000), and other measures. Results indicated that the subscales of the new measure were higher in reliability compared to the existing scale. Further comparisons between the two scales and a confirmatory factor analysis of the new scale will be discussed.

#### G111

**NON-RECOGNITION OF SAME-SEX UNIONS AND RELATIONSHIP COMMITMENT: A LOOK AT THE EFFECTS OF THE CALIFORNIA SUPREME COURT'S DECISION TO UPHOLD PROPOSITION 8** Daniel L. McKinnis<sup>1</sup>, Goldshid Fadakar<sup>1</sup>, Christina Ortiz<sup>1</sup>, Nickolas M. Jones<sup>1</sup>, Kristin P. Beals<sup>1</sup>; <sup>1</sup>California State University, Fullerton – The benefits of marriage have been well studied and documented. One consequence of denying GLB individuals legal access to marriage is that they may also lose out on the benefits that marriage bestows. In addition, Herek (2006) demonstrated that the non-recognition of same-sex unions on the state and federal levels may serve as stressors for people in same-sex relationships. Marriage also serves as a barrier to leaving a relationship, which results in greater levels of commitment. The recent passage of Proposition 8 in California, subsequent review of the constitutional amendment by the state's Supreme Court, and the court's controversial decision provided researchers with an opportunity to empirically look at the affects that this non-recognition has on same-sex unions. It was predicted that levels of commitment would decrease as a result. In this study, 67 individuals in same-sex relationships completed an online survey assessing their relationship commitment before and after the court decision. Overall, relationship commitment significantly decreased,  $t(64) = 2.013, p < .05$ . Those who did not marry during the June-November window reported a greater decrease in commitment than those who did  $t(39) = 2.52, p < .05$ . Additionally, those whose relationships were upheld by the court showed no change in commitment level. These findings support past research that marriage is beneficial to relationships. Further research should include more in-depth studies of the effect of marriage on same-sex couples; specifically, does marriage truly create more stable and committed relationships among the GLB community?

#### G112

**PERSONALITY CORRELATES OF DIFFERENT ROMANTIC INTENTIONS IN SPEED DATERS** Ashley M. Vivlamore<sup>1</sup>, Lindsay T. Graham<sup>1</sup>, Samuel D. Gosling<sup>1</sup>; <sup>1</sup>The University of Texas at Austin – Research on Sociosexuality has identified patterns of mating that reflect a range of mating preferences and strategies (Gangestad & Simpson, 2000). Previous research suggests that short-term mating behavior is associated with high extraversion, low agreeableness, and low conscientiousness for both men and women (Shackleford & Schmitt, 2008). Given the increasing prevalence of practices such as speed-dating and online dating, we searched for correlates of romantic intentions in the context of speed-dating. Prior to an experimental speed-dating session, 112 participants (55 male, 57 female; mean age= 21.97 years SD= 3.16) seeking a range of romantic interactions indicated the primary type of romantic interaction they were seeking (casual sex, dating, a relationship, or marriage) and completed self-ratings on the Big Five and other personality traits (e.g., athleticism, wealth and intelligence). Persons seeking casual sex showed high self-reported levels of wealth, narcissism and self esteem, while those seeking dating showed lower levels of intelligence and higher levels of religiosity. Additionally, persons seeking long-term relationships or marriage showed relatively high levels of intelligence and honesty. Future attention should focus on how these self views relate to impressions formed by others as well as actual behavior of the daters.

#### G113

**SENSE OF BELONGING MEDIATES PERCEPTIONS OF THE OSTRACISM SOURCE AMONG AFRICAN-AMERICANS** Alison Dingwall<sup>1</sup>, Candice Wallace<sup>1</sup>, Lloyd Sloan<sup>1</sup>; <sup>1</sup>Howard University – Extant literature suggests that being ostracized has detrimental effects on one's sense of social well-being, including sense of belonging (Williams, 2001). Threats to social well-being may result in differing judgments of the source of ostracism. The current research explores the mediating role of sense of belonging on participants' perceptions of the ostracism source. 222 Black participants from an HBCU played Cyberball, a cyber-ostracism scheme in which players are either ostracized or included by a co-player believed to be at a remote location. Cyberball was imbedded in a series of ques-

tionnaires that assessed participants' attitudes toward the ostracism source as well as social well-being measures. Results revealed that being ostracized significantly and negatively impacted participants' social well-being and judgments of the ostracism source. As expected, ostracism sources were perceived as more prejudiced, less trustworthy, and more arrogant than those co-players who included the participants. Moreover, a participant's sense of belonging mediated the relationship between being ostracized and the perception of the source. A participant's sense of belonging fully mediated the relationship between being ostracized and perceiving the co-players as less trustworthy and more arrogant. Sense of belonging partially mediated the relationship between being ostracized and perceiving the co-players as more prejudiced. These findings illustrate the powerful impact that ostracism has not only on the individual but how that individual views their rejecters. Exclusion produced reduced satisfaction of needs, including sense of belonging, which in turn lead to negative perceptions of the ostracism source.

#### G114

**RACIAL IDENTITY MODERATES OSTRACIZER ETHNICITY IMPACTS ON SELF-ESTEEM FOR AFRICAN-AMERICANS.** Candice Wallace<sup>1</sup>, Alison Dingwall<sup>1</sup>, Lloyd Sloan<sup>1</sup>, <sup>1</sup>Howard University – Ostracism has been shown to have pervasive impact on many dimensions of one's sense of well being including one's sense of belonging, self-esteem, sense of control and meaningful existence (Williams, 2001). While prior research has investigated many antecedents of, and responses to, ostracism, little evidence of any impact of the ostracizer's in-versus out-group membership exists. Moreover, existing results suggest that ostracism has a negative impact on sense of belonging, self-esteem, sense of control and meaningful existence despite the ostracizer's in-group/out-group membership or membership in despised groups (Gonsalkorale & Williams, 2007). The current research explores the effects of group membership and the potential moderating role of identity on the experience of ostracism. Black participants from an HBCU were ostracized by African-American or White-American co-players. Participants played Cyberball, a cyber-ostracism scheme in which they were either ostracized or included by co-players believed to be at a remote location. The Cyberball activity was imbedded among a series of questionnaires that assessed participants' levels of ethnic identification, attitudes toward the in-group/out-group and self-reported needs-feelings following the manipulation. Results revealed that ostracism strongly and significantly impacted participants' social well-being on all four needs. In addition, levels of participant racial identity moderated the impact of co-player ethnicity and ostracism on self-esteem needs. Only high ethnic identification centrality (MIBI) participants showed higher self-esteem when included by Blacks than by Whites but this disappeared under ostracism. Participants were impacted by their degree of identity with the co-players' ethnicity suggesting a multi-layered construal of the ostracism experience.

#### G115

**WHEN ASKING HOW IS BETTER THAN ASKING WHY: THE EFFECTS OF CONSTRUAL LEVEL ON SOCIAL REJECTION** Fionnuala A. Butler<sup>1</sup>, Cynthia L. Pickett<sup>1</sup>; <sup>1</sup>University of California, Davis – Research in the domain of social rejection and ostracism has shown that after an unexpected rejection, participants can experience a cascade of negative effects. However, the manipulations used to elicit these effects have differed in terms of their temporal distance, from immediate rejection to distant future rejection. In particular, the forever alone manipulation has fostered especially negative responses in those to whom it has been administered (Twenge, Baumeister, Tice, & Stucke, 2001). Work in Construal Level Theory suggests that such responses may stem from the mental representation of a rejection, such that temporally distant events are represented abstractly while those that are near in time are represented concretely (Trope & Liberman, 2003). We hypothesized that individuals who construed a rejection concretely would respond less negatively than those who construed a rejection abstractly. To test this, participants were randomly assigned to complete a concrete or abstract mindset induction task (Freitas, Gollwitzer, & Trope, 2004). Following this task, participants were

randomly given false acceptance or rejection feedback. Results indicated that while rejected participants endorsed antisocial behaviors at significantly greater levels than accepted participants, a significant interaction between mindset and rejection emerged, such that among rejected participants, those who concretely construed their rejection were buffered against antisocial responding favored by those who abstractly construed their rejection. Further analyses showed that these effects were driven by the rejected participants. These findings suggest that the mental representation of a rejection has a powerful impact on behavioral intentions and evaluations.

#### G116

**A PAIN IN HER ARM: ATTACHMENT, ROMANTIC PARTNER SUPPORT, AND THE TOURNIQUET PROCEDURE** Carol L. Wilson<sup>1</sup>, Mollie Ruben<sup>2</sup>, Nicole Neiman<sup>3</sup>, Karen Blacher<sup>4</sup>, Stacy Silberman<sup>5</sup>, Erika Marshall<sup>6</sup>, Carolyn Belles<sup>7</sup>; <sup>1</sup>Penn State Erie, The Behrend College, <sup>2</sup>Northeastern University, <sup>3</sup>Franklin & Marshall College, <sup>4</sup>Yale School of Medicine, <sup>5</sup>Syracuse University – Prior research has linked attachment anxiety to both heightened perceptions of chronic pain and to lowered perceptions of social support. However no research to date has examined attachment and social support (1) simultaneously in the context of acute pain, a potential precursor to chronic pain, and (2) with regard to romantic partner support. The current study sought to address this gap by recruiting 66 chronic pain-free college females to undergo an ischemic pain task (i.e., the tourniquet procedure) in the presence of their romantic partner. Both partners completed personality and relationship measures including the Experiences in Close Relationships Inventory – Revised. Females then engaged in the tourniquet task during which they self-reported pain perceptions every 30 seconds using a visual analogue scale while also wearing a pulse monitor. Females completed post-tourniquet measures including the McGill Pain Inventory and the Pain Catastrophizing Scale, and both partners reported social support perceptions. As expected, higher female anxiety was linked to lower satisfaction with partner support, greater pain catastrophizing, and greater subjective pain reports, independent of partner attachment. Female anxiety was unrelated to physiological arousal during the tourniquet procedure, indicating a discrepancy between subjective and objective pain responses for high anxiety individuals. Higher avoidance scores were associated with lower subjective pain and, surprisingly, lower physiological arousal. Females' perceptions of greater partner support predicted lower subjective pain; however few interactions between support perceptions and attachment emerged, contrary to expectations. Implications exist for attachment insecurity – particularly anxiety – as a vulnerability factor in coping with pain.

#### G117

**LOVING ME IS LOVING YOU: SELF-COMPASSION, SELF-REGULATION AND DESTRUCTIVE RELATIONSHIP BEHAVIOUR.** Melanie A. C. Damphousse<sup>1</sup>, Kelley J. Robinson<sup>2</sup>, Jessica J. Cameron<sup>2</sup>; <sup>1</sup>University of Winnipeg, <sup>2</sup>University of Manitoba – It's often said that people must learn to love themselves before they can love another person. From an interpersonal perspective however, how might loving oneself promote positive relationship functioning? A self-compassionate orientation involves treating oneself kindly, feeling a sense of common humanity and taking a mindful approach to managing feelings associated with negative events (e.g., Neff, 2003). In the present study, we investigated a self-regulatory focus associated with self-directed actions following negative experiences that could account for interpersonally-directed reactions following hurtful relationship events. Over 250 participants in heterosexual romantic relationships completed online measures of self-regulation, self-compassion, and destructive interpersonal behaviour. As hypothesized, individuals higher in self-compassion reported engaging in less destructive behaviour following hurtful relationship experiences. This link was partially mediated by trait self-regulation such that individuals higher in self-compassion reported greater self-regulatory abilities, which, presumably helps them to inhibit destructive impulses following

hurtful relationship events. We argue that the self-regulatory skills refined by learning to love oneself readily apply to interpersonal contexts, promoting harmonious relationships with others. Further implications will be discussed.

### G118

#### WHEN LOVE "BLINDS": ROMANTIC INSECURITY INCREASES EMOTION INDUCED FAILURES OF VISUAL PERCEPTION

Jean-Philippe

Laurenceau<sup>1</sup>, Steven B. Most<sup>1</sup>, Elana C. Graber<sup>1</sup>, Amber J. Belcher<sup>1</sup>, C. Veronica Smith<sup>1</sup>, Lauren C. Pulinka<sup>1</sup>, Matthew J. Shaffer<sup>1</sup>; <sup>1</sup>University of Delaware – It is widely recognized that social relationships can affect our moods, behaviors, and health. However, is it possible that social relationships can also impact perception? Research by Most et al. (2005) demonstrated that emotionally evocative pictures can impair visual processing. Coan et al. (2006) found that a close relationship partner's support can decrease the neurophysiological impact of negative emotional stimuli. The current study extends these findings by asking whether a perceived threat to a close relationship can modulate emotion's impact on perception. We tested 22 heterosexual couples where female partners performed a rapid target detection task in which immediately preceding negative emotional distractors tend to disrupt awareness of targets (Most et al., 2005). Each female partner first engaged in this task while her male partner rated the attractiveness of landscapes. Partway through the experiment, the male partner's task was switched (with the female partner's knowledge) so that he began rating the attractiveness of women who presumably were romantically accessible. At the end of the experiment, the female partner rated her level of unease regarding her male partner's latter task. Results revealed that the female partner's self-rated unease correlated significantly with the degree to which negative emotional distractors disrupted their target perception. This correlation emerged specifically during the time that her partner was rating other women (i.e., not during the initial baseline period), and it was robust even when controlling for individual differences in baseline performance. Thus, emotions elicited by perceived relationship threat can modulate mechanisms that underlie visual awareness.

### G119

#### MARRIAGE MYTHS AND BENEVOLENT SEXISM AS PREDICTORS OF PREMARITAL OUTCOMES

Bren Michelle Chasse<sup>1</sup>, Bettina J. Casad<sup>2</sup>;

<sup>1</sup>California State University, Fullerton, <sup>2</sup>California State Polytechnic University, Pomona – Marriage is a rite of passage associated with unrealistic expectations. Clinicians note that many couples endorse marriage myths that can lead to hardship later in the relationship. Further, many women endorse benevolent sexism, expectations that men should be heroic and chivalrous. This research examined the relationship between endorsing marriage myths and benevolent sexism in predicting premarital outcomes among college women. Females (N = 42) under the age of 30 and engaged to be married within 12 months completed an online questionnaire measuring their endorsement of marriage myths and benevolent sexism. It was hypothesized that endorsement of marriage myths and benevolent sexism predicts less relationship satisfaction and more negative outcomes. Results indicated several interactions between endorsement of marriage myths and benevolent sexism in predicting relationship satisfaction, career ambitions, beliefs about marriage, and self-esteem. There were no significant effects among women who strongly endorsed marriage myths. However, women with less myth endorsement and higher endorsement of benevolent sexism had lower relationship satisfaction, lower career ambitions, weaker beliefs that marriage is hard work, and lower self-esteem than participants with lower endorsement of benevolent sexism. Thus, contrary to the hypothesis, endorsing marriage myths was a buffer for engaged women and predicted positive outcomes. In contrast, women who did not endorse myths, but instead endorsed benevolent sexism had more negative outcomes. Insight gained from exploring the myths of marriage and beliefs

about gender roles that couples hold before and during marriage would help marital therapists in treating patients and increasing the likelihood of relationship longevity.

### G120

#### BETWEEN GIVE AND TAKE: EFFECTS OF PERCEIVED INEQUITY IN MARITAL FORGIVENESS

Camillo Regalia<sup>2</sup>, Paleari Giorgia<sup>1</sup>, Fincham Frank<sup>3</sup>;

<sup>1</sup>Catholic University of Milan, IT, <sup>2</sup>University of Bergamo, IT, <sup>3</sup>Florida State University, US – In the psychological domain, forgiveness has mainly been examined from the perspective of the victim rather than of the offender. As a result, little attention has been paid not only to the perceived imbalance between receiving and giving forgiveness. According to equity theory and research, people who perceive an inequity between their own and their partners contributions and outcomes have a lower level of well-being and are less satisfied with their interpersonal relationships (e.g., Wright & Aquilino, 1998). This is the case for both the over-benefited, who feel guilty because they are receiving more than they give, and the underbenefited, who are disappointed, angry, and hurt because they feel that they received less than they give. Informed by this equity theory perspective, the present study investigated whether a perceived imbalance between granting and receiving forgiveness in marriage affects subsequent psychological well-being and marital satisfaction. About 120 Italian married couples participated at the study. Across spouses there was agreement that husbands tended to be under-benefited and wives overbenefited in regard to marital forgiveness. Consistent with previous research showing that the quality of exchanges is more important to the marital satisfaction and well-being of wives than husbands, for wives perceived inequity in marital forgiveness predicted an increase in depressive symptoms, and marital dissatisfaction and a decrease in subjective well-being over a 6 month period. Interestingly, the prediction was significant even when controlling for the total levels of forgiveness given and of forgiveness received as well as for the under-benefited vs overbenefited status.

### G121

#### WHAT DOES BOREDOM HAVE TO DO WITH IT? - SOCIAL EXCLUSION AND BOREDOM AS DISTINCT PROCESSES IN OSTRACISM

Johann Jacoby<sup>1</sup>, Kai Sassenberg<sup>1</sup>;

<sup>1</sup>Knowledge Media Research Center, Tübingen – Ostracism, or being ignored and excluded, has large negative effects on the senses of belonging, control, and meaningful existence, and self-esteem (Williams, 2009). In addition to the obvious social process explaining the link between social exclusion and satisfaction of these fundamental needs, boredom (i.e., understimulation and lack of control), a non-social process, is hypothesized to account for a portion of the effects on control and meaningful existence, but not those on the genuinely social needs to belong and for self-esteem. Studies 1 (using Cyberball, Williams & Jarvis, 2006) and 2 (using an eyegaze paradigm, Wirth et al., 2008) show that ostracism is indeed associated with increased experiences of boredom and understimulation as well as a lack of interest. A further prediction following from the hypothesis is that episodes of understimulation void of a social context will still be detrimental for meaningful existence and control, but not for belonging and self-esteem. To test this hypothesis, modified versions of the Cyberball game were created which preserve the structure of the game, but replace the alleged human agents in the game by non-social contexts (e.g., 'Cyberdrops'). In a series of studies with such games, it was indeed found that meaningful existence (Studies 3 and 4) and the sense of control (Studies 4 and 5) are thwarted by understimulation, but not belonging and self-esteem. These studies show that boredom is involved in bringing about the detrimental ostracism effects and thereby contribute to the growing body of research examining the processes involved in ostracism.

**G122****RELATIONSHIP QUALITY AND PARTNER PERCEPTIONS IN DATING COUPLES: PROJECTION, PERCEIVED SIMILARITY, AND PSYCHOLOGICAL BENEFITS**

Marian Morry<sup>1</sup>, Mie Kito<sup>1</sup>; <sup>1</sup>University of Manitoba, Canada – According to the attraction-similarity model (Morry, 2005, 2007), relationship quality (RQ) leads to perceptions of partner-self similarity. RQ and perceived similarity then provide psychological benefits for the perceiver. Perceived trait similarity provides an understanding of the ways in which people form and maintain social relationships. If perceived similarity is only observed for some personality characteristics and not others, this raises the question of why individuals only project some aspects of their own personality. Drawing on balance theory (Heider, 1958; Newcomb, 1959), the attraction-similarity model predicts that increases in RQ or in the relevance of personal characteristics to the relationship should increase the desire to perceive similarities. Across three studies, RQ positively predicted perceptions of trait similarity. Study 1 also indicated that for moderate, but not low, relationship relevant traits, individuals projected the self onto the dating partner as a way of perceiving similarities. In Study 2, priming high, as opposed to low, RQ led to greater perceived similarity on the moderately relevant traits. Study 3 indicated greater perceived similarity between self and dating partner than between self and average same-sex student on the moderately relevant traits. RQ and perceived similarity with the dating partner on the moderately relevant traits also predicted the psychological benefits of positive affect and state self-esteem. Supporting the attraction-similarity model and balance theory, RQ and relationship relevance were both important predictors of perceived similarity. The relationship relevance of the traits was also an important factor across all analyses: projection, perceived similarity, and psychological benefits.

**G123****DOES SELF-IDEALIZATION HELP OR HURT RELATIONSHIPS? THE INTERACTIVE EFFECTS OF SELF-COMPASSION AND CONSCIENTIOUSNESS ON RELATIONSHIP MAINTENANCE.**

Levi Baker<sup>1</sup>, James McNulty<sup>1</sup>; <sup>1</sup>University of Tennessee – How does self-idealization affect romantic relationships? Although self-idealization may benefit relationships by helping intimates maintain a positive sense of self despite their interpersonal mistakes, it is also possible that self-idealization harms relationships by removing intimates' motivations to repair those mistakes. Perhaps the benefits of self-idealization depend on dispositional factors that otherwise motivate intimates to correct relationship problems -- i.e., conscientiousness. Three studies provided support for this prediction among men. All three studies operationalized self-idealization using a measure of self-compassion. Study 1 demonstrated that self-compassion interacted with conscientiousness to account for men's self-reported motivation to fix relationship problems, such that self-compassion was only associated with greater motivation to fix relationship problems among men high in conscientiousness. Study 2 demonstrated that self-compassion interacted with conscientiousness to account for observations of newlywed husbands' avoidance during problem-solving discussions, such that self-compassion was associated with less avoidance among husbands high in conscientiousness, but with greater avoidance among husbands low in conscientiousness. Study 3 demonstrated that self-compassion interacted with conscientiousness to predict the trajectory of husbands' marital problems and marital satisfaction over the first four years of marriage, such that higher levels of self-compassion were associated with less severe problems and more stable satisfaction over time among husbands who were high in conscientiousness, but with greater problems and declines in satisfaction among husbands who were low in conscientiousness. Self-compassion was inconsistently associated with relationship outcomes among women.

**G124****RELATIONAL-INTERDEPENDENCE SELF-CONSTRUAL AND FRIENDSHIP QUALITY: THE ROLE OF RELATIONSHIP-SERVING BEHAVIORS AND NEED FULFILLMENT**

Mie Kito<sup>1</sup>, Marian M. Morry<sup>1</sup>, Lauren Hill<sup>1</sup>, Victoria Suen<sup>1</sup>; <sup>1</sup>University of Manitoba – Relational-interdependence self-construal (RISC) is a person's tendency to define the self through relationships with close others. In previous research (Morry & Kito, 2009), high RISC individuals reported more relationship-serving behaviors, and these behaviors allowed them to perceive that their friendship needs were fulfilled. These perceptions of need fulfillment then predicted high friendship quality. Our research examined this model with 54 female same-sex stranger pairs (108 women) after a short initial conversation (i.e., the formation of friendships; Study 1) and 35 ongoing female same-sex friend pairs (70 women; Study 2). Both studies indicated that when people perceive their friends as being high in RISC, they also perceive their friends as behaving in a relationship-serving manner (i.e., providing and eliciting greater disclosure). These perceptions of the friends' behavior predicted perceptions of the fulfillment of their friendship needs and greater relationship quality. On the other hand, after controlling for perceptions of friend's RISC, one's own RISC and the friend's actual RISC were not significant predictors of self or perceived friend's behaviors, perceptions of need fulfillment, or relationship quality. Our mediation analyses indicated that perceived friend's behaviors mediate the relation between perceived friend's RISC and relationship quality and that perceptions of need fulfillment mediate the relation between perceived friend's behaviors and relationship quality. These results support the model proposed by Morry and Kito (2009) and further demonstrate the relative importance of one's perceptions of friend's RISC and behaviors over actual RISC of the self and a friend as well as own and friend's behaviors.

**G125****PROMOTION AND PREVENTION IN LOVE: THE STRATEGIC ADVANTAGE OF COMPLEMENTARY REGULATORY FOCUS ORIENTATIONS IN CLOSE RELATIONSHIPS**

Vanessa Bohns<sup>1</sup>, Gale Lucas<sup>2</sup>, Daniel Molden<sup>2</sup>, Eli Finkel<sup>2</sup>, E. Tory Higgins<sup>3</sup>; <sup>1</sup>University of Toronto, <sup>2</sup>Northwestern University, <sup>3</sup>Columbia University – Promotion and prevention represent two different strategic orientations to goal pursuit. Specifically, a promotion orientation is concerned with growth and advancement and is associated with eager strategies of goal pursuit, while a prevention orientation is concerned with security and responsibilities and is associated with vigilant strategies of goal pursuit. While either of these strategic means can be used to pursue the same desired outcome, there are clear tradeoffs to using either one strategic approach over the other. For this reason, many goals in life are most effectively achieved using a balance between both of these strategies. In close relationships, such a balance may be obtained through a partnership in which two individuals bring different and complementary strategic orientations to the relationship (i.e., one person generally prefers to use a promotion orientation to goal pursuit, while the other generally prefers to use a prevention orientation). In a series of studies of dating and married couples, we have found that such complementarity in strategic orientations is optimal for close relationships. Specifically, couples in which one partner is predominantly promotion and the other is predominantly prevention demonstrate greater relationship well-being. Moreover, such complementarity effects are moderated by a dyad's level of goal congruence. That is, strategic complementarity is beneficial under conditions of high goal congruence (conditions in which two individuals are in agreement with regard to the goals they wish to pursue together), indicating that these complementarity effects are driven by the strategic advantage of having both orientations represented within a dyad.

**G126****WHY ARE RESPONSES TO SOCIAL EXCLUSION SO VARIABLE? THE ROLE OF EMOTIONS AND THEIR COMPUTATIONAL ELEMENTS** Theresa E. Robertson<sup>1</sup>, Andrew W. Delton<sup>1</sup>, Stanley B. Klein<sup>1</sup>; <sup>1</sup>University of California, Santa Barbara

Social exclusion is universally practiced and is universally painful. Yet responses to exclusion vary radically, from outrage and aggression to anxiety and deference. How can these differences be explained? We investigate the role of a variable indexing social valuation, called a welfare tradeoff ratio (WTR). This variable's magnitude regulates decisions about when to sacrifice or tradeoff one's own welfare to increase the welfare of another. The settings of this variable may determine the appropriate emotional and behavioral response for regaining inclusion after being excluded. We hypothesize that when a person undervalues their group (i.e., has too low a WTR)—and is excluded for this reason—the excluded person experiences guilt and shame. Guilt and shame, in turn, activate behaviors demonstrating increased valuation of the group. We further hypothesize that when the group undervalues a member (i.e., has too low a WTR)—and excludes the member for this reason—the excluded person experiences anger. Anger, in turn, activates behaviors that cause the group to increase its valuation of the excluded person. To test this, participants were primed with one of two situations: being excluded for defecting on an ongoing group task (a low WTR toward the group) or being excluded due to an illness (a low WTR from the group). Participants then rated (a) the extent they felt various emotions and (b) various tactics they might use to regain inclusion. Results show that the different types of exclusion led to the predicted emotional and behavioral patterns.

**G127****INVESTMENT AND ACCOMMODATION IN ROMANTIC RELATIONSHIPS: THE ROLES OF SOCIAL THREAT AND REWARD** Geoff MacDonald<sup>1</sup>, Judith Gere<sup>1</sup>, Marcella Wijaya<sup>1</sup>; <sup>1</sup>University of Toronto

Although research has often focused on the role of perceived threat in regulation of emotional investment in romantic relationships, the current research directly examines the roles of social threats (i.e., potential for negative evaluation) versus rewards (i.e., potential for closeness and intimacy) in predicting key investment model (Rusbult et al., 1998) and accommodation (Rusbult et al., 1991) constructs. Across two samples, the results confirm the independence of perceptions of social threat and reward potential in romantic relationships. Path models reveal that social reward potential accounts for more variance in satisfaction, quality of alternatives, investment, and commitment to a relational partner than does social threat potential. Further, social reward perceptions were related to active responses to accommodative dilemmas (i.e., more voice, less exit) whereas social threat perceptions were related to passive responses (i.e., more loyalty and neglect). These data strongly support the need to consider perceived opportunity for social reward in models of behavior regulation and emotional investment in romantic relationships. The data also further support the validity of the social threat and reward constructs, suggesting that social threat perceptions predict prevention-motivated conflict styles whereas social reward perceptions predict promotion-motivated conflict styles.

**G128****"FORGIVE THEM FOR THEY DON'T KNOW WHAT THEY DO": BELIEF IN FREE WILL REDUCES INTERPERSONAL FORGIVENESS** Johan Karremans<sup>1</sup>, Kathleen Vohs<sup>2</sup>; <sup>1</sup>Radboud University, The Netherlands, <sup>2</sup>University of Minnesota

Despite ongoing scientific debate about the existence of free will, most lay people hold a belief (to varying degrees) in free will. For instance, people in 36 countries were surveyed as to whether their fate is in their own hands, and 70% agreed. Recent research has demonstrated that free will beliefs can also be experimentally altered (Vohs & Schooler, 2008). Manipulations that decreased free will beliefs led to a range of negative interpersonal behaviors such as cheating, aggression, and less willingness to help others in need – suggesting that believing in free will may have important societal benefits. In the

present research we tested whether supporting a belief in free will can also have negative interpersonal consequences. Specifically, we tested the prediction that a strong belief in free will negatively affects interpersonal forgiveness, whereas determinism positively affects forgiveness. We based our predictions on the notion that people are more likely to forgive an offender if the offender's behavior is attributed to external (vs. internal) factors. In fact, some researchers have argued that such external attributions of responsibility are at the core of forgiveness (e.g., Fincham, 2000). Three studies, in which the belief in free will was either measured or experimentally manipulated, supported our prediction: Stronger beliefs in free will were associated with lower levels of forgiveness. These findings not only demonstrate that philosophical views on agency in human nature can influence interpersonal forgiveness, they also have important implications for the recent debate about the value of the belief in free will.

**G129****BEING 'IN' WITH THE IN-CROWD: THE EFFECTS OF SOCIAL EXCLUSION AND INCLUSION ARE ENHANCED BY SHARED INGROUP STATUS** Donald Sacco<sup>1</sup>, Michael Bernstein<sup>1</sup>, Steven Young<sup>1</sup>, Eric Cook<sup>1</sup>, Kurt Hugenberg<sup>1</sup>; <sup>1</sup>Miami University

Three studies tested a critical moderator of social exclusion; perceived essentialism of a group. We argue that groups naturally viewed as having an underlying structure that is immutable, inborn, deeply rooted, and informative about people (Bastian & Haslam, 2006), such as one's racial ingroup, will moderate individuals' reactions to exclusion and inclusion. In Study 1 and 2, White undergraduates played Cyberball with either two Caucasian or two African American confederates and then completed a questionnaire assessing reactions to the game. Results of both studies revealed a main effect of inclusionary status, such that included participants had more fulfilled basic needs than did excluded participants. Importantly, this main effect was qualified by an Inclusionary Status × Confederate Race interaction, indicating that compared to racial outgroups, inclusion by racial ingroups felt better and exclusion felt worse. Study 2 also found that when playing Cyberball with racial ingroup members (White confederates), participants' self-reported basic needs were partially mediated by changes in perceived similarity with the same-race confederates. Study 3 again used Cyberball, but used political party affiliation (Gonsalkorale & Williams, 2007) instead of race as the groups. We found that when participants were led to believe their political affiliation was essentialized, inclusion by their political ingroup felt better and exclusion by their political ingroup felt worse, while low essentialized groups only exhibited the classic main effect pattern. These studies indicate that naturally essentialized groups (e.g., race) and groups manipulated to be essential (e.g., political party) moderate the effects of social inclusion and exclusion.

**G130****ANTECEDENTS AND CONSEQUENCES OF SEEING PARTNERS IN EXTREME AND SEGREGATED VERSUS BALANCED WAYS** Margaret Clark<sup>1</sup>, Oriana Aragon<sup>1</sup>, Steven Graham<sup>2</sup>; <sup>1</sup>Yale University, <sup>2</sup>New College

The difference between saying or thinking "He is always late!" versus "He's late a lot, but it sure is fun when he gets here!" or "She's perfect!" versus "She's a lot of fun, even though she's late sometimes." can make a world of difference in how partners relate to one another. We have investigated the underpinnings of seeing your partner as all good or bad versus seeing your partner in a more balanced way as well as, in our most recent research, some of the consequences of these different ways of viewing partners. Regarding antecedents, our work suggests that people who are low in self-esteem or anxious in attachment style are most likely to perceive partners as all good or all bad at a given point in time and creating variable views across time. Higher self-esteem individuals tend to have more balanced views of their partners which are more consistent across time. Regarding the consequences of segregating positive and negative views of partners versus integrating views is that those who integrate views have been found to make judgments about a partner's traits more quickly. Furthermore, those who integrate are far less

influenced than people with segregated views by primes suggesting that people in general (not necessarily including their partner) are threatening or that other people (not necessarily their partner) are kind. Interestingly, people with segregated viewpoints were particularly slowed in making judgments about their partner when primed with information that people, in general, are kind.

### G131

**OSTRACISM AND ROMANTIC AFFILIATION: BEING SOCIALLY EXCLUDED INCREASES MEN'S DESIRE TO DATE AND THEIR PERCEPTIONS OF THEIR OWN DESIRABILITY** Lisa Zadro<sup>1</sup>, Lara Winten<sup>1</sup>, Rick Richardson<sup>2</sup>, Andrew Jones<sup>3</sup>, Megan Oaten<sup>3</sup>, Carrie L Wyland<sup>4</sup>, Kipling D Williams<sup>5</sup>, <sup>1</sup>University of Sydney, <sup>2</sup>University of New South Wales, <sup>3</sup>Macquarie University, <sup>4</sup>Tulane University, <sup>5</sup>Purdue University – Theorists have proposed that one way to recover from the effects of ostracism is to seek out others, for example by striving to regain group membership (Williams, 2007). However, does being ostracized also lead to an increased desire to seek out romantic partners? Eighty-seven (40 male and 47 female) participants were either included or ostracized whilst playing a virtual ball-toss game (Cyberball). They then rated a) their desire to affiliate romantically with the opposite-sex individuals featured in a series of photographs, and b) their own perceived romantic desirability. Ostracized males, compared to included males, reported both a greater desire to romantically affiliate with targets as well as enhanced perceptions of their own romantic desirability. In contrast, no such effects were observed in females. This pattern of findings can be best accounted for by an evolutionary perspective.

