

# Welcome to SPSP 2010

## **The 11th Annual Meeting of the Society for Personality and Social Psychology**

We are delighted to welcome everyone to Las Vegas for the 11th Annual SPSP meeting. The society and the meeting continue to grow each year, and Vegas is an appropriately lavish city in which to celebrate this growth. To compete with the attractions of the Strip, we offer you an exciting and jam-packed meeting program.

Seventy-seven symposia and over 2,000 posters, which were selected from another record number of submissions, cover a wealth of personality and social psychology topics, representing the diversity, breadth, and depth of our field. In addition, there are several special sessions we wish to highlight, including the Presidential symposium and address, the Block and Campbell award addresses, a Keynote Panel on the role of genetics in social and personality research, and many opportunities and special sessions for graduate students.

This year's meeting opens with an exciting Presidential Symposium entitled "Transcending self-interest: Evolution, brains, and hormones." The symposium is chaired by SPSP President Jennifer Crocker, and features Dachner Keltner, Patricia Churchland, and Paul Zak as speakers. The Presidential Symposium takes place from 5:00-7:00 pm, followed by the Welcome Reception and the first Poster Session of the meeting, running concurrently from 7:00-8:30 pm.

The Presidential Address, entitled "The Social Self: Egosystem or Ecosystem?" is Friday afternoon. Friday's programming also includes the Campbell Award Address, "Envy Up and Scorn Down: How Comparison Divides Us" given by Susan T. Fiske. Saturday's programming includes both the Keynote Panel "The Role of Genetics in Personality and Social Psychology" featuring speakers Frances Champagne, Steve Cole, Robert F. Krueger, and Eric Turkheimer, and the Block Award Address, "On the importance of the FFM Personality Traits" given by Paul T. Costa, Jr.

In addition to the wealth of the regular program, some special programming features for graduate students include the special Graduate Student Symposium "A Graduate Student's Guide to External Funding" at 8:15 am Friday. Mentoring lunches for graduate students, coordinated by the Graduate Student Committee, are both Friday and Saturday, as well as a mentoring lunch sponsored by GASP, the GLBT Alliance in Social and Personality Psychology, held on Friday. The Training Committee Symposium also takes place on Friday.

We hope you'll find plenty of learning opportunities at this year's meeting. And, have fun in Las Vegas!

Monica Biernat, Convention Committee Chair

Serena Chen and William Fleeson, Convention Program Co-Chairs

 2:00 pm *Capri Rooms 112-113*  
 Sponsored by GASP, the GLBT Alliance in Social and Personality Psychology  
 Coordinator: Lisa G. Aspinwall, *University of Utah*

2:00 – **Symposia Session C & Presidential Address**  
 3:15 pm

**C1: PRESIDENTIAL ADDRESS**  
**THE SOCIAL SELF: EGOSYSTEM OR ECOSYSTEM?**  
*Royale Pavilion 1*  
 Speaker: Jennifer Crocker, *University of Michigan*  
 Introducer: Richard Petty, *Ohio State University*

**C2: THE PERSON AND THE POLITICAL MIND: NEW INSIGHTS FROM RESEARCH ON VALUES, MINDSETS, PERCEPTIONS OF THE NATION, AND GENDER**  
*Royale Pavilion 2*  
 Chairs: Anat Bardi, *Royal Holloway University of London*, and Sonia Roccas, *The Open University of Israel*  
 Speakers: Anat Bardi, Gerard Saucier, Dennis T. Kahn, I-Ching Lee

**C3: SOCIAL PSYCHOLOGY FOR AN ECONOMIC RECESSION: EXAMINING THE EFFECTS OF SOCIOECONOMIC STATUS ON PSYCHOLOGICAL PROCESSES**  
*Royale Pavilion 5*  
 Chairs: Natalya C. Maisel, *University of California, Los Angeles*, and Paul K. Piff, *University of California, Berkeley*  
 Speakers: Paul K. Piff, Natalya C. Maisel, Elizabeth Page-Gould, Edith Chen

**C4: CONTENDING WITH DISCRIMINATION: PSYCHOLOGICAL, NEUROLOGICAL, PHYSIOLOGICAL, AND BEHAVIORAL CONSEQUENCES OF ATTRIBUTIONAL AMBIGUITY**  
*Royale Pavilion 6*  
 Chairs: Jenessa R. Shapiro, *University of California, Los Angeles*, and Sophie Trawalter, *University of North Carolina, Chapel Hill*  
 Speakers: Sophie Trawalter, Naomi I. Eisenberger, Brenda N. Major, Jenessa R. Shapiro

**C5: ACCURATE SELF-KNOWLEDGE**  
*Royale Pavilion 3-4*  
 Chair: C. Randall Colvin, *Northeastern University*  
 Speakers: Erika N Carlson, Elizabeth R Tenney, Lauren J Human, C Randall Colvin

3:15 – **Coffee Break**  
 3:30 pm *Grande Ballroom*

3:30 –  
 4:45 pm

**Symposia Session D**

**D1: THE PSYCHOLOGY OF STATUS**  
*Royale Pavilion 1*  
 Chairs: Nir Halevy and Taya Cohen, *Northwestern University*  
 Speakers: Taya Cohen, Sebastien Brion, Nir Halevy, Robb Willer

**D2: POSITIVE AND NEGATIVE EVALUATION IN SELF-REPORTED PERSONALITY**  
*Royale Pavilion 2*  
 Chair: Eric Turkheimer, *University of Virginia*  
 Speakers: Leonard Simms, Martin Bäckström, Amber Thalmayer, Erik Pettersson

**D3: THE SCIENCE OF MONEY AND RELATIONSHIPS: WAYS THAT MONEY HELPS AND HURTS INTERPERSONAL FUNCTIONING**  
*Royale Pavilion 5*  
 Chairs: Peter Caprariello, *University of Rochester*, and Nicole Mead, Kathleen Vohs, *Tilburg University, University of Minnesota*  
 Speakers: Nicole Mead, Scott Rick, Peter Caprariello, Xinyue Zhou

**D4: THE NATURE, CAUSES AND CONSEQUENCES OF OBJECTIFICATION**  
*Royale Pavilion 6*  
 Chairs: Steve Loughnan, *University of Melbourne*, and Anna Newheiser, *Yale University*  
 Speakers: Jeroen Vaes, Anna-Kaisa Newheiser, Jamie L. Goldenberg, Steve Loughnan

**D5: UNDERSTANDING IMPLICIT AND EXPLICIT ATTITUDES: EXPLORING THE DUAL-SYSTEMS PERSPECTIVE**  
*Royale Pavilion 3-4*  
 Chairs: Michael J. McCaslin, *Ohio State University*, and Chris Loersch, *University of Missouri*  
 Speakers: Robert Rydell, Kate A. Ranganath, Aiden P. Gregg, Michael J. McCaslin

**D6: BEYOND RECOGNITION: WHAT ARE THE SOCIAL (AND NOT-SO-SOCIAL) FUNCTIONS OF EMOTION EXPRESSIONS?**  
*Royale Pavilion 7-8*  
 Chairs: Jessica L. Tracy and Azim F. Shariff, *University of British Columbia*  
 Speakers: Azim F. Shariff, Arne Ohman, Alexander Todorov, Adam K. Anderson

**D7: THE ORIGINS, PREDICTORS, AND MODERATORS OF RELIGIOUS BELIEFS AND INVOLVEMENT**  
*Capri Rooms 101-102*  
 Chairs: Joni Sasaki and Heejung Kim, *UC Santa Barbara*  
 Speakers: Azim Shariff, Kristin Laurin, Joni Sasaki, Adam Cohen

**D8: PROHIBITIONS AND PUNISHMENTS: IMPLICATIONS FOR MORAL PSYCHOLOGY**  
*Capri Rooms 103-106*  
 Chairs: Sana Sheikh and Ramila Usoof-Thowfeek, *University of Massachusetts Amherst*  
 Speakers: Sana Sheikh, Fiery Cushman, Ramila Usoof-Thowfeek, Kevin M. Carlsmith

**D9: A PRIMER ON SOCIAL NEUROSCIENCE METHODS FOR CONSUMERS AND PRACTITIONERS: ENDOCRINOLOGY, GENETICS, AND NEUROIMAGING***Capri Rooms 107-110*

Chairs: Elliot Berkman and Matthew Lieberman, UCLA

Speakers: Pranjal Mehta, Baldwin Way, Eddie Harmon-Jones, Elliot Berkman

**D10: EXISTENTIAL EPISTEMOLOGY: THE SCIENCE OF MOTIVATED KNOWLEDGE CONSTRUCTION***Capri Rooms 114-116*Chair: Joshua Hart, *Union College*

Speakers: Sheldon Solomon, Zachary Rothschild, Nathan Heflick, Jessica Tracy

5:00 –  
6:15 pm**Symposia Session E & Campbell Award Address****E1: CAMPBELL AWARD ADDRESS: ENVY UP AND SCORN DOWN: HOW COMPARISON DIVIDES US***Royale Pavilion 1*Recipient: Susan T. Fiske, *Princeton University*Introducer: Peter Glick, *Lawrence University***E2: PERSONALITY TRAITS AS IMPLICIT CAUSAL THEORIES ABOUT PEOPLE***Royale Pavilion 2*Chair: Jim Uleman, *New York University*

Speakers: Laura Kressel, SoYon Rim, Tania Ramos, Randy J. McCarthy

*Capri Rooms 107-110*

Chairs: Elizabeth Levy Paluck, *Princeton University*, and Ruth Dittmann, *Yale University*  
 Speakers: Ruth K. Dittmann, Robert B. Cialdini, Laura G. Barron, Glenn Adams

**F10: EMBODIED MOTIVATION: IMPLICATIONS OF BODY FEEDBACK FOR FUNDAMENTAL PROCESSES UNDERLYING MOTIVATED ACTION**

*Capri Rooms 114-116*

Chairs: Nils B. Jostmann and Jens A. Förster, *University of Amsterdam*  
 Speakers: Jens A. Förster, Simone Schnall, Nils B. Jostmann, Dennis R. Proffitt

11:00 – 11:15 am **Coffee Break**

*Grande Ballroom*

11:15 am – 12:30 pm **Symposia Session G & Keynote Panel**

**G1: "GIMME FIVE!" TACTILE COMMUNICATION AND ITS PROSOCIAL CONSEQUENCES**

*Royale Pavilion 1*

Chairs: Michael W. Kraus, *University of California, Berkeley*, and Christopher Oveis, *Harvard University*  
 Speakers: Matthew J. Hertenstein, Christopher C. Nocera, Christopher Oveis, Michael W. Kraus

**G2: KEYNOTE PANEL THE ROLE OF GENETICS IN PERSONALITY AND SOCIAL PSYCHOLOGY (11:15 AM -12:45 PM)**

*Royale Pavilion 2*

Chairs: Serena Chen, *University of California, Berkeley*, and William Fleeson, *Wake Forest University*  
 Panelist: Frances A. Champagne, *Columbia University*,  
**GENE-ENVIRONMENT INTERPLAY AND THE TRANSGENERATIONAL IMPACT OF THE SOCIAL ENVIRONMENT**  
 Panelist: Steve Cole, *David Geffen School of Medicine at UCLA*,  
**SOCIAL REGULATION OF GENE EXPRESSION IN HUMANS**  
 Panelist: Robert F. Krueger, *Washington University*,  
**GENES AND ENVIRONMENTS IN PERSONALITY AND SOCIAL PSYCHOLOGY: SOME REFLECTIONS ON SCIENTIFIC STRATEGIES**  
 Panelist: Eric Turkheimer, *University of Virginia*,  
**A NULL MODEL FOR THE GENETICS OF COMPLEX HUMAN BEHAVIOR**

**G3: THE BIOLOGY OF THE ATTACHMENT BOND**

*Royale Pavilion 5*

Chair: Paul Eastwick, *Texas A&M University*  
 Speakers: Paul Eastwick, Lisa Diamond, Peter Gray, James Coan

**G4: BEYOND PARTICULARISM IN THE STUDY OF INTERSECTIONAL IDENTITIES: BUILDING AND TESTING GENERAL THEORIES OF IDENTITY INTERSECTIONALITY**

*Royale Pavilion 6*

Chairs: Valerie Purdie-Vaughns, *Columbia University*, and Richard P. Eibach, *University of Waterloo*  
 Speakers: Margaret A. Thomas, Ram Mahalingam, Isis H. Settles, Valerie Purdie-Vaughns

**G5: NEW INSIGHTS INTO SOCIAL EVALUATION BIASES: FROM BRAIN TO BEHAVIOR**

*Royale Pavilion 3-4*

Chair: Jennifer S. Beer, *University of Texas at Austin*  
 Speakers: David Dunning, Jason P. Mitchell, Constantine Sedikides, Jennifer S. Beer

**Box Lunch Served**

*Grande Ballroom*

**Poster Session F**

*Grande Ballroom*

**Mentoring Luncheon**

*Top of Riv, North*

Sponsored by the Graduate Student Committee  
 President: Austin Lee Nichols  
 Coordinators: Marina Milyavskaya & Jennifer Pattershall

**Symposia Session H & Block Award Address**

**H1: POWER AND THE (NARCISSISTIC) SELF: THE EFFECTS OF POWER ON SELF PERCEPTION, SELF PRESENTATION, GOALS FOR THE SELF, AND ETHICAL DECISION MAKING**

*Royale Pavilion 1*

12:30 – 1:30 pm

12:30 – 2:00 pm

1:00 – 2:00 pm

2:00 – 3:15 pm

Chairs: Nathanael J. Fast, *University of Southern California*, and Senia Maymin, *Stanford University*  
 Speakers: Nathanael J. Fast, Senia Maymin, M. Ena Inesi, Jennifer R. Overbeck

## **H2: BLOCK AWARD ADDRESS**

*Royale Pavilion 2*

Recipient: Paul T. Costa, Jr., National Institute of Aging, **ON THE IMPORTANCE OF THE FFM PERSONALITY TRAITS**

Introducer: David C. Funder, *University of California, Riverside*

## **H3: BALANCING CLOSENESS AND DISTANCE IN INTIMATE RELATIONSHIPS**

*Royale Pavilion 5*

Chairs: Gertraud Stadler and Niall Bolger, *Columbia University*

Speakers: Gertraud Stadler, Masumi Iida, Benjamin R. Karney

## **H4: HOW WE FEEL ABOUT 'THEM': EMOTIONAL RESPONSES TO OUTGROUPS' PLEASURES AND PAINS**

*Royale Pavilion 6*

Chair: Mina Cikara, *Princeton University*

Speakers: Max Weisbuch, Matteo Forgiarini, Mina Cikara, Wilco Van Dijk

## **H5: DO I BELONG HERE? IDENTIFYING FACTORS THAT FORTIFY VS. ATTENUATE WOMEN'S SENSE OF BELONGING IN STEREOTYPICALLY MASCULINE ACADEMIC AND PROFESSIONAL DOMAINS**

*Royale Pavilion 3-4*

Chairs: Jane Stout and Nilanjana Dasgupta, *University of Massachusetts, Amherst*

Speakers: Jennifer Steele, Lisa Rosenthal, Jane Stout, Christine Logel

## **H6: THE DIFFERENTIATION OF POSITIVE EMOTIONS: RECENT ADVANCES IN THEORY AND RESEARCH ON POSITIVE EMOTIONS**

*Royale Pavilion 7-8*

Chairs: Michele M. Tugade, *Vassar College*, and Leslie D. Kirby, *Vanderbilt University*

Speakers: Craig A. Smith, Michelle N. Shiota, Michele M. Tugade, Anthony H. Ahrens

3:15 –  
3:30 pm

## **Coffee Break**

*Grande Ballroom*

3:30 –  
4:45 pm

## **Symposia Session I**

### **I1: UNITED AND DIVIDED WE STAND: ON THE COLLECTIVE AND PERSONAL FUNCTIONS OF CONFORMITY AND DISSENT**

*Royale Pavilion 1*

Chairs: Kimberly Rios Morrison, *The Ohio State University*, and Dominic J. Packer, *Lehigh University*

Speakers: Carsten K. W. De Dreu, Jolanda Jetten, Dominic J. Packer, Kimberly Rios Morrison

### **I2: REDRAWING THE BIG PICTURE: FROM PERSONALITY DATA (BACK) TO PERSONALITY THEORY**

*Royale Pavilion 2*

Chair: Daniel Cervone, *University of Illinois at Chicago*

Speakers: Daniel Cervone, Peter Kuppens, Sander Koole, Gerald Matthews

### **I3: A BIOPSYCHOSOCIAL MODEL OF THREATS TO SOCIAL BELONGING: PERSPECTIVES FROM ACROSS THE SPECTRUM OF SOCIAL PSYCHOLOGY.**

*Royale Pavilion 5*

Chairs: Lisa M. Jaremka and Nancy L. Collins, *UC Santa Barbara*

Speakers: Lisa M. Jaremka, Sally S. Dickerson, Vivian Zayas, Daan Scheepers

### **I4: THE AGE OF OBAMA: A NEW ERA OF RACE RELATIONS, OR A NEW ERA OF MODERN RACISM?**

*Royale Pavilion 6*

Chair: Clayton R. Critcher, *Cornell University*

Speakers: Cheryl R. Kaiser, Clayton R. Critcher, Eugene M. Caruso, Carlos David Navarrete

### **I5: WHAT'S SO SPECIAL ABOUT THE SELF? OR IS THERE ANYTHING SPECIAL AT ALL?**

*Royale Pavilion 3-4*

Chairs: Kurt Peters and Bertram Gawronski, *University of Western Ontario*

Speakers: Marret K. Noordewier, Allen R. McConnell, Kenneth G. DeMarree, Kurt R. Peters

### **I6: ACHIEVING SUSTAINABLE HAPPINESS: PATHWAYS AND PITFALLS**

*Royale Pavilion 7-8*

Chair: Lara Aknin, *University of British Columbia*

Speakers: Barbara L. Fredrickson, Elizabeth W. Dunn, Julia K. Boehm, Lara B. Aknin

### **I7: SEX, STATUS, POWER AND PENALTIES FOR GENDER DEVIANCE: NEW DIRECTIONS IN BACKLASH RESEARCH**

*Capri Rooms 101-102*

Chairs: Corinne Moss-Racusin, *Rutgers University*, and Victoria Brescoll, *Yale University*

Speakers: Laurie A. Rudman, Corinne A. Moss-Racusin, Victoria L. Brescoll, Peter Glick

### **I8: A NEW LOOK ON AUTOMATIC BEHAVIOR: MODULATION, INTEGRATION AND CONSEQUENCES**

*Capri Rooms 103-106*

Chairs: Kai Jonas, *University of Amsterdam*, and Joseph Cesario, *Michigan State University*

Speakers: Kai Jonas, Joseph Cesario, Chris Loersch, Dirk Smeesters

### **I9: THE DYNAMIC SOCIAL MIND**

*Capri Rooms 107-110*

Chairs: Melissa Ferguson and Mike Wojnowicz, *Cornell University*

Speakers: William A. Cunningham, Mike Wojnowicz, Jonathan B. Freeman, Robin R. Vallacher

### **I10: HOW TO SURVIVE SIN CITY: THE ROLE OF COGNITIVE CONTROL IN FIGHTING TEMPTATION**

*Capri Rooms 114-116*

Chairs: Wilhelm Hofmann, *Würzburg University*, and Lotte Van Dillen, *Utrecht University Netherlands*

Speakers: Wilhelm Hofmann, Brandon Schmeichel, Lotte Van Dillen, Reinout Wiers

Schedule of Events

5:00 –  
6:15 pm

**Symposia Session J**

**J1: WORKING TOGETHER OR TEARING EACH OTHER  
DOWN: HOW MEMBERS OF LOW STATUS GROUPS TREAT  
THE INGROUP**

*Royale Pavilion 1*

Chair: Kerry Spalding, *University of Washington*  
Speakers: Laurie O'Brien, Dina Eliezer, Grace Lau,  
Kerry Spalding

**J2: UNDERSTANDING NARCISSISM: MODERN, EMPIRICAL  
APPROACHES TO CLASSIC CONTROVERSIES**

*Royale Pavilion 2*

Chairs: Ryan Brown, *The University of Oklahoma*, and  
Keith Campbell, *The University of Georgia*  
Speakers: Virgil Zeigler-Hill, Keith Campbell, Robert  
Horton, Ryan P. Brown

**J3: CONTEXTUALIZING INTERPERSONAL COMMUNICA-  
TION: WHEN "POSITIVE" BEHAVIORS ARE NEGATIVE AND  
"NEGATIVE" BEHAVIORS ARE POSITIVE**

*Royale Pavilion 5*

Chairs: James K. McNulty and V. Michelle Russell,  
*University of Tennessee*  
Speakers: Laura B. Luchies, Jeffrey A. Simpson, James  
K. McNulty, Ronald D. Rogge

**J4: THE SOCIAL FACE: HOW SOCIAL CATEGORIZATION  
INFLUENCES FACE PERCEPTION**

*Royale Pavilion 6*

Chairs: Kurt Hugenberg, *Miami University*, and Oliv-  
ier Corneille, *Catholic University of Louvain*  
Speakers: Olivier Corneille, Natalie Ebner, Kurt  
Hugenberg, Tiffany Ito

**J5: THE PSYCHOLOGICAL MEANING OF THINGS AND  
PLACES**

*Royale Pavilion 3-4*

Chair: Alison Ledgerwood, *UC Davis*  
Speakers: Melissa Ferguson, Courtney Bonam,  
Alison Ledgerwood, Geoffrey Miller

**J6: THE SOCIAL ECOLOGY OF EMOTIONAL DISCLOSURE**

*Royale Pavilion 7-8*

Chair: Kent Harber, *Rutgers University at Newark*  
Speakers: Matthias Mehl, Anita Kelly, Richard  
Slatcher, Kent Harber

**J7: DISTINCT AND COMMON EFFECTS OF VARIOUS  
PSYCHOLOGICAL THREATS**

*Capri Rooms 101-102*

Chairs: Gale M. Lucas and Daniel C. Molden, *North-  
western University*  
Speakers: Dianne M. Tice, Jeff Schimmel, Gale M.  
Lucas, Ian McGregor

**J8: CONSCIOUS AND UNCONSCIOUS THOUGHT IN DECI-  
SION-MAKING**

*Capri Rooms 103-106*

Chairs: Daniel Wegner, *Harvard University*, and Carey  
Morewedge, *Carnegie Mellon University*  
Speakers: Daniel Oppenheimer, Carey Morewedge,  
John W. Payne, Ap Dijksterhuis

**J9: WHEN AND HOW SOCIAL COMPARATIVE STANDING  
IMPACTS WELL-BEING AND AFFECT**

*Capri Rooms 107-110*

Chairs: Jason P. Rose, *University of Toledo*, and Zlatan  
Krizan, *Iowa State University*  
Speakers: William M. P. Klein, Ethan Zell, Jason P.  
Rose, Richard Lucas

**J10: FOR THE LOVE OF THE FRAME: MOTIVATIONAL  
SOURCES OF VARIATION IN EFFECTIVENESS OF HEALTH  
MESSAGES**

*Capri Rooms 114-116*

Chairs: Tamara Sims and Nanna Notthoff, *Stanford  
University*  
Speakers: John A. Updegraff, Ph.D., Nanna Notthoff,  
Tamara L. Sims, M.A., Andrew Ward, Ph.D.

**Poster Session G with Social Hour**

*Grande Ballroom*

6:15 –  
7:45 pm

# Featured Sessions

## Opening Session and Presidential Symposium

### **Transcending self-interest: Evolution, brains, and hormones**

Thursday, January 28, 2010, 5:00 - 7:00 pm, Royale Pavilion 1-4

Chair: Jennifer Crocker, *University of Michigan*

Speaker: Dacher Keltner, *University of California, Berkeley*, **BORN**

**TO BE GOOD: AN EVOLUTIONARY APPROACH TO COMPASSION**

Speaker: Patricia Churchland, *University of California, San Diego*, **BRAIN-BASED VALUES**

Speaker: Paul Zak, *Claremont Graduate Center*, **THE MORAL MOLECULE: OXYTOCIN AND VIRTUE**

## Outreach and Special Sessions

### **SSA1: GSC Special Symposium**

#### **A Graduate Student's Guide to External Funding**

Friday, January 29, 2010, 8:15 - 9:30 am, Capri Rooms 103-106

Sponsored by the Graduate Student Committee

Chairs: Nicole E. Noll, *Temple University*, and Kathleen Fortune, *University of Manitoba*

Speakers: Jenessa R. Shapiro, Amber L. Story, Laura A. King

### **SSA2: Funding Opportunities at the National Science Foundation**

Friday, January 29, 2010, 8:15 - 9:30 am, Capri Rooms 107-110

Speakers: Kellina M. Craig-Henderson and

Amber L. Story

### **SSA3: Funding Opportunities at the National Cancer Institute**

Friday, January 29, 2010, 8:15 - 9:30 am, Capri Rooms 114-116

Speakers: Bill Klein and Heather Patrick

### **SSB1: APA Task Force Reports: Aiding, Advancing, and Applying Research**

Saturday, January 30, 2010, 8:15 - 9:30 am, Capri Rooms 103-106

Sponsored by the American Psychological Association

Chair: Steve Breckler, *Director of the APA Science Directorate*

Speakers: Steve Breckler, Susan Saegert, Brenda Major, Monica Biernat, Eileen Zurbiggen, Janet Swim

### **SSB2: Social Psychology in the Service of National Security: Collaboration Opportunities in Support of the Federal Security Clearance System**

Saturday, January 30, 2010, 8:15 - 9:30 am, Capri Rooms 107-110

Chairs: Bryan Castelda and John Capps, *Office of the Director of National Intelligence, Special Security Center*

Speakers: Eric L. Lang, Bryan A. Castelda, Verónica Benet-Martínez, Cynthia L. Pickett

## Invited Addresses

### **C1: Presidential Address**

#### **The Social Self: Egosystem or Ecosystem?**

Friday, January 29, 2010, 2:00 - 3:15 pm, Royale Pavilion 1

Speaker: Jennifer Crocker, *University of Michigan*

Introducer: Richard Petty, *Ohio State University*

### **E1: Campbell Award Address**

#### **Envy Up and Scorn Down: How Comparison Divides Us**

Friday, January 29, 2010, 5:00 - 6:15 pm, Royale Pavilion 1

Recipient: Susan T. Fiske, *Princeton University*

Introducer: Peter Glick, *Lawrence University*

Introducer:

### **G2: Keynote Panel**

#### **The Role of Genetics in Personality and Social Psychology**

Saturday, January 30, 2010, 11:15 am - 12:45 pm, Royale Pavilion 2

Chairs: William Fleeson, *Wake Forest University*, and Serena Chen, *University of California, Berkeley*

Panelist: Frances A. Champagne, *Columbia University*, **GENE-ENVIRONMENT INTERPLAY AND THE TRANSGENERATIONAL IMPACT OF THE SOCIAL ENVIRONMENT**

Panelist: Steve Cole, *David Geffen School of Medicine at UCLA*, **SOCIAL REGULATION OF GENE EXPRESSION IN HUMANS**

Panelist: Robert F. Krueger, *Washington University*, **GENES AND ENVIRONMENTS IN PERSONALITY AND SOCIAL PSYCHOLOGY: SOME REFLECTIONS ON SCIENTIFIC STRATEGIES**

Panelist: Eric Turkheimer, *University of Virginia*, **A NULL MODEL FOR THE GENETICS OF COMPLEX HUMAN BEHAVIOR**

### **H2: Block Award Address**

Saturday, January 30, 2010, 2:00 - 3:15 pm, Royale Pavilion 2

Recipient: Paul T. Costa, Jr., *National Institute of Aging*, **ON THE IMPORTANCE OF THE FFM PERSONALITY TRAITS**

Introducer: David C. Funder, *University of California, Riverside*

# Symposia & Special Sessions Schedule

## Friday, January 29 - Morning Sessions

Location	Special Session 8:15 - 9:30 am	Session A 9:45 - 11:00 am	Session B 11:15 am - 12:30 pm
Royale Pavilion 1		A1: Beyond Laboratory-Based Test Performance: Exploring The Far-Reaching Consequences and Implications of Stereotype Threat <i>Valerie Jones</i>	B1: Religion and Support of Violence Against the Outgroup <i>Ariel Malka</i>
Royale Pavilion 2		A2: Interpersonal Complementarity <i>Debbie S. Moskowitz</i>	B2: What is below the Big Five? Structure and utility of lower levels of analysis <i>Joshua Jackson</i>
Royale Pavilion 5		A3: Taken for Granted: The Influence of Family on Social Cognition, Social Behavior, and Well-Being <i>Belinda Campos</i>	B3: New Directions in the Study of Love: Neurobiological Perspectives <i>Joshua Poore</i>
Royale Pavilion 6		A4: Check All That Apply: The Psychological Costs and Benefits of Adopting a Multiracial Identity <i>Todd L. Pittinsky</i>	B4: Basic Building-blocks of the Social-Relational Mind <i>Lotte Thomsen</i>
Royale Pavilion 3-4		A5: Finding Mind: Attributing (and Denying) Inner Life to People, Machines and Gods <i>Kurt Gray</i>	B5: Perspectives on Moral Licensing: How Personal Moral History Affects the Entitlement to Transgress <i>Emily Zitek</i>
Royale Pavilion 7-8		A6: Feeling, thinking, and the body: Developments in embodied cognition <i>Norbert Schwarz</i>	B6: Culture and Emotion Regulation <i>Igor Grossmann</i>
Capri Rooms 101-102		A7: Cultural Ladders: Causes and Consequences of Social Hierarchy Depend on National and Regional Culture <i>Joe Magee</i>	B7: Social Image and Culture <i>Susan Cross</i>
Capri Rooms 103-106	S1: GSC Special Symposium - A Graduate Student's Guide to External Funding <i>Nicole E. Noll</i>	A8: Emotion regulation and self-control: Basic psychobiological mechanisms and applications to public health <i>Paige G. McDonald</i>	B8: The Two Faces of Verbal Mimicry: Does Linguistic Synchrony Predict Positive or Negative Social Outcomes? <i>Matt L. Newman</i>
Capri Rooms 107-110	S2: Funding Opportunities at the National Science Foundation <i>Kellina M. Craig-Henderson and Amber L. Story</i>	A9: Mediation and Moderation as Tools for Theory Development in Social and Personality Psychology <i>Patrick Shrout</i>	B9: Survey Says?: Investigating the Potential and Limits of Survey Research <i>Amanda Snook</i>
Capri Rooms 114-116	S3: Funding Opportunities at the National Cancer Institute	A10: Making Meaning: The Human Quest for Understanding and Coherence <i>Keith Markman</i>	B10: Experiential Needs and Behavioral Motives: Different things or same difference? <i>Kennon Sheldon</i>

## Friday, January 29 - Afternoon Sessions

Location	Session C 2:00 - 3:15 pm	Session D 3:30 - 4:45 pm	Session E 5:00 - 6:15 pm
Royale Pavilion 1	C1: Presidential Address: The Social Self: Egosystem or Ecosystem? <i>Jennifer Crocker</i>	D1: The Psychology of Status <i>Nir Halevy</i>	E1: Campbell Award Address: Envy Up and Scorn Down: How Comparison Divides Us <i>Susan T. Fiske</i>
Royale Pavilion 2	C2: The Person and the Political Mind: New Insights from Research on Values, Mindsets, Perceptions of the Nation, and Gender <i>Anat Bardi</i>	D2: Positive and Negative Evaluation in Self-Reported Personality <i>Eric Turkheimer</i>	E2: Personality Traits as Implicit Causal Theories about People <i>Jim Uleman</i>
Royale Pavilion 5	C3: Social psychology for an economic recession: Examining the effects of socioeconomic status on psychological processes <i>Natalya C. Maisel</i>	D3: The Science of Money and Relationships: Ways that Money Helps and Hurts Interpersonal Functioning <i>Peter Caprariello</i>	E3: Cognitive Underpinnings of Attachment Representations: Examining Relevant Knowledge Structures <i>Bulent Turan</i>
Royale Pavilion 6	C4: Contending with discrimination: Psychological, neurological, physiological, and behavioral consequences of attributional ambiguity <i>Jenessa R. Shapiro</i>	D4: The Nature, Causes and Consequences of Objectification <i>Steve Loughnan</i>	E4: Different Aspects of Essentialism: Looking across Race, Status, Religion, Age, and Sexual Orientation <i>Negin R. Toosi</i>
Royale Pavilion 3-4	C5: Accurate Self-Knowledge <i>C. Randall Colvin</i>	D5: Understanding Implicit and Explicit Attitudes: Exploring the Dual-Systems Perspective <i>Michael J. McCaslin</i>	E5: Giving them wings to fly: Advice for soon-to-be, new, and established faculty in the training of graduate students <i>Jamie Arndt</i>
Royale Pavilion 7-8		D6: Beyond Recognition: What are the Social (And Not-So-Social) Functions of Emotion Expressions? <i>Jessica L. Tracy</i>	E6: Biases in processing social cues: Links to early aversive experiences and functioning across the lifespan <i>Karin G. Coifman</i>
Capri Rooms 101-102		D7: The origins, predictors, and moderators of religious beliefs and involvement <i>Joni Sasaki</i>	
Capri Rooms 103-106		D8: Prohibitions and Punishments: Implications for Moral Psychology <i>Sana Sheikh</i>	
Capri Rooms 107-110		D9: A primer on social neuroscience methods for consumers and practitioners: Endocrinology, genetics, and neuroimaging <i>Elliot Berkman</i>	
Capri Rooms 114-116		D10: Existential Epistemology: The Science of Motivated Knowledge Construction <i>Joshua Hart</i>	

# Symposia & Special Sessions Schedule

## Saturday, January 30 - Morning Sessions

Location	Special Session 8:15 - 9:30 am	Session A 9:45 - 11:00 am	Session B 11:15 am - 12:30 pm
Royale Pavilion 1		F1: How Psychological Processes Shape Culture <i>Jonah Berger</i>	G1: "Gimme Five!" Tactile Communication and its Prosocial Consequences <i>Michael W. Kraus</i>
Royale Pavilion 2		F2: Panel Discussion: Forging connections between Social Media and Social/Personality Psychology <i>Samuel D. Gosling</i>	G2: Keynote Panel: The Role of Genetics in Personality and Social Psychology (11:15 am -12:45 pm) <i>William Fleeson and Serena Chen</i>
Royale Pavilion 5		F3: Self-regulation in response to rejection and social threat <i>Maire Ford</i>	G3: The Biology of the Attachment Bond <i>Paul Eastwick</i>
Royale Pavilion 6		F4: SPSP Diversity and Climate Committee Symposium A Multi-Stage Approach to Understanding Intergroup Contact: Challenges and Potential Solutions <i>Tamar Saguy</i>	G4: Beyond particularism in the study of intersectional identities: Building and testing general theories of identity intersectionality <i>Valerie Purdie-Vaughns</i>
Royale Pavilion 3-4		F5: Where am I? Cultural products and self-experience <i>Jean Twenge</i>	G5: New Insights into Social Evaluation Biases: From Brain to Behavior <i>Jennifer S. Beer</i>
Royale Pavilion 7-8		F6: Impulse and Reflection: Understanding Behavior and Moving Beyond the Implicit-Explicit Distinction <i>Michael Haefner</i>	
Capri Rooms 101-102		F7: The Selfish Origins of Selflessness: Integrating Evolutionary, Economic, and Psychological Models of Helping & Cooperation <i>Vladas Griskevicius</i>	
Capri Rooms 103-106	S4: APA Task Force Reports: Aiding, Advancing, and Applying Research, <i>Steve Breckler</i>	F8: Free Will, Moral Action, and Moral Responsibility <i>Yoel Inbar</i>	
Capri Rooms 107-110	S5: Social Psychology in the Service of National Security: Collaboration Opportunities in Support of the Federal Security Clearance System <i>Bryan Castelda</i>	F9: Outdoors Psychologists: Advancing Social Psychological Theory and Experimental Methods in the Field <i>Elizabeth Levy Paluck</i>	
Capri Rooms 114-116		F10: Embodied Motivation: Implications of Body Feedback for Fundamental Processes Underlying Motivated Action <i>Nils B. Jostmann</i>	

## Saturday, January 30 - Afternoon Session

Location	Session C 2:00 - 3:15 pm	Session D 3:30 - 4:45 pm	Session E 5:00 - 6:15 pm
Royale Pavilion 1	H1: Power and the (Narcissistic) Self: The Effects of Power on Self Perception, Self Presentation, Goals for the Self, and Ethical Decision Making, <i>Nathanael J. Fast</i>	I1: United and Divided We Stand: On the Collective and Personal Functions of Conformity and Dissent <i>Kimberly Rios Morrison</i>	J1: Working Together or Tearing Each Other Down: How Members of Low Status Groups Treat the Ingroup <i>Kerry Spalding</i>
Royale Pavilion 2	H2: Block Award Address On the Importance of the FFM Personality Traits <i>Paul T. Costa, Jr.</i>	I2: Redrawing the Big Picture: From Personality Data (Back) to Personality Theory <i>Daniel Cervone</i>	J2: Understanding Narcissism: Modern, Empirical Approaches to Classic Controversies <i>Ryan Brown</i>
Royale Pavilion 5	H3: Balancing Closeness and Distance in Intimate Relationships <i>Gertraud Stadler</i>	I3: A biopsychosocial model of threats to social belonging: Perspectives from across the spectrum of social psychology <i>Lisa M. Jaremka</i>	J3: Contextualizing Interpersonal Communication: When "Positive" Behaviors are Negative and "Negative" Behaviors are Positive <i>James K. McNulty</i>
Royale Pavilion 6	H4: How we feel about 'them': Emotional responses to outgroups' pleasures and pains <i>Mina Cikara</i>	I4: The Age of Obama: A New Era of Race Relations, or a New Era of Modern Racism? <i>Clayton R. Critcher</i>	J4: The Social Face: How Social Categorization Influences Face Perception <i>Kurt Hugenberg</i>
Royale Pavilion 3-4	H5: Do I belong here? Identifying Factors that Fortify vs. Attenuate Women's Sense of Belonging in Stereotypically Masculine Academic and Professional Domains <i>Jane Stout</i>	I5: What's so special about the self? Or is there anything special at all? <i>Kurt Peters</i>	J5: The Psychological Meaning of Things and Places <i>Alison Ledgerwood</i>
Royale Pavilion 7-8	H6: The Differentiation of Positive Emotions: Recent Advances in Theory and Research on Positive Emotions <i>Michele M. Tugade</i>	I6: Achieving Sustainable Happiness: Pathways and Pitfalls <i>Lara Aknin</i>	J6: The Social Ecology of Emotional Disclosure <i>Kent Harber</i>
Capri Rooms 101-102		I7: Sex, Status, Power and Penalties for Gender Deviance: New Directions in Backlash Research <i>Corinne Moss-Racusin</i>	J7: Distinct and Common Effects of Various Psychological Threats <i>Gale M. Lucas</i>
Capri Rooms 103-106		I8: A New Look on Automatic Behavior: Modulation, Integration and Consequences <i>Kai Jonas</i>	J8: Conscious and Unconscious Thought in Decision-Making <i>Daniel Wegner</i>
Capri Rooms 107-110		I9: The dynamic social mind <i>Melissa Ferguson</i>	J9: When and How Social Comparative Standing Impacts Well-being and Affect <i>Jason P. Rose</i>
Capri Rooms 114-116		I10: How to Survive Sin City: The Role of Cognitive Control in Fighting Temptation <i>Wilhelm Hofmann</i>	J10: For the love of the frame: Motivational sources of variation in effectiveness of health messages <i>Tamara Sims</i>

# Poster Schedule

Poster sessions are scheduled on Thursday, January 28, Friday, January 29, and Saturday, January 30. The presenting author must be present at least one full hour during the assigned session and the other authors should be present during the remaining time. The following times indicate when you are expected to set-up and take-down your poster. Note that we are asking you to leave your poster up for longer than the formal session. This will allow people to look at your poster throughout the day. You should plan to be at your poster from the start until the end of your formal session.

The doors to the poster room will open at 6:30 pm on Thursday and at 7:45 am on Friday and Saturday for poster authors who are setting up their posters only. The room will not be open to the rest of the attendees until the exhibits open hour in the schedule of events. You may post your materials on the board assigned to you starting at the scheduled "Set-up Begins" time shown below. Please note that any posters not removed by "Take-down Complete" time will be discarded. The doors will close and lock for the evening at 8:45 pm on Thursday and 8:00 pm on Friday and Saturday. There is no re-entry after this time. Do not leave personal items in the poster room.

Poster Session	Date & Time	Set-up Begins	Session Begins	Session Ends	Take-down Complete	Self-Identified Keywords Included
A	Thursday, January 28	6:30 pm	7:00 pm	8:30 pm	8:45 pm	Close Relationships/Belonging/Rejection; Emotion, Motivation/Goals; Person Perception/Impression Formation; Self/Identity; Social Judgment/Decision-Making; Stereotyping/Prejudice
B	Friday, January 29	7:45 am	8:00 am	9:30 am	12:15 pm	Applied Social Psychology; Gender; Individual Differences; Intergroup Relations; Mental Health; Motivation/Goals; Other; Prosocial Behavior; Psychophysiology/Genetics; Social; Social Development; Social Judgment/Decision-Making; Social Neuroscience; Social Support
C	Friday, January 29	12:15 pm	12:30 pm	2:00 pm	6:00 pm	Aggression/Anti-Social; Aggression/Anti-Social Behavior; Attitudes/Persuasion; Close Relationships/Belonging/Rejection; Groups/Intragroup Processes; Norms and Social Influence; Self-Regulation; Self/Identity
D	Friday, January 29	6:00 pm	6:15 pm	7:45 pm	8:00 pm	Culture; Emotion; Lifespan Development; Methods/Statistics; Person Perception/Impression Formation; Personality Processes; Self-Esteem; Stereotyping/Prejudice; Traits; Well-Being
E	Saturday, January 30	7:45 am	8:00 am	9:30 am	12:15 am	Assessment; Attitudes/Persuasion; Emotion; Evolution; Gender; Intergroup Relations; Norms and Social Influence; Other; Personality Processes; Physical Health; Self-Esteem; Social; Social Judgment/Decision-Making
F	Saturday, January 30	12:15 pm	12:30 pm	2:00 pm	6:00 pm	Culture; Groups/Intragroup Processes; Individual Differences; Motivation/Goals; Not Specified; Person Perception/Impression Formation; Prosocial Behavior; Stereotyping/Prejudice; Well-Being
G	Saturday, January 30	6:00 pm	6:15 pm	7:45 pm	8:00 pm	Applied Social Psychology; Attitudes/Persuasion; Close Relationships/Belonging/Rejection; Intergroup Relations; Self-Regulation; Self/Identity; Social Judgment/Decision-Making

# SPSP 2010 Exhibitors

**SAGE**

**Sona-Systems Ltd.**

**Tobii Technology**

**W.W. Norton & Company**

**Wadsworth Cengage Learning**

**Wiley**

Please visit our exhibitors in the Grande Ballroom. Exhibit hours are:

Thursday, January 28, 6:30 - 8:30 pm

Friday, January 29, 8:00 am - 8:00 pm

Saturday, January 30, 8:00 am - 8:00 pm

## **Future Meetings**

SPSP 2011 will be held January 27-29, 2011, in San Antonio, Texas.

SPSP 2012 will be held in San Diego, California.

# Graduate Student Committee Events

The Graduate Student Committee (GSC) endorses SPSP goals and represents the interests, concerns, and ideas of its graduate students. We serve as liaisons between students and those more advanced in the field. The Graduate Student Committee (GSC) is pleased to be hosting several student-oriented events and the Graduate Student Poster Award program at the 2010 SPSP Conference. The Poster Award and Mentoring Lunch are returning by popular demand. In addition, we are hosting a Preconference, a Symposium, and a Poster that cover various professional topics. This page contains a detailed description of each event. We encourage you to attend and show your support for these programs so that they may continue in the future!

## **GSC Co-Sponsored Preconference Bridge(s) Over Troubled Waters: Traditional and Non-Traditional Careers for Personality and Social Psychologists**

*Thursday, 8:30 am - 4:30pm, Capri Rooms 109 & 110*

Dwindling support from state legislatures, shrinking investments and endowments, hiring freezes, and delays in the retirement plans of senior academics—to name but a few consequences of the downturn in the U.S. economy—mean that graduate students may be forced to consider alternatives to traditional career trajectories. This pre-conference is designed to provide attendees with information on both traditional (i.e., postdoctoral positions and tenure-track positions in research universities and four-year colleges) and non-traditional career options for personality and social psychologists, including academic appointments outside psychology departments, appointments in universities outside the U.S., and work in both the public and private sectors. A number of distinguished personality and social psychologists who have pursued both traditional and non-traditional career paths will speak of unique challenges and opportunities, both inside and outside academia. Among the topics to be covered: the work demands of traditional and non-traditional careers for personality and social psychologists; similarities and differences in securing professional positions; and the skills that it takes to succeed. In short, this pre-conference should be valuable and relevant for both junior psychologists who face immediate career challenges, and for senior psychologists for whom information will be valuable as they train the next generation of personality and social psychologists.

Given the intended training orientation of this pre-conference, ample time is reserved for questions and audience involvement. In particular, a roundtable lunch hour will present pre-conference attendees with the opportunity to discuss and receive feedback from speakers about career options. In addition, to round out the day, there will be panel discussion in which audience members can ask the speakers about the ins-and-outs of pursuing both traditional and non-traditional careers informed by expertise in personality and social psychology.

## **GSC Special Symposium A Graduate Student's Guide to External Funding**

*Friday, 8:15 - 9:30 am, Capri Rooms 103-106*

External funding is a topic of critical interest to graduate students and faculty alike. Yet for many academics, applying for grants and fellowships is a somewhat daunting task. In this symposium, our goal is to make that task more manageable by outlining the funding application process from several perspectives. Jenessa Shapiro will share lessons she learned as a graduate student applying for grants from various agencies and offer tips for success. Amber Story will explain the funding process at the National Science Foundation and give advice from the agency's perspective. Laura King will draw on her experience as a grant review panelist to provide insights as to what grant reviewers are looking for and the value of the proposal-writing process. The session will conclude with a discussion panel to address audience members' questions. This symposium will benefit both graduate students—by informing them of the ins and outs of graduate funding—and faculty—by arming them with knowledge they can pass on to their graduate students.

## **Mentoring Luncheon**

*Friday and Saturday, 1:00 - 2:00 pm, Top of Riv, North*

The mentoring lunch offers graduate students an informal opportunity to discuss their research interests and career development with an established professional in the field. The mentoring lunch will be held both days, providing over 300 students the opportunity to participate. Pre-registration for this event is necessary.

## Graduate Student Committee Poster **What Graduate Students Want Faculty to Know**

*Saturday, 6:15 - 7:45 pm, Session G, Grande Ballroom*

Do you ever wonder how your graduate school experience is similar to or different from the experiences of other graduate students? The SPSP GSC asked, and approximately 250 graduate students answered, providing their feelings and opinions about their advisors, their departments, their graduate coursework, their teaching requirements, their career aspirations, and more! Check out what we found. It is sure to be enlightening!

## **GSC Student Poster Award**

*Ongoing throughout the conference in the Grande Ballroom*

The GSC is hosting the Student Poster Award (SPA) again for the eighth year! Contenders submitted their poster abstracts for consideration last fall, and peer reviewers selected finalists to be judged in Las Vegas. Finalists are interviewed by secret judges throughout their poster session, and these judges select the winners. Three awards will be given out in each poster session—one First-Place award and two Runner-Up awards—to students whose poster presentation reflects excellence in research, clarity in presentation, and personal knowledge in a discussion with the judges. Award winners receive a small monetary prize, hardware and software provided by Empirisoft, and public recognition for their achievement.