### G132

**HUMAN COPYING OF MATE CHOICE PREFERENCES** Peter Todd<sup>1</sup>, Skyler Place<sup>1</sup>, Robert Bowers<sup>1</sup>, <sup>1</sup>Indiana University, Bloomington – When searching for a mate, one must gather information to determine the mate value of potential partners. But not all of that information comes from the potential partners themselves—one can also look for the reactions and preferences of others. By focusing on individuals who have been previously chosen by others, one's selection of mates can be influenced by another's successful search—a phenomenon known as mate copying. We show evidence of mate copying in humans with a novel methodology that closely mimics behavioral studies with non-human animals and goes beyond the use of staged still-picture stimuli in previous human mate copying studies. After viewing instances of real mating interest in video recordings of speed-dates, both male and female participants demonstrate mate copying effects for short-term and long-term relationship interest when they perceived the dates as successful. We also found that attractiveness can mediate whom an individual will choose to copy. We further investigated the extent to which this effect generalizes to other potential mates with shared characteristics, or is restricted to an increased attractiveness of the individuals seen in the interactions—that is, whether humans show trait-based or just individual-based mate choice copying. These findings bridge the gap between animal and human mate copying research and highlight a new methodology to further the study of this phenomenon.

### G133

**TOO MUCH OF A GOOD THING? CURVILINEAR EFFECTS OF PERCEIVED PARTNER IDEALIZATION ON MARITAL SATISFACTION** Jennifer M. Tomlinson<sup>1</sup>, Harry T. Reis<sup>2</sup>, Cheryl L. Carmichael<sup>2</sup>, Arthur Aron<sup>1</sup>, <sup>1</sup>Stony Brook University, <sup>2</sup>University of Rochester – Perceived partner idealization (PPI) refers to my perception of how positively my relationship partner sees my traits and abilities, over and above how positively I see them myself. Previous research on PPI, focused on linear effects, finds that PPI is positively linearly associated with increases in relationship well-being (Murray, et al., 2003) and negatively with activating an exchange script (Murray et al., 2009). We propose, however, that there is an optimal level of PPI, such that too little or too much PPI (seeing my partner as "putting me on a pedestal") is associated with lower relationship satisfaction. This implies a curvilinear effect. In a sample of 89 married couples, we

assessed a potential curvilinear (quadratic) relation of PPI with relationship satisfaction. For wives, PPI had a strong curvilinear effect (linear  $\beta = -.004$ ,  $p = .98$ ; quadratic [controlling for linear]  $\beta = -.45$ ,  $p < .01$ ). For husbands, PPI had a significant linear effect and a marginal curvilinear effect (linear  $\beta = .44$ ,  $p < .05$ , quadratic [controlling for linear]  $\beta = -.26$ ,  $p = .07$ ). In both, the pattern was that as PPI increased, satisfaction increased up to a point, but near the high end, it peaked and began to decrease. Thus, feeling idealized by one's partner at extreme levels may actually have detrimental effects, particularly for women. In addition to the first demonstration of which we are aware of negative effects of overidealization, these results speak to the general importance of considering non-linear relationships in social psychology.

### G134

**BEYOND "THANKS!": HIGH-QUALITY EXPRESSIONS OF APPRECIATION AS RELATIONSHIP GLUE** Sara Algoe<sup>1</sup>, Barbara L. Fredrickson<sup>1</sup>, Shelly L. Gable<sup>2</sup>, Amy Strachman<sup>3</sup>, <sup>1</sup>University of North Carolina at Chapel Hill, <sup>2</sup>University of California, Santa Barbara, <sup>3</sup>eHarmony Labs – Expressions of appreciation convey felt gratitude for benefits received. But, like smiles, some "thank you"s are ineffective or insincere. Because they have been co-opted for broad use, their power is obscured and has been overlooked. Based on our social functions account of the emotion of gratitude (Algoe, Haidt, & Gable, 2008) we predict what makes a high-quality expression of appreciation and the consequences for the person being thanked. Two studies measured expressions of appreciation for benefits provided within romantic relationships. In each study, high-quality expressions of appreciation predicted relationship outcomes at six months, including breakup (Study 1) and increases in relationship satisfaction (Study 2). In addition, in Study 2, each couple-member expressed appreciation to the partner for a specific event for which he or she felt grateful. As predicted, observers' coding of expresser's behavior in videotaped conversation was associated with the target's positive evaluation of the interaction at the time it occurred. This evaluation of perceived partner responsiveness, in turn, positively predicted the target's everyday satisfaction with the self and the relationship across 14 nights of responding. Importantly, these effects were independent from those related to evaluations of the expresser's behavior during other interpersonal tasks in the laboratory (i.e., social support provision and capitalization responses). These findings suggest expressed appreciation as a potent interpersonal skill within ongoing relationships. Moreover, by addressing how the emotion of gratitude functions socially, this research positions gratitude as an evolved vehicle for the promotion of relationships through the building of mutually responsive patterns of behavior.

### G135

**COMMUNICATING THE NEED FOR ACCEPTANCE THROUGH SPEECH ACCOMMODATION: A DYADIC INTERDEPENDENCE APPROACH** Lauren Aguilar<sup>1</sup>, Geraldine Downey<sup>1</sup>, Robert Krauss<sup>1</sup>, Jennifer Pardo<sup>1</sup>, Niall Bolger<sup>1</sup>, <sup>1</sup>Columbia University – One of the primary functions of mimicry is to promote feelings of similarity and social connection between individuals. Therefore, we predicted that those with a greater need for acceptance should accommodate their speech more than those with less need. Need for acceptance was assessed as rejection sensitivity (RS), referring to how much one experiences chronic anxiety and insecurity about social rejection (Downey & Feldman, 1996). Participants, High (HiRS) or Low (LoRS) in RS engaged in a dyadic task. Drawing on Kenny, Kashy, and Cook's (2006) Actor-Partner Interdependence Model, we examined how an individual's speech accommodation to her partner was influenced by her own RS and influenced by interacting with a partner who was HiRS or LoRS. Results show that HiRS individuals displayed more speech accommodation than LoRS individuals; however, partners of HiRS individuals displayed less speech accommodation than partners of LoRS individuals. Dispositional composition of the dyad also mattered, such that dyads of matched RS level had significantly more speech accommodation than mismatched RS dyads. Replicating the nonverbal mimicry research, accommodation elicits feelings of connection in one's partner;

however, in a novel mimicry finding, being accommodative does not promote feelings of connection toward the partner. This research extends nonverbal mimicry work, demonstrating that speech mimicry also leads to social bonding and that rejection sensitivity predicts non-conscious speech accommodation. Furthermore, it elucidates the utility of using dyadic designs to investigate individual differences in mimicry and evaluate the benefits, and possible costs, of this nonconscious social behavior.

### G136

**WHAT DOES PERCEIVED PARTNER RESPONSIVENESS MEAN?** Arthur Aron<sup>1</sup>, Jennifer Tomlinson<sup>1</sup>, <sup>1</sup>State University of New York at Stony Brook – What does it mean to feel that a romantic partner is responsive to your needs? Recently, the perception of partner responsiveness (PPR) to self has become a significant focus of relationship research. However, different research programs have developed different measures and it is not clear all are assessing the same construct. We gathered the PPR measures used in all published and unpublished studies of PPR of which we were aware, administered these 13 scales to a large sample, and explored their latent structure. Two main factors emerged: One, Global, was characterized by scales emphasizing a more general, overall evaluation of partner's concern for self (e.g., Derrick & Murray, 2007; Lemay & Clark, 2008; Tomlinson [Rodden] & Aron, 2008). The other, Specifics, was characterized by scales that focused on particular supportive/responsive partner behaviors toward self (e.g., Collins & Feeney, 2001; Kuncz & Shaver, 1994; Reis, 2003; Pierce, Sarason, & Sarason, 1991). This two-factor structure is consistent with McNulty and Karney's (2004) distinction between global and specific traits in perceptions of partner idealization of self. Further, the Global scale factor was associated overall with relationship length ( $r = .44$ ), while the Specific factor was only minimally associated with length ( $r = .04$ ; difference,  $p < .01$ ). Thus, over time, perception of the partner's concern for the self appears to become generalized into a schema that is only minimally related to the reality of partner behavior. We conclude with a consideration of the significant implications of these results for theory, application, and measurement.

### G137

**"IF YOU DON'T 'GET IT', IT DOESN'T COUNT:" THE ROLES OF APOLOGY AND RESPONSIVENESS IN FACILITATING FORGIVENESS IN ROMANTIC COUPLES** Carolina Pansera<sup>1</sup>, Jennifer G. La Guardia<sup>1</sup>, <sup>1</sup>University of Waterloo – There is currently limited empirical research examining the partner behaviours which promote or alternatively thwart forgiveness in romantic relationships. This study examined the role of apology in predicting forgiveness of real-life hurtful events occurring within romantic partnerships, and tested that perceived partner responsiveness (i.e. perceptions that a partner understands and validates one's experience) would mediate this link. In an online study, participants ( $N=188$ ) described an unresolved event in which their current romantic partner had hurt them in some way and tried to seek their forgiveness. Results showed that partner responsiveness emerged as a key predictor of forgiveness and as an important mediator of the apology-forgiveness relationship suggesting that apology seems to facilitate forgiveness because it conveys that one's partner has understood and validated one's experience of the hurtful event. This mediational model was further moderated by event severity and relationship satisfaction, such that at high levels of event severity and low levels of relationship satisfaction, both apology and responsiveness showed unique, positive direct effects on forgiveness. Finally, exploratory analyses indicated that not all forgiveness-seeking behaviours are "created equal"—verbal behaviours that directly address the hurtful event are perceived to be apologetic and responsive while those behaviors (verbal and non-verbal) which attempt to smooth over the relationship but do not directly address the hurtful event appear to undermine forgiveness. This research extends current understanding of the partner behaviours which may facilitate or thwart forgiveness within romantic relationships. Implications of these behavioral signatures for intervention will be discussed further.

### G138

**THE EFFECTS OF SPOUSE PRESENCE DURING A STRESSFUL SOCIAL INTERACTION: ANXIETY REDUCING OR PROVOKING?** Bethany L. Fisackerley<sup>1</sup>, Beth A. Pontari<sup>2</sup>, <sup>1</sup>East Carolina University, <sup>2</sup>Furman University – The presence of a supportive other has been associated with benefits and drawbacks in the social support literature (e.g., Bolger and Amarel 2007). We tested the effects of spousal involvement on anxiety during an anticipated stressful social interaction. Married couples believed they were participating in research about personality assessment. Spouses received bogus unflattering feedback after they separately completed a personality test online and then believed they would meet with a psychologist for a face-to-face assessment regarding that feedback. Participants ( $N = 76$ ) thought this meeting would occur with their spouse present, after their spouse had met individually with the psychologist (support not present condition) or alone. Anxiety level was assessed immediately before the meeting. Trait social anxiety level and relationship strength were measured in a separate session as potential moderators. We expected participants to express lower levels of anxiety in the spouse present versus alone conditions, and that these effects would depend on the aforementioned moderators. In support of these predictions, participants with high social anxiety showed the least anxiety in the spouse present condition, whereas participants with low social anxiety showed more anxiety in the spouse present than alone conditions. For relationship strength, participants with strong feelings showed less anxiety in the spouse present than alone or not present conditions but participants with weak feelings showed more anxiety in the present than alone conditions. The results demonstrate the complex nature of social support in that spousal involvement during stressful situations can be beneficial to some while detrimental to others.

### G139

**INFLAMMATION AND SOCIAL EXPERIENCES: CYTOKINES INDUCE FEELINGS OF SOCIAL DISCONNECTION** Tristen K. Inagaki<sup>1</sup>, Naomi I. Eisenberger<sup>1</sup>, Nehjla Mashal<sup>2</sup>, Michael R. Irwin<sup>1</sup>, <sup>1</sup>University of California, Los Angeles, <sup>2</sup>Northwestern University – Although recent studies have demonstrated links between feelings of social isolation and inflammatory processes, it is not known whether feelings of social isolation activate inflammatory processes, whether inflammatory processes contribute to feelings of social isolation, or some combination of both. Based on the role that proinflammatory cytokines play in initiating 'sickness behavior,' a motivational response that includes symptoms such as decreased social activity, it is possible that cytokines may also play a role in the subjective experience of social isolation or 'social disconnection.' Although previous studies have shown that proinflammatory cytokines can increase depressed mood in healthy subjects, no studies have examined the effect of cytokines on feelings of social disconnection. The present study investigated whether proinflammatory cytokines increased feelings of social disconnection in addition to depressed mood. Participants were injected with either endotoxin, an inflammatory challenge, or placebo. The proinflammatory cytokine, interleukin-6 (IL-6), was collected at baseline and then hourly for the next six hours via blood draws. Participants also completed self-report measures of sickness symptoms (e.g., fatigue), depressed mood (e.g., unhappy), and social disconnection (e.g., 'I feel disconnected from others') with every blood draw. Confirming the notion that endotoxin induces an inflammatory response, results indicated that endotoxin induced a significant increase in IL-6 and sickness symptoms from baseline. In addition, subjects in the endotoxin group showed increases (from baseline) in feelings of social disconnection as well as depressed mood, even after controlling for sickness symptoms. These results highlight the important links between inflammation and social processes.

## Intergroup Relations

### G140

**YOU WANT TO GIVE A GOOD IMPRESSION? BE HONEST! MORAL TRAITS DOMINATE IMPRESSION FORMATION** Marco Brambilla<sup>1</sup>, Patrice Rusconi<sup>2</sup>, Simona Sacchi<sup>2</sup>, Paolo Cherubini<sup>2</sup>; <sup>1</sup>University of Bologna, <sup>2</sup>University of Milan-Bicocca – Research on social perception has provided converging evidence that two core dimensions (i.e., warmth and competence) underlie social judgments (Abele et al., 2008; Cuddy et al., 2008; Judd et al., 2005). In addition, research showed that global impressions on others are better predicted from warmth than competence trait ascriptions (Wojciszke, 2005; Wojciszke et al., 1998). More recently, it has been shown that the warmth dimension encompasses two distinct aspects: sociability and morality (Leach et al., 2007; 2008). In two studies we explored whether the sociability and morality components of warmth play a distinct role in the impression formation process. In study 1, participants (N=48) rated real groups on sociability, morality and competence. In addition, they reported their global impression of the targets. In study 2, participants (N=119) read an immigration scenario depicting an unfamiliar social group in terms of high (vs. low) morality, high (vs. low) sociability, and high (vs. low) competence. As in the first study they were asked to report their global impression of the target. In line with our hypothesis, in both studies, global impressions were better predicted by morality than by sociability and competence. Overall, the findings indicate a distinct and a dominant role of the moral component of warmth in impression formation process.

### G141

**THE INTERGROUP THREAT THEORY AS IT RELATES TO RACIAL GUILT** Stephanie Murray<sup>1</sup>, Jason Senu-Oke<sup>1</sup>, Mark Davis<sup>1</sup>; <sup>1</sup>University of West Alabama – This experiment tested the concept of "white guilt" (Swim & Miller 1999) with the Intergroup Threat Theory (ITT--Stephan, Ybarra, & Rios-Morrison, 2009), which states that when an ingroup receives a threat related to an outgroup, the ingroup should experience prejudice towards the outgroup. In this experiment, the threats were stimuli that negatively portrayed African Americans. The stimuli were administered to African Americans and Caucasians. Contrary to the ITT, it was hypothesized that Caucasian participants will report less prejudicial attitudes toward African Americans after receiving the threat, due to "white guilt." Group One received an article titled "Monkey vs. Negro," which tells of an experiment to replace slave labor with that of monkeys. Group Two received a racially insensitive New York Post cartoon. Group Three received lyrics to a slave period song, "All Coons Look Alike to Me." The control group received a letter from Newt Gingrich on the benefits of marijuana decriminalization. Questionnaires were filled out by each participant in which they rated attributes and emotions possessed by African Americans. The analysis revealed that if Caucasians and other non-African American participants received any negative racial stimuli, they were more likely to have positive attitudes towards African Americans opposed to those who were in the control group. Caucasians who were in any of the experimental groups demonstrated higher levels of acceptance and positive emotions towards African Americans than those who were in the control group. The implication of this research is that not all intergroup threats lead to increased negative attitudes.

### G142

**AN AMERICAN RELIGION? ASSOCIATIONS ABOUT CHRISTIANITY, JUDAISM, AND ISLAM.** Ally Stevens<sup>1</sup>, Thierry Devos<sup>1</sup>; <sup>1</sup>San Diego State University – The United States of America is a secular nation with a separation of church and state and a commitment to religious freedom and tolerance. Although this country is religiously pluralistic, Christianity is still the largest and most influential religion in the public sphere. The goal of the present research was to examine the interconnections between three major religions and the American identity. A sample of undergraduates (predominantly composed of Christians) completed three Implicit Association Tests assessing the direction and strength of

associations between the concept "American" (relative to "foreign") and the concepts "Christianity," "Judaism," and "Islam." Explicit measures were given to assess the perceived Americanness of each religion and the perceived compatibilities or conflicts between these religions and American values. At both levels of responding, the results revealed that the concept "American" was more strongly associated with "Christianity" than with "Judaism" or "Islam," and more strongly associated with "Judaism" than with "Islam." Perceived compatibilities between Christianity and American values emerged with less compatibilities being expressed for Judaism and even less for Islam. The relative compatibilities or conflicts between the religions and American values accounted for the extent to which these religions were differentiated (explicitly or implicitly) in terms of their perceived Americanness. In contrast to the idea of a secular nation and principles of religious tolerance, the present findings document a strong psychological linkage between Christianity and the American identity.

### G143

**NORMATIVE INFLUENCES IN INTERGROUP RELATIONS** Diala R. Hawi<sup>1</sup>, Linda R. Tropp<sup>1</sup>, David A. Butz<sup>2</sup>, Mirona A. Gheorghiu<sup>3</sup>; <sup>1</sup>University of Massachusetts, Amherst, <sup>2</sup>Morehead State University, <sup>3</sup>Queen's University Belfast – The study aims to investigate the influence of norms on people's attitudes towards intergroup conflict and members of other groups. Participants were recruited from different groups in Northern Ireland, South Africa, and Lebanon, in order to assess whether perceived ingroup support for contact would predict greater trust, interest in cross-group friendships, and willingness to work towards reconciliation. According to the hypothesis, positive contact between groups of conflict would be achieved through positive normative expectations (whether cross-group contact is ostensibly supported by the ingroup), where participants would be motivated to comply with ingroup expectations and rely on trusted ingroup members as sources of information. This abstract describes the Northern Ireland survey in which data was collected from Protestant and Catholic participants, who are members of politically opposing groups in that region. Participants were asked whether their ingroup was supportive or against intergroup contact, and the mediating variables included intergroup trust and anxiety. Three dependent variables were measured: 1) interest in future contact, 2) willingness to work towards reconciliation, and 3) optimism about future relations between the two groups. The preliminary findings supported the hypothesis that intergroup trust and anxiety mediated the relationship between normative expectations and the three dependent variables. In other words, participants who reported greater ingroup support for intergroup contact were more likely to report greater trust and less anxiety towards the outgroup. They were also more interested and willing to establish friendships or work towards reconciliation, and were more optimistic about achieving peaceful relations in the future.

### G144

**EXISTENTIAL ANGST AND PREJUDICE TOWARD SINGLE PEOPLE: RESPONSES TO THREATS TO THE INSTITUTION OF MARRIAGE** Tracey Cronin<sup>1</sup>, Nyla R. Branscombe<sup>1</sup>, Jennifer Henslee<sup>2</sup>; <sup>1</sup>University of Kansas, <sup>2</sup>Middle Tennessee State University – Singles in contemporary American society represent a challenge to the idea that marriage is the essential foundation for a happy and meaningful life (DePaulo, 2006). We conducted two studies to test whether people will experience existential angst when the meaning of the institution of marriage is threatened, and whether existential angst predicts more prejudice toward single people. Participants (Study 1, N = 85; Study 2, N = 53) were randomly assigned to read one of two articles about marriage in the United States. Half of the participants read an article that described the institution of marriage as falling apart (the threat condition), while the other half of the participants read that the institution of marriage is alive and well in the United States (the affirm condition). As expected, we found that people reported more feelings of existential angst when the meaning of marriage was threatened. However, people displayed more expressions of prejudice toward singles when the meaning of marriage was affirmed, and this

effect was mediated by feelings of existential angst about ability to find meaning and happiness in life through marriage in the future. Our studies show that single people who are told that the institution of marriage is failing are more apprehensive about expressing prejudice toward their own future group membership. Our studies also show that people, including singles themselves, experience existential angst when the value of marriage is threatened and, as a result, they attempt to protect the institution of marriage by discriminating against single people.

#### G145

##### ATTITUDES TOWARD SEXUAL ORIENTATION ON THE INTERNET Karen

Dickson<sup>1</sup>, Victoria Esses<sup>1</sup>, <sup>1</sup>University of Western Ontario – This study examines attitudes towards information regarding sexual orientation presented on the internet, as well as individual differences in these attitudes. University students were asked to complete a questionnaire about their attitudes toward viewing information about other individuals' sexual orientation on the social networking website, Facebook. Participants reported that it was less appropriate to have public communication on the website with a same-sex romantic/intimate partner than an opposite-sex romantic/intimate partner and it was also less appropriate to post pictures with a same-sex romantic/intimate partner than an opposite-sex romantic/intimate partner. Further, it was also rated as less appropriate to have a same-sex romantic/intimate partner as a friend on the website than an opposite-sex romantic/intimate partner. Individual differences in attitudes toward information regarding sexual orientation were also found. Individuals who are high in right-wing authoritarianism or religious fundamentalism are more likely to view sexual orientation as an acceptable reason for ending contact with another individual by removing that individual as a friend on the website. It has been proposed that the internet may be used to effectively improve intergroup relations by putting into place opportunities for experiencing positive contact situations (Amichai-Hamburger & McKenna, 2006). However, these results indicate that how information regarding sexual orientation is presented may influence the effectiveness of the contact situation in reducing homophobia.

#### G146

##### THE ROAD TO A FRIEND'S HOUSE IS NEVER TOO LONG: MAPPING OUT FACTORS CONDUCTIVE TO CROSS-CULTURAL FRIENDSHIP Ann

Beaton<sup>1</sup>, Denis LeBlanc<sup>2</sup>, Yolanda Levi<sup>3</sup>, DJ Joseph<sup>3</sup>, Jimmy Bourque<sup>1</sup>, Tanya Monger<sup>1</sup>, <sup>1</sup>Université de Moncton, <sup>2</sup>University of New Brunswick, <sup>3</sup>Elsipogtog First Nation – According to the Common Ingroup Identity Model, favorably viewed contact conditions affect group representations that reflect unity and specificities. Majority and minority group members respond differently to group representations. Majority group members who endorse unity report favorable intergroup attitudes whereas minority group members, who maintain a blend of unity and specificities, espouse a positive intergroup orientation (Dovidio, Gaertner, & Saguy, 2009). The purpose of the present study is to map out the preferred responses to group representations among members of a minority and a majority group by considering the impact of these dimensions on intergroup behavior. We investigated how group representations and attitudes map onto cross-cultural friendship closeness and positive affect. We expected that majority group respondents who endorse group commonalities will report positive attitudes toward the minority group and ensuing close and meaningful cross-cultural friends. Minority group members who support a group representation that focuses on both commonality and group specificities will report both positive intergroup attitudes and meaningful, close cross-cultural friendships. A total of 273 high school students completed surveys, including 107 First Nation and 166 of European descent. According to path analysis, among First Nation respondents, group representations, with the exception of separate groups are associated with intergroup attitudes which in turn account for cross-cultural friendship closeness. All group representations are associated with intergroup attitudes among participants of European

descent. These attitudes translate into cross-cultural friendship closeness and positive affect. Strategic responses by majority and minority group members to group representations are discussed.

#### G147

##### WELCOMING OTHERS OR CLOSING THE DOOR: TWO EVALUATIVE PROCESSES UNDERLYING INCLUSION AND PREVENTIVE EXCLUSION OF OUTGROUPS IN SUPERORDINATE GROUPS Sven Waldzus<sup>1</sup>, Thomas W. Schubert<sup>1</sup>, André T. Raimundo<sup>1</sup>, <sup>1</sup>CIS/ISCTE – When outgroups attempt to

join a superordinate group that includes the ingroup, responses are often hotly debated. We propose that such responses are based on two distinct evaluation processes: (1) Affirmation of the outgroup's joining should depend on how much it approaches maximal goals (future ideal states) of the superordinate group, but (2) preventive exclusion of a deviating outgroup should depend on perceived minimal goal violations (non-achievement of necessary states). Moreover, approach to maximal goals should be predicted by relative prototypicality of the outgroup for the superordinate group, resulting in an indirect effect of prototypicality on affirmation of the outgroup's joining. Perceived minimal goal violation should depend on a minimal goal mindset, leading to an indirect effect of mindset on preventive exclusion. Results of a study with Portuguese participants (N = 56) judging Turkey's accession to the European Union support the hypotheses: (1) Relative prototypicality of the outgroup led to more affirmation of the outgroup's joining. (2) Priming of a mindset to focus on minimal goal standards (in an unrelated context) led to more exclusion of the outgroup. The effect of this mindset-priming was mediated by increased perception of the outgroup's minimum goal violations, whereas the relation of prototypicality and affirmation was mediated by approach of maximum goals. These differences confirm that social exclusion is based on two distinct processes linked to maximal and minimal goals. Distinguishing between these two processes helps to understand and eventually solve conflicts between people who are pro and contra an outgroup's joining.

#### G148

##### THE ROLE OF NAIVE REALISM IN POST PROPOSITION 8 CONFLICT

Negin Ghavami<sup>1</sup>, Kerri Johnson<sup>1</sup>, Ashley White<sup>1</sup>, Cori Tucker<sup>1</sup>, Ashley Payne<sup>2</sup>, <sup>1</sup>University of California, Los Angeles, <sup>2</sup>Howard University – On November 4, 2008, California voters narrowly passed Proposition 8, which amended the state constitution to define marriage as between a man and a woman. The considerable anger that erupted targeted and blamed the black community, 70% who voted in favor of Proposition 8 (CNN, 2008), for the outcome. We used naive realism (Robinson, et.al, 1995) as a theoretical foundation to examine this phenomenon. We reasoned that the outrage directed toward the black community was fueled not only by black voters' support of the measure, but also by gay/lesbian voters' mistaken assumptions of how the issue was construed by black voters. We surveyed a community sample of 254 gay men and lesbians, 85 blacks, 90 Latinos, 67 Asians and 77 whites about the extent to which they viewed gay marriage as a civil rights issue, a moral issue, and analogous to the Civil Rights movement of the 1960s. Additionally, gay men and lesbians also predicted the average attitude judgments for each race category. We predicted and found that gay men and lesbians were more likely to view gay marriage as a civil rights issue. Importantly, gay men and lesbians expected black voters - themselves the beneficiaries of the Civil Rights campaign of the 1960s - to do the same. In reality, however, black respondents were more likely to view gay marriage as a moral issue involving religious convictions, not a civil rights issue. The results of this study highlight an important link between lay theories and overt discrimination.

**G149**

**ARGUMENTS AGAINST TORTURE: THE EFFECT OF MORAL VERSUS UTILITARIAN REASONING ON DEMANDS FOR JUSTICE** Peter Kardos<sup>1</sup>, Bernhard Leidner<sup>1</sup>, Emanuele Castano<sup>1</sup>; <sup>1</sup>The New School for Social Research, New York – The arguments dominating the debate over torture range from more utilitarian arguments (e.g., torture does not work) to arguments concerning morality (e.g., torture violates human rights). This study investigated how moral arguments, compared to utilitarian arguments or no arguments, against torture affect US citizens' reactions to US-committed torture: specifically, their group-based compunction, their demands for justice (i.e., punishment, reparations), and their moral disengagement from their country's behavior. In an online experiment, 191 participants (54 male) were randomly assigned to read a fictitious newspaper article reporting on US soldiers torturing and killing Iraqi prisoners, comparable to real events. Depending on the condition, the article concluded with criticism of torture on utilitarian grounds, moral grounds, or no criticism. After the article, participants completed self-report measures for the dependent variables. We hypothesized no differences between the utilitarian and neutral condition, but in line with literature on moral outrage, differences between the moral condition and the other two conditions in terms of compunction and demands for justice. Planned contrasts confirmed that the utilitarian and neutral conditions did not differ,  $F_s(1, 190) < 2.60$ ,  $p_s > .05$ , and that both of these conditions differed from the moral condition in terms of compunction and demands for justice,  $F_s(1, 190) > 5.90$ ,  $p_s < .05$ . Participants expressed more compunction and stronger demands for justice in the moral condition. Although participants still morally disengaged to the same extent they did in the other two conditions, moral disengagement no longer diminished their compunction and demands for justice.

**G150**

**THE ROAD TO EMPATHY: A CRITICAL-DIALOGIC MODEL FOR FOSTERING INTERGROUP EMPATHY** Nicholas Sorensen<sup>1</sup>, Biren (Ratnesh) Nagda<sup>2</sup>, Patricia Gurin<sup>1</sup>, Walter Stephan<sup>3</sup>, Richard Gonzales<sup>1</sup>; <sup>1</sup>University of Michigan, <sup>2</sup>University of Washington, <sup>3</sup>New Mexico State University – We present a critical-dialogic model of intergroup dialogue (IGD) to foster both critical and dialogical empathy across group boundaries. We use the term critical empathy to emphasize empathic reactions to group-based inequality rooted in systems of power and dialogic empathy to emphasize parallel emotional reactions to others' life experiences. A collaborative team across nine universities conducted 53 randomized experiments (26 race, 27 gender) and 26 social science course comparison groups (13 race, 13 gender) involving more than 2000 participants. For the randomized experiments, participants who applied to take a semester-long course on IGD were randomized to take an intergroup dialogue or to a control group. All participants completed a pretest and posttest survey, and another survey one year later. Students in IGD show larger increases in critical and dialogic empathy than do their counterparts in the control group. Effects are similar for race and gender dialogues, for members of all four demographic groups sampled and remain significant one year later. Students in IGD show greater change than in social science comparison groups and effects are mediated by critical-dialogic communication processes within intergroup dialogue. Finally, a path model demonstrates how IGD pedagogy facilitates critical-dialogic communication processes, which foster change in intergroup empathy through cognitive processes, identity engagement and affective processes. Thus, we advance a critical-dialogic model of intergroup dialogue with effects that cannot be achieved through exposure to content on race and gender and provide the most comprehensive picture to date of pedagogical, communication and psychological processes that foster intergroup empathy.

**G151**

**WHOM WE (SAY WE) WANT: STATED AND ACTUAL PREFERENCES IN ONLINE DATING** Andrew Fiore<sup>1</sup>, Lindsay Shaw Taylor<sup>1</sup>, G.A. Mendelsohn<sup>1</sup>, Coye Cheshire<sup>1</sup>; <sup>1</sup>University of California, Berkeley – Contemporary norms encourage colorblindness and openness in social relationships. But do people who say they are open to dating someone from a different group actually do so? We examined the online dating profiles of 11,600 users of a large online dating site along with their actual behavior on the site. That is, we compared their stated preferences for the race/ethnicity of potential partners with the demographics of the users whom they actually contacted and to whom they actually replied. Overall, people tended to say they were more open than they really were. Initial contacts and replies occurred significantly more often between online dating users of the same race/ethnicity than would be predicted by the users' stated preferences or by chance (given the relative prevalence of different groups on the site). White users and older users showed this pattern more. Women also tended to show this pattern more than men. We performed equivalent analyses for age and religion – similar patterns emerged but were much less pronounced, especially for age. We consider potential explanations for our results, including self-presentational pressures, in-group/out-group dynamics, and evolved mate preferences.

**G152**

**IDENTIFYING KEY THEMES IN CROSS-RACE FRIENDSHIP FORMATION** Kristin Davies<sup>1</sup>, Arthur Aron<sup>1</sup>; <sup>1</sup>SUNY Stony Brook – Two studies investigated differences in friendship formation and maintenance between same-race and cross-race friendships. Study 1, an online, retrospective survey ( $n = 295$ ), found that same-race friends reported few initial hesitations; cross-race friends more often seemed "different" and "uninterested." Same-race friends more often endorsed "good things about being friends;" cross-race, potential problems. Initial nervousness with cross-group friends correlated with perceptions of differences and expectations of disapproval by own and friend's groups. The more initial nervousness, the more key interpersonal variables (e.g., friend respects one's views) were reported as being major reasons for friendship formation. Viewing a cross-race friend as "important" and "caring" correlated with empathizing with friend's group. Joining in friend's ethnic activities, interacting with friend's family, and acceptance by own and friend's groups all correlated with less intergroup anxiety. In Study 2, interpersonal and intergroup attitudes of entering undergraduates ( $n = 71$ ) were assessed at 3 time-points. Differences between friendship-type at 5 weeks (greater perceived similarities in personal values, social activities, and interests among same-race friends) were no longer apparent at semester's end. Further, in developing cross-race friendships, increases in admiration for friend's group correlated with increased similarity perception and feeling friend "knows" and is responsive to self; and increases in warmth for friend's group correlated with increased interactions with friend's group's family and friends, and increased concern for friend. These studies suggest that when forming cross-group friendships, people initially see fewer similarities and are nervous, but as they feel more comfortable over time, interpersonal trust and intimacy develop.

**G153**

**BAD FOR WAR AND BAD FOR PEACE: THE CURIOUS CASE OF HUMILIATION** Hammad Sheikh<sup>1</sup>, Bernhard Leidner<sup>1</sup>, Jeremy Ginges<sup>1</sup>; <sup>1</sup>New School for Social Research, New York City – Common sense suggests that experiencing humiliation will lead to an increased propensity for violence against the perpetrator. Some researchers even suggest that humiliation is the main cause of the persistence of intractable conflicts as it leads to mutual acts of retaliation (Lindner, 2007). In contrast, Ginges and Atran suggested recently that humiliation leads to passiveness that prevents moral outrage from translating into violence, but it also renders conflict resolution less likely (2008). Three experimental studies provide support for this hypothesis. Study 1 explored the emotional response to

humiliating experiences. US participants who were reminded of a situation in which they felt humiliated (vs. angry or ashamed), indicated their response on a scale of 26 emotions (taken from Johns et al., 2005) that was factor analyzed subsequently. Anger and humiliation both invoked the same level of outrage, significantly differing from shame. However, humiliation and shame lead to a high level of helplessness, while anger didn't induce such feelings. Outrage alone may increase the propensity for violence, but the simultaneous feeling of helplessness could explain why humiliation was not found to be related to aggressive intentions. This result was replicated in a sample of Muslims in Germany (Study 2). Additionally, compared to anger, humiliation lead to lower approach and higher avoidance tendencies, i.e. to passiveness. In the final study measuring the emotional response of Israeli participants to humiliation vs. anger, and action tendencies towards Palestinians, the findings of the previous studies were extended to the context of intergroup conflict.