# SPSP Diversity Program

In order to increase diversity within personality and social psychology and to foster a supportive climate, SPSP's Diversity and Climate Committee (DCC) sponsors four initiatives to facilitate the career development of members who come from underrepresented groups.

1. **The Diversity Fund Travel Award:** Each year qualified graduate students from underrepresented groups are invited to apply for travel awards to help defray the costs of attending the annual SPSP conference. This year 104 graduate students applied for a Diversity Fund Travel Award and 24 applicants received the award. Awardees received \$500 for travel expenses. They will also attend a diversity reception at the conference where they will have an opportunity to meet and chat individually with senior social psychologists who they admire and whose work has influenced their own intellectual development.

2. **The Undergraduate Diversity Registration Award:** Each year qualified undergraduate students who belong to underrepresented groups are invited to apply for awards that cover the cost of registering for the SPSP conference. Approximately 30 applicants received this award this year. Undergraduate awardees will also attend the diversity reception at the conference to meet graduate students and faculty interested in issues of diversity in social psychology.

3. This year we launched a new mentoring lunch for graduate students, postdocs, and young faculty associated with the Gay Alliance in Social Psychology (GASP). Our goal is to create a space for professional and social networking among social and personality psychologists who identify as gay, lesbian, bisexual, or transgender (GLBT) and/or whose research focuses on issues of sexuality. This lunch is being hosted jointly by the DCC and GASP.

4. Finally, the Diversity and Climate Committee sponsors a symposium at each year's SPSP conference that is closely related to issues of diversity. This year's symposium is entitled "A Multi-Stage Approach to Understanding Intergroup Contact: Challenges and Potential Solutions" scheduled for Saturday from 9:45-11:00 AM.

The Diversity and Climate Committee would like to thank individual SPSP members for their contributions to the Diversity Fund. Members may donate directly to the Diversity Program when paying the yearly SPSP membership dues. Members may also contribute by providing their ideas for additional initiatives by contacting any of the members on the Diversity and Climate Committee (Nilanjana Dasgupta, Denise Sekaquaptewa, and Keith Maddox).

## SPSP Diversity Fund Award Recipients

**Kathleen Bogart** grew up in Baton Rouge, Louisiana. She received her masters' degree in Social Psychology at San Francisco State University where she completed her thesis entitled Facial Expression Recognition, Social Competence, and Adjustment in People with Moebius Syndrome. She is currently a Psychology PhD student at Tufts University. She studies the psychological and social implications of facial paralysis. One of the most significant consequences of

facial paralysis is a face that is inexpressive of one's emotions and unresponsive during social interaction. Her present research examines how people with different types of facial paralysis communicate and how others perceive the emotions and traits of these individuals. She plans to pursue a career in academic research to build the knowledge about the psychology of facial paralysis.

**Tiffany Brannon** is a native of South Florida. Currently, she is a third year Ph.D. student in Social Psychology at Stanford University. Working with her primary advisor, Hazel Markus, she investigates dual cultural identities in African Americans. The goal of this work is to examine how mainstream American and African American culture contexts shape identity and psychological processes for African Americans. In another line of research, Tiffany works with Gregory Walton to examine the influence of social connections and enacting cultural behaviors on prejudice reduction. Tiffany's other research interests include academic disengagement and morality. Tiffany is currently the recipient of fellowships from the Ford Foundation and Stanford Center on International Conflict and Resolution (SCICN). Upon completing her doctorate, Tiffany aspires to become a research professor.

**Priyanka Carr** was born in Bombay, India and moved to Los Angeles, California in junior-high. She received her B.A. in psychology from Williams College in 2007. Her interest in social psychology was piqued there as she conducted research on stereotype threat and culture with Dr. Steven Fein. After graduation, she headed back to a warmer climate: She is currently a third-year Ph.D. student in social psychology at Stanford University. Her research examines stereotypes, achievement, and motivation. With Dr. Carol Dweck, she explores ways of increasing women's comfort and ease in conversations about science and thereby their interest in pursuing careers in science. In another line of research with Dr. Claude Steele, she investi-

gates stereotype threat's effects on cognitive flexibility and decision-making. With Dr. Greg Walton, she examines how minimal social connections can boost motivation and enhance performance. Priyanka plans to pursue a career in academia, conducting research and mentoring students.

**Jacqueline Chen** grew up in Moraga, California and Waterloo, Belgium. She received her B.A. in psychology with a minor in mathematics from Pomona College in 2007. Jackie is a doctoral candidate in social psychology working with Dr. David Hamilton at the University of California Santa Barbara. She conducts research with the hope of facilitating positive intergroup relations in today's demographically diverse society. Currently, she is studying monoracials' perceptions and categorizations of multiracial individuals. Jackie also works with Dr. Diane Mackie, extending Intergroup Emotions Theory, and with Dr. Heejung Kim on cultural differences in the provision of social support and its perceived effectiveness. Upon completing her PhD, Jackie plans to pursue a career as a research psychologist in an academic setting.

ceptions and categorizations of multiracial individuals. Jackie also works with Dr. Diane Mackie, extending Intergroup Emotions Theory, and with Dr. Heejung Kim on cultural differences in the provision of social support and its perceived effectiveness. Upon completing her PhD, Jackie plans to pursue a career as a research psychologist in an academic setting.

**William T.L. Cox** completed a B.S. in Psychology at the University of Florida and is currently in his third year of his PhD in Social Psychology at the University of Wisconsin - Madison. He researches stereotyping and prejudice with Dr. Patricia Devine. One of his projects involves tracking race bias over Barack Obama's presidency, which is an outgrowth of his recent JESP paper, "The Obama Effect: Decreasing Implicit Prejudice and Stereotyping". Will is also developing and testing a theory that stereotyping may function directionally. For example, one can readily identify a target's race, and then stereotype (e.g., assuming a Black man is athletic), but in the case of concealable minorities, one may use stereotyping to identify group membership (e.g., inferring that a man who likes shopping is gay). Addressing the directionality of stereotyping will help advance research on stereotype formation/maintenance, and will help develop better stereotyping interventions.

oping and testing a theory that stereotyping may function directionally. For example, one can readily identify a target's race, and then stereotype (e.g., assuming a Black man is athletic), but in the case of concealable minorities, one may use stereotyping to identify group membership (e.g., inferring that a man who likes shopping is gay). Addressing the directionality of stereotyping will help advance research on stereotype formation/maintenance, and will help develop better stereotyping interventions.

**Priscila Diaz** was born and raised in Blythe, a small desert(ed) town in southern California. Although she loved Blythe, she moved to beautiful San Diego and became a Career Opportunities in Research Scholar under the mentorship of Dr. Terry Cronan and Dr. Thierry Devos at San Diego State University. She graduated (at the top of her class) with a B.A. in Psychology in 2005. A National Science Foundation Graduate Fellow and an American Psychological Association

Minority Fellow, she is currently working on her dissertation at Arizona State University where she works with mentors Dr. Delia Saenz and Dr. Virginia Kwan. Priscila's research goals are to examine the resiliency provided by one's culture when culturally related negative events occur (stereotyping, discrimination) and how the

adaptation of bicultural individuals influences their health decision-making and functioning. After obtaining her Ph.D., Priscila will continue to pursue her research goals and teach at a university.

**Amanda Taylor Eggen** grew up in Texas and Louisiana, and completed a Bachelor of Science degree at Texas A&M University. She identified her enthusiasm for cultural research while working in Vietnam and Ethiopia as an English instructor for several years. Currently a second-year Ph.D. student at University of Wisconsin-Madison, she works with Dr. Yuri Miyamoto. Amanda's research examines cultural differences in explicit and implicit communication practices

and their consequences for relationships. She also has a longitudinal study underway to examine how cognition and communication styles of UW international students change through interactions with Americans, and what that means for their well-being. Building on these studies, she hopes to design an intervention program to improve acculturation experiences for migrants. After completing her Ph.D., Amanda intends to continue these lines of research while teaching cultural and social psychology at a major university.

**Jennifer Gutsell** was born and raised in Hamburg, Germany. After she completed her undergraduate studies at the University of Konstanz, she moved to Canada for graduate school at the University of Toronto. Working with Michael Inzlicht, Jennifer's research interests fall under two central themes. The first examines the relationship between prejudice and interpersonal sensitivity. She finds that, with increasing levels of prejudice, neural simulation - a neural process underlying

many forms of interpersonal sensitivity - is reduced for outgroup members. In her second line of research, Jennifer looks at self-control and how its failure is related to emotional reactivity. Her research suggests that in a state of depleted resources for self-control, people are less emotionally reactive. Upon completion of her Ph.D., Jennifer hopes to continue her research as well as to strike new interesting directions, as a professor at a research oriented University in North America or Europe.

**Arnold Ho** was born and raised in the San Francisco Bay Area, and received a B.A. in Psychology, with highest honors, from the University of California, Davis. He is currently a Ph.D. student in the Department of Psychology at Harvard University, where he studies social perceptions, attitudes, and beliefs that function to maintain social hierarchies. In collaboration with Jim Sidanius and Mahzarin Banaji, he examines the perception of multiracial individuals, with a

focus on the rule of hypodescent (i.e., ascription of such individuals to the socially less advantaged parent group). With Jim Sidanius and Felicia Pratto, he studies hierarchy enhancing attitudes and beliefs and individual differences in the preference for group-based hierar-

chy (i.e., social dominance orientation). Arnold plans to pursue a career in research and teaching at a research-oriented university.

**Deanna Jackson** received her B.A. in Psychology from Hollins University in Roanoke, VA in 2006 while studying under Dr. Richard Michalski. She is currently a third-year PhD student in the Social and Personality Psychology program at Florida Atlantic University. She studies humans as dynamical systems under her advisor Dr. Robin R. Vallacher. She has recently run experiments examining how power affected emotional and behavioral synchronization as well as an

empirical analysis of the phase angles and statistical properties of behavioral synchronization. Deanna's major research aims are examining the dynamical processes that drive the formation and dissolution of social groups and how synchronization could lead to the emergence of societal properties such as norms, scripts, and stereotypes. After Deanna finishes her PhD, she would like to pursue a career in academia performing research and mentoring students.

**Anjali Mishra** was born and raised in New Delhi, India. She came to the United States in 2003 to pursue a B.A. in Psychology at George Mason University, Virginia. Currently, she is a third year student in the Social-Personality Psychology Ph.D. program at the University of California, Davis, and works under the supervision of Dr. Robert Emmons. Her undergraduate honors thesis focused on age and gender differences in the experience, evaluation, and expression of gratitude.

More recently, via daily writing intervention studies, she has been examining the contribution of gratitude and meaning in life to the process of posttraumatic growth and psychological well being. In future, besides her current research, she plans to explore (a) the effects of positive psychological interventions, particularly gratitude, on the quality of romantic relationships, (b) the influence of gratitude on cognitive processes (e.g., self-conceptions and construction of a personal history across the life span), and (c) appraisals and experience of gratitude across cultures. After completing her Ph.D., Anjali plans to pursue a career in academia where she can continue her research and teach.

**Shanette Porter** is a native of Buffalo, NY. She received her B.A. in psychology from Yale University and her M.A. in industrial-organizational psychology from Michigan State University, where she was a recipient of the University Distinguished Fellowship. Currently, she is a fifth year Ph.D. student at Cornell University. Broadly, her research interests include intergroup processes, prejudice and stereotyping, and nonconscious goal pursuit. In collaboration with her advisor, Melissa Ferguson, much of her research has focused on the

impact of national identity on behavior, stereotyping, and intergroup attitudes and beliefs. Among other questions, this research addresses how subtle versus blatant reminders of identity can influ-

ence individuals' momentary cognitions and evaluations, and even predict their behavior days later. She also researches the mechanisms of nonconscious goal pursuit and the effects of language level of abstraction on audience impressions. After receiving her Ph.D., Shanette plans to pursue opportunities in both academia and industry.

**Stephanie Quezada** was born and raised in El Paso, Texas. She received her B.A. in Psychology from Vassar College where her interests in Social Psychology began under the guidance of Dr. Michele M. Tugade and Dr. Jennifer Ma. Stephanie is currently a second year Ph.D. student at the University of Texas at El Paso where she is pursuing her degree under the mentorship of Dr. Michael A. Zárate. Her research examines intergroup conflict among diverse popu-

lations. She is currently investigating the theory of cultural inertia, and is examining the extent to which cultural change threatens or affirms one's cultural identity. She is interested in understanding why cultural change is accepted or resisted by ethnic majority and minority groups. Upon obtaining her Ph.D., Stephanie plans to pursue a career in an applied field relevant to the effects of culture on intergroup conflict.

**Jessica Remedios** grew up in a small town near St. John's, Newfoundland, Canada and moved to Toronto, Ontario to attend university. She completed her Honours B.Sc. in Psychology at the University of Toronto at Scarborough and also received her M.A. in Psychology from the University of Toronto. Jessica, a second-year Ph.D. student, and her advisor, Dr. Alison Chasteen, currently examine group processes related to stereotyping, prejudice and discrimina-

tion behaviours. Primarily, Jessica is interested in how these processes affect individuals with "complex" identities. In one line of work, she examines the unique stigma-related concerns that multiracial people hold. In a second line of research, Jessica explores the strategies used by women of colour to cope with the multiple forms of prejudice that they experience in their daily lives. After obtaining her Ph.D., Jessica plans to conduct research, teach, and mentor undergraduate and graduate students at a research-oriented university.

**Jo Sasota** was born in the Philippines and grew up in Grand Rapids, MI. He received his B. S. in Psychology from the University of Michigan in 2006. He is currently a fourth-year graduate student in Social Psychology at The Ohio State University with Dr. Kentaro Fujita and Dr. William Cunningham and a Department Homeland Security Fellow. The bulk of his basic scientific research lies at the intersection of motivation and cognition with other lines of research examining

the psychological processes that underlie real-world behavior. He, along with his collaborators, have examined how narrative appeals

as opposed to rhetorical appeals increase persuasion towards social policies like affirmative action. In another line of research, they have examined how constructions of the self, self-construals, influence risk taking in a variety of domains.

**Krishna Savani** was born in New Jersey but grew up in western India. He returned to the U.S. for college got his B.A. in Economics at Stanford University. After conducting research in experimental economics, he changed course and decided to pursue a Ph.D. in Psychology, also at Stanford. He is currently a fifth year student working with Dr. Hazel Rose Markus and Dr. Carol S. Dweck. His research interests lie at the intersection of cultural psychology and decision-making,

with a focus on Indian cultural contexts. He has examined cultural variation in the extent to which people construe everyday actions as choices, the consistency between people's choices and evaluations, interpersonal influence and accommodation, and people's beliefs about intelligence and emotion. After his Ph.D., he plans to focus on developing interventions that would help improve people's well-being in educational and organizational settings, with a focus on individuals in cultural transition.

**Roberta Schriber**, a native Houstonian, received her B.A. in Psychology at Reed College in Portland, OR, and is now a fourth-year graduate student at the University of California, Davis. Under the supervision of Dr. Richard Robins, she is examining interpersonal perception and personality Processes as they relate to the experience and expression of the self and emotion. Accordingly, a major anchor for her research is the consideration of "self-conscious emotions" (e.g., pride, embarrassment, shame, and guilt).

Her current line of research investigates how the nonverbal expression of self-conscious emotions affects trait impressions, including whether such behavior might be uniquely suited for exposing, or seeming to expose, such characteristics as a target's level of self-consciousness, self-esteem, narcissism, and differential proclivities to (want to) "get along" versus "get ahead". Moreover, she is interested in how these characteristics in a perceiver might bias his impressions. A tightly overlapping line of research will pursue these questions in contexts of status and power. Like many of her colleagues, Roberta plans to stay in research and academia.

**Tamara Sims** is a first generation college graduate originally from Victorville, CA. She received a B.A. in Psychology from UCLA and a M.A. in Research Psychology from California State University Long Beach. She is now a 4th year Psychology Ph.D. student at Stanford University in the Personality, Psychopathology and Affective Science area. She recently received a Ruth L. Kirschstein NRSA to Promote Diversity in Health-Related Research to study cultural

differences in health care preferences across the life span. With her

advisor, Jeanne Tsai, she is examining ideal affect as one possible source of ethnic differences in health care utilization. She is also interested in how cultural differences in approaches to aging may affect how well people prepare for and adapt to old age. In her future work, she hopes to apply her findings to develop culturally appropriate interventions that optimize health care decisions among underrepresented groups.

**Deborah Son** was born in Chicago, Illinois, but spent her early childhood growing up in South Korea. She received her B.A. in psychology from Northwestern University, where she studied the role of political orientation on interracial romantic attraction with Drs. Jennifer Richeson, Eli Finkel, and Paul Eastwick. Currently, Deborah is a second-year graduate student at Princeton University. Her research with advisors Dr. Nicole Shelton and Dr. Deborah Prentice broadly

address ways to improve intergroup relationships. One line of research investigates attributions to cultural differences to excuse close outgroup friends' negative behaviors. A separate project examines the influence of colorblind and multicultural ideologies on racial minorities' cognitive outcomes during interracial interactions. After obtaining her Ph.D., Deborah plans to pursue an academic career and improve intergroup relations through teaching and research.

**Karen Sixkiller** received her B.S. from the University of Washington, Seattle; and is now pursuing her Ph.D. in Personality Psychology at the University of Illinois, Champaign-Urbana. Her research focuses on the neurophysiology of personality and personality development. Using electroencephalograph (EEG) and functional magnetic resonance imaging (fMRI) technologies, she hopes to document the physiological "location" of personality traits in the brain as they pertain

to relevant patterns of thoughts, feelings and behaviors. Once the physiological indicators are identified, they can be tracked in a longitudinal study of age related personality change. These Neurophysiological landmarks can then serve as objective measurements of personality change due to intervention. Upon completing her graduate studies, Ms. Sixkiller intends to continue developing her research while pursuing a career in academia.

**John Oliver Siy** grew up in a suburb north of Chicago, IL. He obtained his bachelor's degree in psychology from the University of Illinois. A National Science Foundation Graduate Fellow, he is currently a second-year social psychology graduate student at University of Washington. Broadly, his research interests include stereotypes, identity, and belonging. In collaboration with his advisor Dr. Sapna Cheryan, he currently has three lines of inquiry: 1) what are the negative

consequences of positive stereotypes, 2) what factors deter women from participating in the field of computer science, and 3) who is

considered a sellout? Upon completing his graduate studies, he intends to pursue a career in research.

**Negin Toosi** was born in Iran but fled the country soon afterwards with her family to escape religious persecution. She was raised deep in the heart of Texas, and went to Stanford University to receive a B.A. in psychology and international relations. She is currently working on her dissertation under the brilliant supervision of Dr. Nalini Ambady at Tufts University. Negin is interested in examining, crossing, and blurring the lines that are typically drawn between

different social groups. Her research focuses on social identities including race, gender, culture, and religion, and the ways they intersect and shape each other in the realms of essentialism, non-verbal behavior, stereotyping, and group dynamics. She plans to pursue a career in academia upon completion of her graduate studies, and purposefully do her part to contribute to the betterment of the world.

**Matt Trujillo** was born and raised in Phoenix, AZ. He received his B.S. in Psychology, with a minor in sociology from Arizona State University. He is currently in his second year of graduate study at Princeton University. At Princeton he is enrolled in the Joint Degree Program of Psychology and Public Policy. Generally speaking his interests lie in ethnic identity, prejudice, and stereotyping. Under his advisor Nicole Shelton he investigates people's reactions to misperceptions of

their ethnicity. He, with Joel Cooper, is also conducting research applying vicarious cognitive dissonance theory to prejudice. Matt's ultimate career goal is to become a professor where he can conduct research as well as share his passion for psychology through teaching.

**Elena Wright** received a Bachelor's Degree with Honors from Stanford University, where she studied emotion regulation and attentional deployment with James Gross. She is currently a second-year graduate student in Clinical Psychology at Yale University, where she works with Doug Mennin and Jack Dovidio. She has continued to study interpersonal emotion regulation and anxiety, and is also interested in identifying positive coping mechanisms for

minorities exposed to ambiguous versus overt racism. After graduate school, Elena hopes to continue working in academia and exploring ways to integrate clinical and social psychology.

GASP, the GLBT Alliance in Social and Personality Psychology, is an official affiliate of the Society for Personality and Social Psychology. Membership is open to all, regardless of sexual orientation or research interest. GASP provides social support and professional resources to Gay, Lesbian, Bisexual, and Transgender students and faculty in social and personality psychology. GASP's major goals are to maintain a safe and welcoming professional forum for LGBT students and faculty and their heterosexual allies, and to serve as a resource for researchers, teachers, and other professionals.

## Website and Listserv

Find us on the web at <http://www.psych.utah.edu/gasp/>

Our private moderated listserv sends noncommercial postings about GLBT research and professional issues to more than 270 members worldwide. To subscribe, <http://lists.csbs.utah.edu/listinfo.cgi/gasp>

## GASP Measures Database

Searchable database of measures designed for GLBT issues or populations, <https://apps.psych.utah.edu/psych/gasp/newdbindex.jsp>

## Contact Information

GASP was founded by Lisa G. Aspinwall and Lisa M. Diamond, both members of the psychology faculty at the University of Utah. You may reach us at [gaspmail@earthlink.net](mailto:gaspmail@earthlink.net)

# General Information

## Audiovisual Equipment for Talks

LCD projectors (for PowerPoint presentations) are provided in all rooms where spoken sessions are scheduled; however, computers are NOT provided. Presenters must bring their own computers and set them up BEFORE the start of the session in which they are presenting. Equipment is provided to allow several computers to be connected to the LCD projector in a room. Presenters are strongly encouraged to arrive in their scheduled symposium room a minimum of 30 minutes before their talk so that they know how to set up their equipment.

Overhead projectors are NOT provided unless the speaker has specifically requested such equipment.

## Automatic Teller Machine (ATM)

An ATM is located in the convention center lobby outside Capri Room 101. Please see the information desk for information about the location of a specific bank.

## Baggage Check

SPSP attendees staying at the Riviera Hotel may utilize the free baggage check at the Bell Desk adjacent the Front Desk in the main hotel foyer.

## Business Center

The Business Center located within easy walking distance to your guestroom or convention location, offers full business services including fax, copying, computer and secretarial services, Notary service, shipping and receiving, office supplies, printing and temporary support personnel.

Monday - Friday, 7:00 am - 6:00 pm  
Saturday and Sunday, 8:00 am - 5:00 pm

## Certificate of Attendance

To receive a Certificate of Attendance please visit the Registration Desk in the Grande Ballroom Foyer. If you require any amendments, we will be happy to email or mail a copy after the meeting. See also Receipts.

## Chair People

Please ensure that you are in your presentation room at least thirty minutes before the start of the session. It is the responsibility of the symposium chair to ensure that the session starts and ends on time.

## Contact Us

To contact us onsite, visit the Registration Desk, or send an email to [SPSP\\_Registration@TaraMillerEvents.com](mailto:SPSP_Registration@TaraMillerEvents.com). We will respond to your email at our soonest opportunity.

## Hotel Services

The Riviera Hotel and Casino is our exclusive hotel for the SPSP 2010 Annual Meeting. All SPSP 2010 meeting events are held at the Convention Center attached to the hotel.

The Riviera Hotel and Casino offers the following services.

*Aqua Massage Relaxation Station* - Soothing therapeutic massage. Located near Le Bistro Theatre.

*Bell Desk* - Assistance with luggage, packages and other carry-ons, plus call service for laundry. Located next to the Front Desk.

*Box Office* - Riviera show information and ticket reservations. Located next to the Le Bistro Theatre.

*Hertz Car Rental* - Daily and weekly rates available. Located in the Mediterranean South Tower Lobby.

*Jitters Coffee* - Gourmet coffee, pastries and sandwiches. Located near the Front Desk.

## Food Service

Complimentary food and beverage is available to all attendees at the following times in the Grande Ballroom.

*Thursday*

Welcome Reception, 7:00 - 8:00 pm

*Friday and Saturday*

Continental Breakfast, 8:30 - 9:00 am

Coffee Break, 11:00 - 11:15 am

Boxed Lunch, 12:30 - 1:30 pm

Coffee Break, 3:15 - 3:30 pm

## Internet Access

Free Internet terminals are located in the Grande Ballroom Foyer near the SPSP Registration Desk. Internet terminals are available during meeting registration hours on Friday and Saturday when not needed for onsite registration. See Onsite Meeting Registration.

## Lost & Found

Please check with the SPSP Registration Desk for any items lost and found.

Found items at the end of the conference will be taken to Hotel Security and held for claim up to 6 months.

## Meeting Rooms

Meeting rooms for symposia and special sessions are on the ground floor of The Riviera Convention Center.

## Messages

A bulletin board will be available for messages and job postings near the SPSP Registration Desk in the Convention Center foyer.

## Mobile Phones

Attendees are asked to silence their mobile phones when in sessions.

## Name Badges

The Riviera Hotel and Convention Center is open to public access. For security purposes, attendees, speakers and exhibitors are asked to wear their name badges to all sessions and social functions.

Entrance into sessions is restricted to registered attendees only. Entrance to the Exhibition is limited to badge holders only. If you misplace your name badge, please go to the SPSP Registration Desk for a replacement.

## Onsite Meeting Registration

The SPSP Registration Desk is located in the Grande Ballroom Foyer of the Riviera Hotel and Casino. Please see the SPSP Registration Desk to register onsite or to pick up your badge if you are pre-registered.

We recommend that you visit the SPSP Registration Desk as soon as possible after your arrival to avoid the long registration lines that develop immediately prior to the first sessions of the day.

SPSP Registration Desk hours are:

Thursday, 3:00 - 8:00 pm

Friday, 7:30 am - 6:30 pm

Saturday, 7:30 am - 5:30 pm

## Parking

SPSP attendees are offered free parking for the duration of the conference. Parking is open 24 hours a day, everyday.

*Valet Parking* - Elevator access to the front underground Valet is located on the casino level, behind the ABC store near the Front Desk.

*Self-Parking* - Easy street access to the Convention Center Entrance is located at the Convention Center Lobby.

## Photography and Videotaping

Photography, audiotaping, video recording, digital taping or any other form of duplication is strictly prohibited in the sessions and poster areas.

## Receipts

A receipt is located on the back of your name badge. SPSP does not mail badges, so the badge acts as both the receipt and assurance of attendance. You will also receive two receipts online, one from SPSP for registration and one from PayPal for payment. See also Certificate of Attendance.

## Registration

See Onsite Meeting Registration.

## Room Service

Room Service is available 24 hours per day. Please see individual restaurants for hours. Food Court closes at 2:00 am.

## Shipping

The closest shipping center is:

FedEx Office (formerly Kinko's)

Las Vegas Convention Center

3150 Paradise Road

Las Vegas, NV 89109

1.702.943.6780

usa5042@fedexkinkos.com

Hours: 8:00 am - 5:00 pm., 7 days a week

Kinko's offers large-format color printing, signs and banners, pre-convention printing and file assistance, scooter and wheelchair rental, coat and bag check.

## Smoking

Smoking is not permitted in or outside any of the meeting rooms or the exhibit hall.

## Social Hour

The final poster session of the day on Friday and Saturday (6:15-7:45 pm) includes a social hour. The social hour is

## General Information

meant to allow attendees to mingle with cash bar refreshments while viewing the posters.

## Speakers

All speakers must register and wear their name badge to present. Please ensure that you are in your presentation room at least thirty minutes before the start of your session. See also Audiovisual Equipment for Talks.

## Special Dietary Requirements

If you have informed us of special dietary requirements, please see a member of the catering staff at lunchtime. The catering staff will have a list of attendees who have requested a special meal.

## Transportation Around Las Vegas

*Taxi* - A taxi stand is located at the front entrance of the Riviera Hotel and Casino. The taxi ride from the Riviera Hotel to McCarran International Airport is approximately 20-30 minutes. A one-way is \$23-\$25, including tip.

*Shuttle* - Airport to hotel shuttles are located at McCarran Airport and the south lobby of the Riviera Hotel and Casino. Shuttle fare starts at \$6.50 per person.

*Bus* - Citizens Area Transit (CAT) operates a double-decker bus nicknamed the Deuce that operates along the Las Vegas strip. The Deuce runs 24 hours a day, 7 days a week. One-way transportation is \$3 and a day pass is \$5. Tickets can be purchased on the bus or at Deuce ticket vending machines located at bus stops along the strip.

*Monorail* - The Las Vegas Monorail travels along the east side of The Strip behind the resorts. Monorail hours are 7:00 am to 2:00 am, Monday through Thursday, and 7:00 am to 3:00 am, Friday through Sunday. A single ride ticket is \$5, a one-day pass is \$13, and a three-day pass is \$28. The closest station is located at the Las Vegas Hilton .

## Opening Session and Presidential Symposium

Thursday, January 28, 5:00 - 7:00 pm

---

### TRANSCENDING SELF-INTEREST: EVOLUTION, BRAINS, AND HORMONES

Thursday, January 28, 5:00 - 7:00 pm, Royale Pavilion 1-4

Chair: Jennifer Crocker, University of Michigan

Speaker: Dacher Keltner, University of California, Berkeley

**Born to be good: An evolutionary approach to compassion**

Speaker: Patricia Churchland, University of California, San Diego

**Brain-based values**

Speaker: Paul Zak, Claremont Graduate Center

**The moral molecule: Oxytocin and virtue**

The idea that humans are ultimately motivated by self-interest has wide currency in psychology and the social sciences more generally. Indeed, animals from reptiles to humans have evolved motivational systems for self-preservation. Recently, researchers from a variety of disciplines have argued that humans also have an evolved motivational system for species-preservation—caring about and acting to promote the well-being of others. The speakers in this symposium—a social psychologist, a philosopher, and a neuroeconomist—discuss recent evidence for and implications of this innate human capacity for “goodness.”

## Special Session A

Friday, January 29, 8:15 - 9:30 am

---

Special Session A1

### GSC SPECIAL SYMPOSIUM

#### A GRADUATE STUDENT'S GUIDE TO EXTERNAL FUNDING

Friday, January 29, 8:15 - 9:30 am, Capri Rooms 103-106

Chairs: Nicole E. Noll, Temple University, and Kathleen Fortune, University of Manitoba

External funding is a topic of critical interest to graduate students and faculty alike. Yet for many academics, applying for grants and fellowships is a somewhat daunting task. In this symposium, our goal is to make that task more manageable by outlining the funding application process from several perspectives. Jenessa Shapiro will share lessons she learned as a graduate student applying for grants from various agencies and offer tips for success. Amber Story will explain the funding process at the National Science Foundation and give advice from the agency's perspective. Laura King will draw on her experience as a grant review panelist to provide insights as to what grant reviewers are looking for and the value of the proposal-writing process. The session will conclude with a discussion panel to address audience members' questions. This symposium will benefit both graduate students – by informing them of the ins and outs of graduate funding – and faculty – by arming them with knowledge they can pass on to their graduate students.

---

### ABSTRACTS

#### DEMYSTIFYING GRANT-GETTING FOR GRAD STUDENTS Jenessa R.

Shapiro<sup>1</sup>; <sup>1</sup>University of California, Los Angeles – Getting grant funding as a graduate (or undergraduate) student is not easy, but it is an important time to start getting in the habit of thinking about grants and obtaining practice writing grants. In my talk I will focus primarily on resources for graduate students and the process of applying for (and getting) grants. I will talk about my experiences applying for grants, including how I have found information about funding sources, lessons I have learned, and how my perspective has changed over time. Some other, more general, topics that I will cover include: (1) Apply! Most people don't realize how many grants people apply for before they get one. (2) Think big and small. NSF and NIH always come to mind first, but there are many other agencies that give (smaller) grants for graduate research. (3) Ask for help. (4) Know your audience. Overall, my goal is to help demystify early career grant-getting for graduate students.

#### NATIONAL SCIENCE FOUNDATION: FUNDING OPPORTUNITIES AND STRATEGIES Amber L. Story<sup>1</sup>; <sup>1</sup>National Science Foundation – The funding process at the National Science Foundation will be described and funding opportunities will be discussed. Emphasis will be placed on opportunities and tips for graduate students and early career faculty.

#### CRAFTING A REALLY GREAT LOTTERY TICKET Laura A. King<sup>1</sup>; <sup>1</sup>University of Missouri, Columbia – When facing the challenge of writing a graduate fellowship application, many students find themselves facing a confluence of expectation and dread: The job is difficult, the odds of success seem slim, and yet the value of the pay-off seems inestimably high. Having mentored successful (and unsuccessful) fellowship applications and served on countless review panels, I hope to share with students what I have learned over the years. I will review the differences between writing for other venues and writing a grant application. Focusing on the differences in values and mindsets of the grant reviewer vs. the manuscript reviewer, I will highlight some common errors that students and their advisors can avoid. Finally, I will briefly consider the ultimate pay-off, not just in actually receiving funding, but in the process of crafting the application itself, the lessons that can be learned, and the pay-offs that come even from crafting the unfunded proposal.

Special Session A2

### GSC SPECIAL SYMPOSIUM

#### FUNDING OPPORTUNITIES AT THE NATIONAL SCIENCE FOUNDATION

Friday, January 29, 8:15 - 9:30 am, Capri Rooms 107-110

Speakers: Kellina M. Craig-Henderson and Amber L. Story

Special Session A3

### GSC SPECIAL SYMPOSIUM

#### FUNDING OPPORTUNITIES AT THE NATIONAL CANCER INSTITUTE

Friday, January 29, 8:15 - 9:30 am, Capri Rooms 114-116

Speakers: Bill Klein and Heather Patrick

## Symposia Session A

Friday, January 29, 9:45 - 11:00 am

### Symposia Session A1

#### BEYOND LABORATORY-BASED TEST PERFORMANCE: EXPLORING THE FAR-REACHING CONSEQUENCES AND IMPLICATIONS OF STEREOTYPE THREAT

Friday, January 29, 9:45 - 11:00 am, Royale Pavilion 1

Chair: Valerie Jones, Princeton University

Speakers: Priyanka Carr, Sonia K. Kang, Valerie Jones, Greg M. Walton

Hundreds of experiments demonstrate that stereotype threat (ST) undermines intellectual performance in laboratory circumstances (Steele, Spencer, & Aronson, 2002). Nonetheless, it has been charged that ST is of little consequence beyond laboratory tests (e.g., Sackett, Hardison, & Cullen, 2004; Stricker & Ward, 2004). Moreover, observed between-group differences in many domains unexamined in past ST research, including decision-making, aggression, and even learning, are hypothesized by some to have biological and genetic causes (e.g., Apicella et al., 2008; Herrnstein & Murray, 1994). Challenging these assumptions, four talks examine the broad-ranging effects of ST in previously untested and non-overtly stereotyped domains and in real-world performance environments. Carr and Steele find that ST modulates decision-making, leading to increased loss- and risk-aversion and potentially affecting financial outcomes. Kang and Inzlicht demonstrate that the negative psychological effects of ST spillover to affect outcomes in non-stereotyped domains. For instance, they provide neuro-physiological evidence that ST disrupts performance-monitoring, thwarting peoples' ability to exercise self-control in domains including aggression, eating, and decision-making. Jones and Walton show that ST undermines how well stereotyped students learn new information. The results suggest that ST contributes to group differences in achievement both by undermining learning and by undermining performance. Finally, Walton, Spencer, and Erman show in two meta-analyses that common real-world measures of academic performance—both grades and test scores—systematically underestimate the ability of stereotyped students. Their performances are dragged down by stereotype-related threats. Discussion addresses the importance of fostering identity-safe environments in a wide variety of academic, professional, and social domains.

#### ABSTRACTS

**STEREOTYPE THREAT AFFECTS WOMEN'S DECISION-MAKING** Priyanka Carr<sup>1</sup>, Claude Steele<sup>2</sup>; <sup>1</sup>Stanford University, <sup>2</sup>Columbia University – Women make up over half of the labor force in Fortune 500 companies, but lead only 3% of these companies (Catalyst, 2009). Prevalent gender stereotypes argue that women are not as adept as men in decision-making or math and finance and therefore may not be fit for leadership roles requiring tough decision-making and finance management. These stereotypes can affect hiring and promotion decisions. By triggering stereotype threat, these stereotypes can also affect women's decision-making, further affecting their chances of success. Past research finds gender differences in decision-making (loss-aversion and risk-aversion) and attributes these differences to biology or socialization (e.g., Apicella et al., 2008). The present research argues that these gender differences result from stereotype threat. Across three studies, we find support for this hypothesis. Men and women in academic and business settings were told that we were investigating either math and rational reasoning abilities (stereotype-relevant condition) or puzzle-solving (stereotype-irrelevant condition). Compared to those not under threat, participants experiencing stereotype threat (women in the stereotype-relevant condition) exhibited significantly greater loss-aversion (Study 1) and risk-aversion (Studies 2 and 3). The gender differences in decision-making

seen in past research were evident only when negative stereotypes about women's abilities were relevant. Furthermore, Study 3 finds that the effect of stereotype threat on decision-making was mediated by depletion of cognitive resources, the fuel for deliberative decision-making (Vohs, 2006). This research suggests that stereotype threat can have broad effects, affecting work and personal decision-making, and highlights the need to create identity-safe environments.

#### STEREOTYPE THREAT SPILLOVER: HOW THREATS TO SOCIAL IDENTITY AFFECT AGGRESSION, EATING, DECISION-MAKING, AND ATTENTIONAL CONTROL

Sonia K. Kang<sup>1</sup>, Michael Inzlicht<sup>1</sup>; <sup>1</sup>University of Toronto – Traditional examinations of stereotype threat (ST) have focused on the negative consequences that stereotypes can have for an individual's performance in stereotyped domains. In five studies, we examined whether the negative effects of ST spillover into various life domains where stereotypes are usually not considered to be "in the air". Study 1 examined if the experience of taking a threatening math test could lead women to respond with greater aggression and hostility. Study 2 investigated whether the experience of ST would lead women to indulge in unhealthy food and examined the moderation of this effect by personal characteristics that contribute to identity-threat appraisals. Study 3 examined the accrued effect of these personal characteristics by asking if Muslim (3a) and female (3b) students who tend to make identity-threat appraisals also show signs of uncontrolled eating (i.e., being heavier and more obese). In Study 4, we investigated if vividly remembering an experience of prejudice results in risky decision-making. Finally, in Study 5, we asked if coping with threat could directly influence attentional control and if the effect was implemented by disrupted performance-monitoring, as assessed by electroencephalography (EEG). Our results show that ST can spillover and impact self-control in a diverse array of non-stereotyped domains for members of a broad range of stereotyped groups including women and racial and religious minorities. Taken together, the diversity of domains and of affected groups reveals the potency of ST and suggests that its negative consequences extend much further than previously thought.

#### STEREOTYPE THREAT UNDERMINES LEARNING

Valerie Jones<sup>1</sup>, Greg M. Walton<sup>2</sup>; <sup>1</sup>Princeton University, <sup>2</sup>Stanford University – This research examines a far-reaching possible consequence of stereotype threat: Does stereotype threat undermine learning? Two experiments tested whether stereotyped students who learned novel material in threatening environments would perform less well on tests of that material even in psychologically safe settings. In Study 1, Black and White students learned novel words in either threatening (i.e., evaluative of learning ability) or non-threatening (i.e., non-evaluative of learning ability) conditions. One week later, participants recalled half the words' definitions in a non-threatening "warm-up" and half in a threatening "test." Replicating past stereotype threat effects, Black students performed worse on the "test" than on the "warm-up." White students were unaffected. But, critical was evidence of learning decrements: Black students who had learned in a threatening environment performed worse on the non-threatening "warm-up" than those who had learned in a non-threatening environment. Further, the performance and learning effects were additive. Black students who both learned and performed under threat performed 50% worse than those who both learned and performed without threat. Indeed, the latter was the best performing group overall. Study 2 conceptually replicated the effects using self-affirmation. Black students learned under threatening conditions after half had completed a self-affirmation. Self-affirmation eliminated the performance drop one week later. The results of these studies show that stereotype threat can contribute to achievement gaps both by preventing students from learning new material and by preventing students from performing well on tests of that material. The results underscore the importance of creating psychologically safe academic environments.

### **LATENT ABILITY: GRADES AND TEST SCORES SYSTEMATICALLY UNDERESTIMATE THE INTELLECTUAL ABILITY OF NEGATIVELY STEREOTYPED STUDENTS**

Greg M. Walton<sup>1</sup>, Steven J. Spencer<sup>2</sup>, Sam Erman<sup>3</sup>; <sup>1</sup>Stanford University, <sup>2</sup>University of Waterloo, <sup>3</sup>University of Michigan – Past research assumes that group differences in academic performance entirely reflect genuine differences in ability. By contrast, we provide evidence that standard measures of academic performance are biased against non-Asian ethnic minorities and against women in quantitative fields. This bias results not from the content of performance measures but from the context in which they are assessed – from psychological threats in common academic environments (e.g., stereotype threat), which depress the performances of people targeted by negative intellectual stereotypes. Like the time of a track star running into a stiff headwind, such performances underestimate the true ability of stereotyped students. Two meta-analyses, combining data from 18,976 students in five countries, tested this “latent ability” hypothesis. Each found that, under conditions that reduce psychological threat, stereotyped students performed better than non-stereotyped students at the same level of past performance. Discussion addresses the magnitude of the bias, implications for the interpretation of and remedies for achievement gaps, and implications for meritocracy and affirmative action.

### **Symposia Session A2**

#### **INTERPERSONAL COMPLEMENTARITY**

Friday, January 29, 9:45 - 11:00 am, Royale Pavilion 2

Chairs: Debbie S. Moskowitz, McGill University, and Iven Van Mechelen, University of Leuven

Speakers: Debbie S. Moskowitz, Iven Van Mechelen, Pamela Sadler

A key finding in the study of social behavior is that of interpersonal complementarity: Perceived communal behavior (ranging from quarrelsome to agreeable) tends to evoke similar behavior from the partner, whereas perceived agentic behavior (ranging from submissive to dominant) tends to evoke its opposite. The present symposium corroborates this finding and deepens it in several respects. For this purpose it relies on a plethora of behavioral data collected in everyday and laboratory settings. These data are analyzed with a broad spectrum of methods, ranging from multilevel methods, advanced time-series analyses, and novel interactive 3D graphics. The results reveal that interpersonal complementarity is a very rich phenomenon that shows up: (a) as a finding that holds for both normal controls and for clinical populations, (b) as a general psychological principle as well as a principle that is subject to (multidimensional) individual differences, and (c) as a pattern of covariation across situations as well as of synchrony or covariation across time.

#### **ABSTRACTS**

#### **INTERPERSONAL PERCEPTION AND BEHAVIOR: EFFECTS OF SOCIAL ANXIETY AND BORDERLINE PERSONALITY DISORDER**

Debbie S. Moskowitz<sup>1</sup>, Jennifer J. Russell<sup>1</sup>, Gentiana Sadikaj<sup>1</sup>, David C. Paul<sup>1</sup>, David C. Zuroff<sup>1</sup>; <sup>1</sup>McGill University – Considerable research has accumulated demonstrating the principles of interpersonal complementarity which posits that communal behavior (agreeable and quarrelsome behavior) evokes similar levels of communal behavior in others while agentic behavior (dominant and submissive behavior) evokes a reciprocal behavioral response from others such that dominant behavior evokes submissive behavior and its reverse also occurs. The present studies examined whether interpersonal perceptions and reports of interpersonal behaviors correspond to these interpersonal principles and the extent to which these principles also apply to individuals with psychopathology. Results will be presented from studies of individuals with Borderline Personality Disorder, individuals with Social Anxiety Disorder, and nonclinical controls. These individuals collected records including information about their behavior and their perceptions of others about their social interactions using event contingent recording over a 20-day period. Compared to controls, individuals with Borderline Personality Disorder

showed greater agreeable and quarrelsome behavior in association with the perception of high and low agreeableness in others, while individuals with Social Anxiety Disorder showed greater submissive behavior in response to the perception of dominance in others. Research on individual differences in interpersonal complementarity has the potential to illuminate the subjective cues that provoke exaggerated levels of behavioral responding in individuals with psychopathology.

#### **INDIVIDUAL DIFFERENCES IN INTERPERSONAL COMPLEMENTARITY**

Tinneke Timmermans<sup>1</sup>, Iven Van Mechelen<sup>1</sup>; <sup>1</sup>University of Leuven – Individuals are almost always interacting with other people. Interpersonal behaviors can be ordered making use of the interpersonal circle or circumplex (Carson, 1969; Kiesler, 1983; Leary, 1957; Wiggins, 1991), characterized by the two orthogonal dimensions of communion (ranging from agreeable to quarrelsome behavior), and agency (ranging from dominant to submissive). Within the interpersonal theory tradition, researchers reported evidence for the occurrence of complementarity patterns pertaining to how an individual's interpersonal behavior may vary due to the perceived behavior of the other person in the interaction. Although these patterns have been investigated as general psychological phenomena, there are intriguing indications that point to the existence of individual differences in their appearance. In this paper we report on an experience sampling study in which we systematically investigated this issue. On a general psychological level we found confirmation for the principle of complementarity. Furthermore, individual differences in interpersonal behavior showed up at all levels of perceived behavior of the partner, with the largest individual differences showing up at the more extreme levels. Finally, the found individual differences were multidimensional, in that they displayed a limited cross-situational consistency only, and in that at different perceived levels of the partner's behavior, individual differences in interpersonal behavior were related in a distinct way to Extraversion and trait Agreeableness. The latter results were interpreted in terms of behavioral inclinations linked to Extraversion and Agreeableness that come up only in situations where an appeal is made to them.

#### **ARE WE ON THE SAME WAVELENGTH? NUMERICAL AND GRAPHICAL CHARACTERIZATION OF RHYTHMIC PATTERNS OF MOMENT-TO-MOMENT COMPLEMENTARITY IN INTERACTING DYADS**

Pamela Sadler<sup>1</sup>, Erik Woody<sup>2</sup>, Nicole Ethier<sup>2</sup>, Gregory R Gunn<sup>2</sup>; <sup>1</sup>Wilfrid Laurier University, <sup>2</sup>University of Waterloo – The present study addressed individual differences in the patterns of cyclical entrainment between interacting dyad members in their moment-to-moment levels of dominance and affiliation. Using a computer joystick technique, four independent observers recorded the continuous stream of behavior separately for each partner in 50 mixed-gender dyads, and the data for each dyad were submitted to time-series analyses, including cross-spectral analysis. In most dyads partners shared behavior cycles of roughly the same frequency with strongly correlated variations in amplitude (coherence). Consistent with interpersonal theory, partners' affiliation behaviors tended to be strongly in phase, whereas their dominance behaviors were strongly out of phase. Of particular relevance, dyads varied considerably in their degree of entrainment: The range extended from close to zero (the minimum possible value) to close to one (the maximum possible value). Consistent with interpersonal theory, behavioral synchrony on affiliation was uncorrelated with behavioral synchrony on dominance. These cyclical forms of interpersonal complementarity were also distinguishable from other forms of complementarity, such as mutual adjustment in overall levels. A fascinating way to study the behavioral patterns of a dyad is to plot a three-dimensional graph of the partners' behavior, using dominance, affiliation, and time as the three axes. The talk will show, using interactive 3D graphics from the R statistics package, how this three-dimensional structure can be rotated to examine its structure and draw inferences about the interaction patterns of a particular dyad. Finally, we will discuss the promise that these new techniques have for studying important, subtle differences between dyads.