#### G154

##### **EFFECTS OF COLORBLIND AND MULTICULTURAL MESSAGES ON INTERRACIAL INTERACTIONS** Deborah Son<sup>1</sup>, Nicole Shelton<sup>1</sup>; <sup>1</sup>Princeton University

Colorblindness and multiculturalism are two ideologies that aim to promote interracial harmony, albeit from divergent perspectives. Colorblindness advocates interracial integration by minimizing racial differences, whereas multiculturalism embraces and promotes racial diversity. Although colorblindness is theorized to promote interracial integration, we predicted that exposure to a colorblind message would lead to adverse interpersonal and cognitive outcomes for racial minorities during live interracial interactions. In the present study, participants either read a colorblind or multicultural message prior to interacting with another participant. Previously unacquainted White-White and White-minority dyads then had two race-related discussions for ten minutes. After interacting, participants completed measures regarding the other participant and completed the Stroop task to assess cognitive depletion. As predicted, exposure to a colorblind message led racial minorities to become significantly more depleted during interracial interactions compared to exposure to a multicultural message. These results suggest that in contrast to lay perceptions promoting colorblindness as a strategy to navigate interracial interactions, colorblind messages actually cause negative outcomes for minorities.

#### G155

##### **DIFFERENCES IN SUPPORTING SOCIAL CHANGE: PROMOTION VS. PREVENTION GOAL FRAMING** Sarah M. Banchevsky<sup>1</sup>, Amanda M. Johnston<sup>2</sup>, Amanda B. Diekman<sup>2</sup>, Heather M. Claypool<sup>2</sup>; <sup>1</sup>University of Colorado at Boulder, <sup>2</sup>Miami University

Regulatory Focus Theory (Higgins, 1997) proposes two motivations for framing goals: promotion (e.g., seeking gains) and prevention (e.g., avoiding losses). Research examining task continuation found promotion-oriented individuals were open to change, whereas prevention-oriented individuals preferred stability (Lieberman et al., 1999). The present research explored how framing social change in terms of promotion or prevention goals influences acceptance. Initial research found that White participants were more supportive of an African-American organization with prevention rather than promotion goals. Two follow-up studies explored how the individual differences of regulatory fit (goal frame and chronic goal orientation match; Higgins, 2005) and ambivalent sexism (Glick & Fiske, 1996) further influence the acceptance of social change. Study 1 participants first completed a measure of regulatory focus; read about a university policy change with promotion, prevention, or control goals; and reported their evaluation and willingness to support the change. Prevention-focused individuals demonstrated regulatory fit: Willingness to support the change was highest and negativity was lowest in the prevention-framed condition. Promotion-focused individuals did not differ across conditions on negativity or support. Study 2 participants completed the Ambivalent Sexism Inventory; read about a group of nontraditional women with promotion, prevention, or control goals; and reported their emotions and acceptance toward the group. Males, especially those high in hostile sexism, were most influenced by the framing of the group:

Willingness to support the group was greatest in the prevention-focused condition. These studies demonstrate that discussions of social change with prevention rather than promotion goals increase support for the change.

#### G156

##### **WHEN SECURE IS THREATENING: SECURE PRIMES HEIGHTEN INTERGROUP BIAS IN THE INSECURELY ATTACHED** Pauline Light<sup>1</sup>, Yarrow Dunham<sup>1</sup>; <sup>1</sup>University of California, Merced

— Prior research (Mikulincer & Shaver, 2001) found that priming attachment security led to decreased explicit bias in Israeli adults. We sought to extend this result by examining the effect of this form of priming on explicit and implicit bias in a more diverse U.S. sample. 132 ethnically diverse undergraduates reported on their attachment patterns and self-esteem and were subliminally primed with either the secure base of attachment or neutral words. They were then tested on both explicit and implicit bias. The majority of participants showed either a fearful or preoccupied attachment pattern with Asian American participants showing greater attachment-related anxiety than either Hispanic or Caucasian participants. Regardless of condition or ethnicity, participants with preoccupied attachment showed greater implicit bias against the gay population. Most strikingly, when primed with the secure base, these preoccupied participants actually showed greater explicit bias against the gay and lesbian targets than when primed with neutral words, thus showing the opposite pattern observed by prior research with a less diverse sample. These results suggest that attachment related primes interact with individual-level attachment patterns to produce varied results; while securely attached participants may become less biased following these primes, individuals with preoccupied attachment patterns show the reverse pattern, responding to secure primes with increased out-group derogation. We suggest that, for these individuals, secure-related words such as "hug" and "closeness" function as a form of threat. Future work will seek to validate this possibility.

#### G157

##### **WHITES' EVALUATIONS OF RACIAL MINORITIES WHO CONFRONT AND PLAY THE "RACE CARD"** Judy Tan<sup>1</sup>, Felicia Pratto<sup>1</sup>, Tessa West<sup>2</sup>; <sup>1</sup>University of Connecticut, <sup>2</sup>New York University

— Whether or not people perceive racial discrimination often varies as a function of ethnic group membership (Sidanius and Pratto, 1999) and these differences in perception may undermine race relations (Dovidio et al., 2002). Study 1 examined perceptual differences in the degree to which intergroup behaviors were perceived to be discriminatory. Items adapted from a race-based rejection sensitivity measure (Mendoza-Denton et al., 2002) were administered to 1,460 undergraduate African-, Asian-, and White-Americans. Results indicated that Whites attributed actions to be discriminatory significantly less than African Americans [ $F(1,681)=225.56, p<.001$ ] and Asian Americans [ $F(1,715)=362.44, p<.001$ ]. Study 2 extended these findings and examined whether Whites' ( $n=1,020$ ) evaluations of racial/ethnic minority targets would differ depending on whether targets attributed how they were treated to their race, and on whether or not targets confronted the perpetrators. Results demonstrated that when African American targets attribute treatment to race and confront the perpetrator, Whites evaluated them less favorably (i.e., they are less liked and respected), whereas targets were evaluated most favorably when targets attribute treatment to and address something other than race. Results also indicated that targets were evaluated as being more responsible when they make attributions to race, but did not confront the perpetrator. These results suggest that ethnic minorities may often experience a "double-bind": they are negatively evaluated when they make attributions to race, regardless of whether or not they confronted the perpetrator. Inter- and intrapersonal consequences for ethnic minorities (Shelton et al., 2006) are discussed in relation to strategies directed at managing interracial interactions.

**G158****THE PATH TO OUTGROUP DEROGATION: OUTGROUP-DIRECTED NEGATIVITY AS A FUNCTION OF PERCEIVED THREAT IN MORALITY-BASED GROUPS**

Michael Parker<sup>1</sup>, Ronnie Janoff-Bulman<sup>1</sup>; <sup>1</sup>University of Massachusetts Amherst – Two studies investigated motivations for ingroup favoritism and outgroup derogation. In Study 1 participants indicated the extent to which they felt positively about their ingroup and negatively about an outgroup in a context where group membership was based in either a moral belief (pro-choice versus against abortion) or a non-moral belief (Red Sox versus Yankees fan). Results indicated that greater negativity was directed towards the moral outgroup compared to the non-moral outgroup and that this was mediated by perceived threat from the outgroup. Non-moral ingroups were rated more positively on the emotion measure. Controlling for outgroup threat increased the magnitude of this relationship, suggesting that identification with ingroups based in moral beliefs is rooted in threat from an outgroup. Study 2 investigated whether dichotomous group memberships generally produce greater outgroup derogation. Participants wrote a free response about a particular group membership: a campus group, a group based on their religious beliefs, an important moral issue, or their gender identity. Two independent coders rated the responses for ingroup positivity, mention of an outgroup, and (if yes), how positively or negatively they felt about the outgroup. Both types of dichotomous group memberships (i.e., the moral and gender conditions) discussed the outgroup more than the other two conditions, but only the moral condition described the outgroup negatively. These results suggest that groups defined as dichotomies facilitate the salience of the outgroup; however, outgroup derogation does not simply result from the dichotomous nature of groups but necessarily involves the perception of threat.

**G159****THE ORIGINS OF THREAT PERCEPTIONS IN COMPETITIVE CONTEXTS**

Matthew Maxwell-Smith<sup>1</sup>, Clive Seligman<sup>1</sup>; <sup>1</sup>The University of Western Ontario – Martens' (1990) Competitive Anxiety Theory proposed that perceived threat in competitive contexts can be traced to high levels of outcome importance and outcome uncertainty. This hypothesis was tested in two studies. In Study 1, we asked 105 participants to discuss their personal experiences in a competitive event that occurred during their adult or late adolescent years. In Study 2, 179 participants were asked to generate hypothetical situations, based on their personal goals, occupation and lifestyle, in which they would be in competition against one or more people and to describe their expected reaction to this situation. In both studies, outcome importance and outcome uncertainty were manipulated by asking participants to think of competitive situations that were either very important or not at all important to them, and, in addition, to think about whether they were either very sure they would win the competition, very sure they would lose, or not at all sure they would win or lose. Across both studies, higher levels of importance, but not outcome uncertainty, led participants to report feeling significantly more threatened by the competition. Perceived threat was also predicted by the degree to which participants thought the competition represented an important part of their identity or self-definition. These findings imply that perceptions of threat in competitive contexts are primarily driven by the importance of the competition, and the desire to confirm an important aspect of one's personal identity through competition, rather than subjective estimates of winning or losing the reward.

**G160****AFFECTIVE AND COGNITIVE MECHANISMS UNDERLYING THE BENEFICIAL EFFECTS OF PERSPECTIVE TAKING**

Lisa Pagotto<sup>1</sup>, Alberto Voci<sup>1</sup>; <sup>1</sup>University of Padova – Previous research shows that assuming the perspective of a stigmatized group member leads to improved attitudes and increased prosocial responses toward the individual and the whole group. However, the underlying mechanisms accounting for these beneficial effects are still controversial. The present study investigates the role of different affective and cognitive mediators. Participants (N=170) were

asked to read the story of a Moroccan young woman, narrating her difficulties in Italy. Beforehand, they were instructed to imagine either how she feels or how they would feel in her shoes or to remain objective (control). Afterwards, participants reported their empathic responses (concern, injustice and sadness) and completed measures tapping self-other overlap: the IOS scale, a pictorial scale assessing independent movements of self and other, perceived similarity, discrepancy on descriptive traits, and care felt for the other. As criterion variables, attitudes and prosocial responses were measured both at interpersonal and intergroup level. Participants in the two perspective taking conditions showed greater empathic responses and self-other overlap compared to control, reported improved attitudes toward the individual and immigrants in general, and expressed more willingness to help the individual and support for pro-immigrants policies. A CFA performed on the mediators revealed that empathic responses and self-other overlap reflected different, although highly associated, latent constructs, whereas traits discrepancy represented a separated, more cognitive, factor. Mediation analyses using SEM indicated that all variables, except for discrepancy, played a role in explaining the effects of perspective taking. These findings shed new light on understanding of mechanisms underlying perspective taking.

**G161****RACIAL BIAS IN INFANTS?**

Kristin Concannon<sup>1</sup>, Kristin Shutts<sup>1</sup>, Elizabeth Spelke<sup>1</sup>, Wendy Mendes<sup>1</sup>; <sup>1</sup>Harvard University – Recent data suggest that White children in the U.S. can show implicit and explicit racial bias by age six (Baron & Banaji, 2006). Even more intriguing are findings that infants as young as 3 months look longer at own-race compared to other-race faces (Bar-Haim, et al., 2006). It is unclear, however, if the infant looking effects reflect social preferences or ease of processing effects tied to familiarity. Accordingly, we presented infants with a task designed to assess their social preferences in a live interaction with novel same- and other-race individuals. We recruited 13-month-old, healthy, full-term White infants for a study. Infants (N=15), arrived at the lab with their mothers and sat on her lap during the study. Two male research assistants (one Black and one White) individually entered the room in counterbalanced order. Each male had a scripted 2-minute conversation with the mother. At the end of the conversation the man offered a toy to the infant, and we measured infants' affect, interest, and reaching for the toys. After the individual toy offering events, the men re-entered the room together and then each offered the same toys to the infants in simultaneous offering events. Due to small sample size non-parametric tests were used to determine if there were racial preferences during the toy offerings. We found babies were equally likely to take the toy from the Black and White research assistants. Current research is extending this paradigm by examining how mothers' intergroup stress responses influence infants' social preferences.

**G162****TERROR MANAGEMENT IN THE 2008 PRESIDENTIAL ELECTION**

Marc D. Kinon<sup>1</sup>, Carolyn B. Murray<sup>1</sup>; <sup>1</sup>University of California, Riverside – Unlike animals, humans have been gifted with the capacity to self-reflect; to remember the past, to envision the future, and to hold in their minds what does not yet exist and turn these internal representations into a manifest reality. But this self-reflective capacity also enables humans to realize that one day they will surely die. Understanding the inevitability of death in juxtaposition to the will to live forever has the potential of causing immense terror; a terror that Terror Management Theorists posit is mitigated through the investment and, subsequent, protection of immortality conferring systems ("cultures"). The present data, collected two weeks prior to the 2008 Presidential Election, conceptualizes "political party membership" as such a "culture." Utilizing the Terror Management framework, it was predicted that Democrats in a mortality salience condition would exhibit a greater pro-Obama bias (i.e., mean evaluation of Obama minus mean evaluation of McCain) as compared to Democrats in control conditions. It was also hypothesized that Republicans in a mortality salience condition would exhibit a lesser pro-Obama bias as

compared to Republicans in control conditions. 66 Democrats and 38 Republicans from two southern California universities participated in the study. The hypotheses were upheld (in some cases marginally significant) and moderated by level of self-esteem. These findings are discussed in terms of limitations and future research.

#### G163

##### **OUT OF MANY, ONE?: PATRIOTISM AND THE ROLE OF SOCIETAL FAIRNESS**

Ludwin E. Molina<sup>1</sup>; <sup>1</sup>University of Kansas – “E Pluribus Unum” – “Out of many, one” – is a motto found on the Great Seal of the United States and captures one of the greatest challenges facing America today – how to engender unity amidst diversity? A brief look at the social psychological literature examining subgroup differences on patriotism demonstrates results have been mixed (e.g., see Sidanius, Feshbach, Levin, & Pratto, 1997; De la Garza, Falcon, & Garcia, 1996). The present research attempts to clarify one of the psychological factors associated with the formation and maintenance of patriotism among various ethnic subgroups. In brief, how do perceptions of societal fairness (e.g., group discrimination) impact feelings of patriotism? Study one is correlational and examines whether societal fairness moderates ethnic subgroup differences on patriotism. Findings indicate that this construct is related to levels of patriotism and interacts with respondent ethnic group membership. Study two is experimental and primes societal fairness – via an item order manipulation – within a questionnaire. In particular, half of the participants were randomly assigned to answer societal fairness items before responding to patriotism items (i.e., prime societal fairness) while the other half answered the same items in the reverse order (i.e., no prime). Findings indicate that the item order manipulation had a significant impact on feelings of patriotism that varied as a function of respondent ethnic group. For instance, White respondents who were primed with societal fairness had higher levels of patriotism compared to Latino respondents who received the same prime.

#### G164

##### **THE RELATIONSHIP OF ETHNIC IDENTITY, SELF-ESTEEM, AND OUTGROUP DIVERSITY AMONG AFRICAN AMERICANS**

Bianca T. Holmes<sup>1</sup>, Lilia Briones<sup>1</sup>, Carolyn Murray<sup>1</sup>; <sup>1</sup>University of California Riverside – Ethnic identity (EID), the degree to which an individual feels part of a particular ethnic group, has been shown to be especially beneficial to ethnic minorities. For African Americans, there is evidence that a strong ethnic identity is associated with positive social psychological outcomes such as academic success and subjective well-being. However, only a few studies have examined the relationship between ethnic identity and inter-group contact, especially in a context in which African Americans are underrepresented (e.g., academia). The purpose of the current study was to explore the relationship between African-American EID and out-group contact as well as individual self-esteem. 121 African American undergraduate students were surveyed about their friendship networks, ethnic identity, out-group contact and self-esteem. Self-esteem was found to be positively correlated with EID such that those higher in ethnic identity exploration (or willingness to find out more about their ethnic culture) were also higher in self esteem. EID was also related to high out-group contact, though not significantly. Not surprisingly, out-group contact and diversity of friendship networks were positively correlated. There was a gender effect such that the overall network of friends for African American males was significantly more diverse than for females. The implications and benefits of high EID are discussed in relationship to academic and other social-psychological variables.

#### G165

##### **EFFECTS OF INTERGROUP DIALOGUE ON ANTICIPATED INTERGROUP COOPERATION**

Delia Saenz<sup>1</sup>, Patricia Gurin<sup>2</sup>; <sup>1</sup>Arizona State University, <sup>2</sup>University of Michigan – The effects of intergroup dialogue on changes in intergroup attitudes, understanding, and cooperation were assessed in concurrent field studies conducted at 9 private and public universities across the country. 1042 undergraduates volunteered to participate in a for-credit course on race or gender, and were randomly assigned to an

intergroup dialogue (IGD) course (experimental condition) or to a control condition (wait list control or social science comparison). A standardized curriculum, inclusive of communication skills, intergroup understanding, group work, and critical self-reflection content, was administered by trained facilitators to IGD participants over the course of 13 weeks (26 contact hours). Social science participants enrolled in a regular course focused on race or gender; wait list control participants received neither relevant content nor experiential training. Dialogue groups were each comprised of: 4 males of color, 4 females of color, 4 white males, 4 white females. Participants in the control groups were matched demographically to IGD participants. A longitudinal, randomized design with mixed methods (qualitative, quantitative methods) was utilized. Measures of intergroup attitudes, understanding, and collaboration were administered prior to the start of the term, at the end of the term, and one year later. As predicted, significant positive changes occurred in pre- to post-measures for IGD participants only. For the primary measures of interest (action outcomes), IGD participants indicated greater inclination to engage in social justice, anti-bias behaviors in the present as well as in the future. Implications of this work for higher education, diversity, and intergroup theory are discussed.

#### G166

##### **A COLLATERAL ADVANTAGE OF DRAWING ATTENTION TO THE PROBLEM OF GLOBAL WARMING: INCREASED SUPPORT FOR PEACE-MAKING AND DECREASED SUPPORT FOR WAR**

Mike Sowa<sup>1</sup>, Tom Pyszczynski<sup>1</sup>, Matt Motyl<sup>2</sup>, Ken Vail<sup>3</sup>, Zach Rothschild<sup>4</sup>, Jamie Arndt<sup>3</sup>, Gilad Hirschberger<sup>5</sup>; <sup>1</sup>University of Colorado at Colorado Springs, <sup>2</sup>University of Virginia, <sup>3</sup>University of Missouri, <sup>4</sup>Kansas University, <sup>5</sup>Bar-Ilan University – Today's world remains locked in violent conflicts while facing a multitude of other serious problems such as economic recession, crises in health care, and the specter of global climate change. Terror management theory research has documented the role of existential fear in international conflicts by showing that reminders of death often increase support for war and terrorism. Global warming and the many other problems humankind is facing could exacerbate each other, leading to increased competition for resources, increased international conflict, and global catastrophe. It is also possible, however, that facing a shared global threat might encourage cooperation among rival groups and promote peaceful coexistence. Three studies showed that focus on the superordinate threat of global warming can help bridge the gap between competing cultures, encourage peaceful coexistence, and discourage support for war in the face of existential threat. In Study 1, mortality salience (MS) increased Americans' support for international peace-building after imagining the consequences of global warming, but not when asked to imagine a local catastrophe, an earthquake in San Francisco. In Study 2, MS increased Americans' support for war against Iran after imagining the local catastrophe of mass flooding in China; imagining global warming completely eliminated this effect. Study 3 was conducted among Arab citizens of Israel during the January 2009 Israeli invasion of Gaza. For those high in the perception of shared humanity, MS increased support for peaceful coexistence with Israeli Jews after imagining global warming but not a local catastrophe.

#### G167

##### **THE EFFECTS OF LEARNING AND PERFORMANCE GOALS ON PSYCHOLOGICAL AND BEHAVIORAL RESPONSES TO INTERGROUP CONTACT**

Katya Migacheva<sup>1</sup>, Linda R. Tropp<sup>1</sup>; <sup>1</sup>University of Massachusetts Amherst – The effects of learning and performance goal orientations on experiences during intergroup contact were examined. White female participants received either learning or performance goal instructions prior to an interaction with a Black or White partner, during which they would discuss a race-sensitive or race-neutral topic. Participants reported their affect and expectations prior to the interaction, and participants' verbal and nonverbal behaviors during the interaction were videotaped and coded. Participants who received learning goal instructions showed more willingness to engage with a Black partner on a race-sensi-

tive topic than participants who received performance goal instructions (as demonstrated through greater eye contact, less fidgeting, and fewer speech disfluencies). However, with a less threatening, race-neutral topic, performance goals affected positively participants' engagement during the interaction. Potential mechanisms underlying effects of different goal settings in more or less threatening contexts are discussed.

#### G168

**LET'S AGREE TO DISAGREE: SOCIAL DOMINANCE ORIENTATION, OBAMA, AND THE 2008 ELECTION** Kristin E. Henkel<sup>1</sup>, Mark D. Cistulli<sup>2</sup>, Judy Tan<sup>1</sup>, Amy Huntington<sup>1</sup>, Valerie Earnshaw<sup>1</sup>; <sup>1</sup>University of Connecticut, <sup>2</sup>University of Hartford – Social Dominance Orientation (SDO; Pratto et al., 1994) has long been associated with political orientation such that those low on SDO tend to be more liberal and those high on SDO tend to be more conservative (e.g. Lippa & Arad, 1999). SDO is also correlated with negative intergroup attitudes (e.g. Sidanius & Pratto, 1999). On November 4, 2008, Americans elected their first Black president and in doing so, brought to light many questions about intergroup attitudes in America. With this event as a backdrop, two studies were designed to explore the relationship between SDO, feelings about the election, and perceptions of Barack Obama using the C4 Scale (measuring competence, credibility, compassion, and charisma; Buck & Vieira, 2002). Both studies were survey studies and data were collected on the internet. As expected, in a student sample, SDO predicted participants' happiness with the outcome of the election such that high SDO participants were less happy with the outcome. Perceptions of Obama's charisma fully mediated this relationship. However, a second study showed that in a community sample, perceptions of Obama's competence fully mediated the relationship between SDO and happiness with the election. A second dependent variable, perceptions of the majority of Americans' happiness with the outcome of the election, was measured in the second study as well. Perceptions of Obama's competence, credibility, and compassion mediated the relationship between SDO and perceptions of the majority's happiness. Implications of these results for the American political process and intergroup relations are discussed.

#### G169

**FORGET ME NOT? CRIMINAL STEREOTYPES AFFECT EYEWITNESSES' MEMORY OF THE PERCEIVED STEREOTYPICALITY OF A SUSPECT** Danny Osborne<sup>1</sup>, Paul G. Davies<sup>2</sup>, Jennifer L. Eberhardt<sup>3</sup>; <sup>1</sup>University of California, Los Angeles, <sup>2</sup>University of British Columbia, <sup>3</sup>Stanford University – Despite the intergroup nature of the criminal justice system (Eberhardt, Davies, Purdie-Vaughns, & Johnson, 2006), no studies have looked at the impact racial stereotypes have on eyewitness identifications. This is unfortunate, as past research demonstrates that people remember information in a stereotype-consistent manner (Roediger & McDermott, 1995). As such, different racial stereotypes about the assumed race of criminals associated with different crimes could systematically influence eyewitness identifications. Specifically, stereotypically "Black crimes" could cause eyewitnesses to remember a suspect as appearing more phenotypically representative of Blacks (i.e., higher in perceived Black stereotypicality) than stereotypically "White crimes." The current program of research conducted three studies that test this possibility. In Study 1 (N = 33), we demonstrate that different racial stereotypes exist about the assumed race of criminals suspected of committing different crimes. Study 2 (N = 116) builds on this finding and shows that, despite watching the same video, participants led to believe that they saw a suspect accused of a stereotypically Black crime remember the suspect as appearing higher in perceived Black stereotypicality than participants led to believe that they saw a suspect accused of 1) a stereotypically White crime or 2) a control event. Finally, Study 3 (N = 119) provides a conceptual replication of this finding using different crimes and shows that the effect is due to errors that occur during the encoding (as opposed to retrieval) process. This research has important implications for eyewitness identifications and also suggests that stereotypicality can function as a dependent variable.

#### G170

**USING COLLECTIVE IDENTITY THREATS TO MANIPULATE THE LEGITIMACY OF VIOLENCE** Michael King<sup>1</sup>, Tal Zelinger<sup>1</sup>, Donald M. Taylor<sup>1</sup>; <sup>1</sup>McGill University – Security and intelligence agencies assert that the al-Qaeda movement legitimizes terrorism by propagating the "single narrative". This narrative depicts Islam as being under attack by Western leaders and their allies. Indeed, our interviews with jihadists in Indonesia and Canada confirm that, although people who engage in violence might not necessarily feel personally threatened, they perceive their collective identity as being under attack. The present study uses the framework of social identity theory to investigate if the legitimacy of violence can be manipulated using such identity threats. Jewish students were presented with a fictitious news article depicting a court trial of a Jewish man who pled guilty to bombing a market in Gaza. Participants were asked to recommend a sentence length for the alleged terrorist, and to rate the bombings on negative and positive attributes. The study included three conditions, each of which involved the terrorist citing a different threat to the Jewish identity as justification for the bombings. The first threat concerned Jewish collective self-esteem, the second threat concerned Jewish distinctiveness, and the third was a general threat to Jewish identity. High identifiers, as opposed to low-identifiers, exposed to a justification based on a collective self-esteem threat, gave shorter sentences to the terrorist. Moreover, high identifiers in the same condition also rated the bombing as more positive and less negative than participants in other conditions. The implications of these findings for counter-radicalization and strategic communications are discussed.

#### G171

**HIDING INTERGROUP DISPARITIES UNDER A CLOAK OF EQUALITY: ANTI-EGALITARIAN WHITES' MOTIVATED PERCEPTIONS OF THE ACHIEVEMENT OF RACIAL EQUALITY** Rebecca S Schaumburg<sup>1</sup>, Brian S Lowery<sup>1</sup>, Rosalind M Chow<sup>2</sup>, Eric D Knowles<sup>3</sup>; <sup>1</sup>Stanford University, <sup>2</sup>Carnegie Mellon University, <sup>3</sup>University of California, Irvine – The election of Barack Obama reminded this country of the progress it has made towards achieving racial equality. Nevertheless, exactly what Obama's presidency signals about the state of racial equality remains open to interpretation. We present evidence that Whites' endorsement of the belief that the United States has achieved racial equality may stem from a desire to protect their group's advantages. Study 1 investigated the prediction that dominance concerns may motivate the construal that Obama's election indicates that the United States has achieved racial equality. A longitudinal assessment of White's perceptions of Obama's election revealed that among anti-egalitarian Whites (i.e., Whites high in social dominance orientation) the more they recognized their racial group to be unfairly advantaged, the more they endorsed the belief that Obama's election signaled the achievement of racial equality. Study 2 was designed to provide further support that a desire to protect their group's advantages drives anti-egalitarian Whites' perceptions of racial equality. This study manipulated both the perceived nature and legitimacy of racial inequality. Among anti-egalitarian Whites, information that Whites are unfairly advantaged prompted greater endorsement of the belief that the United States is a colorblind society. These studies suggest that a desire to obscure and protect their group's advantages may motivate anti-egalitarian Whites to endorse the belief that the United States has achieved racial equality.

#### G172

**THE RACISM PROTOTYPE AND ATTRIBUTIONS TO DISCRIMINATION: ARE DOMAIN STEREOTYPES MORE IMPORTANT THAN GROUP STATUS?** Zoe Kinias<sup>1</sup>, Laurie O'Brien<sup>2</sup>, Brenda Major<sup>3</sup>; <sup>1</sup>INSEAD, <sup>2</sup>Tulane University, <sup>3</sup>University of California, Santa Barbara – This research investigated elements of racism prototypes (cognitive representations of racism) as factors that influence observers' attributions to discrimination when a job applicant is rejected under ambiguous circumstances (e.g., Inman & Baron, 1996; O'Brien, Kinias, & Major, 2008). Observer ethnicity, target ethnicity, and situational context interact to shape attributions to dis-

crimination. Consistent with prior evidence of status asymmetry, participants generally thought Black targets were discriminated against more than White targets. Results also supported stereotype asymmetry. White participants were influenced by situationally-relevant stereotypes, such that they were more likely to make an attribution to discrimination when a White applicant was rejected for a job that required stereotypically Black (vs. White) skills and when a Black applicant was rejected for a job that required stereotypically White (vs. Black) skills. Ethnic minority participants, in contrast, were only influenced by situationally-relevant stereotypes when the target was Black; when the target was White, they perceived low levels of discrimination regardless of the situational context. Rejection events fitting participants' racism prototypes mediated the process.

### G173

**EMOTION AND APOLOGY IN MACEDONIA: TESTING THE ROLE OF RESPONSIBILITY AND SUFFERING INFERENCES IN INTERNATIONAL CONFLICT** Milica Vasiljevic<sup>1</sup>, Roger Giner-Sorolla<sup>1</sup>; <sup>1</sup>University of Kent at Canterbury – A model of the effect of emotion in apologies between social groups has recently been developed using the issue of second-hand smoking (Giner-Sorolla & Zebel, 2009). In that model, inferences of suffering and responsibility taking mediated the effects of emotional language on acceptance of the apology. But can this model translate to apologies between rivals in more deeply entrenched national conflicts? The work on smokers has not found that suffering directly leads to satisfaction with apology, while such retributive feelings might show more strongly in a more bitter conflict. We ran an experiment among 228 citizens of the former Yugoslav republic of Macedonia against the backdrop of its long-standing border conflict with Greece. The experiment described the apology of an anonymous Greek citizen for Greece's role in a recent incident of friction between the two countries, varying which of six emotional and non-emotional expressions he used. We assessed the mediating role of inferences of suffering, responsibility taking, and forthcoming reparations in predicting satisfaction and insult. Unlike previous samples, emotional language largely influenced inferences of suffering rather than responsibility, and suffering had a stronger role in creating expectations of better behavior from Greeks, which in turn predicted positive reactions most strongly. As suspected, direct inferences of suffering, independently of expected behavior, were the main predictor of reduced insult from emotional apology. Thus, although Macedonians took little joy in the suffering of their rivals, suffering did expiate insult. We will discuss some cultural and situational explanations for these results.

### G174

**EMOTION REGULATION AND INTERRACIAL INTERACTION: IMPLICATIONS FOR PREJUDICE MAINTENANCE AND EXECUTIVE FUNCTION** Adam R. Pearson<sup>1</sup>, John F. Dovidio<sup>1</sup>, Curtis Phillips<sup>2</sup>; <sup>1</sup>Yale University, <sup>2</sup>York University – Interracial interactions in the U.S. are often stressful for members of both majority and minority groups. Ironically, efforts to manage one's behavior to navigate these interactions can often backfire, leading to impaired cognitive functioning and more negative interactions, particularly for more implicitly biased Whites. We hypothesized that these consequences may stem, in part, from different emotion control strategies employed by high and low prejudiced Whites to navigate these interactions. In this study, more implicitly prejudiced Whites who were instructed to suppress negative emotions during an interracial interaction or were given no explicit regulation instructions performed worse on a Stroop color-naming task and perceived a Black confederate as less friendly than Whites lower in implicit prejudice. Instructing participants to suppress positive emotions, however, produced the opposite pattern: Compared to their lower prejudiced counterparts, higher prejudiced Whites made more favorable judgments of the confederate and showed no evidence of stroop impairment. Together, these results suggest that efforts to suppress negative emotions in interracial interactions may, in part, underlie previously documented deficits in executive function among high prejudiced Whites and, ironically, enhance these individu-

als' tendencies to see prejudice in others. More generally, these findings underscore the importance of examining how emotions are not only experienced but also self-regulated in intergroup interactions for understanding the often varied intrapersonal and interpersonal consequences of intergroup contact.

### G175

**CULTURE AND MIMICRY AS AGENTS FOR PREJUDICE REDUCTION: THE ROLE OF SOCIAL LINKS AND ENACTING CULTURAL BEHAVIORS IN CROSS-GROUP FRIENDSHIPS** Tiffany Brannon<sup>1</sup>, Gregory M. Walton<sup>1</sup>, A. David Nussbaum<sup>2</sup>, Steven J. Spencer<sup>2</sup>, Emiko Yoshida<sup>2</sup>; <sup>1</sup>Stanford University, <sup>2</sup>University of Waterloo – Three studies tested a novel process by which intergroup contact may reduce prejudice. The studies feature behavioral mimicry as a means to manipulate a perceived social connection to a member of another group (Lakin & Chartrand, 2003). Extending research on "mere belonging" (Walton & Cohen, 2009), we hypothesize that people develop culturally-specific interests on the basis of even minimal social connections to members of other groups. In turn, we propose that enacting these interests behaviorally reduces prejudice through cognitive dissonance. In Study 1 trained Chinese-Canadian confederates did or did not mimic European-Canadian participants in a "getting to know you" conversation. As predicted, mimicked participants subsequently reported greater interest in Chinese culture. They also completed more lottery tickets to win Chinese cultural products. Study 2 replicated these results correlationally. Study 3 included a manipulation of the opportunity to take part in a culturally-specific activity. Trained Mexican-American confederates did or did not mimic non-Hispanic participants. The two worked together to create a video for a pop song said to be by either a popular Mexican band or a popular Portuguese band. We predicted that mimicked participants in the Mexican band condition—who believed themselves to have taken part in creating a distinctive Mexican cultural product—would show greater interest in Mexican culture and reduced prejudice against Mexican-Americans. Results showed initial support for the hypothesis. Discussion addresses implications for intergroup contact, for socially-shared interests, and for prejudice reduction.

### G176

**UNDERSTANDING DIVERSITY AND PERCEPTIONS OF AMERICANNES** Melissa-Sue John<sup>1</sup>, John Dovidio<sup>2</sup>; <sup>1</sup>University of Connecticut, Storrs, <sup>2</sup>Yale University – The United States is a diverse society composed of many identifiable racial and ethnic groups. However, despite demographic trends toward increased diversity, the standard for being American remains singular – being White (Devos & Banaji, 2005; Sidanius, Feshbach, Levin, & Pratto, 1997) and the model of intergroup relations revolves around White-Black relations. The present research tested the hypothesis, in two studies, that different racial and ethnic groups systematically vary from the prototypical White representation of American. Study 1, using a category norm framework, demonstrated that participants perceived groups along a continuum of "Americanness," and not merely in terms of White versus not White. Whereas the category norm methodology of Study 1 suggested a specific ordering of different groups in Americanness, Study 2 investigated potential dimensions of difference that underlie the rank ordering of the different groups. In Study 2, participants were instructed to rate the similarity of different Americans to each other. Using multi-dimensional scaling, Study 2 found that American prototypicality was determined by two dimensions, reflecting ethnic and civic (ideological) differences. Taken together, these two studies reveal the value of going beyond a model of majority-minority groups focused in White-Black relations in the US to consider the how different racial and ethnic groups vary in Americanness. Implications for understanding the different conditions that moderate bias toward various groups and ways of developing interventions to combat different types of bias are considered.

**G177****WHEN DOES EXTENDED CONTACT WORK BEST AND WHAT ARE ITS LONG-TERM EFFECTS?**

Anja Eller<sup>1</sup>, Dominic Abrams<sup>2</sup>, Angel Gomez<sup>3</sup>; <sup>1</sup>University of St Andrews, UK, <sup>2</sup>University of Kent, UK, <sup>3</sup>UNED, Spain – Extended contact theory proposes that knowledge of ingroup-outgroup friendships leads to reductions of intergroup bias. However, the evidence is largely cross-sectional and experimental rather than longitudinal and generalizable. We investigate (a) when extended contact is more or less effective than direct contact, (b) long-term effects of contact (over a period of two years), and (c) the causal direction between direct and extended contact. These questions are assessed across one cross-sectional and five longitudinal studies (total N = 1340) that examine the effects of direct and extended intergroup contact on five measures of cognitive outcomes, six measures of affective outcomes, and one measure of behavioral outcome, with different participant populations, time frames, age groups, and countries/cultures. Cross-sectionally and longitudinally extended contact improved intergroup relations only when direct contact was low, rather than high. Direct and extended contact both had long-term effects on criterion variables and the causal direction was predominantly from contact to criterion variables. Finally, despite some indication of circularity, extended contact predicted direct contact over time, thus preparing people for direct contact. These findings confirm the major tenets of intergroup contact theory and provide valuable longitudinal support for extended contact theory.

**G178****PERSONALIZATION AND THE REDUCTION OF INGROUP FAVORITISM**

Nathan Arbuckle<sup>1</sup>; <sup>1</sup>The Ohio State University – Research has demonstrated that people are motivated to favor their ingroups. This has been demonstrated in a variety of domains, such as event construal (Hastorf & Cantril, 1954), allocation of resources (Tajfel, Billig, Bundy, & Flament, 1971), and moral reasoning (Valdesolo & DeSteno, 2007). Self-categorization theory suggests that a self-construal shift underlies this motivation; when one is self-categorized at the group level, identity is depersonalized and self-interest becomes group-interest (Turner, Hogg, Oakes, Reicher, & Wetherell, 1987). However, no research has directly examined the role of personal self-construal in preventing the motivation to favor one's groups. In a series of studies, we set out to determine whether construing oneself at the personal level, or personalization, would eliminate ingroup favoritism. If a shift from personal to collective self provides the motivational fuel for ingroup favoritism, then preventing this shift should prevent the favoritism. Personalization was induced by having participants answer questions about their personal qualities and uniqueness. In one study, those participants who were personalized showed a reduced tendency to see news reports and scientific research as biased against their group, relative to those in a control condition. A second study found that personalized participants were less likely than those in a control condition to say that an ingroup member's unfair behavior was justified. Taken together, these studies demonstrate that preventing shifts in self-construal through personalization can decrease motivation to favor one's group.

**G179****AFFECTIVE MEDIATORS AND BEHAVIOURAL CONSEQUENCES OF IMAGINED INTERGROUP CONTACT**

Rhiannon Turner<sup>1</sup>; <sup>1</sup>University of Leeds – Extensive research over the past fifty years has shown that contact between members of different groups is, under optimal conditions, effective at reducing intergroup prejudice (Pettigrew & Tropp, 2006). Extending intergroup contact theory, recent research has shown that simply imagining contact with an outgroup member results in a more positive attitude towards that group. Two studies show that (a) imagined contact has diverse consequences for intergroup relations, and (b) affective processes underlie the impact of imagined contact. In Experiment 1, British high school students who imagined talking to an asylum seeker subsequently had a greater tendency to approach asylum seekers than participants in a control condition. Path analysis revealed that this

relationship was mediated by outgroup trust and outgroup attitude. In Experiment 2, straight undergraduate students who imagined an interaction with a gay individual subsequently had a greater tendency to approach, and a reduced tendency to avoid, gay people. Path analyses showed that these relationships were mediated by outgroup trust, outgroup attitude, and reduced intergroup anxiety. These findings suggest that, by changing affective reactions to the outgroup, imagining contact may help to prepare people for face-to-face intergroup encounters by increasing their desire to form outgroup relationships, and reducing their desire to avoid such relationships.

**G180****FUNGIBILITY OF MASCULINE AND FEMININE FORMS OF POWER**

Eileen V. Pitpitan<sup>1</sup>, Felicia Pratto<sup>1</sup>; <sup>1</sup>University of Connecticut – Throughout history and in societies that accumulate wealth, men, on average, possess more power than women. The types of power that are monopolized more by men are force, legitimacy, resources, and obligations from others. Whereas women on average, possess more obligations to others and a more desirable sexuality. Not only are they more powerful, but the types of power that men hold may also be more readily exchanged for more or other types of power. That is, men's assets or forms of power are more fungible than women's forms of power. We tested this hypothesis with two studies using different methods. In Study 1, participants rated the ease of use in gaining one power type by using another specific power type (e.g., using resources to gain legitimacy). Results indicated that on average, the forms of power that are traditionally held by men were seen as more easy to use to gain power (i.e., more fungible) than the forms of power traditionally held by women. This study also shows how different ethics of men and women using power relates to power fungibility. In Study 2, we used an innovative power dynamics game to examine the extent to which holding more or different masculine or feminine power types can lead one to be perceived or not be perceived as powerful. Results will be discussed with respect to theoretical advances in examining and understanding power dynamics and gender inequality.

**G181****THROUGH THE LENSE OF THE PAST: HOW INCLUSIVE AND EXCLUSIVE CONSTRUALS OF INGROUP VICTIMIZATION AFFECT INTERGROUP RELATIONS**

Johanna Ray Vollhardt<sup>1</sup>; <sup>1</sup>Clark University – The scarce social psychological literature on collective victimization has primarily examined negative effects of focusing on ingroup suffering (Noor et al., 2008; Wohl & Branscombe, 2008). I refer to this as "exclusive victim consciousness" and propose that victim consciousness can also be inclusive, entailing awareness of similarities between the ingroup's and other groups' experiences of collective victimization. A survey study was conducted among 170 members of various ethnic, religious and racial minority groups in the US to test the hypothesis that while exclusive victim consciousness predicts destructive intergroup outcomes, inclusive victim consciousness predicts prosocial outcomes. The findings indicate that the developed measures of inclusive and exclusive victim consciousness were reliable, and support for the hypotheses was obtained. Inclusive victim consciousness predicted - moderated by personal centrality of ingroup victimization - prosocial attitudes and behaviors toward other victim groups and increased willingness to reconcile with the perpetrator group. Exclusive victim consciousness, in contrast, predicted desire for revenge. In conclusion, pathways toward potentially constructive outcomes of collective victimhood are demonstrated.

**G182****THE MOTIVATIONAL DYNAMICS OF SOCIAL MEMORY: IDENTIFICATION WITH A MIXED-RACE GROUP REPLACES OWN-RACE BIAS WITH OWN-GROUP BIAS**

Jay Van Bavel<sup>2</sup>, Rachel O'Connor<sup>1</sup>, William Cunningham<sup>1</sup>; <sup>1</sup>The Ohio State University, <sup>2</sup>New York University – Dozens of studies have documented own-race bias - superior recognition memory for own-race faces compared to other-race faces. According to the perceptual expertise model, people are more likely to interact with members of their own race and therefore become more expert at distinguishing the physiognomy of

own-race faces. According to the social cognitive model, own-race bias occurs because people perceive in-group members as individuals and out-group members according to their social category membership. We contrasted these two models and examined the effects of motivational salience, goal strength and situational affordances on social memory. Participants were randomly assigned to a mixed-race minimal group or a control condition in which participants merely learned about two mixed-race groups. Consistent with the social cognitive model, participants assigned to a mixed-race group had less own-race bias than participants in the control condition. Instead, participants assigned to a mixed-race group had own-group bias – superior recognition memory for in-group faces compared to out-group faces. Follow-up experiments showed that own-group bias was moderated by the strength of participants' commitment to their minimal group and situational affordances. Specifically, participants who reported the strongest identification with their mixed-race minimal group had the largest own-group memory bias. However, own-group bias was attenuated among participants who were assigned to a role that directed their attention toward out-group members: they showed equal recognition memory for in-group and out-group faces. These experiments provide evidence that the motivational aspects of our social identities help organize social memory and can override the robust effects of race.

### G183

**THE IMPACT OF INGROUP IDENTIFICATION ON CONSTRUALS OF INTERGROUP VIOLENCE AMONG PERPETRATOR AND VICTIM GROUPS** Rezarta Bilali<sup>1</sup>; <sup>1</sup>University of Massachusetts Boston – The present research examines the relationship between ingroup identification and construals of intergroup violence in perpetrator and victim groups. Drawing on social identity theory, hypotheses regarding cross-group and within-group variations in these construals were tested in two different contexts of collective victimization. Study 1 examined the effect of ethnic (Turkish) identification (N = 124) on construals of an ingroup perpetrator event (the massacres of Armenians by Turks between 1880-1920). Study 2 (among 194 ethnic Turks and 80 ethnic Kurds) examined the influence of both ethnic and national ingroup identification on individuals' construals of victimization in the Turkish-Kurdish conflict that took place between 1984 and 2005. Across both studies, the results showed that stronger ethnic ingroup identification was related to perceiving the ingroup as the victim of the conflict. In both studies, multiple regression analyses revealed that stronger ethnic identification was related to (a) attributing more outgroup responsibility, but less ingroup responsibility for the violence, and (b) to higher perceived ingroup victimization and lower perceived outgroup victimization. In Study 2, each group endorsed a conflict frame that portrayed the ingroup as a victim (i.e., Turks perceived the conflict as a terrorism issue whereas Kurds perceived the conflict as a minority rights issue). These conflict frames mediated the effect of ingroup identification on perceived ingroup victimization. Furthermore, for the perpetrator group (Turks) ethnic and national identification had parallel effects, whereas for the victim group (Kurds) national and ethnic identification had opposite effects on perceived ingroup victimization.

## Self/Identity

### G184

**ON THE PANCULTURALITY OF SELF-ENHANCEMENT: SELF-ENHANCEMENT INCREASES WELL-BEING IN THE US AND CHINA** Erin M. O'Mara<sup>1</sup>, Lowell Gaertner<sup>1</sup>, Constantine Sedikides<sup>2</sup>, Xinyue Zhou<sup>3</sup>, Yanping Liu<sup>3</sup>; <sup>1</sup>University of Tennessee, <sup>2</sup>University of Southampton, UK, <sup>3</sup>Sun Yat-Sen University, China – There is a debate in the literature as to whether self-enhancement is a byproduct of Western culture (e.g., Heine, Lehman, Markus, & Kitayama, 1999) or a universal motive (e.g., Sedikides, Gaertner, & Vevea, 2005). Consistent with the universal account are data demonstrating that both Westerners and Easterners tactically self-enhance by positively differentiating self from others on important attributes but not

on unimportant attributes (Sedikides et al., 2005). The current research examines the functional association between tactical self-enhancement and psychological well-being using a longitudinal, cross-cultural study. College students in the US (n = 90) and China (n = 131) completed measures of well-being. A week later, they (a) listed an attribute that they deemed personally important, (b) described (based on random assignment) how that attribute is either more descriptive of themselves than of other students (i.e., self-enhancement), or less descriptive of themselves than of other students (i.e., self-deprecation), and (c) completed the same measures of well-being from the prior week. A residualized analysis of change in well-being from Time 1 to Time 2 revealed that participants who were randomly assigned to self-enhance reported greater well-being than did participants who self-deprecated. This pattern was evidenced in both the US and China and was most pronounced in both cultures among persons initially lower in well-being. That both cultures evidenced the same functional association between self-enhancement and well-being is consistent with the possibility that self-enhancement is a universal human motive.

### G185

**SELF-SUSPENSION AND SELF-CONTROL: UNDERMINING THE SELF LEADS TO POORER SELF-CONTROL** Steven Shirk<sup>1</sup>, Lisa Krusemark<sup>1</sup>, Chris Burgin<sup>1</sup>, Leonard Martin<sup>1</sup>; <sup>1</sup>University of Georgia – The self serves as an important source of information in guiding individuals' behavior. According to the self-suspension hypothesis (Martin, Shirk, & Burgin, 2009), self-control failure occurs when individuals fail to consult their self as a source of information. Therefore, undermining the validity of the self as a source of information should lead to poorer self-control because the self is no longer consulted. To test this hypothesis, we gave participants a list of traits and had them choose five traits that best describe either themselves or a friend. Next, of those individuals who picked traits describing themselves, some of them wrote about a time they acted consistently with each trait while some wrote about a time they acted inconsistently with each trait. Those participants asked to describe a friend wrote about times that the friend behaved consistently with the traits. Next, all the participants completed an executive function task as a measure of self-control ability. Lastly, participants completed a series of scales (e.g., rumination, self-determination, and self-awareness). As predicted, participants who wrote about times they acted inconsistently with each trait performed worse on an executive function task compared to those participants who wrote about times they acted consistently or about a friend. There was no difference between the three conditions in reported rumination, self-determination, or self-awareness. Thus, undermining the validity of the self as a source of information can negatively affect and undermine individuals' ability to self-control.

### G186

**EXPERIENCING TRANSITIONAL LIFE EVENTS: ENDORSING PERSONAL VALUES WHILE VISITING AN UNFAMILIAR COUNTRY** Chris J. Burgin<sup>1</sup>, Leonard L. Martin<sup>1</sup>; <sup>1</sup>The University of Georgia – Caspi and Moffitt (1993) propose that in the midst of novel life-transitions individuals will favor dispositional values and characteristics, when information on how to behave adaptively is not available. To test this hypothesis, we presented participants (N = 68) with a list of values (e.g., Humble, Ambitious, etc.) and had them rate how much they personally value each item and how much others (their culture) value each item. Next, we asked participants to describe either an average day of their life, what their life would be like 2 weeks after moving to a familiar country, 2 weeks after moving to an unfamiliar country or, 2 years after moving to an unfamiliar country. While the latter three would be considered life-transitions, only the third (2 years / unfamiliar country) would produce effects consistent with those proposed by Caspi and Moffitt. Specifically, in this condition individuals in an unfamiliar environment will prefer personal values to the values of others. Finally, we had participants rate how much they valued each item at that moment. Consistent with our hypothesis, participants who wrote about what life would be like 2 weeks after living in an unfamiliar country (compared to the other three conditions) were more likely

to prefer values they had originally endorsed over cultures values,  $F(3, 64) = 4.20, p = .009$ . In short, participants who described a transitional life event were more likely to base their current value evaluations more on prior personal values than cultural values.

### G187

**INDEPENDENCE AND VOLUNTARY SETTLEMENT: THE ROLE OF SELF-PERCEPTIONS IN THE MIGRATION PROCESS** Yao Wang<sup>1</sup>, Paula Pietromonaco<sup>1</sup>; <sup>1</sup>University of Massachusetts Amherst – Two studies tested the voluntary settlement hypothesis that economically motivated voluntary settlement in the frontier fosters independent agency (Kitayama et al., 2006). Although the frontier has ceased to exist, two components of the hypothesis may still be at work for international migration today: a) Voluntary migrants were predicted to have more independent self-views than non-migrants (self-selection); b) Migrants were expected to become even more independent after they settle down in the new country (reinforcement). Using Chinese college students who are currently going through the migration process, we examined the role of self-perceptions before and after migration. In Study 1, students at Beijing University reported their self-perceptions and post-graduation plans. As predicted, participants with more independent self-views reported greater likelihood of going abroad after graduation, while participants with more interdependent self-views were more willing to return to China if they left the country. Study 2 was a short-term longitudinal study on Chinese college students who recently arrived in the United States. Participants completed a questionnaire at the beginning and end of their first year in the U.S. As predicted, participants became significantly more independent over time, while their overall level of interdependence did not change. Socialization activities and social support were found to be partly responsible for changes in self-views. Moreover, independent and interdependent self-views were both revealed to be beneficial for participants' well-being. In sum, these studies supported the voluntary settlement hypothesis. Future research needs to examine international migration in other directions to establish the generalizability of the findings.

### G188

**"AT ONE WITH NATURE": COLLECTIVE SELF-BREADTH AND ENVIRONMENTALISM** Ellen J. Glenn<sup>1</sup>, Wendi L. Gardner<sup>1</sup>; <sup>1</sup>Northwestern University – At the collective level of self-concept, people obtain self-definition from group memberships (Brewer & Gardner, 1996). Social identity complexity theory indicates that for some people, having more social identities leads to a more inclusive definition of the ingroup, to the point where ingroup-outgroup distinctions are blurred, and all others are evaluated equivalently (Roccas & Brewer, 2002). The present research investigates whether greater collective self-breadth, or viewing the self as having membership in broad social groups (including the world at large, for example), promotes environmental consciousness and pro-environmental behavior. In Study 1, participants high and low in chronic self-breadth completed measures of environmentalism. Results revealed that naturalistic differences in self-breadth affect environmentalism, such that participants high in chronic self-breadth demonstrated greater environmental consciousness and pro-environmental behavior than participants low in chronic self-breadth. In Study 2, collective self-breadth was manipulated by priming participants to think of themselves as a member of a broad versus narrow group, and participants again completed measures of environmentalism. Participants low in chronic self-breadth who were primed to think of themselves as a member of a broad (versus narrow) group demonstrated greater environmental consciousness and pro-environmental behavior, whereas participants high in chronic self-breadth demonstrated more environmental consciousness and pro-environmental behavior regardless of prime condition. Greater collective self-breadth increases concern for broader issues including the world at large and has implications for promoting environmental concern and behavior.

### G189

**SMOKING AND IDENTITY MAINTENANCE** Matthew Brooks<sup>1</sup>, William Swann<sup>1</sup>, James Pennebaker<sup>1</sup>; <sup>1</sup>University of Texas at Austin – While much work has been done on issues related to long-term cigarette smoking, less attention has been paid to the process by which young people become fully-fledged smokers. We sought to explore the identity processes underlying so-called 'social smoking' by investigating the applicability of the Identity Maintenance model as an explanation for the behavior of emerging smokers. New smokers may be able to use social smoking to engage in the behavior without having to accept the 'smoker' identity. Research showed that, when primed with a looser definition of the 'smoker' identity, participants expressed greater willingness to smoke in social settings, but not in non-social settings. These results provide insight into how young people are able to become fully-fledged smokers despite the stigma involved in the behavior.

### G190

**SELF-COMPASSION AS A BUFFER AGAINST HOMESICKNESS, DEPRESSION, AND LOW SELF-ESTEEM IN THE TRANSITION TO COLLEGE** Meredith Terry<sup>1</sup>, Mark R. Leary<sup>1</sup>, Sneha Mehta<sup>1</sup>; <sup>1</sup>Duke University – Life transitions in which people move to a new location are typically experienced as stressful, particularly when difficulties arise in the new environment. First year college students often experience homesickness, depression, lowered self-esteem, and feelings of regret when they encounter difficulties. This study focused on the role of self-compassion in moderating students' reactions to social and academic difficulties in adjusting to the transition to college. Incoming university students ( $N = 119$ ) completed a measure of self-compassion before starting college, and then, at the end of their first semester, they ( $N = 97$ ) reported their social and academic difficulties (liking of social and academic life, number of friends made, and difficulty getting good grades). In addition, they completed measures of homesickness, depression, self-esteem, and satisfaction with their decision to attend the university. Results showed students high in self-compassion reported lower homesickness and depression, greater satisfaction with their decision, and higher self-esteem. Additionally, self-compassion provided a buffer against difficulties. Students who scored lower in self-compassion were more sensitive to variations in the perceived quality of their lives, experiencing greater homesickness and depression, lower satisfaction with their decision, and lower self-esteem as their difficulties increased. People high in self-compassion were unaffected by their social difficulties. For those high in self-compassion, treating themselves kindly in times of failure, allowed them to experience difficulties in academic or social adjustment without those difficulties resulting in depression, homesickness, lowered self-esteem or feelings of regret about their decision to attend the university.

### G191

**CONNECTION WITH NATURE: MEDITATION AND DEATH AWARENESS AS CATALYSTS** Janice Templeton<sup>1</sup>; <sup>1</sup>Fort Lewis College – Terror management theory (TMT; Greenberg, Pyszczynski & Solomon, 1986) suggests individuals may distance themselves from nature in an effort to defend against their human mortality. However, the current study hypothesized that existential anxiety about death may increase an individual's connection to nature if a worldview emphasizing connection to others is made salient. To test this hypothesis, a typical TMT procedure was followed by a loving-kindness meditation or one of two guided imagery control conditions. The purpose of the loving kindness mediation, a spiritual practice with the goal of promoting compassion and connection with others, was to activate an inclusive, interconnected worldview. Participants who were made aware of their own death and who then listened to a guided loving-kindness meditation reported greater connection to nature than those who listened to one of the guided imagery controls following death awareness. The results suggest that death awareness may serve as a catalyst to increase a sense of connection with nature when an inclusiveness worldview is made salient for individuals.

**G192****DYNAMIC RELATIONSHIP BETWEEN ASPECTS OF ETHNIC IDENTITY AND TRAJECTORIES OF PERCEIVED RACIAL DISCRIMINATION DURING THE TRANSITION TO ADOLESCENCE AMONG AFRICAN-AMERICAN CHILDREN**

Chih-Yuan Weng<sup>1</sup>, <sup>1</sup>Dartmouth College – Background: Little is known about how development of various aspects of racial identity is linked to the trajectories of experiencing racial discrimination during the transition from late childhood to adolescence, knowledge of which is presumably helpful in devising racial socialization strategies for minority group children that may effectively reduce the likelihood of experiencing racial discrimination and ensuing detrimental consequences. Method: The study is based on 4 waves of panel data from 806 African American children who were 10 to 12 years old (mean = 10.5) at T1. Two major aspects of racial identity were identified: ethnic identity exploration (EIE) and ethnic identity affirmation and belonging (EIAB). A latent growth curve model within the SEM (structural equation modeling) framework was tested to examine the extent to which development of the two aspects of racial identity over the first two waves was associated with the chronic level (intercept) and rate of change (slope), respectively, for perceived racial discrimination from T1 to T3, which in turn influenced the change in the scores on the black pride scale later at T4. Results: Despite their positive contemporaneous correlation with each other, EIE and EIAB were in fact linked to disparate trajectories of discrimination experiences when African-Americans got out of childhood, which further had an impact on the formation of black pride in mid- to late adolescence. It is concluded that a theoretical or/and empirical distinction between various aspects of racial identity is essential for understanding its dynamic interrelationship to the experiences of discrimination.

**G193****MEDIATORS OF THE RELATIONSHIP BETWEEN RACIAL IDENTITY AND LIFE SATISFACTION AMONG A COMMUNITY SAMPLE OF AFRICAN AMERICAN WOMEN AND MEN**

Stevie C. Y. Yap<sup>1</sup>, Isis H. Settles<sup>1</sup>, Jennifer S. Pratt-Hyatt<sup>2</sup>, <sup>1</sup>Michigan State University, <sup>2</sup>Northwest Missouri State University – Racial identity has been conceptualized as a stable, multi-dimensional construct. Racial centrality, private regard and public regard are three facets of racial identity which that may have important implications for well-being among African Americans. There is past evidence that each of these dimensions being associated with psychological outcomes for African Americans. To further understand these complex relationships, we propose that associations between the racial identity dimensions and well-being may be mediated by different identity functions, or perceptions of positive and negative aspects of identity. In the present study, we recruited a community sample of 161 African American men and women and examined whether the relationship between life satisfaction and three racial identity dimensions (centrality, private regard and public regard) were mediated by two identity functions: support and belongingness to family and group and perceptions of discrimination. We tested a separate model for each identity dimension in which the two identity functions were simultaneously tested as the mediators. Our results indicated that racial centrality, public regard, and private regard were positively associated with life satisfaction. Support and belongingness to family and group mediated two relationships: racial centrality and life satisfaction, and private regard and life satisfaction. Further, the relationship between public regard and life satisfaction was mediated by perceptions of discrimination towards one's racial group. Implications of these findings on social identity theory and the functions of racial identity are discussed.

**G194**

**ERP CORRELATES OF SELF OWNERSHIP** David Turk<sup>1</sup>, Joanne Brebner<sup>1</sup>, Kim van Bussel<sup>1</sup>, C. Neil Macrae<sup>1</sup>, Olav Krigolson<sup>2</sup>, Todd Handy<sup>2</sup>, <sup>1</sup>University of Aberdeen, <sup>2</sup>University of British Columbia – Information is better remembered when processed in relation to the self – the putative self-reference effect. Many studies have observed Self-Reference Effects (SREs) when

participants are instructed explicitly to relate information to themselves (e.g., "are you creative?"). Cunningham, Turk, Macdonald, and Macrae (2008) demonstrated that self-memory biases are also evident when information is related to self in an indirect fashion, namely when self forms associations with objects through mere ownership. However it is not clear whether these memory effects are related to enhanced perceptual processing of owned objects and/or increased cognitive elaboration. We used ERPs to explore these two contributing factors to the ownership SRE. Fifteen participants engaged in a shopping encoding task where everyday objects were assigned to self or other on the basis of a coloured ownership cue. Participants responded to the ownership of each item by way of a button press. A subsequent memory test revealed a self-owned memory bias. We found significant amplitude increases in the N1, N250, and P300 ERP components elicited by self vs. other cues to ownership. These data suggest that self-ownership increases the extent to which we both perceptually and cognitively evaluate objects, relative to when we do not own them. These contributing factors in regard to the SRE will be discussed.

**G195****TABOO TOPICS IN THE MEDICAL INTERVIEW: SELF-PRESENTATIONAL MOTIVES FOR DECEPTION**

Jodi Grace<sup>1</sup>, Giselle Inoa<sup>1</sup>, <sup>1</sup>St. Thomas University, Miami, Florida – Health behavior models often overlook the central role that self-presentational motives play in health decision-making. In the patient/physician interaction, people convey desired identities of themselves to one another. To maintain a desired identity, patients fear revealing information that is stigmatizing; however, physicians depend on patients to report all information honestly. Using impression management theory (Schlenker, 1980), the present survey study (N = 104) investigates deception in patient/physician communications. Specifically, what topics do patients consider taboo? Why do they avoid discussing these topics, and who is more likely to lie? Although the survey solely used self-report measures, analyses revealed that participants admitted lying to their physician. Coding of both open-ended and checklist items revealed participants reported sexual history as the most taboo topic in medical appointments followed by smoking, alcohol and drug abuse. Self-presentational motives guided the reasons for non-disclosure. Fear of judgment from one's physician was the most reported reason for deception. Two personality variables were associated with patient deception. Higher levels of fear of negative evaluation were associated with less honesty and more withholding from physicians. Conversely, participants high in social desirability were less likely to admit lying to their physician. A hypothetical scenario investigated potential lying on two taboo topics while varying the other person present in the medical interview (e.g., mother, significant other). Our findings encourage medical practitioners to explicitly communicate non-judgment to their patients on sensitive topics to provide a comfortable environment for honest disclosure.

**G196****ALLY STATUS AND RESPONSES TO DISCRIMINATION: DEVELOPMENT, VALIDATION, AND APPLICATION OF A NEW SCALE.**

Julie Garcia<sup>1</sup>, Carrie Langner<sup>1</sup>, <sup>1</sup>California Polytechnic State University, San Luis Obispo – Research on discrimination has primarily focused on how bias affects people who share the targeted group's social identity (e.g., Branscombe, Schmitt, & Harvey, 1999). Little empirical research has examined how discrimination may also affect the psychological well-being and political involvement of people who consider themselves allies of targeted outgroups. We conducted two studies to fill this gap in the literature. In Study 1, we developed a new scale of ethnic minority and lesbian, gay, bisexual, and transgender (LGBT) alliances. We asked European American college students to complete an ethnic minority ally questionnaire. Similarly, heterosexual college students completed an LGBT ally questionnaire. Students also filled out outgroup prejudice and positive outgroup attitudes questionnaires. As expected, both ally measures positively correlated with positive outgroup measures and negatively correlated with outgroup prejudice measures. In Study 2, we examined

how ally identification affected the psychological well-being and political involvement of college students who experienced an actual campus hate crime towards ethnic minorities and LGBT students by having students complete an online questionnaire after the event occurred. As predicted, students who identified as allies experienced greater negative emotion, stress, and were more likely to participate in campus political action compared to students who did not identify as allies. These results were generally consistent across both race and LGBT allies. This research demonstrates that even those not directly implicated in hate crimes may experience negative psychological outcomes and be motivated to participate in subsequent political activities. Implications for administrators' responses to campus hate crimes are discussed.

### G197

**SELF-RECOGNITION, SELF-AWARENESS AND PERSONALITY: IS THAT REALLY ME?** Julie Norem<sup>1</sup>, Shoshana Effron<sup>1</sup>, Diana Betz<sup>2</sup>, Gabrielle Weber<sup>1</sup>, Emily Good<sup>1</sup>, Joa Ahern-Seronde<sup>1</sup>, <sup>1</sup>Wellesley College, <sup>2</sup>University of Michigan – Self-recognition, the ability to recognize the self as an external object (e.g., in a mirror), has typically been viewed as a categorical species-specific capacity (Lin, Bard, & Anderson, 1992). We looked at whether there is systematic variation within a non-clinical sample in self-recognition ability and feelings upon self-recognition. One hundred female participants, ranging in age from 18-30, filled out 14 personality measures theoretically related to self-awareness. They then completed a reaction time measure of self-recognition. Each participant viewed six videos: three portrayed an unknown person's face changing into another unknown face, and three showed an unknown face changing into the participant's face. Reaction times for self-recognition were recorded. Reaction times and feelings about the task were significantly correlated with individual difference variables of theoretical interest. For example, impostors feelings (Clance & Imes 1978) were correlated with longer reaction times and more negative affect about the task, while overt narcissism was related to faster reactions and positive feelings about the task. Discussion focuses on potential implications of these results for understanding the development of self-knowledge and self-concept.

### G198

**DISENTANGLING COLLECTIVE IDENTITY FROM IDENTIFICATION THROUGH THE USE OF "PIPING".** Richard D. Harvey<sup>1</sup>, Rachel E. Tennial<sup>1</sup>, LaMarcus R. Bolon<sup>1</sup>, Erin Solomon<sup>1</sup>, Amy Garczynski<sup>1</sup>; <sup>1</sup>Saint Louis University – While distinguished in some fields (e.g., I/O Psychology), identity and identification are often treated as though they are synonymous constructs within the Social Psychological literature. Thus, researchers often confound the measurement of one construct under the label of the other. The purpose of the current study was to examine a measurement protocol that allowed for the simultaneous measurement of both identity and identification via an online survey "piping" function. This function allows computerized surveys to go beyond limitations posed by paper and pencil surveys. We tested this measurement technique with two separate collectives: Racial Identity among African-Americans and Organizational Identity among employed workers (N=225). We first measured their collective identity by asking participants to write in attributes to describe their collective (i.e., race or organization). We then measured their collective identification by piping these attributes into a set of questions that then ask participants to rate the degree to which these attributes were descriptive of themselves. Thus, identification is reflected in the degree which participants describe themselves with the same attributes that they used to describe the collective. Results demonstrated evidence of convergence with and better predictive validity than other measures of identification for both identification collectives. Furthermore, content validity analyses on the total list of attributes reported for the racial collective yielded six reliable dimensions reflecting perceived racial identity for Black Americans within our sample: Proud, Strong, Hard Working, Resilient, Beautiful, and Intelligent. The implications of this piping methodology for the measurement of identity and identification are discussed.

### G199

**RACIAL AND GENDER IDENTITY DISTANCING IN RESPONSE TO RACE & GENDER DISTINCTIVENESS** Jill Bennett<sup>1</sup>, Denise Sekaquaptewa<sup>1</sup>; <sup>1</sup>University of Michigan – Social identity can change in response to being distinctive in terms of race or gender (Keller & Sekaquaptewa, 2008; Sekaquaptewa et al., 2007). However, gender/race intersectionality theory (Cole, 2009) suggests that perceptions of racial identity may differ by gender, and perceptions of gender identity may differ among races. The current study examines how racial and gender identity change in response to being distinctive in terms of race vs. gender. 53 Black female undergraduates were randomly assigned to one of three groups: gender solo (being the only woman in a group of Black and White males); race solo (the only Black person in a group of White males and females); and a non-solo control group (gender and race balanced). Participants completed race and gender identity scales, and questions concerning perceived group similarity. A one-way ANOVA revealed differences in identity based on condition ( $F(2,50)=2.41, p=.10$ ). Planned contrasts showed that race solos disidentified from race ( $p<.05$ ) more than non-solos, and tended to disidentify from gender more than both gender solos and non-solos ( $p=.05$ ), even though gender salience was not directly increased in this condition. Thus, being distinctive in terms of race appeared to activate both gender and racial identities for Black women. Moreover, race solos felt less similar to their group when compared to gender solos and non-solos ( $p<.03$ ). We suggest that Black females may have seen Black males (in gender solo conditions) as "gender allies", reducing feelings of gender distinctiveness, whereas race solos may not see White women as "race allies."

### G200

**PREFERENCE FOR INDIVIDUATION PREDICTS IRONIC EFFECTS OF RACE-BASED ACCEPTANCE** Kavita Reddy<sup>1</sup>, Rainer Romero-Canyas<sup>1</sup>, Geraldine Downey<sup>1</sup>; <sup>1</sup>Columbia University – Acceptance from others is generally regarded as a positive experience, but recent evidence suggests that for some people there can be negative effects when acceptance is based primarily on one's membership in certain social groups (Reddy, Romero-Canyas, & Downey, 2008). To better understand this ironic effect of race-based acceptance, we looked at people's preference to be individuated as a predictor of negative effects of race-based acceptance. Asian American participants re-lived one of three situations they had experienced: race-based rejection, race-based acceptance, or their daily commute. They then completed the prompt "Because I am Asian American, I am \_\_\_\_" with up to twenty statements (i.e., self-attributes derived from one's identity) and rated the positivity and importance to the self of each attribute. Preference to be individuated predicted feeling upset after reliving race-based acceptance or rejection. Replicating past work, high positivity of attributes boosted self-esteem after race-based rejection, but lowered self-esteem after race-based acceptance. In the acceptance condition, but not in the rejection condition, importance assigned to these attributes was negatively related to self-esteem and positively related to collective self-esteem. Only in the acceptance condition, preference to be individuated led to seeing listed attributes as less important, and to having higher self-esteem, but lower collective self-esteem. Thus, people with a preference to be individuated protected self-esteem at a cost to collective self-esteem. These findings suggest that race-based acceptance distresses some people and leads them to situationally discount the importance of that identity to their self-concept. Implications for theory and diversity are discussed.