**Symposia Session A3****TAKEN FOR GRANTED: THE INFLUENCE OF FAMILY ON SOCIAL COGNITION, SOCIAL BEHAVIOR, AND WELL-BEING**

Friday, January 29, 9:45 - 11:00 am, Royale Pavilion 5

Chair: Belinda Campos, University of California, Irvine

Speakers: Belinda Campos, Kimberly J. Saudino, Gregory R. Maio, Karen L. Fingerman

The relational context of family is unique and understudied by social-personality researchers. Interdisciplinary perspectives, including evolutionary, developmental, and anthropological, have documented the pre-eminent role that family plays in the acquisition of social understanding, caregiving, health, and well-being. In contrast, social-personality researchers who study relationships have primarily focused on romantic bonds and marriages. The four talks in this symposium demonstrate that family relationships are a unique relationship context that influences cognition, emotion and behavior. Campos will present a framework for organizing the elements of family that are unique from other relationships and a series of studies showing that family is characterized by "assumed bonds" (e.g., shared biology) wherein the relationship is less voluntary and more tolerant of aversive social behavior. Saudino will present a study that illustrates a unique consequence of family relationships for social cognition - that parents show a rater bias for perceiving differences among siblings that are not supported by more objective measures or non-family perceivers. Maio will present research showing that the relational context of family uniquely affects forgiveness processes, which repair distressed relationships. Fingerman will present recent work showing that family relationships, which typically last throughout the life course, affect the current well-being of the parents of adult children. Together, these talks highlight the important contributions to understanding cognition and social behavior that can be gained by considering the unique elements of the family relationship context and offer directions for future research.

**ABSTRACTS****ASSUMED BONDS: THE RELATIONAL CONTEXT OF FAMILY INFLUENCES LOVE, TEASING, AND MORAL JUDGMENT**

Belinda Campos<sup>1</sup>, Dacher Keltner<sup>2</sup>, Serena Chen<sup>2</sup>; <sup>1</sup>University of California, Irvine, <sup>2</sup>University of California, Berkeley – Family bonds are important in all human societies. Anthropologists regard kinship as a universal feature of human social life that varies in terms of the culture based social roles and expectations assigned to family relationships. Although psychologists take great interest in family, little research has examined how the unique elements of this relational category influence cognition, emotion, and behavior. From a psychological perspective, family relationships are a prototypical communal relationship type that differs from other prototypical communal relationships by the unique fitness opportunities (e.g., shared genes) that typically characterize these relationships. The present work tested the hypothesis that an assumed bond rooted in shared biology would lead family to be regarded as less voluntary and more tolerant of aversive behavior than romantic relationships and friendships. Studies 1 and 2 used open-ended narrative methods to examine whether assumed bonds and tolerance for aversive behavior accounted for family specific variation in experiences of love, an emotion central to communal relationships, and teasing, a social behavior that tests relationships. Study 3 used social cognition methodology and a between-subjects experimental design to test whether the concept of "assumed bond" served as a relational schema for appropriate behavior toward family. As expected, social behavior that exemplified assumed bonds and an aversive willingness to push boundaries was rated as more morally acceptable and emotionally positive in family relationships. Across studies, family was uniquely characterized by assumed bonds and tolerance for aversive behavior and this pattern was associated with both positive and negative relational consequences.

**ARE PARENTS' PERCEPTIONS OF SIBLING DIFFERENCES IN TEMPERAMENT VERIDICAL?**

Kimberly J. Saudino<sup>1</sup>; <sup>1</sup>Boston University – Twin studies suggest that parent ratings of temperament are prone to rater biases that exaggerate differences between twins. These contrast biases may not be limited to twins. It is possible that whenever parents rate the temperaments of their children, they evaluate each child in the context of other children within the family. Thus, the rating of one sibling's temperament may be influenced by the perceived temperament of another sibling. Because most temperament research involves only one child per family these biases may go undetected. The present study explored contrast biases in nontwin siblings. 95 nontwin sibling pairs (ages 3-8) were assessed for activity level and shyness via parent ratings and objective measures. Parents completed questionnaires regarding each child's temperament, sibling relationship quality, and parental treatment. To obtain objective measures of activity level and shyness, children wore actigraphs (motion recorders) continuously for 48 hours and children's reactions to examiners upon laboratory arrival were the basis of behavioral observations of shyness. Siblings displayed no resemblance in parent-rated activity or shyness but sibling resemblance for actigraph activity and observer-rated shyness was substantial. Further, parents' perceptions of sibling differences in activity and shyness were not associated with observed behavioral differences. Thus, parents contrast their nontwin siblings when rating temperaments and parents' perceptions of sibling differences are not veridical. Moreover, the importance of sibling differences in temperament to sibling relationship quality and parental treatment varied across the different measures of activity and shyness, suggesting that parent perceptions may play a role in these associations.

**FORGIVENESS AND MOTIVES TO FORGIVE IN FAMILY RELATIONSHIPS**

Gregory R. Maio<sup>1</sup>, Geoff Thomas<sup>2</sup>, Frank D. Fincham<sup>3</sup>, Katherine B. Carnelley<sup>4</sup>; <sup>1</sup>Cardiff University, <sup>2</sup>Aston University, <sup>3</sup>Florida State University, <sup>4</sup>University of Southampton – Our research tested the hypothesis that the process of forgiveness is intrinsically different for, and within, family relationships. We tested this hypothesis by examining the role of forgiveness in different family relationships over time. In addition, we included novel analyses of motives to forgive, based on interviews with couples and theories of attitude function. In two lab sessions one year apart, 114 families (each including two parents and one child) completed a new measure of family forgiveness, a new measure of motives to forgive, and many individual-level, relationship-level, and family-level variables that have been previously linked with forgiveness. After validating the measure of family forgiveness and the measure of motives to forgive in cross-sectional analyses, longitudinal analyses examined the role of forgiveness in each family relationship over the one-year interval. Results indicated many potential consequences of forgiveness on individual traits, aspects of each family relationship, and general family environment. More important, there were asymmetries in associates of forgiveness and motives to forgive across parent-child and parent-parent relationships. Overall, the results demonstrate the relationship-specific nature of forgiveness.

**MIXED BLESSINGS: MIDDLE-AGED PARENTS' WELL-BEING AND PERCEPTIONS OF HOW THEIR GROWN CHILDREN TURNED OUT**

Karen L. Fingerman<sup>1</sup>, Yen-Pi Cheng<sup>1</sup>, Kira S. Birditt<sup>2</sup>, Laura Vanderdrift<sup>1</sup>; <sup>1</sup>Purdue University, <sup>2</sup>University of Michigan – Perceptions of family ties may influence own well-being, particularly for parents. Parents invest a great deal in raising children, and continue to help their children even after they are grown. As such, they may view their children's accomplishments and problems as a reflection on themselves as parents. We examined how multiple grown children in the same family may influence parental well-being. 633 middle-aged parents (302 men, 331 women) reported on each of their grown children (n = 1, 251) and rated their own psychological well-being. Parents rated each grown child's achievement with regard to work/education and relationships. They indicated problems each child had experienced using a standard inventory of problematic life events. We categorized participants based on perceptions of each

grown child into 4 family pattern composites: (a) all children successful, (b) all children problem ridden, (c) mixed, children with problems and with successes, and (d) no children in upper half for problems or success. Parents who perceived all of their grown children as successful reported better well-being than parents with an adult child who suffered problems. Parents provided help to children who were successful as well as to children with problems. Relationship quality and appraisals of how stressful or rewarding they found helping problem ridden and high-achieving grown offspring partially accounted for associations between family pattern variables and well-being. Discussion focuses on the role of social cognition and perceptions of family help that may allow parents to derive benefits or suffer detriments from how their grown progeny turn out.

### Symposia Session A4

#### CHECK ALL THAT APPLY: THE PSYCHOLOGICAL COSTS AND BENEFITS OF ADOPTING A MULTIRACIAL IDENTITY

Friday, January 29, 9:45 - 11:00 am, Royale Pavilion 6

Chair: Todd L. Pittinsky, Harvard University

Speakers: Lisa S. Giamo, Diana T. Sanchez, Margaret J. Shih, Kristin Pauker

Multiracial people have always challenged the conventional notions of racial categorization, exemplified by the recent debate over President Obama's racial identity—was he “Too Black” or “Not Black enough”? Despite his biological multiracial background, he consistently self-identifies as Black. This example illustrates the inherent flexibility in racial identification and raises questions about how this flexibility affects both the target and perceiver. This symposium assembles four diverse programs of research that explore race as a flexible construct. Our findings demonstrate how examining multiracial people can offer novel insight into the relationship between racial identification and discrimination, as well as their links to health and cognitive outcomes. Giamo and colleagues discuss how both perceptions of discrimination and parental ethnicity influence multiracial individuals' conveyance of their racial identity. Sanchez and colleagues investigate how White ancestry reduces multiracial individuals' credentials as an ethnic minority, affecting their worthiness as a candidate for affirmative action. Shih and La Plante explore the prevalence of health risk behaviors among monoracial and multiracial individuals. Finally, Pauker and Ambady examine whether multiracial individuals can flexibly adopt different racial identifications to guide preferential “own-race” memory and the involvement of discrimination narratives in such changes in racial identification. These studies introduce new advances in thinking about how perceived experiences with discrimination shape both self and other perceptions of racial identity. Additionally, they highlight that the adoption of a flexible, multiracial identity can engender a complex set of consequences and benefits, including both negative health outcomes and positive cognitive outcomes.

#### ABSTRACTS

#### THE INFLUENCE OF PERCEPTIONS OF DISCRIMINATION AND PARENTAL ETHNICITY ON MULTIRACIAL IDENTITY

Lisa S. Giamo<sup>1</sup>, Michael T. Schmitt<sup>1</sup>, H. Robert Outten<sup>1</sup>; <sup>1</sup>Simon Fraser University – Multiracial people may choose a variety of ways of communicating their racial identities that differ from the conventional ways in which we conceptualize racial categorization. However, we know little about what factors influence how multiracial people choose to convey their multiple identities. The current study examines how perceptions of discrimination and parental ethnicity influence the identity choices of multiracial people. Multiracial participants (N=257) were asked to list all the terms they would use to describe their ethnic identity, as well as provide information about their parents' ethnicity. They also completed measures of perceived discrimination and psychological well-being. Results demonstrate that multiracials describe themselves in a variety of ways: as mixed, multiracial, or “halfie”, by creating new group terms to describe a specific combination

of ethnicities (e.g., “Eurasian, Blackanese”), or listing multiple ethnic groups. In addition, both perceived discrimination and parental ethnicity were related to the terms participants used to describe their multiracial identity. Perceived discrimination was positively related to identifying as multiracial and or identifying with one ethnic group in particular. Perceived discrimination was negatively related to identifying as halfie. Parental ethnicity was related to identifying as halfie; those with one white parent were more likely to use this label. In addition, choosing the halfie label was most likely among multiracials with one White parent and who also did not perceive much discrimination. As found in other studies of ethnic discrimination, perceived discrimination was also negatively related to measures of psychological well-being.

#### MINORITY STATUS PERCEPTIONS OF BLACK/WHITE BIRACIAL INDIVIDUALS

Diana T. Sanchez<sup>1</sup>, Jessica J. Good<sup>1</sup>, George Chavez<sup>1</sup>; <sup>1</sup>Rutgers University – Affirmative action contexts may be particularly relevant in understanding perceptions of part-White biracial individuals (Sanchez & Bonam, 2009). Politicians have long debated about how to determine who should be considered an ethnic minority, and hence eligible for race-based affirmative action. For example, in their special report on affirmative action policies, the United Nations commission on human rights struggled with whether children of racially mixed marriages should be considered ethnic minorities. These dilemmas highlight the need to research whether perceivers consider biracial individuals to be ethnic minorities and thus, deserving of access to resources reserved for ethnic minorities, such as affirmative action. Using experimental methodology, the present studies examine how White ancestry influences the perceived minority status of Black/White biracial individuals as well as the implications of minority status for affirmative action decisions and stereotype use. Study 1 suggests that people judge those of Black/White biracial descent as having less minority status and thus, less appropriate recipients of affirmative action than those of Black monoracial or Black/Native American descent. Study 2 shows that a greater degree of White ancestry among Black individuals predicts being perceived as having less minority status, lower appropriateness for affirmative action type opportunities, and less use of Black stereotypes in impression formation. These findings persist regardless of the gender of the target and the framing of affirmative action. Study 3 also shows that the link between White ancestry and minority status can be explained by expectations about the target's skin color and experiences of racial discrimination.

#### HEALTH RISK BEHAVIORS OF MULTIRACIAL AND MONORACIAL YOUNG ADULTS

Margaret J. Shih<sup>1</sup>, Debi A. LaPlante<sup>2</sup>; <sup>1</sup>University of California Los Angeles, <sup>2</sup>Harvard Medical School – Research in public health finds that experiencing racial discrimination increases risk for negative health outcomes (e.g. Gee et al., 2007). While this research has mainly examined monoracial minority populations, the findings suggest that multiracial individuals may also be at risk. However, multiracial individuals also tend to perceive race as a social construction (Shih, et al. 2007) which might buffer the risk. Little is known about health discrepancies between multiracial and monoracial adults. Most public health data on multiracial individuals concern adolescents. Multiracial adolescents are more likely to have smoked a cigarette, to drink alcohol (Choi et al., 2006) and to get drunk on a regular basis (Udry et al., 2003) than monoracial adolescents. Multiracial adolescents are also more likely to engage in physically violent behavior (Choi et al., 2006), and to report using illegal drugs than their monoracial adolescent peers (Price et al., 2002). We examine whether such differential risk continues into early adulthood. It is possible that while multiracial individuals engage in more risky behavior during adolescence, they may “age out” of these behaviors as they mature. We conducted a secondary data analysis on the 3rd wave of the National Longitudinal Study of Adolescent Health (ADD Health) dataset. We found that compared to monoracial minority peers, multiracial young adults continue to be more likely to report engaging in numerous health risk behaviors. Parental closeness and support did not mediate this rela-

tionship. These findings suggest that multiracial individuals do not appear to “age out” of differential risk behaviors.

**MULTIRACIAL INDIVIDUALS’ FLEXIBLE “OWN-RACE” MEMORY** Kristin Pauker<sup>1</sup>, Nalini Ambady<sup>2</sup>; <sup>1</sup>Stanford University, <sup>2</sup>Tufts University – Situated within a society that overemphasizes race and confronted by constant queries about their racial background, multiracial individuals often become cognizant of the arbitrary, socially constructed nature of race. This flexible view of race may allow for multiracial individuals to adopt the framework of multiple racial identities. We explored whether contextual cues to social identity could direct biracial (Black/White) perceivers’ racial identification and subsequent memory for Black, White, and biracial faces. Biracial perceivers were asked to write an essay about a time they connected with their mother or father’s ethnic identity before completing a face recognition task. Results indicate that biracial individuals recognized in-group relevant faces better than out-group relevant faces, based on the identity prime they received. In other words, “Black primed” biracial individuals displayed a memory advantage for Black faces compared to “White primed” biracial individuals, and “White primed” individuals displayed a memory advantage for White faces. Furthermore, changes in biracial individuals’ racial identification—measured by their perceived closeness to their Black or White identity—explained the effect of the racial identity prime on memory performance. Interestingly, when the essays were coded for content, biracial individuals cited more discrimination experiences overall and used discrimination-related experiences as a way to adopt a stronger Black identification. These results provide novel evidence that contextual changes in social identification can shape in-group memory effects. Moreover, not only can biracial individuals flexibly adopt the perceptual lens of different racial identities, but discrimination narratives may be intricately tied to these shifts in racial identification.

### Symposia Session A5

#### FINDING MIND: ATTRIBUTING (AND DENYING) INNER LIFE TO PEOPLE, MACHINES AND GODS

Friday, January 29, 9:45 - 11:00 am, Royale Pavilion 3-4

Chair: Kurt Gray, Harvard University

Speakers: Nicholas Epley, Kurt Gray, Jesse Bering, Nick Haslam

How do you create a mind? It may seem that outlandish methods like cloning or magic are necessary to make a mind, but simply perceiving something as having a mind changes how we treat it. As we automatically see thoughts behind people’s actions and effortlessly anthropomorphize pets, appliances and supernatural agents, it seems we create minds every day. Perception can also take minds away, however, such as when we dehumanize people by refusing to see them as capable of cognition and emotion. The act of attributing or deny a mind has important moral consequences, for only those with minds are worthy of rights and justice. This symposium explores how we attribute and deny minds. It examines the emerging field of mind perception and uncovers the motivational, cognitive and affective conditions under which we perceive (or fail to perceive) the minds of both earthly and supernatural entities. Epley and colleagues investigate when we perceive minds behind pets and machines and discover the motivations that lead to anthropomorphism. Gray and Wegner explore perceptions of God’s mind, finding not only that God has a unique type of mind, but that its perception seems to thrive on suffering. Bering and Heywood examine the thought process of those who explicitly deny God’s mind – atheists – and show that they reason in much the same way as believers. Finally, Haslam explores the topic of dehumanization, investigating which mental qualities we deny people and which ethnic groups we are most likely to dehumanize.

### ABSTRACTS

**MAKING SENSE BY MAKING SENTIENT** Nicholas Epley<sup>1</sup>, Adam Waytz<sup>1</sup>, Carey Morewedge<sup>2</sup>, George Monetaeleone<sup>1</sup>, Jia-Hong Gao<sup>1</sup>, John T Cacioppo<sup>1</sup>; <sup>1</sup>University of Chicago, <sup>2</sup>Carnegie Mellon University – People commonly anthropomorphize nonhuman agents, imbuing everything from computers to pets to gods with humanlike capacities, particularly humanlike minds. Although widely observed, the determinants of anthropomorphism are poorly understood and rarely investigated. We propose that people anthropomorphize, in part, to satisfy effectance motivation—the basic and chronic motivation to attain mastery of one’s environment. We will present a series of experiments demonstrating that increasing effectance motivation (such as by increasing the apparent unpredictability of a nonhuman agent) increases the tendency to anthropomorphize that agent. Neuroimaging demonstrates that the neural correlates of this process are the same ones engaged in mentalizing other humans. Finally, increasing the extent to which people anthropomorphize a stimulus increases predictability and understanding of that stimulus, suggesting that anthropomorphism satisfies effectance motivation. Using the self or humans in general as a guide to nonhuman agents seems to satisfy the basic motivation to make sense of an otherwise uncertain environment.

**PERCEIVING THE MIND OF GOD: THE ULTIMATE MORAL AGENT** Kurt Gray<sup>1</sup>, Daniel M. Wegner<sup>1</sup>; <sup>1</sup>Harvard University – Believing in God requires not only a leap of faith, but an extension of our normal capacity to perceive the minds of others. Usually, we perceive minds of all kinds by trying to understand their conscious experience (what it is like to be them) and their agency (what they can do). While humans are perceived to have both agency and experience, we appear to see God as possessing agency, but not experience. This suggests that instead of having a superhuman mind, the Almighty may have only half of one. God’s one-dimensional mind means that He is capable of moral agency—doing right or doing wrong—but relatively incapable of moral patiency—being the target of right or wrong action. Recent research on moral typecasting suggests that God is perceived to lack experience not in spite of his capacity as a moral agent, but because of his capacity for moral action. We provide evidence to suggest that God’s unique mind is due to his position as the ultimate moral agent, the entity to whom all unexplained help and harm is attributed. God’s role as ultimate moral agent has some surprising implications, for example, belief in Him seems to thrive especially on human suffering.

**DO ATHEISTS REASON IMPLICITLY IN THEISTIC TERMS? EVIDENCE OF TELEO-FUNCTIONAL BIASES IN THE AUTOBIOGRAPHICAL NARRATIVES OF NONBELIEVERS** Jesse Bering<sup>1</sup>, Bethany Heywood<sup>1</sup>; <sup>1</sup>Queen’s University, Belfast, Ireland – Since many people argue that they are immune to any form of supernatural reasoning, recent theoretical claims regarding the universality or “default” cognitive bases of religious belief are justifiably met with skepticism by non-religious individuals. Indeed, atheists pose a special problem for such cognitive accounts of religion because they appear to contradict the assumption that human beings intuitively reason in supernatural terms. Although religious belief is increasingly the subject of empirical attention by cognitive scientists, the phenomenon of disbelief has been a comparatively neglected topic of investigation. Either atheists are qualitatively different types of thinkers from religious individuals (lacking so-called supernatural intuitions) or they somehow manage to suppress or executively override their supernatural intuitions. In the present study, a sample of US and UK self-professed theists (n=34) and atheists (n=34) were told that they were participating in an online study of autobiographical memories. Although theists gave significantly more teleological (i.e., inherent purpose-based) explanations regarding their major life events, the majority of atheists also reasoned about their major life events in such terms—things happened to them “because they needed to learn a lesson” or were “meant to be at that time.” These data suggest that reasoning in teleo-functional terms about one’s own major life events may be a sort of “explanatory default” oper-

ating even in the narrative styles of those who explicitly reject supernatural explanations.

**HUMANNESS, MIND, AND MIND DENIAL** Nick Haslam<sup>1</sup>; <sup>1</sup>University of Melbourne, Australia – This talk will present a program of research on the attribution and denial of humanness to individuals and groups. People are shown to understand humanness in terms of two distinct dimensions of mental attributes. One dimension (human uniqueness) consists of mental attributes that distinguish humans from animals and the other (human nature) consists of attributes that distinguish humans from machines. The two dimensions may be selectively attributed and denied to self and others. First, I present evidence of a universal tendency to ascribe greater human nature to the self than to others. Second, I report a study in which people perceive their humanness (human nature) to have been diminished when they experience social rejection. Third, I present two studies in which particular human ethnic groups are denied each form of humanness. Finally, I briefly discuss recent studies showing that objectified people are denied mental attributes, and that similar kinds of mind denial are involved in stigmatizing attitudes towards people with mental disorders. My fundamental claim is that attributing and denying mind is central to the process of humanizing and dehumanizing people, but that this process is not a unitary one.

### Symposia Session A6

#### FEELING, THINKING, AND THE BODY: DEVELOPMENTS IN EMBODIED COGNITION

Friday, January 29, 9:45 - 11:00 am, Royale Pavilion 7-8

Chairs: Norbert Schwarz, University of Michigan, and Spike W. S. Lee, University of Michigan

Speakers: Norbert Schwarz, Fritz Strack, Arthur Glenberg, Jonathan Zadra

We explore the role of the body in the interplay of feeling and thinking and highlight that an understanding of embodied cognition requires attention to specific body parts and functions. Addressing the role of embodiment in moral reasoning, Lee and Schwarz show that the morality-hygiene metaphor works in body-specific ways: leaving an unethical message on voice mail (using one's mouth) requires a cleaning of the mouth, but leaving the same message on email (using one's hands) requires a cleaning of the hands. Exploring the bodily underpinnings of fluency experiences, Topolinski and Strack show that fluency effects depend on stimulus-specific motor simulations: competing oral tasks, like chewing gum, eliminate fluency effects (from mere exposure to false fame), whereas competing manual tasks do not. Turning to the embodiment of affective reactions, Havas and Glenberg highlight the role of the recipient's facial movements in understanding emotional sentences. They show that Botox injections selectively impair comprehension when the paralyzed muscle is relevant to the emotion expressed in the message. Finally, Clore and Zadra revisit hypotheses of the "New Look" from an embodied perspective. They propose that emotion and perception are connected because both are embodied reflections of the available and required resources for coping with the world. Throughout, the contributions illustrate the need to pay close attention to specific body parts and functions and their interface with task characteristics.