### G201

**INFLUENCE OF SELF-IDENTIFYING AS A SMOKER ON SUBSTANCE USE AMONG HIGH-RISK YOUTH** Renee Magnan<sup>1</sup>, Angela Bryan<sup>1</sup>; <sup>1</sup>University of New Mexico – Although many people smoke cigarettes, not all self-identify as a "smoker." Cigarette smoking is harmful and has been associated with other substance-use behaviors. We investigated substance-use behavior among youth aged 14-17 involved in the juvenile-justice system. Participants (n=730) reported the frequency with which they

used 11 common substances of abuse (e.g., alcohol, ecstasy, marijuana) at a baseline assessment and six months later. Individuals were first asked "Do you smoke?", and they were considered "nonidentifiers" if they reported they did not smoke, but then reported smoking in the past six months. They were considered "identifiers" if they reported smoking and also reported smoking in the past six months. We hypothesized that individuals identifying as smokers would be more likely to report other substance-use behaviors at baseline and this self-identification would predict greater substance-use six months later. The most common substances used were alcohol (69.1%), marijuana (68.7%), and cigarettes (67.1%). Of those who reported smoking in the last six months, 68.5% were considered identifiers. Identifiers reported smoking more cigarettes ( $p < .001$ ), but the two groups did not significantly differ on smoking-onset age and the amount of time they had been smoking. Across all substances, a larger percentage of identifiers reported using than non-identifiers. Identifying as a smoker was associated with greater odds of using alcohol at baseline, and predicted alcohol- and cigarette-use at six months. Understanding when and why adolescents who smoke cigarettes begin to self-identify as a smoker may be important in the prevention of multiple substance-use behaviors.

### G202

**COGNITIVE STRUCTURES OF THE SELF IN RELATION TO PREJUDICIAL ATTITUDES AND EXPERIENCE** Andrew J. Leister<sup>1</sup>, Carolin J. Showers<sup>1</sup>; <sup>1</sup>University of Oklahoma – Cognitive structures represent our knowledge of groups and our self. Showers's (1992) model of evaluative self-structure differentiates individuals who categorize these structures as either compartmentalized (the organization of positive and negative self-attributes into separate self-aspects) or integrative (the organization of positive and negative self-attributes into the same self-aspects). The current study tests whether individuals with a compartmentalized style of thinking have more extreme attitudes toward either the self or outgroups, specifically, whether a compartmentalized structure of beliefs about the self is associated with explicit or implicit measures of prejudice. Participants ( $N = 51$ ) completed a self-descriptive card sort to assess compartmentalization and measures of own experiences (perceived discrimination; stigma consciousness), explicit prejudice (social dominance orientation; modern racism); and implicit prejudice (stereotypic explanatory bias, IAT). Initial analyses show that self-structure predicts measures of own experiences, but not explicit measures of prejudice. For example, negatively integrative individuals reported the greatest stigma consciousness,  $\beta = -.41$ ,  $p < .05$ ; and, for White participants, compartmentalized individuals reported less perceived discrimination,  $\beta = -.46$ ,  $p < .04$ . These findings are consistent with a view that compartmentalized individuals tend to deny or minimize negative experiences. Additional analyses examine whether a compartmentalized style of thinking is associated with implicit measures of prejudice toward outgroups.

### G203

**PERCEIVED SOCIAL SUPPORT AND AUTHENTICITY IN ROMANTIC RELATIONSHIPS** Heather Clingenpeel<sup>1</sup>, Amy Hackney<sup>1</sup>; <sup>1</sup>Georgia Southern University – The present study employed individuals ( $N=54$ ) currently involved in a romantic relationship in order to examine variables related to self and relationship satisfaction. Correlational analyses revealed that perceived social support was strongly correlated with perceived autonomy support ( $r=.726$ ,  $p<.001$ ), relationship assessment ( $r=.644$ ,  $p<.001$ ), basic needs satisfaction ( $r=.750$ ,  $p<.001$ ), and a low degree of correlation with authenticity in relationships ( $r=.296$ ,  $p=.03$ ). Consistent with the hypothesis that social support would predict authenticity in romantic relationships, the overall regression model was significant,  $F(1, 52)=4.987$ ,  $p=.03$ ,  $r^2=.088$ ,  $SE=1.06$ . In examining the predictor, it was found that authenticity in relationships was significant ( $\beta=.296$ ,  $p=.03$ ,  $SE, .243$ ). Further analyses were run to examine authenticity for self and authenticity for partner. The individual predictors showed that authenticity in relationship for partner approached significance ( $\beta=.326$ ,  $p=.055$ ,

$SE=.147$ ), but authenticity in relationship for self was not statistically significant ( $\beta=.070$ ,  $p=.675$ ,  $SE=.242$ ). These results reveal important differences in authenticity for self and partner, and implications are discussed.

### G204

**BEING ALL THINGS TO ALL PEOPLE: MANAGING THE MIXED AUDIENCE DILEMMA** Melissa L. Martin<sup>1</sup>, Beth A. Pontari<sup>1</sup>; <sup>1</sup>Furman University – When people are faced with simultaneously making an impression on people with differing values and expectations (i.e., the multiple audience problem), it is challenging to please all observers (e.g., Van Boven et al, 2000). We extended this research by examining the way people present either themselves or their friends to a multiple audience. Participants believed they were pilot testing application (or recommendation) forms that the university would use to select student organization leaders. Participants believed there were two evaluators who would assess the forms; one preferred creative and independent thinkers whereas the other preferred rule and detail-oriented followers. Participants described themselves to the two evaluators simultaneously (the multiple audience) via a written open-ended statement. However, some participants first described themselves or a friend to each evaluator individually (i.e., known condition) whereas others did not (i.e. unknown condition). Taking the role of one of the evaluators, naïve coders rated these statements on five-point scales for the qualities preferred by the evaluators. Using Mixed Analyses of Variance, we assessed whether or not the statements gave coders the impression preferred by each evaluator. In the known condition, participants succeeded at managing the appropriate impression, but were better able to do so for themselves than a friend. In the unknown condition (in which coders only read the statement provided to the multiple audience), participants' impressions did not favor either evaluator's preferences. Results suggest that without the benefit of a first impression, managing impressions to a multiple audience is an arduous and nearly impossible task.

### G205

**VEGETARIAN SELF CATEGORIZATION AND THE IMMEDIATE COGNITIVE ASSOCIATIONS TO ANIMAL-BASED AND PLANT-BASED FOODS.** Keith Rozendal<sup>1</sup>; <sup>1</sup>California State University, Channel Islands – Some immediate cognitive associations to animal-based foods are revealed in an Internet-based cognitive priming task (the Implicit Associations Task; IAT). In U.S. and international surveys, vegetarians express social and political attitudes consistent with low authoritarianism and low social dominance orientation-even after controlling for their reliably liberal political views (Allen, et al., 2000; Allen & Baines, 2002; Rozendal, 2007). Ethically or morally motivated vegetarianism is a political identity that women adopt at nearly double the rate of men (Kalof, et al., 1999), and this may be related to the way in which masculinity and gender roles are nearly universally expressed through rituals of meat production, preparation, and consumption (Adams, 2000; Dahlberg, 1981; Fiddes, 1992). Many sources suggest that meat (animal flesh-based food) is a cultural symbol for masculinity, power, and social status/dominance (Adams, 2000, 2003, 2005; Fiddes, 1994; Spencer & Spencer, 2002) and that the consumption of meat may be an expression of attitudes and values that support inequality, domination, and power (Adams, 2000; Adams & Donovan, 1995; Allen, et al., 2000; Fiddes, 1994; Spencer & Spencer, 2002). These hypotheses were tested using a Java-based web application that implemented two versions of the IAT (Greenwald, et al., 2003). The English-speaking samples associated the concepts of power/dominance and masculinity with animal-based foods more than plant-derived foods. Self-identification as either a health or ethically motivated vegetarian only weakly moderated the strength of these associations. Discussion proposes preliminary statements of a social and political psychology of vegetarian self categorization and social identity processes.

**G206**

**WHEN YOU AND I ARE 'WE', YOU ARE BETTER THAN AVERAGE: MODERATORS OF FRIEND ENHANCEMENT** Helen Boucher<sup>1</sup>; <sup>1</sup>Bates College – While personal self-esteem has been linked reliably to enhancing the individual self, very little research has sought to identify moderators of relationship-partner enhancement. We investigate whether self-other inclusion moderates friend enhancement. In Study 1, individuals who chronically include close relationships in the self (i.e., those scoring high on the Relational-Interdependent Self-Concept Scale, or RISC) were more likely to enhance a close/best friend over an acquaintance than those who do not. In Study 2, high- and low-RISC participants rated their friends in comparison to a target (either an acquaintance or the average student at their school) on attributes differing in ambiguity. Since ambiguous attributes can be defined in ways that are maximally self-serving, enhancement of ambiguous over unambiguous attributes is taken to reflect enhancement. High-RISCs were more likely to exploit attribute ambiguity to favor their friends compared to low-RISCs. In Study 3, we tested whether friend enhancement serves the function of sustaining meaningful, satisfying relationships, especially for those who are high-RISC. To that end, high- and low-RISCs rated their friend in comparison to the average student at their school on attributes connoting agency (i.e., qualities reflecting individuality and achievement) and communion (i.e., affiliative, prosocial qualities), and then rated how satisfied they were with the relationship. Friend enhancement on communal, but not agentic, attributes predicted relationship satisfaction, but only for high-RISC individuals. Effects from all studies held when controlling for personal self-esteem, suggesting that self- and other-enhancement are separate constructs, serving distinct functions. We discuss implications and directions for future research.

**G207**

**TO BELONG OR NOT TO BELONG: AMBIVALENT IDENTIFICATION** Irem Uz<sup>1</sup>, Markus Kemmelmeier<sup>1</sup>, Emrah Yetkin<sup>2</sup>; <sup>1</sup>University of Nevada, Reno, <sup>2</sup>Hacettepe University, Ankara Turkey – Concurrent sense of belonging and not belonging is called ambivalent identification. Capitalizing on an attack by Islamist terrorists in a Muslim nation, we examined ambivalent identification and its management. The terrorists were, although Muslims, from a different religious sect than the respondents. This allowed for experimentally varying the degrees of similarity between participants and deviants. We argued that ambivalent identification is a different structure than either plain identification or from ingroup ambivalence. The former does not capture the conflict in the belongingness, whereas the latter refers to ambivalence in attitudes toward ingroup members. Principal components analyses supported our arguments. Moreover, the experimental effects were different for those three constructs. There were no effects of similarity with the deviants on the identification, and ingroup ambivalence was higher when the terrorists were referred to by their specific sect than as Muslims. Conversely, participants had markedly higher ambivalent identification when the respondents and terrorists were categorized as fellow Muslims. Self-stereotyping as a strategy in managing ambivalent identification appeared to be differentially successful under different categorization of the respondents and deviants. The present study provided some answers, but ultimately more questions than answers were generated calling for future studies.

**G208**

**ENVIRONMENTAL TUNING OF THE SELF: BEYOND SIMPLE PRIMING EFFECTS** Jesse Pappas<sup>1</sup>, Gerald Clore<sup>1</sup>; <sup>1</sup>University of Virginia – Drawing inspiration from the Social Tuning Hypothesis (Sinclair, Huntsinger, Skorinko, & Hardin, 2005), we examined how individuals' perceptions of their environments moderate priming effects. Numerous studies have demonstrated that physical environments influence cognitive processes in predictable ways, but we found that these effects may vary depending on the nature of one's relationship with their surroundings. In Study One, students surveyed at a campus library expressed stronger attitudes

about the importance of reading compared to students surveyed in a hallway ONLY IF they felt positively connected to the library environment. In Study Two, students surveyed at their university homes expressed more agreement with romanticized notions about the concept of home compared to students surveyed elsewhere ONLY IF they felt positively connected to their home environment. We review these findings and discuss their implications in priming and self-concept research domains.

**G209**

**UNCERTAINTY AND IDENTIFICATION WITH CELEBRITIES** Dana Turcotte<sup>1</sup>, Namrata Mahajan<sup>1</sup>, Michael Hogg<sup>1</sup>; <sup>1</sup>Claremont Graduate University – This study attempts to understand if uncertainty is a factor in an individual's desire to identify with celebrities who display negative behaviors. Uncertainty Identity Theory (Hogg, 2007) predicts that people do not like to feel uncertain and identifying with groups allows them to reduce uncertainty by providing a framework for how to feel, think, and behave. The more people feel uncertain, the more they should identify with a group of celebrities, regardless of appropriate or inappropriate behavior, because it provides these directions. When people are not uncertain, they should only want to identify with groups in which members display socially appropriate behavior. A survey was administered to 145 introductory psychology students, in which participants read a short description of a hypothetical group of celebrities who exhibited positive behaviors (i.e., charity work) or a group of celebrities who exhibited negative behaviors (i.e., drunk driving). Uncertainty was assessed by rating of personal attributes and certainty about them. Identification with the group of celebrities was assessed and demographics were collected. A multiple linear regression revealed a main effect for celebrity behavior, in that participants were more likely to identify with a group that displayed positive behaviors than negative behaviors. There was a significant two-way interaction between celebrity group's behavior and uncertainty. Specifically, as uncertainty increased so did identification with the group displaying negative behavior. This study provides one potential explanation for understanding identification with celebrities who exhibit negative behavior.

**G210**

**NARCISSISM AND SELF-JUDGMENT CHANGE IN FIRST-YEAR COLLEGE STUDENTS** Harry Wallace<sup>1</sup>, Ashley Arsenau<sup>2</sup>; <sup>1</sup>Trinity University, <sup>2</sup>University of Texas at San Antonio – Stellar high school students often must confront the unpleasantly novel experience of receiving not-so-hot grades in their first college semester. Past research has shown that students with relatively high narcissism levels are especially likely to overestimate their academic prospects. Our research used a longitudinal design to explore how academic setbacks influence the self-judgments of narcissistic first-year college students. Trinity University students taking introductory biology or psychology courses (N = 112, 70% female) completed similar surveys at the beginning (Time 1) and end (Time 2) of their first college semester. Survey items assessed narcissism (40-item NPI), self-perceptions, and judgments of future personal outcomes. Students' actual course grades were also obtained. Analyses revealed that students substantially overestimated their final grades at Time 1 and then made more realistic estimates at Time 2. Narcissism did not predict performance but did predict grade overestimation at both Time 1 and 2. Narcissists lowered first semester performance estimates in response to grades received, but their high self-rated intelligence and comparatively optimistic forecasts of final college G.P.A., career success, and future earnings varied little between Time 1 and 2. Narcissists apparently maintained positive self-views partly by pinning failures on others: They were far more likely than others to blame professors for academic problems. Contrary to models linking narcissism with emotional vulnerability, narcissism was unrelated to self-reported stress or magnitude of setbacks experienced during the semester. Other results confirmed past evidence that narcissistic students are more concerned with seeking glory (e.g., a prestigious career) than avoiding failure.

**G211****DON'T THINK GAY!: EVIDENCE FOR STRAIGHT MEN'S SPONTANEOUS SUPPRESSION OF GAY STEREOTYPES FOLLOWING A MASCULINITY THREAT** Matthew F. Crooks<sup>1</sup>, Thomas J. Allen<sup>1</sup>, Paula M. Do<sup>2</sup>;

<sup>1</sup>University of California, Davis, <sup>2</sup>United States Department of Agriculture, Agricultural Research Service – Previous research suggests that when their masculinity is threatened, straight men are more apt to derogate Gay men. Newman et al. (2005) proposed that defense-based prejudices like these may result from people suppressing unwanted characteristics (e.g. femininity) and projecting them on to groups perceived as having those characteristics (e.g. Gay men). This led us to hypothesize that when their masculinity is threatened, that straight men may attempt to suppress gay stereotypes (i.e. feminine characteristics). Furthermore, in accordance with Ironic Process Theory (Wegner, 1997), we expect that successful suppression will occur only when ample time is available and fail when time is minimal, with the later producing more intrusive thoughts about gay stereotypes (i.e. ironic effects). In the present study, we either threatened or did not threaten straight men's masculinity. Then they performed a task where they categorized target words related to gay stereotypes (e.g. sin, fashion), not related to Gay stereotypes, or pseudowords as words or nonwords. In between trials a subliminal prime was presented ("Gay" versus letter string) for 10 ms. The SOA (stimulus onset asynchrony) was long (2 s) or short (140 ms). Results demonstrated that when SOA was long, threatened males responded more slowly to Gay target words following the Gay prime relative to the control prime (i.e. successful suppression). When the SOA was short, threatened males responded faster to the gay targets following the Gay prime relative to the control prime (i.e. ironic effects). As predicted, threatened straight men attempted to suppress the Gay stereotype.

**G212****THE ROAD FROM PRIOR REVISIONS OF POSSIBLE SELVES TO LATER DISTURBANCES IN CORE PRESENT SELVES** Patrick Carroll<sup>1</sup>, Robert Arkin<sup>1</sup>;

<sup>1</sup>The Ohio State University – Three studies explored the determinants and processes that drive the effect of changes in self-defining goals on ultimate patterns of growth vs. decay in core self-images. In Phase 1, participants completed measures of chronic self-doubt and depression. In Phase 2, participants reported the number of times they had abandoned a career goal. Phase 2 also required participants to rate the stress associated with each change and the extent to which each change was due to lack of (1) personal competence/ability vs. (2) lack of effort or temporary situational obstacles that they could have surmounted in time. The results supported our predictions. First, Study 1-2 findings showed that higher experience with prior downward self-revisions uniquely predicted greater transitional stress as well as declines in self-serving bias generation (e.g., later vs. earlier changes predicted the diminished generation of self-serving biases for failure). Moreover, declines in self-serving bias generation mediated the link between higher experience with downward self-revision and higher levels of chronic self-doubt and depression. Study 3 ruled out the possibility that higher recollections of prior downward self-revision could result from vs. precipitate higher negative experiences of chronic self-doubt. Taken together, these findings suggest that greater experience with prior downward self-revisions may translate into ultimate disturbances in core self-image through steady declines in the generation of self-serving bias to protect against the painful implications of personal failure.

**G213****WHEN BICULTURAL IDENTITIES VARY: A SITUATED APPROACH AND THE ROLE OF BICULTURAL CONFLICT AND AUTHENTICITY IN EXPLAINING THE RELATION BETWEEN IDENTITY VARIATIONS AND PSYCHOLOGICAL WELL-BEING** Rui Zhang<sup>1</sup>, Kimberly A. Noels<sup>1</sup>;

<sup>1</sup>University of Alberta – Drawing on personality research on the variability of trait expression and its relation to well-being, we tested a situated approach to ethnic identity (Clément & Noels, 1992). In 2 studies, first- and second-generation Canadian bicultural students exhibited identity variations that differed systemati-

cally across situational domains and generational status. While identity variations were not found to be consistently correlated with psychological well-being for either generation, the relations were moderated by two variables -- bicultural identity conflict and identity authenticity felt across contexts. Results from regression analyses indicated a complex picture in that the effects of conflict and authenticity on well-being are channelled directly and indirectly via identity variability. In study 1 (N=121), identity variations were correlated negatively with well-being for those who reported high conflict. In study 2 (N=123), it is those low in conflict who suffered from unstable identities. While authenticity had a generally salutary effect, low identity consistency took a psychological toll on those expressing high mean levels of bicultural autonomy among the first generation. The seemingly contradictory results were explained in terms of whether there is a direct association between well-being and conflict or authenticity at the bivariate level. In conclusion, it is the subjective meaning of identity variations that seems to matter to the well-being of bicultural individuals.

**G214****I AM WHAT I OUGHT TO BE: CONFLATING DESCRIPTION WITH PRESCRIPTION IN SELF JUDGMENT** Corey Guenther<sup>1</sup>, Mark Alicke<sup>2</sup>;

<sup>1</sup>Creighton University, <sup>2</sup>Ohio University – The idea that people consistently evaluate themselves as better than average across a wide array of traits, abilities, and moral dimensions—known as the better-than-average effect—is one of the most robust in the social psychological literature. However, the preponderance of research in this area has focused on the process by which judgments of the average peer are generated in this comparative context (see Alicke & Govorun, 2005). By contrast, far less is known about how evaluations of the self are derived during such comparison. The present study addresses this question, contending that such self judgment predominantly comprises a heuristic-driven process during which evaluations of the self are naturally, and perhaps automatically, conflated with idiosyncratic perceptions of how much of various traits a person should have. Participants rated the self and their ideals perceptions—judgments of how much of various traits a person ideally should have—across 23 trait dimensions. Results indicated that, when made in isolation, self and ideal judgments were nearly identical across dimensions—they failed to differ on 20 of the 23 trait dimensions. On the remaining three dimensions, self judgments were more favorable than ideal judgments. Such similarity did not emerge when comparing judgments of the average peer with ideal prescriptions, nor when self and ideal judgments were provided simultaneously. These findings suggest that self evaluation in better-than-average contexts comprises a natural tendency to conflate self judgment with idiosyncratic prescription of how much of various traits an individual should have, a tendency which greatly contributes to robust better-than-average findings.

**G215****SELF-ENHANCEMENT AND COUPLE RELATIONSHIP: PREDICTORS AND CONSEQUENCES OF COUPLE POSITIVE ILLUSIONS** Claudia Manzi<sup>1</sup>,

Miriam Parise<sup>1</sup>, Raffaella Iafra<sup>1</sup>, Camillo Regalia<sup>1</sup>, Vivian L. Vignoles<sup>2</sup>;

<sup>1</sup>Catholic University of Milan, IT, <sup>2</sup>Sussex University, UK – Many studies have shown that self-enhancing perceptions toward the self are extended to close others and relationships suggesting that the more central a target is to one's identity the more it is positively perceived. The present study focuses on three specific forms of self-enhancement referred to one's couple relationship: the positive illusions. Many studies have shown that one's own romantic relationship is often perceived with positive illusions (e.g. Buunk & Van Yperen, 1991; Martz et al., 1998; Van Lange & Rusbult, 1995), but little efforts have been made to investigate the factors that may contribute to or inhibit these illusions and to explore how couple positive illusions are related to both relational and individual well-being. The aim of this study (conducted on 387 dating couples) is to clarify these issues and specifically to test the following hypotheses: positive illusions with the family of origin are significant predictors of couple positive illusions and this relationship is moderated by family respect for individual identity (Scabini & Manzi, in press); couple positive illusions

are significant predictors of couple and individual well-being. Data are analyzed through structural equation models. Results give evidence to the tested hypotheses.

### G216

#### **STEREOTYPE THREAT AS SYMBOLIC VIOLENCE: WHY "CLEARING THE AIR" MAY NOT BE ENOUGH** Jean-Claude Croizet<sup>1</sup>, Mathias Millet<sup>2</sup>;

<sup>1</sup>University of Poitiers & CNRS, <sup>2</sup>University of Poitiers – Negative stereotypes alleging intellectual inferiority can disrupt the performance of stereotyped targets. People usually react to stereotype threat by distancing themselves from problematic social identities. By imposing a certain framing of one's identity and preventing alternative more resourceful ones, evaluative situations perpetrate a form of symbolic violence (Bourdieu & Passeron, 1970): a given interpretational framework that imposes itself as legitimate, affects how people make sense of evaluative situations and themselves and ultimately results in social reproduction. In this presentation we will present one study that show that female students can draw upon the problematic, stereotyped identity as a symbolic resource to overcome stereotype threat. The experiment (n = 207) involved male and female undergraduate taking a difficult math test. Results showed that female participants that affirmed their social identity prior to taking a difficult math test performed better than non-affirmed participants and were identified more with their ingroup. We will reframe stereotype threat in terms of symbolic violence and discuss theoretical and practical implications.

### G217

#### **THE INFLUENCE OF SELF-AFFIRMATION AND UNREALISTIC RISK PERCEPTIONS ON REACTIONS TO PERSONALIZED RISK FEEDBACK**

Jennifer L. Cerully<sup>1</sup>, William M. P. Klein<sup>1</sup>, Isaac M. Lipkus<sup>2</sup>, Sarah M. Scholl<sup>1</sup>, Amy McQueen<sup>3</sup>, Peter R. Harris<sup>4</sup>; <sup>1</sup>University of Pittsburgh, <sup>2</sup>Duke University Cancer Center, <sup>3</sup>Washington University, <sup>4</sup>University of Sheffield – The effects of self-affirmation on unrealistically optimistic, unrealistically pessimistic, and realistic individuals' decisions to engage in colorectal cancer (CRC) screening were investigated. All participants were adults in the recommended age range for screening who had not yet done so and were given tailored risk feedback. One group was additionally given threatening risk feedback of a socially comparative nature, and a second group was given this information after a self-affirmation. A third control group did not receive any socially comparative information. Relative to the control group, participants who were self-affirmed and unrealistically optimistic about their CRC risk (as determined by comparison to a risk algorithm) were more interested in screening. Non-affirmed unrealistically optimistic participants were less likely to want to get screened when compared to the control group. Both unrealistic pessimists and realistic participants were less interested in screening when self-affirmed. These findings suggest that the accuracy of people's risk perceptions must be taken into account when determining whether or not self-affirmation is a productive strategy for encouraging healthy behavior in the face of threatening information.

### G218

#### **THINK OF CAPABLE OTHERS AND YOU CAN MAKE IT! SELF-EFFICACY MEDIATES THE EFFECT OF STEREOTYPE ACTIVATION ON BEHAVIOR**

Jochim Hansen<sup>1</sup>, Michaela Wänke<sup>2</sup>; <sup>1</sup>New York University, <sup>2</sup>University of Basel – Previous research has shown that activating a stereotype can influence subsequent behavior in a stereotype-consistent way. The present research investigates the role of self-efficacy beliefs in this effect. Specifically, we demonstrate that being primed with the stereotype of professors increases knowledge confidence compared to being primed with a less educated profession (Experiments 1 and 2), and that these higher self-efficacy beliefs result in higher performance at a general knowledge test (Experiment 2). These findings are corroborated in Experiment 3 that shows that participants primed with the stereotype of athletes persist longer in a physical exercise than participants primed with a stereotype less associated with persistence. Again, behavior was mediated by self-efficacy beliefs. The findings are in line with the active-

self account (Wheeler & Petty, 2001; Wheeler, DeMarree, & Petty, 2007) that proposes that priming with a stereotype influences a person's behavior through altered self-representations.

### G219

#### **THE BLOND, THE DUMB AND THE UGLY: SELF-CONSTRUALS' INFLUENCE ON PRIME-TO-BEHAVIOR EFFECTS**

Clementine Bry<sup>1</sup>, Alice Follenfant<sup>2</sup>, Fabrice Gabarrot<sup>3</sup>, Thierry Meyer<sup>4</sup>; <sup>1</sup>Université Catholique de Louvain, <sup>2</sup>Université de Bordeaux Victor Segalen, <sup>3</sup>Université de Lausanne, <sup>4</sup>Université Paris Ouest Nanterre La Défense – Stereotype priming can lead to assimilation or contrast behavioral effects. The Active Self Account (Wheeler, DeMarree & Petty, 2007) argues that such changes in behavior can be explained by consistent changes in the Active Self. Independent and interdependent self-construals determine the tendency to, respectively, exclude others' features from or include others' features in the self-concept (Kühhnen & Hannover, 2000). As such, one can expect independent self-construal to lead to contrast effects and interdependent self-construal to lead to assimilation effects. In three studies, we manipulated self-construal prior to participants being primed with the dumb Blonde stereotype or a control prime and completed a subsequent general knowledge questionnaire. In the third study, we measured self-attributions of Blondes' typical and counter-typical features before the knowledge test. We expected participants to endorse more Blondes' features in the interdependence condition than in the independence condition, and that it would mediate prime-to-behavior effects, consistently with the Active Self Account. In all studies, we found assimilation among interdependence-primed participants (i.e., worse performance) and contrast among independence-primed participants (i.e., better performance). We also found that interdependence led participants to endorse more Blondes' stereotypical features than independence. However, such changes in the self did not mediate prime-to-behavior effects. We discuss the implications of these findings for the Active Self Account and prime-to-behavior effects literature.

### G220

#### **CLOSING THE FLOODGATES: VOICE AND SILENCE AS CULTURAL TOOLS FOR COLLECTIVE MEMORY**

Phia S Salter<sup>1</sup>, Glenn Adams<sup>1</sup>; <sup>1</sup>University of Kansas – From the standpoint of the nation, representations of history can provide constructions of the past that aid in the creation and maintenance of "useful" collective identities. Because people typically do not have direct experience of foundational historical events, cultural repositories of memory – for example, school classrooms, textbooks, museums, and national holidays – mediate their understanding of the collective past. These cultural tools for memory and identity are not neutral or objective accounts of past realities, but instead are infused with particular beliefs and desires (e.g., concerning national glorification). To investigate the identity implications of different representations of history, the present investigation explored the hypothesized, bidirectional relationship of silence about racism in a historical disaster (the 1927 Mississippi floods), with American identification and comparisons to contemporary events (Hurricane Katrina). In one direction, both failing to mention past racism (omissive silence) and utilizing passive voice to obscure perpetrators of past wrong-doing (commissive silence) produced more positive experiences of American identity than representations that confronted historical racism by describing the events in active voice. In the other direction, representations that confronted historical racism in active voice triggered greater defensive distancing of racism-relevant events than did both omissive and commissive (i.e., passive voice) silencing, but only when identity concerns were salient. Discussion focuses on the extent to which the typical American school classroom – particularly, history education practices – provides scaffolding for denial of racism and serves as a cultural tool for the production of nation-glorifying citizens.

**G221**

**RACIAL IDENTITY MATTERS IN COPING AND ACHIEVEMENT FOR AFRICAN AMERICAN COLLEGE STUDENTS** Santiba Campbell<sup>1</sup>, James M Jones<sup>1</sup>; <sup>1</sup>University of Delaware – Factors are explored that determine whether African American college students maintain positive psychological health, achieve academic success and reach personal goals or adopt negative self images and under perform in school. TRIOS explores the dual adaptation and coping processes of self-protective and self-enhancing motivations for targets of racism (Jones, 2003). TRIOS levels are empirically linked to decreases in depression and anxiety; positive coping attitudes when responding to racist scenarios. Empirical results show that highly TRIOSic African Americans experienced elevated levels of psychological well-being even though they had high racial sensitivity. Results suggest a buffering role for TRIOS in relationship to perceptions and experiences of racism and their adverse impact on psychological well-being. Other results suggest that TRIOS may interact with racial identity to enhance positive psychological outcomes. The present study explores these associations, specifically the degree to which the relationship between TRIOS and psychological well-being is mediated by racial identity. The relationship was partially mediated by a dimension of racial identity; Centrality. The standardized regression coefficient between TRIOS and well-being decreased when controlling for Centrality, however remained significant. The significance of this partial mediation effect was tested using the Sobel test, 1.92,  $p = .05$ . This finding suggests that the importance of and how one may define themselves by their race plays a considerable role in personal health and coping. Racial Identity may help facilitate psychological survival and mental health for African American college students.

**G222**

**RELATIONAL SELF-CONSTRUAL AS A MODERATOR BETWEEN PERCEIVED SOCIAL SUPPORT AND DISTRESS AND LIFE SATISFACTION** Samantha J. Heintzelman<sup>1</sup>, Pamela L. Bacon<sup>1</sup>; <sup>1</sup>College of Saint Benedict/Saint John's University – In previous research, social support has been inconsistently related to distress, associated with both increases and decreases in distress levels, and sometimes being entirely unrelated. The current study evaluates the impact of the relational self-construal on the relationship between social support and distress as well as the relationship between social support and life satisfaction. To test the impact of the relational self-construal as a moderating variable clarifying the relationship between social support and these outcomes, 206 students from a liberal arts college and 79 students from a technical college completed a survey assessing their relational self-construal, perceived social support, distress, and satisfaction with life. The relational self-construal was found to be a moderating variable in the relationship between social support and distress, and again between social support and life satisfaction. High relationals reported lower distress and higher life satisfaction as they received higher levels of social support. For low relationals, however, distress and life satisfaction levels were unrelated to the amount of social support received. These findings help to explain past contradictory findings in the field, suggesting that differences in the response to social support are due to individual differences in the self-concept.

**G223**

**THE ROLE OF PERSONAL PERSPECTIVE IN CONSUMER DECISION MAKING** Laura Smarandescu<sup>1</sup>, Deanne Brocato<sup>1</sup>; <sup>1</sup>Iowa State University – Understanding how consumers attend to decision inputs and weigh different types of information is one of the main questions in decision making research. This research investigates how the weights assigned to information inputs change when consumers make decisions from a distant or a proximal perspective. Construal-level theory shows that psychological distance alters the mental representations consumers have for different inputs and the weights given to low and high level criteria in judgment (Trope, Liberman & Wakslak, 2007). Our research examines a form of psychological distance that has received less attention in decision making research, the role of personal perspective and mental imag-

ery in decision making (Libby, 2007). We find that when individuals pictured themselves from a third person perspective, a high psychological distance context, they weighted more information related to feasibility than when they pictured themselves from a first person perspective, a low psychological distance context. This result is consistent with a more rational decision making process at high construal levels. Study 2 shows that individuals were more likely to support a public policy program in a third person perspective than in a first person perspective; a third person view resulted in greater ratings on both "should" and "want" to support the public policy program. Study 3 shows that when participants took a third person perspective they were more likely to place more weight on ideal than pragmatic attributes. The results support a conclusion that indicates that in a third person perspective inputs are represented at a high construal level.

**Self-Regulation****G224**

**INDIVIDUAL DIFFERENCES IN OUTCOMES OF EGO-DEPLETION: THE CASE OF SELF-PERSPECTIVE TAKING** Jinyoung Park<sup>1</sup>, Hongmi Lee<sup>1</sup>, Eunkook Suh<sup>1</sup>; <sup>1</sup>Yonsei University – Research on self-control energy has largely focused on the effect of momentary energy depletion (ego-depletion) on self-control failure. However, there is another issue to consider: The effect of chronic individual differences in energy level on self-control. For example, it is possible that individuals with chronically high self-energy level are less affected by the effect of ego-depletion than those with low energy. The present research aimed to examine this possibility in relation to self-perspective taking. Previous work has shown that taking a third-person perspective is an effortful process; it requires one to override one's natural egocentric state (first-person perspective). The main hypotheses are as follows: (a) Taking a third-person perspective requires larger amount of self-control energy than taking a first-person perspective, (b) in an ego-depleted situation individuals with chronically high energy are able to take third-person perspective more easily than those with low energy. Participants were assigned to two conditions (depletion condition using the Stroop task and control condition), and were instructed to draw the number "3" on their forehead. The direction of 3 drawn was taken as an indicator of the participant's self-perspective (either self- or other-oriented 3). The individual energy difference was measured with items such as "energetic", "strong", and "active". As expected, participants with low self-energy were significantly less likely to draw 3 from a third-person perspective than those with chronically high energy.

**G225**

**SELF-CONTROL MOTIVE: ON THE MANIFESTATION AND IMPLICATION OF WANTING TO HAVE MORE SELF-CONTROL** Liad Uziel<sup>1</sup>, Roy F. Baumeister<sup>2</sup>; <sup>1</sup>Bar-Ilan University, <sup>2</sup>Florida State University – Self-control often brings about favorable outcomes that facilitate adaptation. Notwithstanding, high levels of self-control sometimes come with personal costs (e.g., resisting one's desires). It is therefore reasonable to expect that, in general, people would want to have more self-control, but also that there will be variability in the expression of this motive. In the present research we introduce a new scale to measure (state and trait) motive to have more self-control, the self-control motive scale (SCMS). In two studies (a longitudinal field study and a laboratory experiment) we demonstrate that the SCMS has good internal consistency, that it is sensitive to changes in external demand for self-control, and that it interacts with trait self-control in predicting levels of stress and success in task performance.

**G226****WHY INTROVERTS DO NOT ACT EXTRAVERTED MORE OFTEN: A POTENTIAL COST OF COUNTER-DISPOSITIONAL BEHAVIOR** Maya

Santoro<sup>1</sup>, John Zelenski<sup>1</sup>, <sup>1</sup>Carleton University – Recent research has demonstrated that acting extraverted increases positive affect for both dispositional introverts and extraverts (McNeil & Fleeson, 2006). Despite increased positive affect, there appear to be factors holding introverts back from acting extraverted more often than they do. The present study examined the hypothesis that introverts must self-regulate their behaviour to act extraverted, thereby inducing cognitive fatigue or ego-depletion. Participants (n = 87) engaged in an interview with a confederate where they were randomly assigned to act introverted (e.g., reserved, quiet) or extraverted (e.g., bold, talkative). Following the interview, participants completed a measure of positive affect. Cognitive fatigue was then assessed using Stroop task performance and change in blood glucose (c.f., Gailliot & Baumeister, 2007). Mood results replicated previous work in a new context; extraverted behavior during the interview produced significantly higher levels of positive affect than introverted behavior, regardless of disposition. In addition, acting counter-dispositionally (e.g., introverts in the extraverted condition) was associated with slower Stroop reaction times; however it was not related to change in blood glucose. The Stroop findings support the hypothesis that acting counter-dispositionally is depleting. This hypothesis was not supported by the physiological measure, but the null result might reflect the complexity or imperfection of blood glucose as an indicator of ego depletion (c.f., Gailliot, 2008). Identifying cognitive fatigue as a potential cost is important, because it negatively affects self-regulatory functioning across many domains. This deficit may help explain why introverts do not act extraverted more often, even though it produces positive affect.

**G227****FOOD FIGHT FOR ATTENTION: TEMPTATION-ELICITED ENHANCED SIZE PERCEPTION OF FOOD OBJECTS AMONG CHRONIC DIETERS** Guido M.

van Koningsbruggen<sup>1</sup>, Wolfgang Stroebe<sup>1</sup>, Henk Aarts<sup>1</sup>, <sup>1</sup>Utrecht University, The Netherlands – We examined the impact of temptations on chronic dieters' size perception of food objects. Dieters motivated to attain a slim figure, e.g., may be able to resist a tempting muffin when an apple on the same buffet is perceived as bigger, rendering a food object instrumental to the dieting goal easier to find. Importantly, the motivation to achieve goals result in enhanced size perception of goal-instrumental objects especially when goals are cognitively accessible. Among dieters, temptations activate the dieting goal for those successful in dieting, but inhibit this goal for unsuccessful dieters. Consequently, we hypothesized that temptations increase or decrease chronic dieters' size perception of food objects, depending on its relevance to the dieting goal and self-regulatory success in dieting. Participants were exposed to a tasty food or control prime and subsequently estimated the size of an apple (instrumental for dieting goal) or a muffin (interfering with dieting goal). As expected, successful dieters perceived the apple to be bigger than the muffin after being primed with the temptation to consume palatable food. In contrast, unsuccessful dieters perceived the muffin to be bigger than the apple. However, when chronic dieters' dieting goal was rendered accessible by a diet prime, the apple (vs. muffin) was perceived as bigger, regardless of self-regulatory success. The findings highlight the importance of self-regulatory success in determining how temptations affect the perceived size of overriding goal-instrumental objects. Implications for research on self-regulatory processes in chronic dieters and how people deal with temptations more generally will be discussed.

**G228****IT'S NOT EASY BEING GREEN: EXCESSIVE CHOICE AND THE BUFFERING EFFECT OF HABIT ON PRO-ENVIRONMENTAL BEHAVIORS** Kaitlin Toner<sup>1</sup>,

David T. Neal<sup>2</sup>, Wendy Wood<sup>3</sup>, <sup>1</sup>Duke University, <sup>2</sup>University of Southern California, <sup>3</sup>University of Southern California – Over the past decade, Americans have been inundated by lists of easy ways to save the planet. Do these lists promote green behaviors or does an abundance of choice get

in people's way? This research tested whether excessive choice undermines pro-environmental behavior and whether habit formation buffers against the burdens of choice. College students tracked their green behaviors over the course of a day. Amount of choice was manipulated by providing some participants with 6 pro-environmental behaviors (few options) from which to choose to perform that day and others with 24 behaviors (many options). In addition, each participant's pre-existing habit strength for each behavior was measured. As anticipated, for non-habitual green behaviors, high choice apparently depleted people's self-regulatory resources, leading them to fall short of their target. In contrast, for habitual green behaviors, high choice did not undermine performance because habits can be activated and implemented with few demands on self-regulatory capacity. The results suggest that pro-environmental messages and public policy interventions should take care not to burden consumers with excessive choice unless consumers have already formed habits for the target behaviors.

**G229****OVERCONFIDENT SELF-EVALUATION AND ORBITOFRONTAL CORTEX: EVIDENCE FROM FMRI AND A RECOVERING SUBSTANCE DEPENDENT POPULATION** Jamil Bhanji<sup>1</sup>, Jennifer Beer<sup>1</sup>, <sup>1</sup>University of Texas, Austin –

While overconfident self-evaluation has been shown to have various advantages and disadvantages in normal individuals, overconfident self-assessment may have special importance in the recovery from substance dependence. For example, overconfidence may make an individual resistant to treatment methods or it may lead to thoughts that a single instance of substance use will not lead to a full relapse. Previous research has shown that function in orbitofrontal cortex is impaired in individuals recovering from dependence on psychostimulants such as cocaine and methamphetamine. The current research examines overconfident self-evaluations of performance in recovering cocaine and methamphetamine dependent individuals, as well as the neural substrates that attenuate overconfident evaluations in normal individuals. Participants answered general knowledge questions and then rated their confidence in their performance. Knowledge question domains were designed to either elicit accurate self-evaluations or overconfident self-evaluations in normal participants. Findings show that recovering substance dependents make overconfident online self-assessments regardless of the knowledge domain. Furthermore, accurate online self-assessments of performance depend on medial orbitofrontal cortex in drug naïve individuals. Future research may show that overconfident self-assessment is related to orbitofrontal dysfunction in recovering psychostimulant dependent individuals.

**G230****VIOLENT VIDEO GAMES AND EXECUTIVE FUNCTIONING: ARE ALL EXECUTIVE FUNCTIONS AFFECTED THE SAME?** Christopher R.

Engelhardt<sup>1</sup>, Scott J. Saults<sup>1</sup>, Eduardo A. Vasquez<sup>1</sup>, Bruce D. Bartholow<sup>1</sup>, <sup>1</sup>University of Missouri –

Although considerable research has focused on deleterious effects of violent video games, recent research suggests playing some types of video games produces cognitive benefits. For example, studies suggest action video games (games requiring constant vigilance of the visual periphery) lead to increased flexibility in task switching, one measure of executive functioning ability. Most action games, however, also contain violence. The current studies investigated the role of violence in video games on other measures of executive control. In study 1, 60 participants were assigned to a violent, non-violent, or no-game control condition before completing a flanker task measuring interference control. Although the compatibility effect in reaction time (incompatible RT – compatible RT) did not differ across groups, a significant Group x Trial type interaction showed violent video game participants committed the most errors on incompatible trials. In study 2, 60 participants assigned to the same conditions as in study 1 completed a version of the spatial Stroop task, in which both the proportion of congruent to incongruent trials, as well as inhibitory control ("no-go") trials, was manipulated. Results showed that violent video game players tend to make more inhibition errors than their nonviolent game or no-game con-

tol counterparts. Interestingly, inhibition errors predicted estimates of cognitive control as measured by a processing dissociation procedure (PDP), but only for those in the no-game control condition. Taken together, the results suggest that although gamers may derive benefits in specific facets of executive functioning (task switching), they may also experience decrements in others (interference control).

### G231

**REGULATING GOAL COMMITMENTS IN EVERYDAY LIFE BY CONTRASTING FUTURE WITH REALITY** A. Timur Sevincer<sup>1</sup>, Gabriele Oettingen<sup>2</sup>; <sup>1</sup>University of Hamburg, <sup>2</sup>New York University and University of Hamburg – Mentally contrasting a positive future with negative reality helps people regulate their goal commitments. Specifically, mental contrasting makes people pursue goals that are feasible and it makes people dismiss goals that are unfeasible. To the contrary, indulging in the positive future or dwelling on the negative reality leads to goal pursuit that does not reflect chances of success. (Oettingen, Pak, & Schnetter, 2001). In two online studies, the authors investigated to what extent people mentally contrast future and reality when asked to freely think about a desired future outcome. Only a relatively small number of participants contrasted their future with reality (Study 1). Participants who mentally contrasted a desired future in one life domain did not necessarily do so in another domain. Interestingly, when the desired future pertained to their ideal self, participants were particularly likely to indulge in their desired future (Study 2). Finally, across both studies, after mentally contrasting their future with reality, participants displayed expectancy-based commitments as have been found for experimentally induced mental contrasting. The results offer an explanation for why people happen to succeed or fail in effectively regulating their goal commitments during everyday life.

### G232

**WHERE DID I GO WRONG? DETECTION OF CONFLICT IN HABITUAL AND NOVEL BEHAVIORS** Jennifer S. Labrecque<sup>1</sup>, David T. Neal<sup>1</sup>, Wendy Wood<sup>1</sup>; <sup>1</sup>University of Southern California – Many of our daily actions are motivated by intentions and goals, whereas others are habitual and prompted directly by context cues or preceding actions without requiring activation of goal states (Wood & Neal, 2007). The present study tested one implication of these different mechanisms guiding behavior. That is, when behaviors go awry, how is this conflict detected in habitual as compared with novel behaviors? In an initial survey, participants identified behaviors and goals that they personally associated with exercising at the gym, and these responses were then incorporated into a lexical decision task tailored to each participant. Reaction times in this task indicate that, for novel behaviors, participants more readily recognize a conflicting goal, whereas for habits, participants more readily identify a conflicting behavior. Thus, participants who rarely go to the gym recognized goals that impede their exercise (e.g., academics), whereas participants with a strong gym habit recognized behaviors that impede exercise (e.g., chatting). These findings provide initial evidence of how people detect conflicts or interruptions in habitual behaviors. This question has not been addressed by self-control researchers, although this detection is an initial step in effective self-regulation of habits.

### G233

**CUES FOR ACTION INCREASE IMPULSIVITY** Justin Hepler<sup>1</sup>, Dolores Albarracín<sup>1</sup>, Kathleen C. McCulloch<sup>2</sup>, Kenji Noguchi<sup>3</sup>; <sup>1</sup>University of Illinois at Urbana-Champaign, <sup>2</sup>Idaho State University, <sup>3</sup>University of Southern Mississippi – People are often urged to be as active as possible to increase productivity and to achieve socially beneficial outcomes. However, as not all forms of active behavior are in fact desirable, this focus on being active may result in some unintended, troubling consequences. This research examined whether exposure to action- and inaction-related concepts can influence impulsive behaviors. Participants were presented with action- and inaction-related concepts, such as "go" and "start" or "stop" and "pause", and subsequently completed a delay discounting task (Experiment 1) or a Go/No-Go task (Experiment 2). The results sug-

gest that simply being exposed to action or inaction concepts can cause individuals to behave more or less impulsively, respectively. This raises the intriguing possibility that Western culture's overwhelming focus on being active may have the inadvertent effect of making people more impulsive.

### G234

**ON THE LINK BETWEEN INTERGROUP THREAT AND PREJUDICE: HOW DOES SOCIAL MOTIVATION INTERVENE?** Lisa Legault<sup>1</sup>; <sup>1</sup>University of Toronto – Although plenty of evidence supports the causal link between intergroup threat and outgroup prejudice, few psychological moderators of this association have been investigated. One such moderator involves the source of motivation to self-regulate prejudice. Integrating self-determination theory and threat theories of prejudice, this research addresses the role of motivation in the association between intergroup threat and various outgroup attitude variables (i.e., modern racism, outgroup affect, interracial anxiety, automatic racial bias, and behavioral discrimination). In Study 1, we experimentally examined the influence of self-determined motivation to be nonprejudiced in moderating the impact of intergroup threat on outgroup attitudes. Thus, two independent variables were manipulated: level of self-determined motivation to regulate prejudice (high vs. low) and perceived intergroup threat (realistic and symbolic threat). Results suggest that being self-determined in one's motivation to regulate prejudice fully buffers the impact of intergroup threat on prejudice, whereas regulating prejudice primarily for non-self-determined (i.e., external-social) reasons serves to exacerbate the threat-prejudice effect. In Study 2, a cross-sectional corroboration of this interaction was obtained using structural equation modeling. Results revealed that when the threat-prejudice link was constrained across groups (i.e., self-determined and non-self-determined prejudice regulators), it was found to be noninvariant. The role of self-determination in reducing both intergroup threat and prejudice is discussed, and implications for diversity education and policy are identified.

### G235

**SOCIAL ANXIETY AND THREAT ACTIVATION FOLLOWING SOCIAL STRESSORS** Niels Christensen<sup>1</sup>, Madeleine Reedy<sup>1</sup>, Sarah Clark<sup>1</sup>, James Austin<sup>1</sup>; <sup>1</sup>Radford University – Previous research has suggested that the socially anxious experience initial activation, then subsequent avoidance of, socially-threatening stimulus words (Amir et al., 1998). However, our research suggests that social stressors fundamentally alter the ability of the socially anxious to self-regulate cognitions. Therefore, the goal of the present research was to evaluate whether the activation-then-avoidance process would replicate following a social stressor. The 165 undergraduates were prescreened on social anxiety and later participated in one of three experimental conditions. Some completed a 5-minute social interaction with a stranger. Others completed a 5-minute cognitively demanding task by themselves. Remaining participants sat quietly by themselves for 5 minutes. After the experimental manipulation all participants completed a semantic decision-making task on a computer. On key trials, the task required self-regulating attention away from the socially threatening meaning of a homograph (e.g., recognizing that the homograph STERN refers to a "boat" rather than a "harsh personality"). Slower reaction times on homograph trials indicate greater social threat activation. The 3-way interaction of social anxiety, experimental condition, and stimulus onset (immediate versus delayed) was marginally significant,  $F(2, 158) = 2.80, p = .06$ . Most importantly, the interaction between social anxiety and stimulus onset in the social stressor condition,  $F(1, 56) = 6.54, p = .01$ , indicated a reversal of the activation-then-avoidance process. Social anxiety was associated with greater avoidance on the immediate trials and activation on delayed trials. This result highlights the socially embedded nature of self-regulatory processes for the socially anxious.

**G236****ATTACHMENT, EGO DEPLETION AND REPRESSIVE DEFENSIVENESS OF EMOTIONAL MEMORIES**

W. Steven Rholes<sup>1</sup>, Jamie L. Rentfro<sup>1</sup>; <sup>1</sup>Texas A&M University – Attachment theory proposes that individuals with a dismissive avoidant attachment style actively attempt to block the recall of memories that generate strong, negative affect, particularly when they involve close others. Individuals with other attachment styles (secure, preoccupied, and fearful avoidant) do not block these memories. The present study proposed that this blockage used by dismissive avoidant persons relates to affect regulation. As such, we examined whether this regulation could be undermined by Baumeister and colleagues' ego strength depletion. In the experimental condition, participants first completed an ego depletion task. In the control condition, participants completed a non-depleting task. Then all participants were asked to recall 4 separate childhood events involving their parents in which they experienced either sadness, anger, anxiety, or happiness. The dependent variable was latency to recall the memory. It was hypothesized that individuals with a dismissive avoidant attachment style would recall affectively negative events more quickly in the ego depletion condition than in the control condition, while other attachment styles would show no differences. Results were consistent with the hypothesis. Also, ego depletion did not influence the recall of affectively positive events for any attachment style. As hypothesized, individuals with a dismissive avoidant style attempt to block the retrieval of affectively negative events, and this action requires ego strength. These findings are consistent with the literature, which characterizes dismissive avoidant persons as more likely to actively control cognition and emotion. High self-regulation may be one way to remain affectively neutral and emotionally detached within close relationships.

**G237****CAN'T STOP: RESTRAINING RESPONSE TO POSITIVE AFFECTIVE STIMULI**

Martin Ryan<sup>1</sup>, Nicole Wilson<sup>1</sup>, Yuichi Shoda<sup>1</sup>; <sup>1</sup>University of Washington – In the emotional go/no-go task, subjects are presented with a series of happy and scared faces. In one condition ("scared no-go") they must press a button when they see a happy face and refrain from pressing the button when they see a scared face. In the other condition ("happy no-go"), the scared faces are the "go" cue and happy faces are the "no-go" cue. Previous research has found that subjects perform this task less quickly and make more errors in the "happy no-go" condition (Hare et al., 2005), consistent with the hypothesis that happy faces function as a positive/approach cue, and as such are more difficult to withhold a response from. The present research replicated Hare et al. (2005) with a larger sample (N=122) and demonstrated that individual differences in performance on this task are related to a measure of impulsivity. Subjects made more errors in withholding responses in the "happy no-go" condition than in the "scared no-go" condition (Ms=27% and 25%,  $t(126)=2.35$ ,  $p=.02$ ,  $d=.37$ ). Furthermore, scores on the Barratt Impulsiveness Scale (BIS) were related to errors in restraining responses to happy faces ( $\beta=.27$ ,  $p<.01$ ). Impulsivity remained a significant predictor of error in the "happy no-go" condition after controlling for latency, error rates on the "scared no-go" condition, and on a related task using neutral faces ( $\beta=.20$ ,  $p<.01$ ). Our findings suggest that impulsivity relates to subjects' ability to resist the affective "pull" of happy faces and focus on the task at hand.

**G238****NO THANKS! LOW SELF-CONTROL PREDICTS IMPOLITE BEHAVIOR**

Amber DeBono<sup>1</sup>, Mark Muraven<sup>1</sup>; <sup>1</sup>University at Albany - SUNY – Social norms appear to be followed seamlessly and automatically. Yet, self-control may be required to resist temptations to behave antisocially. The Ego Depletion Model suggests that self-control is like a muscle that can be weakened (Baumeister, Bratslavsky, Muraven, & Tice, 1998). When self-control is expended on a task, this self-control depletion decreases performance on subsequent self-control related tasks. Previously, lowered self-control was found to decrease adherence to specific prescriptive

norms such as cheating. To explore the possibility that conforming to other norms necessitates self-control, we tested the Ego Depletion Model with politeness, a descriptive norm. We predicted that participants depleted of their self-control would be impolite whereas those with maintained self-control would adhere to politeness rules. Thirty-six participants were instructed to type two paragraphs. Non-depleted participants typed both paragraphs normally. Depleted participants did not type "e" or spacebar during the second paragraph. This task exhausts self-control resources because resisting the natural urge to push these forbidden keys requires self-control strength. Next, the participants followed the experimenter to another room. To assess polite behavior, the experimenter secretly counted how many times the participants said thank you while holding open eight doors for them. Overall, depleted participants were less polite than their non-depleted counterparts. Participants with lowered self-control said thank you significantly less often. In fact, depleted participants were more likely to never say thank you than those who were not depleted. The results suggest that low self-control causes fewer adherences to social norms, such as politeness.

**G239****MINDFULNESS STRATEGIES DECREASE PAIN TOLERANCE ASSOCIATED WITH HIGH HEART RATE VARIABILITY**

Tory A. Eisenlohr-Moul<sup>1</sup>, Daniel R. Evans<sup>1</sup>, Daniel F. Button<sup>1</sup>, Ruth A. Baer<sup>1</sup>, Suzanne C. Segerstrom<sup>1</sup>; <sup>1</sup>University of Kentucky – One interesting manifestation of self-regulation is the ability to withstand pain rather than escape. As a self-regulatory trait, this ability may be reflected in high resting heart rate variability (HRV; a measure of parasympathetic control of the heart), which has been associated with better self-regulation at difficult tasks. As a self-regulatory skill, mindfulness (i.e., experiential observation, description, and acceptance) is often taught to increase both pain tolerance and self-regulatory capacity. The current study tested the hypothesis that high HRV, mindfulness, and their interaction predict persistence on a painful task. Participants ( $n = 63$ ) not previously trained in mindfulness were randomly assigned to either mindfulness training or control. HRV was measured during a 10-minute baseline, during which those in the mindfulness condition learned about strategies including observing, describing, and accepting. They were then instructed to apply these strategies during a cold pressor task. Those in the control condition were instructed to cope with the pain however they chose. Higher resting HRV predicted longer persistence on the task ( $b = .31$ ,  $p < .05$ ). However, instructions to be mindful predicted shorter persistence ( $b = -.28$ ,  $p < .05$ ), and group status moderated the effect of HRV on persistence such that HRV predicted longer persistence in the control group only ( $b = -.41$ ,  $p = .05$ ). The self-regulatory demand of applying novel mindfulness strategies may have taxed self-regulatory strength during the cold pressor task so as to attenuate the benefit associated with high HRV.

**G240****MOTIVATED USE OF CONSTRUAL LEVELS TO ENHANCE SELF-CONTROL**

Karen E. MacGregor<sup>1</sup>, Kentaro Fujita<sup>1</sup>, Andrew J. Senita<sup>1</sup>; <sup>1</sup>Ohio State University – Previous research has demonstrated that thinking abstractly, or using high-level construals, improves self-control (Fujita, 2008; Fujita et al., 2006). Empirical evidence for this construal level approach to self-control has revealed that inducing people to think abstractly leads to increased physical endurance, more negative evaluation of temptations and reduced temporal discounting (Fujita et al., 2006). The unique contribution provided by the current program of research lies in the suggestion that high-level construals may be recruited strategically by individuals facing a self-control conflict. Specifically, this research demonstrates that when faced with the prospect of temptations undermining valued goals, people can and will adopt high-level construals of future events, a practice which is likely to promote self-control. In study one, all participants imagined that they would be taking part in a cookie taste test. Half were asked to imagine being concerned with eating too many cookies (restraint goal), whereas the others were asked to imagine being worried about maximizing their enjoyment of the cookies (enjoyment goal). Individuals with the hypothetical restraint goal were more likely

to adopt a high-level construal of the cookie taste test than were those with the hypothetical enjoyment goal. In study two, correlational data revealed that greater personal concern with maintaining a healthy diet was associated with an increased tendency to adopt high-level construals of a real cookie taste test believed to be forthcoming. Taken together, the results of these studies provide initial evidence for the strategic use of high-level construals to enhance self-control.

#### G241

**PRAYER CAN REDUCE AGGRESSION** Ryan H. Bremner<sup>1</sup>, Sander Koole<sup>2</sup>, Brad J. Bushman<sup>1,2</sup>, <sup>1</sup>University of Michigan, <sup>2</sup>Vrije Universiteit, Amsterdam, the Netherlands – One popular notion across religious traditions is that prayer can be used as an instrument to reduce anger. Given its widespread use as well as the relationship between certain types of religiosity and violence, it is important to know whether prayer really can be an effective way to reduce anger and aggression. We examined this using 2 (angered versus not angered) X 2 (pray for versus think about the person who angered you) between-subjects factorial design. Participants were told that they would form an impression of another participant by writing an essay, exchanging essays with their partner, giving and receiving feedback on the essays, and playing a competitive reaction time task. Half of the participants were angered by receiving very negative essay feedback, whereas the others received positive feedback. Participants were then randomly assigned to pray for or think about the person who angered them, after which they played the competitive reaction time task in which the winner could blast the loser with loud noise through headphones (aggression measure). Results showed that participants who were angered and then prayed for the person who angered them were less aggressive than those who were angered and thought about the person who angered them ( $d=0.63$ ). These results show that prayer can reduce aggression in angry people.

**OVERCOMING REGRET: THE SHORT-TERM IMPACT OF SELF-REGULATION STRATEGIES** Jamie C. Farquhar<sup>1,2</sup>, Carsten Wrosch<sup>1,2</sup>; <sup>1</sup>Concordia University, <sup>2</sup>Centre for Research in Human Development – Research suggests that older adults, who often possess low opportunities to undo their regrets, should disengage from regrets that cannot be undone. In contrast, it may be more adaptive for younger adults, who possess the opportunity to undo their regrets, to remain engaged in attempting to undo the negative consequences of regrets that can be undone. The current study used a writing intervention to manipulate younger and older adults' self regulation processes to determine the causal mechanisms involved in the management of regret. One-hundred younger adults (aged 18 – 30 years) and 100 older adults (aged > 60 years) were randomly assigned to one of two experimental writing conditions (or a third control condition). In the 'Let Go' condition, participants were asked to focus on unfavorable opportunities to undo their regrets, and to generate thoughts and actions that would help them let go of the regrets. In contrast, in the 'Undo' condition, participants were asked to focus on favorable opportunities to undo their regrets, and to generate thoughts and actions that would help them to undo the consequences of the regretted events. We hypothesized an age by condition interaction so that older adults would benefit most from letting go (i.e., disengaging) from their regrets whereas younger adults would benefit most from their efforts to undo their regrets. The impact of the writing intervention was measured using regret-specific (e.g., intrusiveness, regret emotions) and general well-being measures (i.e., mood). The results supported the hypotheses. Implications of the findings will be discussed.

#### G243

**WHEN DEPLETION HELPS: DEPLETION AS EXAGGERATION OF ENVIRONMENTAL INFLUENCE** Michael Cahill<sup>1</sup>, Ronald T Kellogg<sup>1</sup>, Donna Eisenstadt<sup>2</sup>, Nic LeFevre<sup>1</sup>, Kristen Maltarich<sup>1</sup>, <sup>1</sup>Saint Louis University, <sup>2</sup>Illinois State University – Self-regulatory exertion has been shown to deplete resources and impair subsequent self-regulation. However, ambiguity still surrounds the identity of this resource and its role in self-regulatory processes. The current study tested the possibility that a primary characteristic of depletion is diminished voluntary control of attention. By this account, depletion diminishes strategic attentional control and exaggerates the influence of salient environmental cues. Unfortunately, the environment often lacks the appropriate stimuli to direct attention to abstract goals, and thus depleted participants typically show self-regulatory decrements. However, goal primes that are present in the environment should be particularly attention-demanding and influential for depleted individuals, leading to a possible self-regulatory advantage of depletion. The purpose of the current experiment was to test the possibility that depletion benefits rather than impairs self-regulation in the presence of a salient stimulus (a mirror) thought to prime abstract goals. Participants followed either a simple or complex rule as a manipulation of depletion and then completed the competitive reaction time task as a measure of aggression either in the presence or absence of a small mirror. In the absence of a mirror, depleted participants exhibited marginally more aggression than did non-depleted participants, but in the presence of a mirror, depleted participants displayed significantly less aggression than did non-depleted participants. Rather than leading to unequivocal self-regulatory impairment, the depletion effects may depend heavily on contextual factors. Broader implications for theory in self-regulation are also discussed.

#### G244

**THE IMPACT OF PERCEPTION ON EXECUTIVE CONTROL: DOES ILLUSORY FATIGUE IMPAIR WORKING MEMORY CAPACITY?** Joshua J. Clarkson<sup>1</sup>, Edward R. Hirt<sup>2</sup>, D. Austin Chapman<sup>2</sup>, Lile Jia<sup>2</sup>; <sup>1</sup>University of Florida, <sup>2</sup>Indiana University – The human mind is quite adept at modifying and regulating one's thoughts, judgments, and behaviors. Interestingly, self-regulatory failures have been linked to impairments of this executive function. That is, individuals who are depleted of valuable self-regulatory resources show reduced executive functioning in the form of restricted working memory capacity. However, emerging research suggests that the mere perception of depletion (i.e., illusory fatigue) affects subsequent self-regulatory performance independent of one's actual state of depletion (Clarkson, Hirt, Jia, & Alexander, in press). Might the effect of illusory fatigue on subsequent self-regulation be attributed to restricted working memory capacity? In other words, could the mere perception of resource availability affect one's capacity to engage in executive functioning? To manipulate illusory fatigue, participants completed a modified misattribution paradigm in which they were exposed to a depleting or non-depleting task before being presented with false feedback about the effects of the initial task on their state of resource depletion. Participants then completed a well-established index of working memory capacity. Findings revealed that individuals provided with feedback that matched (versus mismatched) their state of depletion exhibited greater working memory capacity (independent of individuals' actual state of depletion). These findings offer: (1) important insight into the mechanism underlying the link between perceived resource availability and self-regulatory performance, and (2) supportive evidence that subjective perceptions can impact executive functioning, which suggests a fluid conceptualization of working memory. Implications for spontaneous resource replenishment are discussed.

**G245****TRAIT MEASURES OF SELF-CONTROL AND THE TEMPORAL DISCOUNTING OF DELAYED REWARDS**

Kerstin Schroder<sup>1</sup>, Joseph Wanzek<sup>1</sup>, Ryan Greene<sup>1</sup>, <sup>1</sup>Utah State University – Aims: We examined the associations between two trait measures of self-control and the temporal discounting for delayed rewards. Methods: Self-control was assessed in a sample of 68 male and 58 female undergraduate students using the Rosenberg Self-Control Scale and a measure of Habitual Self-Control. Temporal discounting was assessed in individual lab sessions asking participants to make a series of choices each between an immediate, smaller reward and a delayed larger reward. Delay intervals and reward amounts were systematically varied to obtain individual hyperbolic functions for discounting. Three different vignettes (lottery, survey participation, and exercise) were used to also observe effects of different behavioral efforts required. The area under the curve of the hyperbolic function was used as an indicator of discounting and as dependent variable for correlational analyses. Further, HLM was used to model decisions (0=immediate reward, 1=delayed reward) with time delay and reward amount as Level-1 predictors and self-control as Level-2 predictor. Results: We found correlations between self-control and discounting up to -.25. HLM analyses predicting the log-Odds of delayed choices indicated strong effects of reward size ( $t=7.45$ ,  $p<.0001$ ) and delay ( $t=-30$ ,  $p<.0001$ ). Self-control added to the prediction of delayed-reward choices in some but not all analyses. Further, self-control moderated the effects of both Level-1 predictors, reducing both the impact of reward size and time on the choice of a delayed reward. Conclusions: Trait measures of self-control are relatively weak predictors of lab-induced delay choices but limit the effects of primary determinants (delay, size of reward) on discounting.

**G246****PRESSURE KICKING IN THE NFL: DOES ICING THE KICKER HINDER PERFORMANCE?**

Nadav Goldschmied<sup>1</sup>, Max Nankin<sup>2</sup>, <sup>1</sup>University of San Diego, <sup>2</sup>Barry University – 'Icing' is a common strategy used in basketball and American football to minimize the success rate of opposing teams. When the game is on the line, an opposing coach may ask for a time-out, to allow the player who is about to make a crucial free-throw or a decisive kick more time to mull the negative outcomes if he fails to score. Our archival study corroborates that this strategy is successful in the ranks of the NFL (the National Football League). We also propose, through comparison between different game situations before the kick, a possible mechanism behind the icing effect; namely, icing may work because the player is taxed twofold as he has to prepare – both mentally and physically – twice for the kick under 'icing' conditions, and not because he becomes overly anxious due to negative thoughts (i.e., rumination). Additionally, our results indicate that other "environmental" factors such as experience, lack of time-out availability by the opponent (i.e., sense of control) and score (tied vs. behind), do not appear to bolster kicker's ability to convert a pressure kick.

**G247****ANTECEDENTS OF PSYCHOLOGICAL WELL-BEING: EMOTIONAL INTELLIGENCE AS A MEDIATOR IN THE RELATIONSHIP BETWEEN SELF-DETERMINED REGULATION STYLE AND WELL-BEING**

Melinda Morgan<sup>1</sup>, Celine Blanchard<sup>1</sup>, Danielle Patry<sup>1</sup>, Isabelle Therrien<sup>1</sup>; <sup>1</sup>University of Ottawa – Self-determination theory research has shown that self-determined self-regulation styles (e.g. intrinsic, integrated and identified) are associated with positive outcomes such as psychological well-being (PWB). Little is known as to the mechanism of the relationship between such regulation styles and PWB. Exploratory analyses of emotional intelligence (EI) as a potential mediator will be examined in two studies. In Study 1 a cross-sectional design was used and a 3-month longitudinal design was used in Study 2. Student samples were used for both studies. Global self-regulation, four facets of EI (Appraisal of Emotions (AE), Mood Regulation (MR), Utilization of Emotions (UE) and Social Skills (SS)) and PWB were measured for Study 1 ( $n = 103$ ). In Study 2 ( $n = 283$ ), global self-regulation was measured at Time 1 and EI and PWB were measured at Time 2.

For Study 1, regression analyses revealed that only intrinsic motivation, introjected regulation (negative), AE, and MR significantly predicted PWB. Both AE and MR emerged as significant partial mediators. Regression analyses for Study 2 revealed that integrated, identified, introjected (negative), AE and MR significantly predicted PWB. In Study 2, AE and MR emerged as partial mediators for both integrated and identified regulation. Results suggest that the relationship between self-determined regulation and PWB may be partly due to one's self-reported comprehension of emotions and one's self-reported regulation of mood.