#### ABSTRACTS

#### OF DIRTY HANDS AND DIRTY MOUTHS: THE EMBODIMENT OF THE MORALITY-HYGIENE METAPHOR IS SPECIFIC TO THE MOTOR MODALITY USED

Spike W. S. Lee<sup>1</sup>, Norbert Schwarz<sup>1</sup>; <sup>1</sup>University of Michigan – People make an intuitive distinction between the metaphoric "dirty mouth" (as in frequent swearing) and "dirty hands" (as in corrupt politics). We test whether these body-part specific metaphors give rise to a desire for mouth-rinsing after unethical utterances, but a desire for hands-cleaning after unethical acts. Re-analysis of published data from other labs and two studies of our own consistently show that the morality-hygiene metaphor operates in ways that link cleaning to the specific body parts

involved. Study 1 coded for motor modality in people's recall of their virtuous acts or moral transgressions. Mouthwash became more attractive after recalling an unethical behavior involving the mouth; hand sanitizer became more attractive after recalling an unethical behavior involving the hands. Study 2 manipulated motor modality in the lab. People left a voice message or wrote an email, in which they acted unethical by telling a lie or acted ethical by telling the truth. An unethical mouth made mouthwash more attractive; unethical hands made hand sanitizer more attractive. Throughout, the general principle is that whichever motor modality is involved in an unethical experience, the product that cleans it becomes more attractive. The observed role of the motor modality of the ethical or unethical act is compatible with the general emphasis on modality in embodiment processes. Theoretical implications will be discussed.

#### HOW NOT TO BECOME FAMOUS OVERNIGHT: EMBODIED CONTRIBUTIONS TO MEMORY

Sascha Topolinski<sup>1</sup>, Fritz Strack<sup>1</sup>; <sup>1</sup>University of Wuerzburg, Germany – In previous research we found that mere exposure effects depend on stimulus-specific motor simulations [Topolinski, S. & Strack, F. (2009). Motormouth: Mere Exposure Depends on Stimulus-Specific Motor Simulations. *Journal of Experimental Psychology: Learning, Memory, and Cognition*, 35 (2), 423-33.]. For example, we found that mere exposure effects for words (oral stimuli) disappear when individuals are engaged in a concurrent oral motor task (e.g., chewing gum), but remain stable during a concurrent manual motor task (e.g., kneading a ball with the hand). In the present approach, we extend these findings to judgments of fame, familiarity, and recollection of actor and brand names that were repeatedly presented [cf. Jacoby, L. L., Kelley, C. M., Brown, J., & Jasechko, J. (1989). Becoming famous overnight: Limits on the ability to avoid unconscious influences of the past. *Journal of Personality and Social Psychology*, 56, 326-338.]. We found that concurrent oral motor-tasks compared to manual motor-tasks prevent the impact of repeated exposure of words on increasing judgments of fame, familiarity, and the 'know'-component in the remember-know paradigm; but leave recollection and the 'remember'-component in remember-know paradigm unaffected. Thus, by these simple behavioral manipulations, we induced the clinical, Capgras-like state of recognizing names without feeling familiar with them. It is concluded that all fluency-based memory forms are genuinely embodied, while recollection is not based on embodied motor simulations.

#### EMBODIED MECHANISMS OF SOCIAL COGNITION: COSMETIC USE OF BOTULINIUM TOXIN AFFECTS EMOTIONAL LANGUAGE PROCESSING

David A. Havas<sup>1</sup>, Arthur M. Glenberg<sup>1</sup>; <sup>1</sup>University of Wisconsin - Madison – Embodied theories offer an exciting approach to social cognition research, but the mechanisms underlying embodiment effects are not well understood, leaving critics to argue that this research remains unconstrained and under-specified. Here, we report progress in understanding one embodied mechanism of interaction between emotions and social cognitive processing. Language can powerfully affect emotions and consequent actions, as when reading a favorite novel, or listening to a skillful orator. Based on earlier findings, we hypothesized that peripheral activity of facial muscles used for emotional expression contributes to a causal mechanism of interaction between emotion and language comprehension. Using electromyographic (EMG) recording from facial muscles, we first found that comprehending emotional (angry, sad, and happy) sentences automatically elicits differential patterns of activity in facial muscles involved in expressing emotions (i.e., smiling and frowning). We then tested the functional role of this facial activity in language processing with a second group of participants receiving injections of Botox for cosmetic treatment of frown lines. We found that Botox-induced temporary paralysis of the facial muscle corrugator supercilli (responsible for producing a frown) hindered processing, relative to pre-injection baseline, for angry and sad sentences, while processing for happy sentences was unaffected. Taken together, these results offer evidence for a functional interplay of language processing, peripheral physiology, and emotion systems. While the results provide strong support

for a “facial feedback” mechanism of emotional and cognitive processing, the novel methodology opens new avenues for investigating mechanisms of embodied social cognition.

**ON THE EMOTIONAL ALTERATION OF PERCEPTION** Gerald L. Clore<sup>1</sup>, Jonathan R. Zadra<sup>1</sup>; <sup>1</sup>University of Virginia – In the 1950’s proponents of the “New Look” in perception proposed that visual perception could be affected by motivation and emotion. Though roundly criticized at the time, related ideas have now re-emerged with more compelling data and a more viable theory. For example, Proffitt and colleagues report that the perception of the physical environment – slant and distance – reflect one’s available bodily resources in addition to visual variables. In this presentation, two experiments are presented in which the emotions of sadness and fear were found to influence judgments of slant as well as height. To integrate emerging results in this field, these data and research from other labs are placed into a general framework. In that view, emotions are seen to act as information about available resources and about the urgency of expending resources, information that in turn affects perception of spatial layout. It is proposed that emotion and perception are connected because both are embodied reflections of the available and required resources for coping with the world.

### Symposia Session A7

#### **CULTURAL LADDERS: CAUSES AND CONSEQUENCES OF SOCIAL HIERARCHY DEPEND ON NATIONAL AND REGIONAL CULTURE**

Friday, January 29, 9:45 - 11:00 am, Capri Rooms 101-102

Chairs: Joe Magee, New York University, and Adam Galinsky, Northwestern University

Speakers: Nalini Ambady, Chen-bo Zhong, Krishna Savani, P.J. Henry

This symposium organizes four papers that collectively offer a range of approaches to explore variation across national and regional cultures in the meanings and conceptualizations of social hierarchy and the consequences of this cultural variation for behavior. In the first paper, Ambady analyzes the neural underpinnings of dominance and submissiveness in Japanese and Americans, finding that regions of the brain involved in processing reward stimuli are activated by dominance in Americans but by submission in Japanese. In the second paper, Magee et al. demonstrate that power is associated with different concepts and goals across cultures that vary in independent versus interdependent self-construals. Amongst Westerners, they found power was associated, both implicitly and explicitly with self-interested action, whereas amongst East Asians, power was associated with inhibition and sacrificing for the collective. In the third paper, Shavani et al. provide evidence that Indians are more accommodating than Americans in their decisions because of the strength of deference norms in India. As a result, Indians primed with authority figures were more likely to adjust their choices in line with the authority’s preferences but without changing their own underlying preferences. In the fourth paper, Henry looks at within-country and cross-national variation in status, using archival data and experimental evidence to show that cultures of honor are connected to the strength of status disparities. Consistent with the theory of low-status compensation, in regions with greater status disparities, low-status groups were more likely to resort to aggressive strategies to combat chronic threats to their social worth.

#### ABSTRACTS

**POWER AND DOMINANCE: SENSITIVITY AND TUNING ACROSS CULTURES** Nalini Ambady<sup>1</sup>; <sup>1</sup>Tufts University – Judgments of power, dominance, and status are some of the core judgments that people make frequently and rapidly in their everyday lives. These judgments have important consequences for later behavior and interactions, and these judgments are vital to optimal social functioning. Behavioral and neural evidence indicate that people in different cultures are differentially

attuned to and differentially accurate in identifying power and dominance-related cues. In one study, Koreans were more accurate in their status judgments of members of dyads and also exhibited better memory for status than did Americans. In another study, we measured neural activity in Japanese natives and Americans using functional magnetic resonance imaging (fMRI) while they viewed some images depicting dominance and other images depicting subordination. We assessed these individuals’ self-reported tendencies toward dominance and subordination using a questionnaire (including statements such as, “I impose my will on others” or “I let others make the decisions”). As expected, Americans indicated a tendency toward more dominant behavior, whereas Japanese indicated a tendency toward more subordinate behavior. Moreover, in Americans, seeing dominant images activated two brain regions (the caudate nucleus and medial prefrontal cortex), whereas native Japanese individuals showed the completely reverse pattern, with these same brain regions activated by subordinate images. These regions are part of “mesolimbic reward circuitry,” which is involved in processing rewarding stimuli like food, alcohol, and status symbols. These results suggest that both behavior and neural activation to cues of dominance and status are shaped by culture.

#### **THE CULTURAL CONTINGENCY OF POWER: CONCEPTUAL ASSOCIATIONS AND BEHAVIORAL CONSEQUENCES** Joe C. Magee<sup>1</sup>, Chen-bo Zhong<sup>2</sup>, Adam D. Galinsky<sup>3</sup>, William W. Maddux<sup>4</sup>; <sup>1</sup>New York University, <sup>2</sup>University of Toronto, <sup>3</sup>Northwestern University, <sup>4</sup>INSEAD – Previous research suggests that the experience of power leads to behavioral approach and action and increases the link between internal psychological states and observable behavior (Galinsky, Gruenfeld, & Magee, 2003), which allow individuals to satisfy their enduring goals (Chen, Lee-Chai, & Bargh, 2001).

We argue that culture shapes enduring goals and that power accentuates cultural differences, making individuals truer representations of their cultures’ underlying values and behavioral tendencies. We contrast East Asians and Westerners and demonstrate that cultural background affects the associations with and the consequences of power. Our first set of studies explored whether Westerners and East Asians associate power with different concepts. Regardless of whether power was subliminally or supraliminally primed, among individuals with a Western cultural background or those primed with an independent cultural orientation, power was associated with more self-deservedness and less restraint. By contrast, among individuals with an East Asian cultural background or individuals primed with an interdependent cultural orientation, power was associated with responsibility and restraint. A second set of studies explored the behavioral consequences of power with regard to assertive action and self-serving behavior. High-power East Asians defected less often in prisoner’s dilemma, restrained themselves in a commons dilemma, were reluctant to make first offers, and were more likely to take others’ perspectives compared to both low-power East Asians and high-power Westerners.

#### **CULTURAL VARIATION IN DEFERENTIAL DECISION MAKING: THE INFLUENCE OF AUTHORITY FIGURES’ EXPECTATIONS ON CHOICES BUT NOT ON PREFERENCES** Krishna Savani<sup>1</sup>, Michael W. Morris<sup>2</sup>, N.V.R. Naidu<sup>3</sup>; <sup>1</sup>Stanford University, <sup>2</sup>Columbia University, <sup>3</sup>M.S. Ramaiah Institute of Technology – A number of scholars and practitioners have suggested that people in Indian contexts are more likely than those in American contexts to accommodate to authorities’ preferences while making decisions. In three studies, we explored three distinct mechanisms for this hypothesized cultural difference between Indians and Americans: (1) value orientations, such as collectivism or hierarchy, which emphasize acting according to and internalizing other’s expectations; (2) susceptibility to priming by significant others’ goals; and (3) control strategies of adjusting one’s behaviors toward expectations of salient others without internalizing those expectations. We found evidence for the third mechanism: a habitual tendency of deferring to authority figures’ expectations in choices, without internalizing those expectations. In Study 1, participants were primed with the expectations of either their managers or

their coworkers and then asked to choose between and evaluate useful academic vs. fun non-academic continuing education courses. In Studies 2 and 3, female participants were primed with the expectations of either their parents or their stylish friends and then asked to choose between and evaluate revealing vs. modest shirts. In each study, Indians' accommodated to authority figures' but not peers' expectations in their choices, whereas Americans accommodated to neither peers nor friends. Merely thinking of an authority figure's expectations altered Indians' behavior, even when the authority would never learn about their choices, suggesting that behavioral deference is a habitual, reflexive response in Indian contexts. Notably, the priming manipulations did not influence participants' evaluations of the courses or shirts, suggesting they did not internalize others' expectations.

### **LOW-STATUS COMPENSATION: A THEORY FOR UNDERSTANDING THE ROLE OF STATUS IN CULTURES OF HONOR** P.J. Henry<sup>1</sup>; <sup>1</sup>DePaul University

Heretofore, mechanisms tying herding to cultures of honor have been speculated about but not empirically tested. Using the theory of low-status compensation as a framework, it is proposed that issues of status may play an important role linking herding regions to cultures of honor. Herding regions may be associated with greater status disparities. Because members of low-status groups are sent chronic messages of their second-class citizenship and lower social worth, they may be more likely to resort to strategies designed to protect their existing sense of worth. These self-protection strategies may involve violence against people who further threaten their sense of worth (through insults, etc.). These status-based strategies therefore may link herding regions to cultures of honor. Four studies are presented. Study 1 replicates the finding that counties in the American South conducive to herding have higher murder rates than do counties conducive to farming but shows those differences are mediated by indicators of status disparities in a county. Study 2 replicates the findings of Study 1 with an international sample of 92 countries. Study 3 tests the theoretical idea that people who are low in socioeconomic status face stigma in society and show self-defensive strategies generally. Finally, Study 4 provides experimental evidence that low-status tendencies toward aggressing in the face of insults may be due to strategies to protect their sense of worth. The results are contextualized within the theory of low-status compensation as a theory for understanding the role status plays in predicting some forms of violence.

### **Symposia Session A8**

#### **EMOTION REGULATION AND SELF-CONTROL: BASIC PSYCHOBIOLOGICAL MECHANISMS AND APPLICATIONS TO PUBLIC HEALTH**

Friday, January 29, 9:45 - 11:00 am, Capri Rooms 103-106

Chairs: Paige G. McDonald, National Cancer Institute, and David M. Amodio, New York University

Speakers: James J. Gross, Wendy Berry Mendes, David M. Amodio

This symposium will highlight recent advances in basic research on emotion regulation and self-control and its application to issues of public health. Paige McDonald will introduce the session with an overview of how such research promises to elucidate key questions concerning the prevention and progression of disease, in line with the National Cancer Institute's goal to support basic behavioral research that can inform the study of cancer control. James Gross will describe of a broad model of emotion regulation and present research on how different emotion regulation strategies may have differential effects on health outcomes. Wendy Berry Mendes will describe a biopsychosocial model of the stress response and its relation to health. She will present data suggesting that poor emotion regulation at the cardiovascular level is associated with impaired social functions, thus affecting both mental and physical health. Finally, David Amodio will discuss how basic research on emotion and self-regulation can shed light on the enduring racial disparities in health. He will present data suggesting that discrimination-related stress may have negative effects on biological health as well as on health-

related decision making processes. Together, these talks highlight ways in which basic research on emotion regulation and self-control can be applied to address issues of cancer control and health.

### **ABSTRACTS**

#### **EMOTION REGULATION AND HEALTH: DIVERSE PROCESSES AND DIVERGENT OUTCOMES** James J. Gross<sup>1</sup>; <sup>1</sup>Stanford University

Emotions are often functional, helping us track important developments in our environments and respond appropriately to crucial challenges and opportunities. However, emotions are not always functional, such as when they are of the wrong type or intensity for a given situation. At such times, people often try to regulate their emotions. In the first part of my talk, I will chart the development of the field of emotion regulation, and describe a framework for conceptualizing emotion regulatory processes. In the second part of my talk, I will use this framework to review recent work from our laboratory and others, focusing on the implications of two common forms of emotion regulation (reappraisal and suppression) for a variety of important psychological and physical health outcomes. In the third part of my talk, I will briefly elaborate a set of questions I regard as some of the most important we now face in this area of emotion regulation and health.

#### **ACUTE PHYSIOLOGICAL REACTIVITY AS A MEDIATOR BETWEEN EMOTION AND PHYSICAL HEALTH** Wendy Berry Mendes<sup>1</sup>; <sup>1</sup>Harvard University

A common strategy among psychologists who are interested in how social factors are linked to health is to examine acute physiological changes that co-occur with emotional, motivational, and stress states, and then speculate that repeated activation of these psychological states will lead to health vulnerability via the physiological response. This "cumulative wear and tear" model, however, poses at least two obstacles: first, it assumes that distinct psychological states can be reliably inferred from physiological changes, and second, it assumes that these physiological responses experienced repeatedly will accumulate to disease etiology. In this talk I will present a series of data addressing these challenges using a variety of physiological responses. The first series of experiments explores individual differences in the biological milieu as a vulnerability factor in experiencing negative affect. Specifically, I will present data linking low levels of adrenal steroids (e.g., dehydroepiandrosterone) to exacerbated negative affect and blunted positive emotions; I will then describe data showing that poor cardiac vagal control (i.e., vagal modulation) is associated with reduced social sensitivity and emotional accuracy; and then present neural data demonstrating that greater right relative to left frontal cortical asymmetry can exacerbate cardiovascular responses to social evaluative threat. In the remaining part of my talk I will present data exploring the association between acute cardiovascular threat reactivity (i.e., peripheral vasoconstriction and low cardiac efficiency) and accelerated cellular aging. Although the data may appear promising, the importance of age, sex, and context as critical moderators of these effects will be emphasized.

#### **EFFECTS OF DISCRIMINATION-RELATED STRESS ON BIOLOGICAL HEALTH AND SELF-REGULATION: IMPLICATIONS FOR RACIAL DISPARITIES IN CANCER** David M. Amodio<sup>1</sup>; <sup>1</sup>New York University

In the United States, having minority-group status may be bad for your health. With few exceptions, Black Americans suffer from cancer at significantly higher rates than White Americans, in terms of tumor progression, treatment efficacy, and mortality, and these effects have been linked to Blacks' experience with discrimination. In this talk, I consider two routes through which discrimination may produce racial disparities in health. First, stress associated with discrimination may interfere with normal endocrine and immune function. Community-based data from my lab links Blacks' perception of discrimination and low public regard to heightened baseline levels of stress hormones and with proinflammatory cytokines implicated in tumor progression. This effect was especially strong among Black individuals with negative implicit evaluations of their racial group. Second, discrimination stress can modulate self-regu-

latory processes, which in turn may promote health-related decisions favoring short-term rewards over healthier long-term goals. I will present a theoretical model of this process, along with experimental data suggesting that acute stressors enhance some aspects of self-regulation but interfere with others. This broad program of research is intended to elucidate basic mechanisms of emotion, self-regulation, and health, while also attempting to address the major society problem of racial disparities in cancer and other forms of health.

### Symposia Session A9

#### MEDIATION AND MODERATION AS TOOLS FOR THEORY DEVELOPMENT IN SOCIAL AND PERSONALITY PSYCHOLOGY

Friday, January 29, 9:45 - 11:00 am, Capri Rooms 107-110

Chair: Patrick Shrout, New York University

Speakers: Patrick E. Shrout, Dominique Muller, Kristopher J. Preacher, David P. MacKinnon

Approaches to mediation and moderation that were described in the classic Baron and Kenny (1986) article are widely used in social and personality psychology, but they have also stimulated extensive methodological advances (e.g. MacKinnon, 2008; Bauer, Preacher & Gil, 2006; Muller, Yzerbyt & Judd, 2005; Shrout & Bolger, 2002), and they have also been critiqued from the causal analysis perspective (e.g. Jo, 2008; Kraemer, Kiernan, Essex & Kupfer, 2008). In this symposium we review advances in mediation/moderation methods with the goal of refining the understanding of social and personality processes. These methods allow emphases on within person mediation paths, and on how mediation effects might vary from person to person beyond specified moderators. Participants discuss ways that conventional Baron and Kenny analyses can be misleading, whether and how variables can serve both as mediators and moderators, benefits of new methods in structural equation models for multilevel data, and integration of formal causal models into mediation analyses. Practical suggestions will be made for more rigorous and informative mediation analyses that yield deeper insights into basic psychological process. We will end with an open discussion about whether publication standards for mediation analyses should be updated from current conventions.

#### ABSTRACTS

#### REFINING INFERENCES ABOUT MEDIATED EFFECTS IN STUDIES OF PERSONALITY AND SOCIAL PSYCHOLOGICAL PROCESSES

Patrick E. Shrout<sup>1</sup>, Niall Bolger<sup>2</sup>; <sup>1</sup>New York University, <sup>2</sup>Columbia University — Mediation analyses attempt to build theory by explaining the processes by which experimental or quasi-experimental manipulations have an impact on outcomes. The mediation steps of Baron and Kenny (1986) are straightforward, but are based on important causal assumptions that are often incompletely considered. Most important is that a manipulation X causes mediating process M to change, which in turn causes a change in outcome Y. We review the basis of the causal assumptions, including the timing of the effects (X to M and M to Y) and the evidence that cross sectional correlations can be systematically misleading about psychological processes that unfold over time. We show how baseline (pre-randomization) measurements of mediating and outcome variables can be used to refine inferences about indirect paths through mediators, and how these adjustments open the door to secondary mediating processes that can be important for theory building. We illustrate the statistical and causal principles with numerical examples that are based on the current literature in social and personality psychology.

#### CAN A VARIABLE BE BOTH A MEDIATOR AND A MODERATOR?

Dominique Muller<sup>1</sup>, Vincent Yzerbyt<sup>2</sup>, Charles M. Judd<sup>3</sup>; <sup>1</sup>Université de Grenoble and Institut Universitaire de France, <sup>2</sup>Université Catholique de Louvain, <sup>3</sup>University of Colorado — Baron and Kenny's (1986) famous article is most often cited as the standard reference work for conducting mediational analyses. At the time the article was written, however, one of its

primary goals was to clarify the distinction between a moderator variable and a mediator. In general these days, researchers are clear about the distinction, so clear in fact that the idea that a single variable can serve simultaneously as a moderator and mediator may seem counterintuitive. Here we explore whether it is in fact possible that in some models a variable be both a mediator and a moderator of a treatment effect. After presenting examples, we lay out the models to be used to test for simultaneous mediation and moderation. Doing this highlights some interesting consequences of the same variable serving as both a mediator and a moderator. First, this implies that the treatment has a nonlinear effect on the outcome. Second, it implies that the treatment variable itself is the moderator in a moderated mediation model.

#### DEMONSTRATING MULTILEVEL STRUCTURAL EQUATION MODELING FOR TESTING MEDIATION: EFFECTS OF SELF-CRITICAL PERFECTIONISM ON DAILY AFFECT

Kristopher J. Preacher<sup>1</sup>, David M. Dunkley<sup>2</sup>, David C. Zuroff<sup>2</sup>;

<sup>1</sup>University of Kansas, <sup>2</sup>McGill University — Psychological data are often collected from groups of clustered individuals or over many repeated occasions from the same individuals. Such data are said to be hierarchically clustered. Methods for tackling mediation hypotheses with hierarchically clustered data include multilevel modeling (MLM) and multilevel structural equation modeling (MSEM). MLM is often used for mediation analysis but MSEM is rarely used, perhaps because it is new and less familiar to psychologists. There are reasons to consider this new method, including provision of model fit indices; unbiased between-cluster and within-cluster components of indirect effects; allowance for level-two outcomes, complex causal models, and latent variables with multiple indicators; and proper handling of the assumption violations associated with clustered data. We review these advantages of MSEM for testing mediation, and discuss the specification, fitting, and interpretation of MSEM mediation models using an example drawn from a study examining mediators of the effect of self-critical perfectionism on daily affect. Demographic information and self-critical perfectionism were assessed for 163 university students in a one-hour lab session on the first day. Daily diary data were then collected on daily affect, hassles, event stress, appraisals, coping, and social support each night for up to seven nights. Hassles, stress, social support, and coping were treated as potential mediators of the effect of perfectionism on both positive and negative daily affect. MSEM results differ from prior published analyses, which used a combination of MLM and single-level SEM. Reasons for these differences are discussed.