**G248****SELF-REGULATING BEHAVIOR IN CLOSE RELATIONSHIPS**

Sylviane Houssais<sup>1</sup>, Gabriele Oettingen<sup>1</sup>, Peter Gollwitzer<sup>1</sup>; <sup>1</sup>New York University – Mental Contrasting with Implementation Intentions (MCII) was hypothesized and observed to help people regulate their behavior in romantic relationships. Mental contrasting leads people to successfully set goals, while forming implementation intentions leads people to successfully plan and implement set goals. Previous work has tested the effectiveness of MCII in the achievement and health domains. The present study investigated its effectiveness in the interpersonal domain. Participants in long-term romantic relationships identified an insecurity-based behavior that they wanted to reduce. They then either learned the MCII strategy, a reverse control strategy, or no strategy. In the MCII condition, participants elaborated in writing a desired outcome of reducing their unwanted behavior, followed by a critical obstacle standing in the way of reducing the unwanted behavior. They then formulated an 'if-then' plan using the obstacle in the if- part of the plan and a relevant behavior to overcome the obstacle in the then- part of the plan. In the reverse control condition, participants followed a similar procedure but in a theoretically ineffective order. In the third condition, participants were given no particular strategy. One week after the experiment, participants in the MCII condition reported being significantly more successful in reducing their unwanted behavior than participants in the other conditions. Additionally, participants in the MCII condition reported a significantly larger increase in relationship commitment than those in the control conditions. The findings have implications for the psychology of goal pursuit as well as for research on improving relationships.

**G249****THE EFFECTS OF MORTALITY SALIENCE ON NAMES PREFERENCES: EVIDENCE FOR THE MORTALITY THREAT-BUFFERING FUNCTION OF IMPLICIT EGOTISM**

Mauricio Carvalho<sup>1</sup>, Chris Bartak<sup>1</sup>; <sup>1</sup>University of Oklahoma – Research on implicit egotism suggests that one way in which people affirm their sense of self-worth in the face of self-concept threat is by automatically enhancing the value of the letters in their names. The current research examines whether the buffering effect of implicit egotism also extends to exposure to mortality threat. Two experiments and one archival study tested the hypotheses that reminding people of their mortality should increase their name letter preferences and influence their preferences for children's names similar to their own names. In Studies 1 and 2, participants were exposed to mortality salience or control conditions. Mortality salience led to increased (a) liking for participants' first and last initials (Study 1) and (b) preference for children's names that shared participants' first initials (Study 2). In Study 3, we examined birth records surrounding the 9/11 terrorist attacks. Analyses of these records revealed that, after the 9/11 terrorist attacks, people were disproportionately more likely to name their children with names that shared the first initials of their own names. Taken together, these studies provide further evidence of the threat-buffering function of implicit egotism and the role it plays when choosing a name for one's children.

**G250**

**THE DOWNHILL BATTLE FOR SELF-CONTROL: COGNITIVE DYNAMICS AS SUBJECTIVE CUES FOR EXPERIENCED AGENCY** Erik G. Helzer<sup>1</sup>, Michael T. Wojnowicz<sup>1</sup>, Melissa J. Ferguson<sup>1</sup>, Michael J. Spivey<sup>2</sup>; <sup>1</sup>Cornell University, <sup>2</sup>University of California: Merced – What does it feel like to exert self-control? Based on previous work in social psychology (Preston & Wegner, 2007) and cognitive dynamics (Wojnowicz, Spivey, & Ferguson, 2009) we explored the counterintuitive possibility that participants would experience greater self-control over decision responses that were objectively easier to give. On a computerized Stroop task, participants saw a stimulus at the bottom of the screen and two response alternatives on either side of the top of the screen. On each trial, participants identified the color of the stimulus by moving their computer mouse toward the corresponding response box. We surreptitiously tilted the computer tabletop toward the left or right, facilitating participants' hand-movements toward responses on one side of the computer screen. As expected, we found that participants ( $n = 57$ ) experienced greater self-control when responding in the direction of the table tilt. Since previous research suggests that high-conflict decisions are characterized by strong cognitive acceleration (Wojnowicz, Spivey, & Ferguson, 2009), participants' increased motor acceleration when responding with the tilt may have provided a cue to agency by mimicking (or feeding back into) cognitive acceleration. We discuss our results in terms of Wegner's (2001) model of conscious will as a causal inference. In addition to static thought-action relationships, which operate on the principles of priority, consistency, and exclusivity, we argue that people derive a sense of agency from the experience of dynamic acceleration within cognitive processing.

**G251**

**INCREASED AUTOMATIC CONTROL IN HEALTHY ELDERLY: EVIDENCE FOR THE POSITIVE AFFECTIVE BIAS IN AGING** Sanda Dolcos<sup>1,2</sup>, Ekaterina Denkova<sup>2</sup>, Keen Sung<sup>1</sup>, Roger Dixon<sup>1</sup>, Florin Dolcos<sup>2,3</sup>; <sup>1</sup>Psychology, University of Alberta, <sup>2</sup>Psychiatry, University of Alberta, <sup>3</sup>Centre for Neuroscience, University of Alberta – Emotion regulation (ER) is an important part of everyday human behaviour. ER undergoes lifespan transformations, with an apparent peak occurring in the elderly. By emphasizing positive aspects of stimuli, older adults may display an enhanced ability to control emotional responses to problematic events. Most of the previous ER research has focused on deliberate, conscious forms of regulation, but little is known about automatic or nonconscious forms of ER, and the effect of aging on these processes. Here, we examined the effects of deliberate and automatic ER in healthy young and older adults. The experimental design manipulated both the goal of regulating emotion (conscious vs. nonconscious) and the intensity of the emotional challenge (high vs. low). Participants rated the emotional content of negative and neutral pictures of varying intensity and were instructed or nonconsciously primed to suppress responses to the pictures. In the young group ( $n = 23$ ) both deliberate and automatic ER decreased subjective responses to low-intensity emotional pictures, but only deliberate ER was effective in suppressing responses to high-intensity pictures. Interestingly, in older adults ( $n = 14$ ) both deliberate and automatic ER were effective in suppressing emotional responses to both low and high-intensity emotional pictures. Our findings suggest that older adults are better at controlling their emotions, and that automatic ER may be contributing to the positive affective bias in healthy aging. In the current investigation we are also examining the effect of aging on the neural correlates of ER.

**G252**

**REGULATORY FOCUS AFFECTS DONATIONS IN TIMES OF RESOURCE CRISIS** Destiny Peery<sup>1</sup>, Daniel C. Molden<sup>1</sup>, Galen V. Bodenhausen<sup>1</sup>, David B. Miele<sup>2</sup>; <sup>1</sup>Northwestern University, <sup>2</sup>Columbia University – Previous research has suggested that Prevention-focused individuals are more attuned to reciprocity norms and feel a stronger sense of obligation to their groups, even groups in social dilemma games. Due to this sense of obligation and their adherence to reciprocity norms, Prevention-focused individuals were expected to contribute more to the group's donation in

a Public Goods Game as a means to foster reciprocity and fulfill their obligation to the group. Promotion-focused individuals were expected to donate less as means to enhance their personal gains. In Study 1, chronic Prevention and Promotion-focused participants played a Public Goods game where feedback about a donation surplus was manipulated to create a pattern of a rising surplus, a plateau, and finally a decline. As predicted, during the stable, plateau period, Prevention-focused participants donated more than Promotion-focused participants. During the surplus decline, the pattern of donations reversed such that Promotion-focused individuals donated more than Prevention-focused participants. This may have resulted from a motivation on the part of Promotion-focused participants to continue the game, while the Prevention-focused participants, feeling a sense of betrayal due to the lack of donations from the group, may have given up. Study 2 manipulated regulatory focus by priming Prevention and Promotion focus. Participants played a similar Public Goods game where the pattern of feedback created a period of surplus stability and then a decline. A replication of the effects from Study 1 was predicted and supported. These results may have implications for economic decisions, particularly in times of resource or economic crisis.

**G253**

**THE MOTIVATED REPLENISHMENT OF SELF-CONTROL RESOURCES THROUGH DIETARY MEANS** E.J. Masicampo<sup>1</sup>, Roy F. Baumeister<sup>1</sup>; <sup>1</sup>Florida State University – This work examined whether people seek out foods that are high in sucrose in order to replenish depleted self-control resources. Self-control uses (and thus relies on the limited availability of) glucose in the blood stream. When a person exerts self-control, glucose is used up and so subsequent self-control efforts are hindered. Recent work, however, has shown that ingestion of sucrose – which replenishes blood glucose – can buffer against self-control fatigue (Gailliot et al., 2007; Masicampo & Baumeister, 2008). While that work involved instructing participants to ingest sucrose, the present work examined whether people actively seek it out. Participants were assigned to perform either a self-control task or a similar task that involved little control. A second manipulation involved telling participants that they would engage in a task later on that would either require a lot of mental effort or that would be relaxing and effortless. All participants then engaged in a taste preferences task. Data from that task suggest that participants who exerted self-control initially (and thus whose glucose levels were presumably depleted) reported a greater craving for high-sucrose food, consumed more of a high-sucrose food, and expressed greater interest in purchasing a high-sucrose food relative to control participants. Moreover, the effect was specific to participants who expected to exert mental effort on a following task and the effect did not generalize to other, low-sucrose foods. These data point to the importance of considering dietary behavior as an integral component of self-control processes.

**G254**

**DOING IT FOR ME: SELF-CONTROL DEPLETES LESS STRENGTH WHEN INTRINSICALLY MOTIVATED** Mark Muraven<sup>1</sup>; <sup>1</sup>University at Albany – Why someone exerts self-control may influence how depleting a task is. Research on Self-Determination Theory has found that actions that feel compelled or forced by the situation tend to undermine feelings of vitality, and require more effort and continued outside motivation as compared to actions that feel more autonomously directed. This may have implications for how much self-control strength an autonomous motivated (vs. compelled) self-control attempt requires. This was tested in several experiments, where individuals who were ordered (versus politely asked) to exert self-control; who were paid to reach a self-control goal (versus paid for doing their best); or who were more intrinsically motivated to exert self-control. Individuals who felt more compelled to exert self-control consistently performed more poorly on a subsequent test of self-control, which suggests that extrinsically motivated self-control depletes more strength. Alternative explanations for the results, such as compelled participants being more anxious, stressed, unhappy, or being less motivated to do well were not supported. Mediation analysis

ses suggested that the more autonomous one feels while exerting self-control, the more vitality that is experienced. This feeling of vitality is related to self-control outcomes. Vitality may help in the replenishment of lost strength. The results suggest that not all self-control is the same; the persons' feelings about the self-control task may moderate the amount of self-control required.

**G255**

**MICHELANGELO PHENOMENON: PARTNER AFFIRMATION, GOAL STRIVING, AND RELATIONAL WELL-BEING** Madoka Kumashiro<sup>1</sup>, Caryl E. Rusbult<sup>2</sup>, Eli J. Finkel<sup>3</sup>, Michael K. Coolsen<sup>4</sup>; <sup>1</sup>Goldsmiths, University of London, <sup>2</sup>Vrije Universiteit Amsterdam, <sup>3</sup>Northwestern University, <sup>4</sup>Shippensburg University – Close relationship partners often play a crucial role in helping individuals achieve their most important goals, dreams, and aspirations. Work on the Michelangelo phenomenon (Drigotas et al., 1999) has shown that partner affirmation, or close partners behaving toward the self in a manner congruent with the self's ideal, facilitates movement toward the self's ideal and promotes greater relational well-being. Yet, research is still scarce on the mechanisms through which partner affirmation promotes movement toward the ideal self. The current presentation proposes that partner affirmation bolsters individual's willingness to work hard toward their most important but challenging goals. We first present findings from a 10-day diary study of 92 dating couples to show that on a daily basis, partner affirmation was associated with willingness to put in effort toward achieving ideal-relevant goals and greater relationship satisfaction, which in turn promoted importance placed on goal pursuits the next day. Next, we present findings from a longitudinal study of 187 romantic couples, showing that partner report of their own affirming behaviors during an ideal-relevant goal conversation promoted post-conversation determination to achieve the goal, which in turn was associated with actual goal achievement 18 months later. For both sets of findings, we also demonstrate that our findings are not due to merely feeling confident about goal achievement, suggesting that it is indeed individual's willingness to put in the necessary time and effort that yields likelihood of goal attainment. Finally, we discuss broader implications of the Michelangelo phenomenon for relationship well-being and personal well-being.

**G256**

**OVERCOMING THE EFFECT OF MOOD ON RISKY AND IMPULSIVE BEHAVIOUR** Thomas Webb<sup>1</sup>, Paschal Sheeran<sup>1</sup>, Peter Totterdell<sup>1</sup>, Warren Mansell<sup>2</sup>, Shyam Baker<sup>2</sup>; <sup>1</sup>University of Sheffield, UK, <sup>2</sup>University of Manchester, UK – Mood states (both positive and negative) seem to be associated with increases in risky and impulsive behaviours. Safe interaction with the environment therefore requires that the person find a way to regulate their mood or the effects of their mood on their decision-making and action. We conducted two experiments to investigate whether forming an if-then plan – or implementation intention (Gollwitzer, 1999) – could break the link between mood and risky or impulsive behaviour. In Experiment 1, participants planned how to deal with negative moods. Next, as part of an ostensibly unrelated experiment, participants were induced into a negative mood (or not) before rating their willingness to perform a series of risky behaviours. There was a significant relationship between induced mood and risk among participants who did not form a plan. However, implementation intention formation overcame the impact of negative mood on risk willingness. In Experiment 2, participants were induced into a state of high arousal (vs. low arousal) by listening to music and then undertook a gambling task. One-half of the sample formed implementation intentions that focused attention on the odds of winning. High levels of arousal led to more impulsive behaviour among control participants. However, forming an implementation intention promoted good risk awareness and, consequently, less impulsive behaviour. Taken together, the present findings suggest that people can strategically avoid the detrimental effect of mood states on risk by forming implementation intentions directed at controlling either the mood itself or the risky behaviour.

**G257**

**MOTIVATING "IRRATIONAL" TRUST: A REGULATORY FOCUS PERSPECTIVE** Daniel Molden<sup>1</sup>, Gale Lucas<sup>1</sup>; <sup>1</sup>Northwestern University – Trust fundamentally involves risking certain vulnerability for uncertain reward. Understanding what motivates acceptance of such risks could therefore provide insight into when and why people "irrationally" display high levels of trust at the outset of a relationship. Previous research on regulatory focus (Higgins, 1997) has shown that concerns with advancement (promotion) produce goal-pursuit strategies that involve seeking gains even while risking losses. In contrast, concerns with security (prevention) produce goal-pursuit strategies that involve protecting against losses even while missing gains. Promotion concerns may therefore encourage people to risk vulnerability and trust others to a greater degree than prevention concerns, perhaps even after trust has been violated, if opportunities for gain remain. Two studies featuring multi-round investment games confirmed these hypotheses. Following a manipulation of their promotion or prevention concerns, participants received \$10 and chose how much to invest; investments were tripled and supposedly transferred to an "anonymous partner" who then decided how much (if any) to return. Returns were in fact controlled by the experimenter and, after several rounds of favorable returns, everyone experienced a violation of trust in the form of an unfavorable return, followed by a resumption of favorable returns. Results showed that promotion-focused individuals trusted their partners with higher investments at the outset, and displayed less withdrawal of trust immediately following betrayal than prevention-focused individuals. However, promotion- and prevention-focused individuals did not differ in trust once favorable returns resumed. The potential role of both trust and reciprocity concerns in these latter results will be discussed.

**G258**

**UNCONSCIOUS GOAL PURSUIT NEEDS CONSCIOUS HELP AFTER ALL!** Roy Baumeister<sup>1</sup>, E.J. Masicampo<sup>1</sup>; <sup>1</sup>Florida State University – Different theories about the role of conscious thought offer two wildly different explanations for the classic Zeigarnik effect (i.e., reminders of unfulfilled tasks intrude spontaneously into consciousness). One is that the unconscious is taking care of pursuing the goal, regardless of conscious thought. The other is that the unconscious needs the conscious mind to do something that the unconscious cannot do – such as making a plan. Two studies favored the latter hypothesis by showing that the Zeigarnik effect goes away if a plan (implementation intention) is formed. In Study 1, students wrote about either their most important upcoming final examination, or wrote about that exam plus made a specific plan for where and when to study for it, or (control) wrote about an upcoming party. After a distractor task, all participants completed word stems. The Zeigarnik effect was measured by number of studying-related words. People who wrote only about the exam generated many exam-related words (significantly more than those who wrote about the party), but that effect disappeared among those who made a plan! Study 2 replicated this effect with the goal of getting exercise. Furthermore, it was moderated by importance. The Zeigarnik effect was found only among people who considered the goal important – and, once again, making the specific plan to pursue the goal eliminated that effect. Thus, the Zeigarnik effect is a way that the unconscious mind induces the conscious part to formulate a specific plan.

**G259**

**THE EFFECTS OF EXPRESSIVE WRITING ON SELF-DISTANCING** Jiyoung Park<sup>1</sup>, Ethan Kross<sup>1</sup>, Ozlem Ayduk<sup>2</sup>; <sup>1</sup>University of Michigan, Ann Arbor, <sup>2</sup>University of California, Berkeley – Previous studies indicate that writing about one's deepest thoughts and feelings surrounding a negative emotional event leads to dramatic physical and mental health improvements. Although prior research suggests that writing leads to these adaptive outcomes by changing the way people cognitively represent their experiences, the psychological mechanisms mediating these effects are not clear. As a first step towards addressing this issue, the present research investigated the effect of writing on psychological distance. Fifty-four

participants recalled and analyzed a recent depression-related experience and were then randomly assigned to an emotional-writing, distraction-writing, or control condition. Participants in the emotional-writing group were told to write about the thoughts and feelings that streamed through their mind as they analyzed their feelings during the study whereas participants in the distraction-writing condition were instructed to describe what they have done since waking up that morning. Participants in the control group were not given any writing instructions. After the writing procedure, participants were asked to indicate the extent to which they adopted a self-distanced (third person) perspective or a self-immersed (first-person) perspective while analyzing their feelings during the study. Results showed that participants in the emotional-writing condition indicated they were significantly more self-distanced when thinking about their past experience than participants in the control condition who were more self-distanced than those in the distraction-writing condition. These findings provide preliminary evidence suggesting that writing about one's feelings surrounding negative emotional events may function to adaptively distance people from their emotions.

### G260

#### CUE-CONTINGENT AUTOMATICITY OF HEALTH RELATED BEHAVIOR.

Sheina Orbell<sup>1</sup>; <sup>1</sup>University of Essex, UK – Three studies addressed the role of environmental cues in controlling unwanted behavioral habits and in promoting self-regulation of healthful responses. In all 3 studies, cue-contingent automaticity was assessed by the Self-report habit index (SRHI: Verplanken & Orbell, 2003). Studies 1 and 2 concerned smoking habits. If people's behavior possesses the qualities of strong cue contingent automaticity, it was anticipated that this would have important consequences for their attention to, and response to, habit cues in the environment. In study 1, smokers were significantly slower to color-name smoking cues in a stroop task. Extent of attentional bias to smoking cues was significantly and positively correlated with SRHI scores. Study 2 utilised a change in public policy to test the proposition that an environmental cue might continue to elicit an unwanted behavioral response. Smokers completed the SRHI with respect to smoking a cigarette when drinking alcohol in a pub, 2 months before the introduction of a law making smoking in pubs illegal. Two months later, cue contingent automaticity predicted the likelihood of a smoker making a behavioral slip, by 'lighting or nearly lighting a cigarette before remembering to go outside'. Study 3 concerned the use of environmental cues in promoting self-regulation of a healthful behavior. The formation of an implementation intention is a self-regulatory strategy that enlists the help of external cues in prompting goal directed behavior. Participants who formed an implementation intention to floss their teeth in a specified location every day were quick to acquire a flossing habit.

## Social Judgment/Decision-Making

### G261

#### REGULATING THE DESIRABILITY BIAS: A DUAL PROCESS ACCOUNT

Shane W. Bench<sup>1</sup>, Heather C. Lench<sup>1</sup>; <sup>1</sup>Texas A&M University – The purpose of this investigation was to examine the conditions under which people will use analytic resources to correct biased judgments. From a dual process perspective, biases that arise from the fast, intuitive and affectively influenced experiential system may be corrected by the slower deliberate analytic system. The desirability bias, which is the tendency to predict outcomes consistent with desires, appears to partially result from affective experiential reactions, and people may thus be able to regulate the bias. In three studies, participants made judgments about outcomes in a game of chance with either positive or negative consequences. The desirability bias was reduced when the consequences were strongly motivating, but not when the consequences were less motivating (Study 1). Participants were only able to reduce the desirability bias when they had sufficient time to consider their judgment, suggesting that bias reduction requires analytic processing (Study 2). Study 3 examined the possibility that this analytic processing consisted of emotion regulation strategies.

Emotion regulation strategies, particularly suppression, appeared to be one analytic strategy that people could employ to reduce the desirability bias (Study 3). These results show that people can and will use analytic resources to correct judgments that arise from affective impulses. Further, the findings suggest the importance of the experiential system in promoting regulation, and that emotion regulation strategies can be employed to effectively reduce biased judgments.

### G262

#### THE BENEFITS OF TUNING OUT: IPODS AND THEIR EFFECT ON DECISION-MAKING

Katherine McMahon<sup>1</sup>, Betsy Sparrow<sup>1</sup>; <sup>1</sup>Columbia University –

Ever since the iPod has become a staple in everyday life, we have been increasingly "tuned out" of our daily activities like studying or shopping. iPods are often criticized for being a distraction, but listening to your favorite mp3's might actually be helpful for certain tasks. Previous research has suggested that within decision-making tasks that require sorting through a lot of information, people who are distracted outperform those who deliberate attentively, which is called the "deliberation without attention effect" (Dijksterhuis, Bos, Nordgren, & van Baaren, 2006). The present study investigates whether or not iPod-listening provides enough distraction to improve decision-making performance. Participants (N=128) are told they must choose the best out of four different cars. They are shown descriptions of four cars each with twelve attributes that are either positive or negative (i.e. "Car 1 has lots of leg-room"). One car is the "right" choice with the highest number of positive attributes. After reading the information for the cars, participants are instructed to spend the next three minutes thinking of the choice consciously, listening to their iPod, or solving puzzles before indicating which car they think is best. The participants who were distracted by listening to their iPod or solving puzzles were better at choosing the best car than the participants in the conscious thought condition. Listening to an iPod (and portable music in general) provides enough distraction to create the deliberation without attention effect and leads to making better decisions. Future studies will explore iPod-listening effects on creative problem-solving.

### G263

#### NORM PERCEPTION BIASES IN CHILDREN AND ADULTS: A LOOK AT DIFFERENCES ACROSS POSITIVE AND NEGATIVE BEHAVIORS

Elaine Bossard<sup>1</sup>, Jason Rose<sup>2</sup>, Kimberly Alex<sup>1</sup>, Irwin Levin<sup>1</sup>, Joshua Weller<sup>3</sup>;

<sup>1</sup>University of Iowa, <sup>2</sup>University of Toledo, <sup>3</sup>Decision Research –

In the present study, self-other projection and above-average effects for behavioral reports were examined in order to uncover biases in how children and parents view the child in comparison to peers. Ten-year-old children and their parents were asked to report on the frequency with which they (their child) engaged in a range of both positive and negative behaviors over the past two months. Participants (both parents and children) were also asked to answer the same questions regarding the behavior of the typical child of the same age and gender. For both positive (e.g., doing a favor for a friend) and negative behaviors (e.g., failing to wear a seat-belt), positive correlations were found between children's reports of their own and their peer's activities – illustrating considerable projection in children's estimates for their peers. However, when examining mean-level differences, children reported a higher (lower) average frequency for positive (negative) behaviors for themselves than their peers – illustrating the presence of better-than-average effects. Parents showed similar results for both types of analyses when judging their children and their children's peers. To the best of our knowledge, this demonstrates the new idea that children as young as ten years old show similar norm perception biases as adults. We will discuss implications and future research aimed at linking self- and peer- perceptions to risky behavior in children.

**G264**

**GROUP PERCEPTION ACTIVATES EGALITARIAN CHOICE** Anna López<sup>1</sup>, Bryan Balvameda<sup>2</sup>, Yaniris Gómez<sup>1</sup>, Valerie Purdie-Vaughns<sup>1</sup>, Gregory Walton<sup>3</sup>, <sup>1</sup>Columbia University, <sup>2</sup>Yale University, <sup>3</sup>Stanford University – This poster reports one experimental study demonstrating that a pervasive feature of selection decisions—perceiving an organization as a group—enables egalitarian values to express themselves. We report that discrimination can be strongly reduced when the identical organization is framed in terms of a group rather than as a series of unrelated individuals. We examine decision-making relevant to ethnic and gender diversity, a context in which people both harbor prejudice and bias and, in many cases, personally endorse egalitarian values. Given these opposing pressures, small situational factors can have a large effect on people's decision-making, by determining which kind of attitude comes online at any given moment. In our study, we used a 2 (perception of Supreme Court justices: group vs. series of individuals) x 2 (counterbalanced order of candidates: Leah Ward Sears on left or right) design. We found that, regardless of candidate order, framing the Supreme Court justices as a group led participants to significantly more often select a minority candidate (Leah Ward Sears) over a majority candidate (Diane Wood) as the next candidate justice. Neither political knowledge nor Social Dominance Orientation moderated the results, suggesting that the effect applies to a broad range of individuals. These findings inform our knowledge on situated cognition and decision-making.

**G265**

**SIMILAR WHEN WE COOPERATE? INTERDEPENDENCE EFFECTS ON SOCIAL PROJECTION** Claudia Toma<sup>1</sup>, Vincent Yzerbyt<sup>1</sup>, Olivier Corneille<sup>1</sup>, Nicolas Kervyn<sup>1</sup>, <sup>1</sup>Catholic University of Louvain at Louvain-la-Neuve – People have a strong tendency to use information about themselves when making predictions about personality of others (e.g., social projection). Social projection has received considerable attention over the last decade. Yet, its boundary conditions have been relatively understudied. The current research moves beyond the traditional focus on target characteristics to develop our understanding about the role of self-other interdependence in social projection. Two experiments tested the hypothesis that more projection should occur under conditions of interpersonal cooperation than under conditions of interpersonal competition. After participants had rated themselves on a list of personality traits, they were led to expect a situation of cooperation or competition with an unknown target and rated this target on the same traits. In both experiments, projection of self-attributed traits was stronger under cooperation than competition. This effect was independent of trait valence, whether defined a priori (Experiment 1) or as an idiosyncratic measure (Experiment 2). While traits used in Experiment 1 were unrelated to cooperation, competition, in Experiment 2 participants rated themselves and the target on traits related to competence and warmth. Experiment 2 revealed an interaction between interdependence and judgment dimension on social projection. Participants projected more in cooperation than in competition, but more on the warmth than on the competence dimension. These findings suggest that the anticipated interdependence context influences the way we perceive similarity with unknown others. We discuss possible cognitive and motivational mechanisms underlying this effect.

**G266**

**THE MORE, THE MERRIER: THE PERVERSE EFFECT OF ADDITIONAL VICTIMS ON MORAL JUDGMENT** Uriel Haran<sup>1</sup>, Daylian M. Cain<sup>2</sup>, <sup>1</sup>Carnegie Mellon University, <sup>2</sup>Yale University – Murdering ten is worse than murdering two; all else being equal, the worse the outcome of an act, the harsher the judgment should be against the agent. However, people's judgments sometimes display the opposite pattern. In two lab studies, we find that as the number of victims of an unethical act increases, perception of the harm done to each victim decreases, and, consequently, the act itself may seem less harmful overall. Past research has shown that people show greater willingness to help one victim than a multitude of

victims. We show that this bias affects not only helping behavior, but also moral judgment. Moreover, our effect is not limited to different reactions to single targets versus group targets, but also exists when comparing small groups of victims to larger ones. In our studies, participants read a story about an unethical act harming one, few, or many victims. We measured participants' perceptions of the individual harm done to each of the victims and the overall harmfulness of the act. Results revealed that the perceived harmfulness of the act, to each victim and overall, decreased when there were more victims. This tendency persisted even when we provided explicit information about the precise magnitude of harm done to each victim, which was identical. Together, our studies demonstrate that victims of unethical acts pay a premium in how people perceive their suffering when other victims of these acts exist. This bias may lead to systematic judgment errors by legal juries and in public opinion.

**G267**

**WHAT LIES BEHIND IDEOLOGICAL DIFFERENCES** Zeljka Buturovic<sup>1</sup>, Grace Ren<sup>1</sup>, Katherine Schwalbe<sup>1</sup>, <sup>1</sup>Zogby International – A view that personality differences and motivated cognitions are the main driving force behind ideological differences appears to be approaching consensus. However, the reported size effects rarely go beyond 0.30 (Jost et al, 2003) and much smaller effects are not uncommon (e.g. Carney, Jost, Gosling, & Potter, 2008), suggesting that a substantial variance in ideology is yet to be explained. We believe that those who adhere to different ideologies have different intuitions about the nature of the surrounding social world – such as the workings of economics and limitations of human nature. In line with this hypothesis we conducted two studies: in our first study, we administered our 8-item Economic Intuition Scale as well as selected 6 items from the Death Anxiety Scale and 10-item subset of the Need for Closure Scale to 4835 adults nationwide. In our second study we administered a 3-item Human Nature Intuitions Scale to another 5000 adults. The results of our first study showed the correlation between economic intuitions (as measured by our scale) and ideology to be 0.57 – an effect which is twice as large as that between ideology and need for closure obtained in the same study. Results of our second study confirm that differing intuitions about human nature play a role in ideological positioning as well, with our 3-item scale producing a correlation of 0.28. Our data suggest new possibilities for what lies behind differing ideological views.

**G268**

**I AM WHAT I DO, NOT WHAT I HAVE: DEFINING ONESELF BY EXPERIENTIAL RATHER THAN MATERIAL PURCHASES** Travis J. Carter<sup>1</sup>, Thomas Gilovich<sup>2</sup>, <sup>1</sup>The University of Chicago Booth School of Business, <sup>2</sup>Cornell University – Previous research has shown that material possessions, things people buy to have, like clothes and electronics, tend to be ultimately less satisfying than experiences, things people buy to do, like vacations and meals at restaurants (Van Boven & Gilovich, 2003). This is partly due a tendency to evaluate possessions more relatively, in comparison to other options, and experiences on their own merits, which has consequences for the decision process and post-choice evaluation (Carter & Gilovich, in press). The present research examines an additional factor, namely the greater centrality of experiences to the self-concept. Unlike material possessions, which physically persist over time, it is primarily the intangible memories of our experiential purchases that persist over time. Because it is our collection of memories that define who we are, compared with possessions, experiential purchases should come to be seen as a greater part of the self. Over time, while memories of experiential purchases tend to improve (Mitchell et al., 1997), most material purchases will tend to decay. Across several studies, we show that compared with material purchases, experiential purchases are indeed more firmly incorporated into the self-concept, which helps to explain differences in satisfaction. Experiential purchases were plotted closer to the self in a Venn diagram, and were mentioned more often when participants told their life story. This tendency to hold on more tightly to

important memories of experiences mediated the greater satisfaction with experiential than material purchases. These studies confirm that, from many angles, experiences will ultimately prove a better investment.

#### G269

**EVIDENCE OF A RACIAL SALIENCE BIAS IN VIDEOTAPED POLICE INTERROGATIONS** G. Daniel Lassiter<sup>1</sup>, Jennifer J. Ratcliff<sup>2</sup>, Victoria M. Jager<sup>2</sup>, <sup>1</sup>Ohio University, <sup>2</sup>The College at Brockport, SUNY – Prior research demonstrates that the camera perspective taken during recording can bias evaluations of videotaped criminal confessions. Specifically, confessions recorded with the camera focused on the suspect – compared with videotapes from other points of view (e.g., focused on the suspect and interrogator equally) – lead participants to judge confessions as more voluntary and suspects as more likely guilty. Although a camera perspective that directs visual attention onto the suspect and interrogator equally appears to be unbiased, investigations to date have used videotapes that depict only Caucasian suspects/interrogators. We examined the possibility that even equal-focus videotapes may become problematic when the suspect is a minority (e.g., African-American) and the interrogator is Caucasian. That is, to the extent that Caucasian observers are inclined to direct more of their attention onto minorities, an effect documented previously, we expected biased judgments of suspects to also occur in equal-focus videotapes. Three experiments examined this proposed racial salience bias. The results were supportive. Studies 1 and 2 established the plausibility of the racial salience bias and ruled out the possibility that it is simply a consequence of racial prejudice. Study 3 further demonstrated that the bias is indeed attentional in nature and thus can be prevented by having minority suspects interrogated by minority detectives. Without this or a similarly effective precaution, having an equal-focus camera perspective as the standard for videotaped interrogations may not provide equal justice for all, especially minorities who already encounter a system of justice that, intentionally or not, frequently treats them inequitably.

#### G270

**TEMPORAL DISCOUNTING RATE PREDICTS POLITICAL AND RELIGIOUS ORIENTATION** Amitai Shenhav<sup>1</sup>, David G. Rand<sup>1</sup>, Anna Dreber Almenberg<sup>1,2</sup>, Lisa Stewart<sup>1</sup>, Joshua D. Greene<sup>1</sup>, <sup>1</sup>Harvard University, <sup>2</sup>Stockholm School of Economics – Recent work relates political and cultural values to more basic cognitive and affective processes. Impulsivity and the ability/willingness to delay future rewards are among the more reliable and predictive personality dimensions. We present survey research showing correlations between temporal discounting and political and religious values. The extent to which individuals value immediate rewards relative to larger delayed rewards can be estimated with a single number, the temporal discounting rate. Responses to hypothetical monetary trade-offs, political/religious orientation, and demographic data were collected from an internet sample of 632 individuals. Temporal discounting rates were estimated based on responses to reward/delay trade-offs and regressed against a belief-in-God rating (anchored at "confident atheist" and "confident believer"), political party preference (only Democrats and Republicans included), as well as a number of demographic variables predicted to covary with each. We found that individuals who placed relatively higher value on immediate rewards (i.e. had steeper discounting curves) were more likely to be more confident believers in God and more likely to be Republicans. These effects remained significant after controlling for potentially mediating demographic factors such as age, gender, income and education level. These correlations have also been replicated in a lab sample of 152 individuals. These findings suggest that political and religious values may be influenced by the more general personality dimension reflected in one's ability/willingness to delay future rewards. Results of subsequent studies aimed at elucidating the mechanisms underlying these correlations will be discussed.