#### THE UNBEARABLE LIGHTNESS OF B: APPROACHES TO IMPROVE CAUSAL INTERPRETATION OF THE M TO Y RELATION

David P. MacKinnon<sup>1</sup>, Angela Pirlott<sup>1</sup>;

<sup>1</sup>Arizona State University — In typical mediation analysis, the b coefficient represents the population relation of the mediating variable (M) to the consequent variable (Y), adjusted for the antecedent variable (X). Standard mediation analysis has been criticized based on causal analysis of the relations among X, M, and Y (MacKinnon, 2008; Chapter 13). Using a potential outcomes approach, Holland (1988) showed under some assumptions (mainly random assignment), the typical regression coefficient for the relation of X on Y, c, and the relation of X on M, a, are valid estimators of the true causal effect, because of the randomization of units to treatment. The regression coefficient, b, (and also c' the relation of X to Y, adjusted for M), is not an accurate estimator of the causal effect of M on Y because this relation is correlational, not the result of random assignment. This ambiguous aspect of b occurs because M serves as both a dependent and independent variable in mediation analysis. In social psychology and other areas, longitudinal relations, theory, and prior empirical research are used to support the causal interpretation of the b coefficient. Furthermore, programs of randomized experiments are used to provide support for the relation of M to Y. This presentation outlines alternative approaches used to accumulate evidence for the relation between M and Y, focusing on blockage, enhancement, double randomization, and distillation designs. Although these designs provide more convincing evi-

dence, several limitations of mediation analysis remain, including the ubiquitous problem of interpreting  $b$  as a causal effect.

### Symposia Session A10

#### MAKING MEANING: THE HUMAN QUEST FOR UNDERSTANDING AND COHERENCE

Friday, January 29, 9:45 - 11:00 am, Capri Rooms 114-116

Chair: Keith Markman, Ohio University

Speakers: Keith Markman, Laura King, Steven Heine, Roxane Cohen Silver

In a landmark 1956 publication, concentration camp survivor Viktor Frankl espoused that an individual's primary motivational force is their search for meaning. Likewise, social-psychological theories have long acknowledged that the need for meaning, manifesting itself in a variety of processes such as consistency seeking, attribution, and sense making, is a fundamental motivation. For quite some time, however, this acknowledgement had been mostly tacit, as few empirical studies were designed to directly manipulate or measure the need for meaning. The purpose of this symposium is to highlight recent work that is directly examining the psychological processes associated with meaning making. Lindberg and Markman begin by describing several studies that implicate the role of counterfactual thinking in eliciting the phenomenology of explanatory coherence – the experiential sense that things “happen for a reason.” Next, King and colleagues focus on the psychological ramifications of “feeling” meaning, and how such meta-cognitive feelings enhance the believability and interpretability of objectively ambiguous stimuli. The next two presentations examine meaning making in a broader context. Heine, Proulx, and Randles describe a meaning maintenance model that provides a common account for individuals' reactions to a range of self-esteem threats, including feelings of uncertainty, cognitive dissonance, perceptions of an unjust world, and mortality salience. Finally, Silver, Updegraff, and Holman review a program of research that demonstrates the role of meaning making in facilitating adjustment in the wake of personal traumatic experiences. In all, this symposium underscores the importance of furthering our understanding of this fundamental human need.

#### ABSTRACTS

##### “IT WAS MEANT TO BE”: COUNTERFACTUAL THINKING AND THE CREATION OF MEANING

Matthew Lindberg<sup>1</sup>, Keith Markman<sup>1</sup>; <sup>1</sup>Ohio University – This work explores the phenomenology of explanatory coherence – the experiential sense that things “happen for a reason.” Participants read about an event that occurred in 1942 in which Boston College (BC) lost a football game to Holy Cross that they were heavily favored to win. Following the loss, the BC players chose not to spend the evening at a nightclub where they had originally planned to celebrate, only to later learn that a fire had killed 500 people at the nightclub that evening. In Study 1, participants who read a scenario describing both BC's loss and the fire retrospectively judged BC's loss as more fated and predetermined than did those who read a scenario that only described BC's loss. Participants apparently perceived that BC was “meant” to lose a game that they should have won in order for them to avoid dying in the fire. Study 2 suggested that the explanatory coherence mechanism is motivated: participants who read that BC was expected to win the game provided higher predestination ratings than did those who read that BC was expected to lose. Finally, in Study 3, the results of meditational analyses indicated that the influence of reading about the counterfactual on enhancing fate ascriptions were driven by perceptions that BC lacked control over the outcome of the game. We conclude that when individuals perceive that an outcome was “meant to be,” they are acknowledging the existence of external forces that help ensure that life events unfold in meaningful and coherent ways.

##### “I TOTALLY GET THAT!” POSITIVE AFFECT, INTUITIVE PROCESSING, AND THE FEELING OF MEANING

Laura King<sup>1</sup>, Joshua Hicks<sup>2</sup>, David Cicero<sup>1</sup>, Jason Trent<sup>1</sup>; <sup>1</sup>University of Missouri, Columbia, <sup>2</sup>Texas A & M University – Feelings of meaning refer to the phenomenological experience of “getting it” – the subjective sense that a potentially ambiguous target is understandable, that it fits with its context and one's expectations, in short, that it “makes sense.” This feeling was well described by James (1893) in his consideration of the non-sensory fringe of the stream of consciousness. The feeling of meaning is a feeling that there is something about a stimulus, an underlying comprehensibility, or a sense that there is a self-evident “there there.” Past research has shown that when faced with ambiguous videotapes of purported UFOs and ghosts, individuals high in intuition and positive affect (PA) rated the tapes as more believable and meaningful. The purpose of the present studies was to examine the possibility that this PA X intuition effect generalizes to the feelings of meaning (not just paranormal meaning) for the phenomena that individuals encounter in daily life. We will present a series of studies demonstrating the relevance of positive affect and individual differences in intuitive processing in the ascription of meaning to a broad range of stimuli, including ambiguous quotations, Zen koans, abstract artwork, the meaning experienced by fans after a football team loss in the conference championship game, and in events surrounding Hurricane Katrina (in individuals not directly affected). Finally, evidence for the accuracy of these feelings of meaning will be presented. Implications of this work for meaning making in response to life events, magical and referential thinking, and aspects of positive schizotypy will be discussed.

##### MAKING SENSE IN THE FACE OF NONSENSE: TESTS OF THE MEANING MAINTENANCE MODEL

Steven Heine<sup>1</sup>, Travis Proulx<sup>2</sup>, Daniel Randles<sup>1</sup>; <sup>1</sup>University of British Columbia, <sup>2</sup>University of California at Santa Barbara – The meaning maintenance model proposes that people have a need for meaning; that is, a need to perceive the world through mental representations of expected relations. When people encounter anomalies that are inconsistent with their schemas they may reaffirm alternative schemas as a way to regain meaning – even if those schemas are from domains different from the original meaning threat. This model provides a common account for people's reactions to self-esteem threats, feelings of uncertainty, cognitive dissonance, perceptions of an unjust world, and mortality salience. This presentation will discuss two experiments that provide convergent evidence for meaning making in response to anomalous cognitions. Study 1 reveals how people become more critical of a hostile out-group member, more defensive of the status quo, and more interested in high status goods following thoughts of the meaninglessness of one's life or of mortality salience. Study 2 demonstrates how counter-attitudinal dissonance can activate pattern-seeking motivations. Further, the results of these studies will be compared alongside more than a half dozen others using a divergent set of anomalies to highlight how responses to diverse meaning threats converge to show a common meaning-making impulse.

##### SEARCHING FOR AND FINDING MEANING IN BOTH PERSONAL AND COLLECTIVE TRAUMAS

Roxane Cohen Silver<sup>1</sup>, John Updegraff<sup>2</sup>, E. Alison Holman<sup>1</sup>; <sup>1</sup>University of California at Irvine, <sup>2</sup>Kent State University – For decades, psychologists have maintained that the need to make sense of the events in one's social world is a fundamental part of everyday social cognition, as well as a central part of theories of adaptation to trauma. This presentation will review a program of research on the role of meaning-making following personal traumatic experiences, including the sudden loss of a loved one, natural disaster, and childhood sexual abuse. In addition, we will address how collective traumatic events can also stimulate a search for meaning, even when one experiences no direct loss. Specifically, results will be presented from a prospective, two-year longitudinal study of a national probability sample of approximately 1,000 Americans that examined the predictors and long-term consequences of searching for and finding meaning in the September 11, 2001 terrorist attacks. Results demonstrate that both searching for meaning

and the ability to find meaning in the 9/11 attacks were predicted by demographics and high acute stress response in the weeks following the attacks. An early search for meaning in the attacks was associated with greater posttraumatic stress symptoms over time, while finding meaning predicted lower symptomatology over the subsequent two years. Consistent with social psychological theories of meaning, we found that the ability to find meaning facilitated adjustment by reducing Americans' fears of future terrorism. Results highlight the role of meaning-making in adjustment, both for individuals directly and indirectly exposed to trauma, and in particular following collective traumas that shatter people's fundamental assumptions about security and invulnerability.

## Symposia Session B

Friday, January 29, 11:15 am - 12:30 pm

### Symposia Session B1

#### RELIGION AND SUPPORT OF VIOLENCE AGAINST THE OUTGROUP

Friday, January 29, 11:15 am - 12:30 pm, Royale Pavilion 1

Chairs: Ariel Malka, Yeshiva University, and Adam Cohen, Arizona State University

Speakers: Gilad Hirschberger, Ariel Malka, Jeremy Ginges, Jesse Graham

Both religion and violence are endemic features of human social organization. Many argue that religion inherently promotes violence toward members of outgroups, casting them as nonbelievers or blasphemers. Is there an inherent linkage between religious sentiment and support of violence? Or does this linkage result from specific types of religiously relevant social messages that appear at particular times and places? The presentations assembled here address this question using a variety of theoretical frameworks and methodologies. Sampling Jewish and Muslim Israelis, Hirschberger demonstrates that the combination of religiosity and motivation to uphold one's cultural worldview sometimes promotes and sometimes decreases support of violence. This depends critically on whether the individual was recently exposed to a belligerent religious message or to a peaceful religious message. Malka then presents evidence, from representative American samples, that the relation between religiosity and violence-supportive attitudes is dependent on level of political engagement: Only among the highly politically engaged have the more religious been more favorable to violent policies. Next, sampling a diverse set of groups (including Palestinians, Israeli settlers, and Indian Hindus), Ginges demonstrates that exposure to collective religious ritual – but not religious devotion – is associated with support of suicide attacks. Finally, Graham demonstrates how group-level moral concerns can help predict and explain the relationships between religiosity and intergroup violence. Taken together, these findings suggest that the connection between religion and violence is neither direct nor simple. Rather, it depends on contextual factors – including the specific messages conveyed by religious and social elites.

#### ABSTRACTS

##### TERROR MANAGEMENT AND RELIGIOUS WRATH: AGGRESSIVE AND PACIFIC MANIFESTATIONS OF DEFENDING THE FAITH

Gilad Hirschberger<sup>1</sup>, Tom Pyszczynski<sup>2</sup>; <sup>1</sup>IDC Herzliya, <sup>2</sup>University of Colorado, Colorado Springs – The current research conducted with Jewish and Muslim citizens of Israel demonstrates that highlighting different aspects of religious faith moderates the influence of mortality salience (MS) on support of violent conflict. In Study 1, MS increased support among Israeli Jews for a pre-emptive nuclear strike on Iran among religious, but not secular Jews, but only after their faith in an afterlife had been threatened. In Study 2, MS led to negative evaluations of Israeli policies by Muslim

citizens of Israel after reading a passage from the Koran depicting Jews in negative terms; MS had the opposite effect after reading another passage from the Koran describing Judaism in positive terms. In Study 3, conducted with Israeli Jews, MS led to greater support of aggressive policies against Palestinians after reading a passage by Maimonides depicting Islam in negative terms. However, MS led to reduced support of such policies after reading a passage describing Islam as similar to Judaism; but this effect was found only among religious Jews. These findings indicate that the role of MS in the perpetuation of violent conflict is complex and depends both on the nature of the religious population, as well as on the aspects of religion that are highlighted.

##### RELIGIOSITY AND SUPPORT OF VIOLENT POLICIES: THE INDISPENSABLE ROLE OF POLITICAL ENGAGEMENT

Ariel Malka<sup>1</sup>, Yphtach Lelkes<sup>2</sup>, Adam Cohen<sup>3</sup>; <sup>1</sup>Yeshiva University, <sup>2</sup>Stanford University, <sup>3</sup>Arizona State University – From the crusades to the 9-11 terrorist attacks, there are plenty of examples of religious sentiment promoting violence against outgroups. Because religious beliefs are supernatural, and supernatural thought is a component of social backwardness, it is easy for commentators to draw the connection between religious devotion and senseless violence against those who are different. The present analyses use national sample survey data to gauge whether religious Americans have in fact been more supportive of violent social policies – such as wars and the death penalty – than have non-religious Americans. The results consistently point to the conclusion that religion has only promoted attitudes toward violent social policies to the extent that the person has been heavily exposed to political messages – and not that religious people are inherently in favor of violent social policies. Among individuals who were not engaged with political discourse, religiosity was not positively associated with, and was sometimes negatively associated with, preferences for violent solutions to social problems. The relations between religiosity and support of violent social policies also varied considerably across demographic (e.g., racial-ethnic) groups, and these effects were mediated by differential exposure to political discourse. Thus it requires cues from political discourse – indicating, for example, that it is “conservative” to be religious and it is also “conservative” to support particular violent policies – to cause the religious to be more supportive of violent policies than the non-religious. These findings are discussed in relation to prior evidence of basic psychological dispositions underlying religiosity and violence-supportive attitudes.

##### RELIGION AND SUPPORT FOR SUICIDE ATTACKS

Jeremy Ginges<sup>1</sup>, Ian Hansen<sup>1</sup>, Ara Norenzayan<sup>2</sup>; <sup>1</sup>New School for Social Research, <sup>2</sup>University of British Columbia – There has been widespread popular and scientific debate regarding the relationship between inter-group violence, suicide attacks and religion, with particular attention paid to Islam (Dawkins, 2003; Harris, 2005). The debate is understandable but empirical investigation of this question has been sorely lacking. In four studies carried out across different cultural, religious and political contexts, we empirically investigated a novel social psychological theory explaining an association between religion and popular support for suicide attacks. Studies 1 and 2, representative surveys of Palestinians, revealed that the frequency of prayer to God, an index of religious devotion, was unrelated to support for suicide attacks. Instead, attendance at religious services, predicted to enhance parochial altruism, positively predicted support for suicide attacks carried out by Palestinians against Israelis. In Study 3 we replicated that result in a cognitive priming experiment carried out with Israeli settlers. Reminders of participation in collective religious ritual, but not reminders of prayer to God, increased support for a suicide attack carried out by an Israeli Jew against Palestinians. In Study 4, a survey of six religions in six nations showed that attendance at collective religious services positively predicted a combination of willing martyrdom and outgroup hostility, while regular prayer did not. Implications for understanding the role of religion in suicide attacks are discussed.

**AROUND THE MAYPOLE: RELIGIONS FOSTER GROUP-FOCUSED MORALITY** Jesse Graham<sup>1</sup>, Jonathan Haidt<sup>1</sup>, Matthew S. Motyl<sup>1</sup>; <sup>1</sup>University of Virginia

— We argue that a social-psychological understanding of the relationship between religion and intergroup violence will require broadening our field's definition of morality. To this end, we present Moral Foundations Theory (Haidt & Graham, 2007), which encompasses not only the individual-focused concerns of compassion and fairness (which are prominent in liberal religious sects), but also the group-focused concerns of group loyalty, respect for authorities and traditions, and physical and spiritual purity. Including group-level moral concerns allows for a social-functional approach to religion in which beliefs, rituals, and other aspects of religious practice are best understood as means to create a tightly-bound moral community. We show the ways that religious practice is socially intertwined with all five moral foundations, particularly the "binding" foundations of Ingroup/loyalty, Authority/respect, and Purity/sanctity. We present data clarifying the relationships between these group-level moral concerns, religious practice, and support for religiously-motivated violence. Recognizing the existence of group morality can help explain the double-edged nature of both moral certainty and religious devotion, which have each been associated with so much good and evil throughout history.

**Symposia Session B2****WHAT IS BELOW THE BIG FIVE? STRUCTURE AND UTILITY OF LOWER LEVELS OF ANALYSIS**

Friday, January 29, 11:15 am - 12:30 pm, Royale Pavilion 2

Chairs: Joshua Jackson and Brent Roberts, University of Illinois

Speakers: Colin DeYoung, Dustin Wood, Joshua J. Jackson, Stacy Eitel Davies

It is commonly accepted that personality structure is arranged hierarchically (Markon, Krueger & Watson, 2005). Presently, however, there is little conceptual or empirical agreement for the structure underlying the Big Five. One reason for the lack of a replicable underlying structure is the overriding focus on the number of factors sufficient to capture trait variance. Identifying the lower order structure for personality traits is one of the next big goals in personality assessment. Using finer grain assessments can provide increases in prediction (Paunonen & Ashton, 2001), reveal greater overlap with related constructs, and may be better attuned to biological level analysis (Roberts & Jackson, 2008). With the interface between personality psychology and other fields becoming more prevalent there is an even greater need to promote personality assessment beyond a Big Five profile. This symposium discusses the recent developments in lower order assessment and highlights advantages a lower order approach offers. DeYoung presents data on lower order aspects of the Big Five and discusses how this lower order approach has implications for statistical artifacts and the neurobiological basis of traits. Wood, Nye and Saucier discuss a new lower order measure that assesses a number of distinguishable dimensions of individual differences in a desire to provide more comprehensive personality assessments. Davies and colleagues validate the facet structure of extraversion and provide evidence for the increased utility of using extraversion facets. Jackson and Roberts demonstrate the benefits of assessing conscientiousness facets for both development and the association between conscientiousness and health.

**ABSTRACTS****EMPIRICAL AND THEORETICAL UTILITY OF A LEVEL OF PERSONALITY STRUCTURE BETWEEN THE BIG FIVE AND THEIR FACETS** Colin

DeYoung<sup>1</sup>; <sup>1</sup>University of Minnesota — Personality is arranged hierarchically; correlated specific traits group together within broader traits, a structure most commonly represented by classifying many lower level traits, or "facets," within the Big Five (though the number and identity of all relevant facets have not been determined). Psychology may benefit from the recognition of a level of trait organization between the Big Five domains and their many facets. The existence of this level was suggested

empirically by a behavior-genetic study indicating that two genetic factors were necessary to explain the covariance among the facets in a widely used measure of the Big Five (Jang et al., 2002). A subsequent phenotypic study replicated the finding of two factors within the facets for each of the Big Five, using a larger number of facets (DeYoung, Quilty, and Peterson, 2007). I will discuss various ways in which consideration of traits at this intermediate level, wherein each of the Big Five has two aspects, can enrich personality psychology. The aspect-level traits allow parsimonious investigation of complexities in the relations among traits that are not evident at the Big Five level, and that have implications for both predictive and explanatory endeavors in personality research. I will present data in which pairs of aspects are involved in statistical suppression, which obscures interesting relations to approach and avoidance and to political ideology. Further, consideration of the relations of aspect-level traits to interpersonal behavior and cognitive function suggests the utility of this level of personality structure for understanding the neurobiological basis of traits.

**IDENTIFICATION AND MEASUREMENT OF A REPRESENTATIVE SET OF PERSON-DESCRIPTIVE ADJECTIVES FROM THE ENGLISH LEXICON**Dustin Wood<sup>1</sup>, Chris Nye<sup>2</sup>, Gerard Saucier<sup>3</sup>; <sup>1</sup>Wake Forest University, <sup>2</sup>University of Illinois, <sup>3</sup>University of Oregon

— We propose methods by which the content in the lexicon can be represented in a smaller number of clusters, and how these clusters can be practically measured for research purposes. First, although data-driven methods have been utilized to identify the most major dimensions of individual differences that are represented in the English lexicon (e.g., the Big Five), similar data-driven methods have not been utilized as successfully to identify and summarize the many distinguishable dimensions of individual differences that can be identified in the lexicon. By applying cluster analysis to Saucier's (1997) list of the 504 most common trait adjectives, we identified 61 clusters which together can be considered to summarize the major content identifiable in the lexicon. Second, we develop an instrument termed the Inventory of Individual Differences in the Lexicon (IIDL) for the assessment of these dimensions through single items. To address reliability concerns, we demonstrate that single-item measures have substantial test-retest reliabilities over a couple days and that IIDL items correlate with standard Big Five measures above  $r = .70$ . Most importantly, we demonstrate that analyses using lower-level clusters regularly reveal relationships between personality traits and variables of interest that are masked through the use of Big Five scales alone. Ultimately, we urge the field to move past the assessment of Big Five traits as the sole means of measuring personality and to instead utilize inventories which can provide more comprehensive assessments of how individual differences relate to variables of interest.

**LOWER ORDER LEVELS OF CONSCIENTIOUSNESS: IMPLICATIONS FOR DEVELOPMENT AND HEALTH** Joshua J. Jackson<sup>1</sup>, Brent W. Roberts<sup>1</sup>;

<sup>1</sup>University of Illinois — Conscientiousness is often defined as individual differences in the propensity to follow socially prescribed norms for impulse control, to be goal-directed, planful, able to delay gratification, and to follow norms and rules (Jackson et al., 2009). As seen in this definition, conscientiousness is a broad trait consisting of many different components. While broad factors like conscientiousness provide bandwidth and parsimony they lack fidelity, possibly obscuring differential associations at a lower level of analysis. In this paper we demonstrate the utility of assessing conscientiousness at a lower order level by highlighting differential relationships among lower order levels of conscientiousness in two domains. First, we review the show that the five replicable facets of conscientiousness (industriousness, orderliness, impulse control, reliability and conventionality; Jackson et al., 2009) have different age related patterns of development. Conscientiousness tends to increase throughout adulthood, however not all facets show similar age differences. Some facets change predominantly during young adulthood whereas other facets increase throughout the lifespan. Secondly, we expand on the relationship between conscientiousness and health outcomes by focusing on specific facets of conscientiousness. Specifically,

we find that some but not all conscientiousness facets mediate the relationship between conscientiousness and health outcomes. We conclude with the suggestion that using lower order facets offer a number of theoretical and practical advantages over the use of traditional broad traits.

**DIFFERENTIAL PREDICTION USING EXTRAVERSION FACETS** Stacy Eitel Davies<sup>1</sup>, Brian S. Connelly<sup>2</sup>, Deniz S. Ones<sup>1</sup>; <sup>1</sup>University of Minnesota, <sup>2</sup>University of Connecticut – Extraversion is a personality trait that appears in almost every taxonomy of personality (Watson & Clark, 1997) and is associated with many important behaviors and life outcomes (e.g., leadership, clinical disorders, and life satisfaction). Personality theorists have identified a handful of specific traits related to Extraversion, but discrepancies persist among trait theorists' conceptualizations of Extraversion's core and constituent facet traits. Therefore, this research has two specific goals: (1) meta-analytically delineate true facets of Extraversion from Extraversion trait compounds that incorporate other Big Five factors and (2) examine whether commonly studied constructs in clinical, health, social, work, academic, and individual differences domains are predicted differentially by Extraversion's facets. Results show that Dominance, Sociability, Activity, and Positive Emotions measures are pure facets of Extraversion since they are strongly uniquely related to Extraversion and not the rest of the Big Five. Thus, full coverage of the Extraversion domain necessitates measuring these four facets. Sensation Seeking and Optimism are deemed compound traits with relationships with Extraversion and at least one other Big Five variables. In addition, measuring facets instead of solely Global Extraversion can make a substantial difference in the predictive validity of Extraversion constructs for predicting important outcomes. For example, the validity of using global extraversion predicting overall managerial job performance is moderate, however, much better predictive validity is obtained with dominance, and much lower validity is found for sociability. On the whole, these results better define Extraversion's facet domain and clarify Extraversion's placement in nomological networks across multiple domains of psychology.

### Symposia Session B3

#### NEW DIRECTIONS IN THE STUDY OF LOVE: NEUROBIOLOGICAL PERSPECTIVES

Friday, January 29, 11:15 am - 12:30 pm, Royale Pavillion 5

Chairs: Joshua Poore, National Institute of Health (NINDS), and Arthur Aron, State University of New York at Stony Brook

Speakers: Stephanie Ortigue, Bianca Acevedo, Joshua Poore

Romantic love sits high atop a list comprised of the most cherished human experiences. Sadly, it remains one of the least understood despite its centrality in daily subjective experience. In the past decade, social neuroscience approaches have been particularly helpful in piecing together love's puzzle. This symposium explores new directions in these approaches, new methodologies, and new insights about love's form and function. Primarily, these new directions investigate the role of love's experience in the development of close romantic relationships. The studies described in this symposium report both neuroimaging and 4D EEG data, validating previous research implicating the role of the brain's reward system in love's experience. Also, they extend the reach of this research agenda by examining how the human reward system is dynamically involved in experiences of romantic passion, the development of relationship-specific attachment orientations, and its association with relationship longevity. Moreover, this research is among the first to explore links between romantic love, relationship development, and cortical areas involved in goal representation, mentalizing, and social mirroring. Overall, the findings presented in this symposium affirm the utility of social neuroscience perspectives and methodologies in uncovering the love's most elusive mysteries.

### ABSTRACTS

**OVERLAPPING NEURAL SYSTEMS MEDIATING SELF-CONSCIOUSNESS, MIRROR NEURONS & LOVE: A COMBINED FMRI AND 4D EEG NEUROIMAGING APPROACH** Stephanie Ortigue<sup>1</sup>, Francesco Bianchi-Demicheli<sup>2</sup>; <sup>1</sup>Syracuse University, New York, <sup>2</sup>University of Geneva, Switzerland – The self-expansion model (Aron & Aron, 1986) assumes that people in close relationships aim to increase their potential efficacy by including cognitively their significant other in the self (thus representing themselves as possessing to some extent other's body image, characteristics, and resources). Combining modern neuroimaging techniques (fMRI and 4D EEG neuroimaging) and psychophysics, our results recently reinforced this self-expansion model by unraveling the neural basis of love within neural systems that mediate body-image, motivation, self-consciousness, and mirror mechanism (Ortigue et al., 2007, 2008). Here we present the spatio-temporal dynamics of these neural systems. Importantly, activation of these neural systems was observed in earlier stages of information processing (i.e., over the 80-120ms, and 120-220ms periods) in participants in high passionate love in comparison with participants in low passionate state. This early activation of brain areas involved in self-representation and mirror mechanisms in participants in high passionate love sheds lights on the chrono-architecture of the cognitive processes that occur during passionate love. The similarities between the mirror matching process, self-representation and the mutual understanding that occur when two persons are in high passionate love suggest that exposure to love might affect functional and neural mechanisms, thus facilitating mutual understanding.

**NEURAL CORRELATES OF PAIR-BONDING IN NEWLYWEDS** Bianca Acevedo<sup>1</sup>, Arthur Aron<sup>2</sup>, Nancy Collins<sup>1</sup>, Lucy Brown<sup>3</sup>; <sup>1</sup>University of California, Santa Barbara, <sup>2</sup>State University of New York at Stony Brook, <sup>3</sup>Albert Einstein College of Medicine – Research suggests that the strength of newlywed bonds predicts marital quality and stability 4 years later (Karney & Bradbury, 1997) and up to 13 years later (Huston et al., 2001). One approach to assessing the underpinnings of pair-bonds builds on neurobiological studies showing that subcortical brain regions that mediate rewards (such as the ventral pallidum/striatum) are implicated in pair-bond formation and maintenance in rodent mammals (e.g., Aragona et al., 2006; Curtis et al., 2006; Gingrich et al., 2000; Young et al., 2001; Lim & Young, 2004). Human studies on early-stage love support these findings (e.g., Aron et al., 2005; Bartels & Zeki, 2000) but have not found evidence of the ventral striatum/pallidum. Moreover, it remains unknown how the system changes over time in response to a mate, and whether activations are associated with marital quality and stability. The present research examines newlyweds' neural activity (using fMRI) in response to their partners. Participants viewed face images of their partners and controls, as in previous studies of romantic love (e.g., Aron et al., 2005). Time 1 findings showed neural activity specific to the partner in the right ventral tegmental area (VTA), found in previous studies of romantic love. Results also showed significant activity in the ventral striatum/pallidum, known to be critical to pair-bond formation and maintenance in rodents, but not found in human research on early-stage romantic love. We conclude that this group of individuals displayed both early attraction and attachment neural activity, critical to the establishment and maintenance of pair-bonds.

**ROMANTIC PASSION AND PREDICTION-ERROR IN THE MESOLIMBIC REWARD SYSTEM: AN EVENT RELATED FMRI STUDY** Joshua Poore<sup>1,2</sup>, Matthew Lieberman<sup>1</sup>; <sup>1</sup>University of California, Los Angeles, <sup>2</sup>National Institute of Health (NINDS) – This research examines the link between experiences of romantic passion and prediction-error signals in the mesolimbic reward system (see Schultz, 1998) and whether these errors, in aggregate, induce uncertainty regarding the perceived likelihood that partners will reciprocate romantic sentiment. Romantic passion is theorized to depend on such a state (Hatfield & Walster, 1978), but this hypothesis has never been tested. The present study implemented a prediction-error

task that either confirmed participants' expectations about their partners' romantic sentiments or violated them, in both positive and negative directions, on a trial-by-trial basis. Findings show VTA activity when expectations were violated in a positive direction and deactivation of the VTA when they were violated in a negative direction. Also, consistent with prediction-error studies of economic losses relative to gains (Seymour, et al., 2007), the posterior ventral striatum showed activity when expectations were negatively violated. Additionally, ventral striatum activity was associated with task-related attachment anxiety, a notion that has been equated with romantic passion (Eastwick & Finkel, 2008). Overall, this research not only validates theory that relates uncertainty to romantic passion, but also suggests that experiences of romantic passion may be related, in part, to prediction-error signals within the reward system. Given the part these errors play in the associative learning of stimulus-outcome contingencies (Ikemoto, 2007), these findings imply a formative role for romantic passion in relationships: Experiences of romantic passion may underlie learning the conditions under which partners are likely to be responsive, as well as how best to elicit responsiveness.

### Symposia Session B4

#### BASIC BUILDING-BLOCKS OF THE SOCIAL-RELATIONAL MIND

Friday, January 29, 11:15 am - 12:30 pm, Royale Pavilion 6

Chairs: Lotte Thomsen, Harvard University, University of Copenhagen, and Andrew Scott Baron, University of British Columbia

Speakers: Lotte Thomsen, Harriet Over, Kiley Hamlin, Andrew Scott Baron

Humans are an ultra-social species (Brewer, 2007) and learning the structure and function of their social world is a critical developmental task for infants. How and when children solve this task has important theoretical implications for social psychology, because psychological phenomena should be present early enough in development to facilitate this learning process if they functionally underpin social interaction and cognition. This symposium presents cutting-edge research with pre-verbal infants through the first 5 years of life revealing the early emergence of representations of social dominance, affiliation, group membership and their influence on altruistic helping, moral evaluation and intergroup bias. Paper I demonstrates that 10-month-olds represent social dominance and use relative size as a cue, expecting a large novel agent to prevail over a small one when their goals conflict in a zero-sum manner. Paper II demonstrates that 18-month-olds engage in altruistic helping when primed with affiliation (embodied as a hug) and that 5-year-olds increase affiliative imitation when primed with spatial ostracism. Paper III demonstrates that 9-15-month-olds not only prefer people who help others or share their own preferences, but also prefer people who a) reward others that have helped another or share their food preferences and b) punish others that have hindered another or differ in their preferences. Finally, Paper IV investigates how representations of ingroups and outgroups differentially shape the emergence of intergroup attitudes and stereotypes among 3-year-olds. Together, these papers demonstrate the early emergence of key social psychological constructs, underscoring significant relational building blocks of human social life.

#### ABSTRACTS

**BIG & MIGHTY: PREVERBAL INFANTS REPRESENT SOCIAL DOMINANCE** Lotte Thomsen<sup>1,2</sup>, Willem E. Frankenhuis<sup>3</sup>, Susan Carey<sup>1</sup>; <sup>1</sup>Harvard University, <sup>2</sup>University of Copenhagen, <sup>3</sup>University of California, Los Angeles – Social dominance hierarchies are ubiquitous across the animal kingdom and human cultures (Fiske, 1991; Sidanius & Pratto, 1999). Predicting the social rank of self and others confers important coordination benefits (Richerson & Boyd, 2004), suggesting infants may adaptively represent social dominance. Two infant-studies using standard looking-time-methodology investigated whether infants use relative size as a cue to social dominance. In Study 1, 13-month-old infants assigned to a Conflicting Goals Condition watched an animation of a large and small

square blocking each other's habitual paths, after which one agent prostrated itself and scooted out of the way to let the other one pass. Infants in the Control Condition watched identical prostration/scooting performed in isolation. The test event (Big versus Small prostrates) interacted with the study condition ( $F(1,28)=4.44, p=.044$ ) such that the size of the prostrating agent mattered in the Conflicting Goals scenarios, but not in the non-social controls. Specifically, infants were more surprised, and looked longer, when a big square bowed and moved away for a small square than vice versa ( $t(15)=2.94, p(\text{one-tailed})=.005$ ); but did not differentiate between agents prostrating in isolation ( $t(15)=.28, n.s.$ ). Study 2 replicated these results among 10-month-olds who are too young to have participated in any dominance contests themselves. These data suggest that preverbal infants have abstract representations of dominance, and use relative size - a cue that covaries with it phylogenetically, and marks it metaphorically across human cultures and languages - to predict which of two agents is likely to prevail in their very first zero-sum competition.

#### PRIMING THIRD-PARTY AFFILIATION AND OSTRACISM INCREASE HELPING AND AFFILIATIVE IMITATION IN INFANTS AND CHILDREN

Harriet Over<sup>1,2</sup>, Malinda Carpenter<sup>2</sup>; <sup>1</sup>Cardiff University, <sup>2</sup>Max Planck Institute for Evolutionary Anthropology – In two experiments, we show that the mere hint of the group can have a profound impact on young children's cognition and behaviour. In one experiment, we tested whether children increase their imitation following exposure to ostracism. Given humans' profound need to belong, we predicted that a mere hint of social exclusion - even third-party social exclusion - would be sufficient to increase affiliative imitation in 5-year-olds. As predicted, children primed with videos in which one shape was ostracized by a group of other shapes subsequently imitated the actions of a model more closely than children in a control condition ( $t(26)=3.02, \text{two-tailed } p=.006$ ). In a second experiment, we tested whether the mere hint of affiliation is sufficient to increase helping behaviour even in infants. We showed 18-month-old infants photographs invoking either affiliation (two dolls standing next to one another) or individuality (e.g. two dolls standing back-to-back) and measured their influence on infants' tendency to be helpful. Results showed that infants helped a person in need more often ( $c2(1)=6.43, \text{two-tailed } p=.011, \eta^2=.33$ ), and more spontaneously ( $c2(1)=8.57, \text{two-tailed } p=.003, \eta^2=.38$ ), after being primed with photographs evoking affiliation, as opposed to photographs evoking individuality.

#### THE ENEMY OF MY ENEMY IS MY FRIEND: INFANTS' PREFERENCES FOR ANTISOCIAL OTHERS

Kiley Hamlin<sup>1</sup>, Neha Mahajan<sup>1</sup>, Karen Wynn<sup>1</sup>; <sup>1</sup>Yale University – Research into infants' social preferences has revealed that infants prefer certain social partners: those who are prosocial (Hamlin, et al, 2007), and those who are similar to them (Kinzler, et al, 2007; Mahajan & Wynn, in prep). Interestingly, adults' social preferences often change depending on who is involved in a situation; for example, liking those who behave antisocially toward those they dislike (e.g. "The enemy of my enemy is my friend." Aronson & Cope, 1968; Gawronski et al, 2005; Heider, 1958). The current studies examine whether infants, like adults, prefer those who are antisocial toward disfavored others. Infants at 9-, 14-, and 19-months of age were shown puppet shows in which one puppet was prosocial and another puppet was antisocial toward a target puppet. Critically, for half of the infants, the target was liked, as it had previously either a) been nice to a third party or b) expressed the same food preference as the infant; for the other half of the infants, the target was disliked, as it had previously either a) been mean to a third party or b) expressed a different food preference from the infant. Following the show, infants were given a choice between the prosocial and antisocial puppets. The target's identity influenced infants' choices: those who had seen the puppets act on a liked target preferred the prosocial character (24/30 infants,  $p<.005$ ), while those who had seen the puppets act on a disliked target preferred the antisocial character (26/30 infants,  $p<.0001$ ).

**US AND THEM: BUILDING-BLOCKS OF SOCIAL-RELATIONS** Andrew

**Scott Baron**<sup>1</sup>; <sup>1</sup>University of British Columbia – Turner, Brown & Tajfel (1979) suggest that the representation of the social world is divided effortlessly and perhaps automatically in terms of ingroups and outgroups and proposed that self-categorizing as an ingroup member has numerous consequences for intergroup cognition including the over extension of positive properties to ingroup members, the greater willingness to help an ingroup member, and the attribution of more secondary emotions to ingroup members (Sherif et. al, 1961; Patterson & Bigler, 2006; Nesdale & Flessler, 2001). Development offers an important window into understanding the role of representations of group membership for intergroup cognition. If concepts such as ingroup and outgroup are the foundation over which more elaborate representations of social groups are scaffold, then such representations should be available early in development and would begin to shape social learning experiences. The present paper explores the consequences of group membership for the construction of social category concepts among 3-year-olds. Experiment 1 demonstrates that children effortlessly acquire representations of ingroups and outgroups and that the processing of group-diagnostic information is differentially shaped by these representations. Experiment 2 extends these results by suggesting that cues to group status (high or low) may be automatically encoded and integrated with representations of ingroups and outgroups. Together, these results suggest that by 3-years-of-age, children are highly attuned to which social groups are the subject of discourse in the environment and that social learning is shaped by a) which groups they identify with and b) the perceived social status of those groups.

**Symposia Session B5****PERSPECTIVES ON MORAL LICENSING: HOW PERSONAL MORAL HISTORY AFFECTS THE ENTITLEMENT TO TRANSGRESS**

Friday, January 29, 11:15 am - 12:30 pm, Royale Pavilion 3-4

Chairs: Emily Zitek and Daniel Effron, Stanford University

Speakers: Emily M. Zitek, Sonya Sachdeva, Caitlin A.J. Powell, Daniel A. Effron

In recent years, an increasing number of scholars have begun tackling the complex issue of how personal history affects moral behavior. This symposium brings together emerging perspectives on this issue, rarely discussed side by side. The first two talks will examine the effects of moral history on actors' behavior. Emily Zitek will discuss how suffering an unfair event can make people feel more entitled to behave selfishly. Sonya Sachdeva will suggest that affirming one's moral identity can license people to refrain from performing altruistic behavior. The second two talks will examine how observers respond to transgressors who have a history of moral behavior. Caitlin Powell will examine observers' feelings of *schadenfreude* when individuals with a history of good deeds receive punishment for transgressions. In contrast, Daniel Effron aims to identify the conditions under which a transgressor's history of moral behavior increases versus decreases observers' willingness to punish the transgression. Two key moderators seem to be the transgression's moral ambiguity, and how closely it relates to the transgressor's moral history. Together, these perspectives on moral licensing suggest that certain moral histories can increase people's willingness to engage in morally dubious behaviors, and depending on the situation, can either increase or decrease observers' willingness to permit such behaviors.

**ABSTRACTS****FEELING WRONGED AND MAKING IT RIGHT: EXPERIENCING AN UNFAIR, NEGATIVE EVENT LEADS TO A SENSE OF ENTITLEMENT AND SELFISH BEHAVIOR**

Emily M. Zitek<sup>1</sup>, Alexander H. Jordan<sup>2</sup>, Benoît Monin<sup>1</sup>, Frederick R. Leach<sup>1</sup>; <sup>1</sup>Stanford University, <sup>2</sup>Dartmouth College – This research explores how feeling wronged can license people to behave selfishly. We propose that wronged individuals feel that they have already suffered enough, and consequently they feel entitled to spare themselves some of life's minor inconveniences, such as being attentive to the needs of oth-

ers, and instead behave in self-serving ways (Zitek et al., in press, JPSP). In Study 1, students who received bad numbers in a housing lottery expressed less intention to give back to their community than did students who received good numbers. In Study 2, participants instructed to recall a time when their lives were unfair, as compared to participants who were instructed to recall a time when they were bored, were more likely to refuse to help the experimenter with an additional, optional task. In Study 3, participants who believed that they lost at a computer game for an unfair reason (a glitch in the program) requested a more selfish money allocation for a future task than did participants who believed that they lost the game for a fair reason (not meeting the predetermined performance threshold), and this relationship was mediated by participants' sense of entitlement to positive outcomes after being wronged.

**MORAL THERMOSTATS: HOW INTERNAL SELF-REGULATION AFFECTS MORAL BEHAVIOR**

Sonya Sachdeva<sup>1</sup>, Rumen Iliev<sup>1</sup>, Doug Medin<sup>1</sup>; <sup>1</sup>Northwestern University – The question of why people are motivated to act altruistically has been an important one for centuries, and across various disciplines. Drawing on previous research on moral regulation, we propose a framework suggesting that moral (or immoral) behavior can result from an internal balancing of moral self-worth and the cost inherent in altruistic behavior (Sachdeva et al., 2009, *Psych Science*). We suggest that affirming a moral identity leads people to feel licensed to act immorally. However, when moral identity is threatened, moral behavior is a means to regain some lost self-worth. In Studies 1 and 2, we establish the framework of moral internal self-regulation and show that participants who are made to feel morally licensed donate one fifth as much as those who are made to feel immoral. In Study 3, we extend these findings to cooperative behavior in an environmental decision making task. Study 4 suggests that the moral licensing effect may be an artifact of particular systems of morality and that in a culture where morality is conceptualized in terms of one's duties or obligations to others we may observe a different pattern. Finally, in an on-going study (Study 5), we attempt to show that moral homeostasis is an implicit process and once participants are explicitly asked to state how moral they perceive themselves to be, we do not observe these compensatory patterns.

**EXPOSING THE IMMORAL BEHAVIOR OF HYPOCRITES: THE MORAL LICENSE FOR THRILLS**

Caitlin A.J. Powell<sup>1</sup>, Richard H. Smith<sup>2</sup>, Laura Van Winkle<sup>3</sup>; <sup>1</sup>Georgia College & State University, <sup>2</sup>University of Kentucky, <sup>3</sup>University of Louisville – When hypocrites suffer the misfortune of having their hypocrisy exposed, they receive little sympathy from others. In fact, *schadenfreude* may be the common reaction. When their initial moral behavior is revealed as counterfeit, it may make their actual immoral behavior seem more repugnant and their misfortune more deserved. Three studies explored *schadenfreude* resulting from the exposing of a hypocrite's immoral behavior. In Study 1, undergraduate participants read a newspaper interview with a student who, in some cases, was an eager member of a campus organization that exposed and punished plagiarism. A follow-up article revealed that the student had later been found guilty of and had been punished for plagiarism. Participants indeed reported greater perception of hypocrisy and greater *schadenfreude* when the student had been a member of the organization. Furthermore, this *schadenfreude* was largely mediated by these perceptions of hypocrisy as well as by the related sense that the misfortune was therefore deserved. Study 2 showed that this pattern was especially pronounced when the student was caught doing the precise behavior he or she accused others of doing, rather than another, equally immoral behavior (stealing). Study 3 varied whether or not the student initially emphasized his or her moral superiority over people who plagiarized or whether or not the student severely criticized others for plagiarizing. Both manipulations enhanced perceptions of hypocrisy, undeservingness of the misfortune, and *schadenfreude* over this misfortune. Apparent moral behavior, when hypocritical, appears to produce a reversal of fortune for the hypocrite -- and *schadenfreude* in observers.

**WHEN DOES DOING GOOD LICENSE DOING BAD?: THE ROLE OF HYPOCRISY AND MORAL AMBIGUITY** Daniel A. Effron<sup>1</sup>, Benoît Monin<sup>1</sup>;

<sup>1</sup>Stanford University – How do observers react to transgressions committed by individuals with a history of moral behavior? Contrary predictions can be derived from previous research. On the one hand, prior moral behavior may license subsequent transgressions in observers' eyes. On the other hand, transgressors with a history of moral behavior may appear hypocritical, prompting observers to be less permissive of their transgressions. The present research suggests that each of these predictions is correct under different conditions. Participants in three studies assigned punishments to individuals who had committed transgressions. Participants were more willing to permit a morally ambiguous transgression (e.g., one that may have been motivated either by racial prejudice, or by a more legitimate motive) when it was related to prior moral behavior (e.g., fighting racial discrimination) than when it was unrelated to prior moral behavior (e.g., fighting sexual harassment). The opposite was the case, however, when the transgression was morally unambiguous (e.g., clearly motivated by racial prejudice): participants were more likely to permit a transgression that was unrelated to prior moral behavior, because related transgressions appeared hypocritical. A baseline condition that did not present the transgressor's moral history revealed that moral behavior licensed unrelated transgressions regardless of their moral ambiguity, but only licensed related transgressions that were morally ambiguous. In fact, moral behavior tended to make participants less permissive of related transgressions that were morally unambiguous. We discuss the implications of these findings for the operation of two distinct pathways to moral licensing.

**Symposia Session B6****CULTURE AND EMOTION REGULATION**

Friday, January 29, 11:15 am - 12:30 pm, Royale Pavilion 7-8

Chairs: Igor Grossmann and Ethan Kross, University of Michigan

Speakers: Michael Boiger, Ethan Kross, Cecilia Cheng, Iris B. Mauss

Although research on emotion has a long tradition in cultural psychology, investigators have only recently begun to focus on how culture shapes the way people regulate their feelings. This symposium brings together four novel programs of research that focus on emerging trends in this rapidly developing area. Although each presentation focuses on a different aspect of emotion regulation their overarching goals are the same: to identify the basic psychological processes that determine how culture influences the way people regulating their feelings. Boiger and colleagues will begin the symposium by describing research examining the role that situation selection plays in emotion regulation across different cultures. They will discuss how Japanese and Americans regulate negative emotions by selecting to engage vs. disengage in situations that are differentially amenable to the experience emotion. Grossmann and Kross will continue by discussing research examining cultural differences in rumination in Russians vs. Americans. Central to their presentation will be a discussion of the role that self-distancing plays in mediating cultural differences in the effects of rumination on depression and distress. Cheng will then discuss how culture influences coping flexibility – the ability to implement different types of emotion regulation strategies depending on the specific needs of the situation. She will specifically discuss the relationship between coping flexibility and collectivism in China. Finally, Mauss and Butler will conclude by presenting research on the role that motivation plays in emotion regulation across different cultures. They will describe how emotion regulatory goals mediate cultural differences between Euro-Americans and Asian-Americans.

**ABSTRACTS****THE CULTURAL REGULATION OF ANGER AND SHAME IN JAPAN AND THE US**

Michael Boiger<sup>1</sup>, Sasha Lebedeva<sup>2</sup>, Yukiko Uchida<sup>3</sup>, Batja Mesquita<sup>1</sup>; <sup>1</sup>University of Leuven, Belgium, <sup>2</sup>Boston College, USA, <sup>3</sup>Kyoto University, Japan – An effective way of emotion regulation is 'situation selection': A person seeks out some and avoids other situations in order to regulate the associated emotions. Engaging in particular cultural contexts has an analogous effect: Situations that elicit culturally normative emotions are afforded more frequently, while those situations that elicit undesirable emotions tend to be avoided (Mesquita & Albert, 2007). Three studies were conducted in order to document the frequency and relevance of anger and shame situations in Japan and the US. In study 1, interviews were conducted with