#### G271

**MY JUDGMENTS ARE BETTER THAN YOURS: ADAPTIVE WEIGHTING OF SOCIALLY VS NON-SOCIALLY PROVIDED INFORMATION** Elizabeth C. Collins<sup>1</sup>, Eliot R. Smith<sup>2</sup>, Elise J. Percy<sup>2</sup>, John K. Kruschke<sup>2</sup>, <sup>1</sup>CIS/ISCTE, <sup>2</sup>Indiana University, Bloomington – Kruschke's (2001) attentional learning model explains how people allocate attention to cues in making categorization judgments. We adapted it to a social context, where participants received information from social sources (regarding investments in Study 1) or both social and non-social sources (medical diagnosis in Study 2, political party affiliation in Study 3). Study 1 replicated Kruschke's findings: Participants exposed to a reliable advisor, A, whose information was always paired with that of a previously learned reliable advisor, B, did not attend to Advisor A, showing the blocking effect. Testing the highlighting effect, participants were first exposed to a pair of reliable advisors, E and F. Then Advisor E was paired with a new advisor, G, whose recommendations disagreed with E and were always correct (so E's recommendations were wrong). When Advisors F and G were paired giving contradictory recommendations, participants preferred to follow Advisor G, showing the highlighting effect. Studies 2 & 3 examined how participants allocate attention to social versus non-social cues. Other people's responses (social information) were pitted against cues participants learned the meaning or accuracy of themselves (non-social information). These studies found evidence of the highlighting effect, but not the blocking effect. Furthermore, both studies found evidence that non-social information (information you learn the meaning of yourself, rather being told by another person) was highlighted over social information (information you learn from another person) more than the reverse. Possible reasons for these effects, and future directions are explored.

#### G272

**PERSPECTIVE TAKING AND STEREOTYPING: THE ROLE OF STEREOTYPE CONTENT** Jeanine Skorinko<sup>1</sup>, Stacey Sinclair<sup>2</sup>, <sup>1</sup>Worcester Polytechnic Institute, <sup>2</sup>Princeton University – Research suggests that perspective taking with an outgroup member leads to less stereotyping (Galinsky & Moskowitz, 2000; Vescio, Sechrist, & Paolucci, 2003). However, findings also show that perspective takers behave more stereotypically (Galinsky, Ku, & Wang, 2008). Based on these contradictory findings, the current research examined how stereotype content moderated these effects. Experiment 1 investigated how perspective taking with a stereotype-confirming target influenced stereotyping. Prior to viewing a photo of an elderly man who was either neutrally stereotyped (e.g., a headshot) or confirmed negative stereotypes (e.g., sick in bed), half the participants were instructed to perspective take with the target. Perspective takers who viewed the neutrally stereotyped target stereotyped less than non-perspective takers, as in past research. However, perspective takers who viewed the stereotype-confirming target stereotyped more and behaved more stereotypically than non-perspective takers. Experiment 2 examined whether perspective takers anchored onto available stereotypes and assessed the degree of self-other overlap felt. Prior to viewing a neutrally stereotyped elderly man, half the participants were primed with stereotypes of the elderly, and half were primed with neutral words. Perspective takers primed with stereotypes anchored onto this information and stereotyped more, behaved more stereotypically, and reported less self-other overlap. Experiment 3 elucidated whether this effect was due to the stereotypes or the negative valence of the stereotypes. Perspective takers stereotyped more only when primed with stereotypes. In conclusion, perspective takers who see a stereotype-confirming target anchor onto the stereotypes, stereotype more, and see less self-other overlap.

#### G273

**PULLING THE MORAL TRIGGER: BLAME IS MORE EXTREME THAN PRAISE, BUT ONLY BLAME CONSIDERS THE AGENT'S MIND** Steve Guglielmo<sup>1</sup>, Bertram F. Malle<sup>1</sup>, <sup>1</sup>Brown University – Research has documented many negativity effects in social cognition, in which negative social events elicit more cognitive processing than positive social events.

Interestingly, researchers have rarely explored asymmetries in moral processing of negative and positive behaviors. This study examined such a possible asymmetry between judgments of blame and praise. Participants rated a series of negative and positive behaviors for their social desirability (overall negativity/positivity) and assigned blame/praise. In a between-subjects manipulation of judgment object, participants rated a target person who either thought about performing each behavior, intended to perform each behavior, or actually performed each behavior. On social desirability ratings, the negative behaviors were seen as slightly more negative than the positive behaviors were seen as positive. However, even when controlling for these ratings, people blamed the negative behaviors substantially more than they praised the positive behaviors. Thus, people assign blame not merely on the basis of overall social desirability. In addition, blame was more differentiated than praise: Blame was highest when the target actually performed the behavior, moderate when the target intended to perform the behavior, and lowest when the target thought about performing the behavior, whereas praise did not differ by condition. This careful consideration of the agent's mental states may be the blame-relevant information that goes beyond mere social desirability. Together, the results indicate that people are more inclined to pull the blame trigger than the praise trigger, but that they nonetheless make fine distinctions among mental and behavioral aspects of negative social events when assessing blame.

#### G274

##### **SURVEY OF NFL REFEREES ABOUT THE HOME FIELD ADVANTAGE - IT IS NOT US!**

Rachel M. Hochuli<sup>1</sup>, Nadav Goldschmied<sup>1</sup>; <sup>1</sup>University of San Diego – Home winning percentages in professional and collegiate sport leagues have exceeded the 50% that would be predicted by chance when playing balanced home and away schedules (Courneya & Carron, 1992), a phenomenon known as the home field advantage (HFA). Research documenting this trend was mostly based on archival data or laboratory experiments specifically aimed at delineating one of a few possible factors behind the HFA, missing almost altogether any validation with research involving participants who are presumed to be influenced by such factors. NFL (The National Football League) referees are considered the most scrutinized officiating group in all sports whose careers last on average much longer than careers of the players on the field. An on-line survey returned by 44 NFL referees (more than a third of all league referees) demonstrated that they (a) acknowledge the existence of the HFA in their league and (b) are good estimators of its magnitude. The responders assessed that the support of local crowds was the main force behind HFA (followed by travel consideration, weather and field familiarity). Critically, NFL referees thought that their decision-making on the field was not influenced at all by the pressure placed on them by fans. In addition, NFL referees assumed that the percentage of games decided in error was significantly higher for the NBA (National Basketball Association) and the MLB (Major League Baseball). Thus, despite growing research of bias in officiating due to crowd pressure, NFL referees perceive themselves to be immune to its impact.

#### G275

##### **SAFETY FIRST! PERCEPTIONS OF PHYSICAL THREAT INFLUENCE FIRST IMPRESSIONS**

Kristin Gonzalez<sup>1</sup>, Darcy Reich<sup>1</sup>, Brandon Randolph-Seng<sup>1</sup>; <sup>1</sup>Texas Tech University – Willis and Todorov (2006) demonstrated a positivity bias when people form specific trait inferences from faces. Specifically, first impressions made after 100 ms exposures to novel faces were more positive than impressions based on longer exposures. Gonzalez, Randolph-Seng, and Reich (2008) further explored the positivity bias for inferences of trustworthiness, and found that participants higher in motivation to avoid negative biases were more prone to the positivity bias, and perceived target faces as more trustworthy based on a brief 100 ms exposure, than did participants with lower motivation. Given that immediate judgments of trustworthiness are relevant for survival (Cosmides & Tooby, 1992), we explored the possibility that these motivational differences would be attenuated if survival-related motives were made salient. In the present study, we manipulated perceived physical

threat and measured individual differences in chronic motivation to avoid negative biases. Participants judged the trustworthiness of pre-tested faces presented for 100 ms, and half were asked to imagine making these judgments in an unsafe environment. Results indicated that targets were perceived as less trustworthy in the threat condition than in the control condition. In addition, the predicted interaction emerged. Control participants high in motivation to avoid negative biases perceived individuals as more trustworthy than those low in motivation, replicating our previous study. However, this difference was attenuated in the threat condition. Results suggest that quick trustworthiness judgments are made vigilantly and conservatively when physical safety is threatened, and that social motivations to avoid negative biases can be overridden by salient safety concerns.

#### G276

##### **HINDSIGHT BIAS AND AFFECT REGULATION: A LONGITUDINAL STUDY OF THE 2008 PRESIDENTIAL ELECTIONS**

Mike Morrison<sup>1</sup>, Neal Roesse<sup>1</sup>; <sup>1</sup>University of Illinois at Urbana-Champaign – People often see past events as relatively predictable, as compared to the uncertainty they felt prior to the same events (hindsight bias). Recent research suggests that hindsight bias can be motivated, in that greater post hoc certainty can make people feel better after loss, yet affect has rarely been measured. We conducted a 10 month longitudinal study that examined the relation of affect to hindsight bias in perceptions of the 2008 Presidential elections and Democratic and Republican nomination races. This relation depended on the importance of the outcome to the participants, or whether they experienced a win vs. loss for their preferred party/candidate. Although a positive relation was found overall between hindsight bias and affect for all 3 races examined, this relation was tightest in response to a loss in the most valued Presidential election race. Our findings provide new support for the motivated basis of hindsight bias and illustrate how its relationship to affect can fluctuate over time.

#### G277

##### **THE EFFECT OF VISUAL IMAGERY PERSPECTIVE ON SOURCE OF REGRET**

Greta Valenti<sup>1</sup>, Lisa K. Libby<sup>1</sup>; <sup>1</sup>Ohio State University – Upon making a poor choice, what determines whether people's regret will stem from the negative outcomes they actually received or the positive outcomes they could have received had they chosen differently? The present research investigates how the visual perspective (own first-person vs. observer's third-person) that people use to picture making a regrettable choice influences the perceived source of their regret. Participants were instructed to either use the first-person or third-person perspective to picture a scenario in which they chose one alternative over another and learned the outcomes associated with each alternative. They then reported the source of their regret. Results show that participants who pictured making their choice from a third-person perspective were more likely to claim that their regret stemmed from the positive outcomes associated with the non-chosen alternative, compared with participants who used the first-person perspective. By showing that third-person imagery makes people more likely to frame the incident as regrettable due to what might have been had they chosen differently, the present study adds to past research that suggests that third-person imagery encourages people to think about how a pictured event relates to other events and outcomes (Libby & Eibach, 2008). In addition, given that regret originating from obtained negative outcomes versus foregone positive outcomes is characterized by distinct subjective experiences (Gilovich, Medvec, & Kahneman, 1998), our results highlight the important role of visual perspective when picturing regrettable events.

#### G278

##### **VISUAL PERSPECTIVE IN IMAGES AFFECTS ABSTRACT AND CONCRETE THINKING**

Eric Shaeffer<sup>1</sup>, Lisa Libby<sup>1</sup>; <sup>1</sup>The Ohio State University – This research investigates how visual perspective (own first-person vs. observer's third-person) in action imagery is related to abstract and concrete thinking. Past work has shown that a first-person perspective in action imagery is linked with construing actions concretely and a third-

person perspective is linked with construing actions abstractly. One explanation for this finding is that visual point of view affects the mindset one adopts. By this account, a shift in one's tendency to think concretely or abstractly causes differences in action identification. Two experiments tested whether manipulating point of view in visual images causes people to adopt either a concrete or an abstract mindset. In each experiment, differences in visual perspective were hypothesized to cause a shift in processing that would affect subsequent judgments unrelated to the images. In Experiment 1, participants viewed photographs of actions taken from either a first-person or third-person visual perspective, then completed the Behavior Identification Form. Participants seeing third-person photographs chose more abstract descriptions of behaviors than those seeing first-person photographs. In Experiment 2, participants viewed first-person or third-person photographs, read Aesop's fables, and rated how well concrete and abstract descriptions of the events fit the stories. Participants seeing third-person photographs judged the abstract fable descriptions as better fitting the stories than those seeing first-person photographs. These findings suggest that viewing third-person images is more strongly associated with adopting an abstract processing style. Together, these studies attest to the significance of visual perspective in images and highlight the broader role of perspective in human cognition.

### G279

**THE ROLE OF MORALITY IN THE SUNK COST ERROR** H. Lyssette Chavez<sup>1</sup>, Markus Kimmelmeier<sup>1</sup>, <sup>1</sup>University of Nevada, Reno – The sunk cost effect refers to the phenomenon when individuals continue with an endeavor because a prior investment (e.g., money, time) has been made. When past investments are irretrievable, continuing to hold on to such investments constitutes a genuine decision-making error because decisions should only be guided by future expectations, not past behaviors. Arkes and Blumer (1985) proposed that the sunk cost error is driven by people's desire to not appear wasteful. Because wastefulness is typically viewed a moral failing we investigated whether considering the moral dimension of a decision would increase the sunk cost error, and whether disregarding the moral stigma of wastefulness would reduce it. Undergraduates (N = 202) received scenarios with four different instructions to consider or disregard the moral implications of their decisions. Results showed that, in a control condition, participants with training in economics or those high in Need for Cognition were less likely to commit the error. The same participants, however, were more likely to commit the sunk cost error when asked to focus on the morals of their decision making. Ironically, the same participants were also more likely to commit the error when instructed not to concern themselves with moral dimensions of their decisions. Participants without training in economics and those low in Need for Cognition were not affected by instructions. Results confirm the importance of morality for the emergence of the sunk cost error, but also highlight that superior reasoning performance is contingent on a framing of the decision problem.

### G280

**THE LABOR ILLUSION: WHEN WAITING INCREASES LIKING** Ryan Buell<sup>1</sup>, Michael Norton<sup>1</sup>, <sup>1</sup>Harvard Business School – While conventional wisdom suggests that waiting for service yields less satisfied customers, we document and explore the ironic benefits of waiting. In particular, we demonstrate that when websites signal the work in which they are engaging, for example by displaying steps in a search process, people not only mind the wait less, but actually value the experience more. Due to what we term the "labor illusion," people can actually prefer websites with longer waits to those that return instantaneous results, even when those results are identical. Through a series of studies that simulated service experiences in the domains of online travel and online dating, we found that the labor illusion increases value perceptions to such an extent that participants who waited for service were more satisfied and had a higher willingness to pay than those who received identical outcomes instantaneously. Moreover, we distinguished the labor illusion as superior to other means commonly used to divert customer attention during service

delivery delays (such as marketing, entertainment and customer interactivity). We also demonstrated in a within-subjects design that while most participants prefer instantaneous service in a comparative frame, nearly twice as many choose waiting for service over instantaneous delivery when the waiting condition employs the labor illusion. These findings highlight a hidden cost of infusing technology into service delivery. Such initiatives, which are designed to enhance technical efficiency for the customer, reducing costs while increasing speed and convenience, may also counter-intuitively erode consumer perceptions of the value of the services they create.

### G281

**THE EFFECTS OF IMPLICIT EGOTISM ON SOCIAL JUDGMENTS ABOUT PEOPLE WHO RESEMBLE THE SELF** Chris Bartak<sup>1</sup>, Mauricio Carvallo<sup>1</sup>, <sup>1</sup>University of Oklahoma – Implicit egotism research suggests that people show preferences for other people who resemble them because similar others activate positive, automatic self-associations. The purpose of this study is to extend this research by examining the effects of implicit egotism on different types of social judgments about other people who are associated with the self. It was predicted that participants would respond to people with similar names by (a) extending to them their own self-serving attributional biases, (b) evaluating them more positively, and (c) making more favorable predictions of their future behavior. Participants read the college transfer application of a bogus individual who performed well or poorly at a previous college institution and whose name resembled or was different from their own name. After reading the application, participants rated the degree to which they perceived that the applicant's past college performance was due to internal vs. external characteristics, predicted the individual's future performance in college, and provided an overall evaluation of the individual. Consistent with our predictions, when participants' names resembled the applicant's name, they were more likely to: attribute the applicants' past success in college to internal dispositions, evaluate the applicant more positively, and predict a more favorable future behavior of the applicant in college. The perceived similarity of the target to self did not influence the results of the study. These findings suggest that implicit egotism influences not only the affective reactions people have toward others who resemble them, but also the judgments they make about these individuals.

### G282

**NEURAL MECHANISMS UNDERLYING THE IMPACT OF SOCIAL INTERACTIONS ON DECISION MAKING: AN FMRI INVESTIGATION** Florin Dolcos<sup>1,4</sup>, Jennifer Argo<sup>3</sup>, Takahiko Masuda<sup>2</sup>, Ekaterina Ninova<sup>1</sup>, Sanda Dolcos<sup>1,2</sup>, Keen Sung<sup>1</sup>, <sup>1</sup>Department of Psychiatry, University of Alberta, <sup>2</sup>Department of Psychology, University of Alberta, <sup>3</sup>Department of Marketing, Business Economics and Law, University of Alberta, <sup>4</sup>Centre for Neuroscience, University of Alberta – Social interactions affect our decisions in business settings (e.g., deciding to buy products depending on whether the seller is friendly or not). The "friend or foe" judgements, which are important for survival, are often based on first impressions, which in turn may affect our financial and social decisions. However, little is known about the impact of affective body language in social interactions on our cognitive responses. In the present study, participants viewed guest-host interactions in business setting, in which the host displayed behaviours that would either encourage (approach condition) or discourage (avoid condition) further social interactions. Then participants then rated their interest in engaging in business relations with the host characters. Analyses of data from 12 participants showed that approach trials were associated with greater interest in doing business compared to the avoid trials, and that these responses did not dissociate between personal vs. impersonal engagement of the subjects (i.e., depending on the congruency between their sex and that of the guest character). However, preliminary analyses of brain imaging data suggest that the personal engagement while viewing social interactions was associated with greater activity in brain regions associated with self-referential processing (e.g., medial prefrontal cortex), despite the similarity in the behav-

ioral responses. Further investigation of these issues has relevance for understanding the neural substrates of the impact of positive and negative social interactions on financial decisions, as well as for understanding clinical conditions in which the impact of emotional content of social situations is altered (e.g., autism and social phobia).

### G283

#### THE ROLE OF MOCK-JURORS' GOALS ON LEGAL DECISION MAKING

Kristin Kiddoo<sup>1</sup>, Michael Cahill<sup>1</sup>, Donna LaVoie<sup>1</sup>, Amanda Whitworth Bequette<sup>1</sup>, DN LeFevre<sup>1</sup>, Daniel Jaster<sup>1</sup>, <sup>1</sup>Saint Louis University – Numerous extra-evidentiary factors have been shown to affect juror decision-making. As Ogloff stated, however, "...it is not enough to know what types of pretrial publicity affect jurors, for example, but why they react the way they do and how the media affects their decision making" (2002, p. 19). This study was designed to add to the theoretical examination of the largely applied-focused literature by measuring the regulatory focus of mock-jurors. It was predicted that chronic regulatory focus would significantly predict jurors' conviction thresholds and verdicts. Contrary to hypotheses based on the theory that promotion-focused individuals are primarily motivated to seek hits (vs. prevention-focused individuals being more concerned with avoiding errors), thus lowering their threshold for conviction and making them more inclined to choose a guilty verdict, only jurors' prevention-focus accounted for a significant amount of the variance in conviction threshold, although only when the case presented by the prosecutor was ambiguous (vs. strong). The higher one's score on prevention-focus, the higher their reported conviction threshold was, suggesting that serving as a mock-juror made participants more concerned with their responsibilities and obligations (prevention-oriented state) than with their ideals (promotion-oriented state).

#### REFLECTING ON DECISION PROCESSES: HOW INTROSPECTION CAN IMPROVE JUDGMENT AND DECISION MAKING

Michaela Huber<sup>1</sup>, Van Boven Leaf<sup>1</sup>; <sup>1</sup>University of Colorado, Boulder – People frequently make judgments and decisions in ways that they – often in hindsight – might prefer to avoid. We argue that introspecting on how judgments and decisions should be made can increase the correspondence between how people make and how they think they should make judgments and decisions, thereby often improve judgments and decisions. Specifically, we focus on how much people weigh and think they should weigh different kinds of information depending on context: heuristic and feeling-based information vs. objective and fact-based information. In one study, people read a policy proposal to address global warming. The policy was strongly supported by either Democrats or Republicans. We expected and found that participants in a control condition evaluated the policy primarily along partisan lines (Cohen, 2003). In a condition where participants reflected on how much they believe partisan politics and personal attitudes toward global warming should influence policy evaluation, their evaluations indicated increased weighting of personal attitudes relative to partisan information. In another study, participants read about two people and they indicated whom they prefer for going out on a date. Before participants chose one person, half of them thought about how much their feelings and how much factual information (e.g. how long they have known the person) should influence their choice. Again, we expected and found that reflecting on beliefs about how they should decide brought participants' decision more in line with these beliefs, indicated by a stronger preference to go out with the person they felt most strongly about.

### G285

#### THE MOTIVES OF MAVERICKS: BIASED PERCEPTIONS OF POLITICIANS' PARTY-INCONSISTENT BEHAVIOR

Amy M. Williams<sup>1</sup>, Peter H. Ditto<sup>2</sup>; <sup>1</sup>University of California, Los Angeles, <sup>2</sup>University of California, Irvine – Understanding the motivations of other people helps us to make orderly sense of their behavior and, in turn, decide whether to trust or distrust them. Motive attributions may often be biased, however, by our feelings about the actor, with individuals seeing the behavior of disliked actors as

revealing more negative motives than the behavior of liked actors. The current research examined this prediction in a political context, exploring motive attributions for U.S. political figures who take party-inconsistent ("maverick") positions. In Study 1, liberal and conservative participants (N = 297) provided open-ended responses regarding the motives of two well-known politicians (Joe Lieberman and Colin Powell) who took a maverick position on a key issue (endorsing a presidential candidate of the opposite party). In Study 2, Democrat participants (N = 166) read about a hypothetical politician taking a maverick political stand and responded to closed-ended motive attribution measures via a web-based survey. In both studies, participants attributed significantly more positive (rational, issue-based) motives to maverick politicians of the opposite political party (who thus moved closer to their own position) and significantly more negative (biased, emotion-based) motives to maverick politicians of their own political party (who thus moved away from their own position). These findings help shed light on how people perceive maverick politicians (they tend to like mavericks of the other party but not their own) and illustrate a key aspect of hyperpartisanship currently seen in U.S. politics – disparaging others motives changes policy disagreements from differences of opinion into moral failings.

### G286

#### THE PRIMARY AND RECENCY EFFECTS IN INTERPERSONAL JUDGMENT: THE ROLE OF IMPLICIT THEORY

Xiang Yao<sup>1</sup>, Lei Wang<sup>1</sup>; <sup>1</sup>Peking University – The function of implicit theories of reasoning processes has been introduced into the study of performance appraisal as a new area of research in social perception. This article reported two studies which examined how implicit theories (categorized as fixed mindsets and malleable mindsets here) affect appraisers' information processing in performance appraisal. Major findings included: the overall ratings of managers with fixed mindsets were more easily influenced by the information presented first in a sequence of performance information, a primacy effect. In contrast, managers with malleable mindsets considered the last behavior description in a sequence of performance information the most important for overall ratings, a recency effect (Study 1). Moreover, Compared with managers with fixed mindsets, managers with malleable mindsets were more likely to change their overall appraisal ratings (consistency effect) when additional performance information is shown. While managers with fixed mindsets insisted with their originally ratings (anchoring effect) (Study 2). The article also discussed the implications of our findings which may help better understand the impact of implicit theories in interpersonal behavior judgment.

#### MORAL PRINCIPLES OR CONSUMER PREFERENCES? ALTERNATIVE FRAMINGS OF THE "TROLLEY" PROBLEM

Tage Rai<sup>1</sup>, Keith Holyoak<sup>1</sup>; <sup>1</sup>UCLA Psychology – We created paired moral dilemmas with minimal contrasts in wording, a research strategy that has been advocated as a way to empirically establish principles operative in a domain-specific moral psychology. However, the candidate "principles" we tested were not derived from work in moral philosophy, but rather from work in the areas of consumer choice and risk perception. Participants were paradoxically less likely to choose an action that sacrifices one life to save others when they were asked to provide more reasons for doing so (Experiment 1), and their willingness to sacrifice lives depended not only on how many lives would be saved, but on the number of lives at risk (Experiment 2). The latter effect was also found in a within-subjects design (Experiment 3). These findings cast doubt on use of artificial dilemmas as a key testbed for revealing principled bases for moral judgment.

**G289****UNDERSTANDING THE COLLECTIVE PREFERENCE FOR SHARED INFORMATION IN DECISION MAKING GROUPS: A CROSS-CULTURAL ANALYSIS**

Yanan Feng<sup>1</sup>, Nicola Bown<sup>1</sup>, Christopher W. Allinson<sup>1</sup>, John Maule<sup>1</sup>; <sup>1</sup>The University of Leeds – Theories of the information sampling process in decision making groups have suggested a probabilistic explanation for the ‘collective information sampling bias’ (CIS bias). However, the simple probability models cannot account for the patterns of information pooling that occur when shared information can be distinguished from unshared information, or where members know what information is shared and unshared. In these cases, other social or motivational dynamics may influence members’ sharing of information. The present study extends the existing literature by focusing attention on contextual analysis of the CIS bias. In particular, the impact of culture on the information sharing process in decision-making groups was examined. 40 Four-person British and Chinese groups decided which of two hypothetical candidates would be recruited for a lecturer position. Some of the information about each candidate was provided to all group members (shared information), whereas the remainder was randomly divided (unshared information). Findings indicated that although no significant difference was found in the total amount of unshared information exchange, the way in which unshared information was exchanged was different: Chinese participants used an indirect way of communication while British participants tended to use a more direct way. The present study is important because it extends the generality of these information sampling phenomena by inclusion of national contextual factor. Also, it reflects an important move away from viewing collective information processing behaviours from the single motivational theme of accuracy seeking and has the potential to advance substantially our understanding of mixed motive decision situations.

**G290****UNDERSTANDING PUBLIC OUTRAGE TO IMMATERIAL HARMS**

David Tannenbaum<sup>1</sup>, Eric Luis Uhlmann<sup>2</sup>, Daniel Diermeier<sup>2</sup>; <sup>1</sup>University of California, Irvine, <sup>2</sup>Northwestern University – Moral psychology has recently become interested in the idea that moral judgments are sometimes person-focused in scope – that moral judgments are as much about judging people (is this a good person?) as they are about judging the permissibility of an act. Consistent with this approach, we show that immaterially harmless acts can elicit strong moral judgments (e.g., public outrage) if such acts provide negative information about the agent. First, we find that people absorb character information independent of evaluations of acts – participants thought it was less wrong to abuse a cat than a person, and more praiseworthy to conduct medical research on animals than to work at a pet store, but in both cases the first act was believed to reflect worse moral character. Second, negative information signaled by a moral act resulted in non-consequentialist judgments, including some actions with positive consequences as worse than an action with neutral consequences, and preferring an agent who did more harm to an agent who does less harm.

**G291****IS CAUTION THE BETTER PART OF VALOR? PREFERENCES FOR ACTION VS. INACTION IN RESPONSE TO BAD NEWS**

Kate Sweeny<sup>1</sup>, James A. Shepperd<sup>2</sup>; <sup>1</sup>University of California, Riverside, <sup>2</sup>University of Florida – People confronting bad news frequently must choose between action and inaction in the face of bad news, and the consequences of their choices can be quite significant. Four studies explored how people regard the responses of action vs. inaction in others and which response they personally prefer when confronting bad news. Across all studies participants perceived action more positively than inaction, and their positive perceptions of action did not waver even when action was difficult and likely to be ineffective. However, participants strongly preferred inaction over action for themselves except when action was pragmatic. Finally, Study 4 revealed that people may prefer inaction while admiring action in others due in part to a general tendency to perceive action as

more pragmatic for others, which in turn leads people to anticipate greater regret over inaction for others. These findings suggest that people may be poor at predicting how others facing the choice between action and inaction will respond and call into question the validity of hypothetical scenarios for predicting responses to bad news.

**G292****CHEAP TALK AND CREDIBILITY: THE CONSEQUENCES OF CONFIDENCE AND ACCURACY ON ADVISOR CREDIBILITY AND PERSUASIVENESS**

Sunita Sah<sup>1</sup>, Don Moore<sup>1</sup>, Robert MacCoun<sup>2</sup>; <sup>1</sup>Carnegie Mellon University, <sup>2</sup>University of California, Berkeley – Persuasiveness and credibility of advice are of great interest to those who wish to influence others. Two studies explore the influence of advisors’ confidence, self-proclaimed expertise and accuracy. In a new paradigm using continuous rather than dichotomous outcomes, clear feedback, and repeated trials, we asked 186 students to estimate the weight of people from photographs before and after receiving advice from one of four advisors with similar accuracy (high or low confidence, expert or non-expert). We found that high confidence made advisors more persuasive, and that simply claiming to be an expert was similarly influential. A second study explored the joint consequences of both confidence and accuracy over time. 285 individuals received advice from one of six advisors, (high, moderate or low confidence, high or low starting accuracy). The results show that advisors’ accuracy moderates the effects of confidence. Highly accurate advisors benefit from confidence, whereas low accuracy advisors prove more credible when they express less confidence. Highly confident but inaccurate advisors received the lowest ratings of credibility. In addition, although we see evidence for primacy effects, in that advisors with high starting accuracy were more persuasive and credible than those with low starting accuracy, we also found that inaccuracy had a disproportionately stronger impact in decreasing persuasiveness than accuracy had on increasing it. Hence, although “cheap talk” claims of expertise and confidence can increase one’s influence over others, high confidence is most persuasive when it is justified by high accuracy.

**G293****THE CHALLENGE OF UNDERSTANDING CLIMATE CHANGE: A SOCIAL PSYCHOLOGICAL FRAMEWORK**

Ezra Markowitz<sup>1</sup>, Sara Hodges<sup>1</sup>; <sup>1</sup>University of Oregon – Although the majority of Americans believe climate change is occurring and must be addressed, various polls and studies suggest that public understanding of the issue is generally shallow, murky, incomplete and to some degree inaccurate (e.g., beliefs about the ozone hole). Many factors play a role in shaping individuals’ understanding of climate change; while some of these factors, such as biased media coverage, have been widely discussed, there has been relatively little recognition of the many social psychological phenomena and processes that influence the public’s understanding. Many features of the phenomenon itself (e.g., variable time delays between inputs and outputs, slow rates of change, probabilistic nature, potential threat to the self) may interact with psychological processes (e.g., attitude change, need for closure, effects of experiential versus analytical learning) to seriously challenge people’s ability to think about and comprehend climate change. Here, we explore how key social psychological phenomena, including construal level, worldviews, and motivated reasoning, mediate the relationship between the three primary sources of climate change information available to laypersons – media exposure, personal experience and social informants – and subsequent understanding. If communicators are to expand and (normatively) improve individuals’ understanding of climate change (for example, via educational campaigns), they must fully take into account the many factors, including social psychological ones, which play a role in inhibiting, promoting and affecting climate understanding.

**G294****SELECTIVE INFORMATION PROCESSING AMONG ADVISORS: THE INFLUENCE OF TRANSFORMATIONAL AND TRANSACTIONAL LEADERSHIP** Andreas Kastenmueller<sup>1</sup>; <sup>1</sup>Liverpool John Moores-

University – Previous research has shown that people prefer selectively supporting to conflicting information (selective information processing). In the present investigation, we examined how advisors process and convey information when they are led by supervisors exhibiting different leadership styles. We hypothesized and found in three studies that advisors who were expecting to give advice to a supervisor with a transactional leadership style compared with advisors expecting to give advice to a supervisor with a transformational leadership style evaluated, sought, and conveyed more selectively in favor of supporting rather than of conflicting information. Study 3 indicated that advisors with transactional (vs. transformational) supervisors experienced decreased positive emotions, which was counterbalanced by selective information seeking and conveying.

**G295****INTERRACIAL MISTRUST: DO INGROUP BIASES PREVAIL EVEN WHEN TRUSTING THE OUTGROUP BENEFITS THE SELF?** Meghan Bean<sup>1</sup>, Jennifer A. Richeson<sup>1</sup>; <sup>1</sup>Northwestern University – The present work sought

to examine whether Whites exhibit greater distrust in racial outgroup members compared to racial ingroup members, even in situations where trusting behavior would benefit the self. In Studies 1a and 1b, we found that White individuals do, in fact, believe that Whites are more trustworthy than Black Americans (1a), and they perceive White faces as being more trustworthy than either Asian or Black faces (1b). Study 2 examined whether participants' interracial mistrust persists in situations when trusting behavior is likely to benefit the self. Specifically, we made use of a dyadic economic task, the Investment Game, in which trusting behavior on the part of the participant was likely to benefit his/her own outcome as well as his/her partner's outcome. Participants imagined that they were playing the Investment Game with a number of White, Black, and Asian target individuals, and results indicated that they trusted White individuals more than they trusted Asian or Black individuals. In sum, the results of these studies suggest that Whites perceive racial outgroup members as being less trustworthy than ingroup members, and, further, they behave in a less trusting manner with outgroup, compared to ingroup, members, even at a potential cost to themselves.

**G296****HAPPINESS COOLS THE GLOW OF FAMILIARITY: PSYCHOPHYSIOLOGICAL EVIDENCE THAT MOOD MODULATES THE FAMILIARITY-AFFECT LINK** Marieke De Vries<sup>1,2</sup>, Rob Holland<sup>2</sup>, Troy Chenier<sup>3</sup>, Mark Starr<sup>3</sup>, Piotr Winkielman<sup>3</sup>; <sup>1</sup>Leiden University Medical Center, the Netherlands, <sup>2</sup>Behavioural Science Institute, Radboud University Nijmegen, the Netherlands, <sup>3</sup>University of California, San Diego – People

often prefer familiar stimuli, presumably because familiarity signals safety. This "warm glow of familiarity" is a classic psychological phenomenon (Titchener, 1910). One source of warm glow is a simple repetition, with such "mere exposure" enhancing familiarity and liking (Zajonc, 1968; 2001). Another, even more robust, source of warm glow is prototypicality. Prototypes are usually rated as highly familiar, even when they are objectively "new", and also highly liked, an effect called "beauty-in-averages". However, is familiarity always warm? As familiarity is a heuristic cue to safety, its validity and hedonic meaning varies by context. Familiarity should be valued in an unsafe environment, but less so in a benign environment. Much psychological research points out that one signal of environmental safety or danger is an individual's mood. Our goal was to test whether the warm glow of familiarity depends on mood. In our main experiment, mood was manipulated. Subsequently, participants were exposed to a category of stimuli. Next, they provided liking ratings for stimuli from the exposed category and their controls from a new, unexposed category. We also used EMG to measure spontaneous affective reactions ("smiling" and "frowning") and SCR towards

familiar and unfamiliar stimuli. Indeed, compared to sadness, happiness eliminates the preference for familiar stimuli, most robustly on prototypes. In happiness familiarity is present, possibly even stronger than in sadness, but it just does not "glow" warmly. It appears that in a happy mood, prototypes are, well, just average. We conclude that mood changes the hedonic implications of familiarity cues.
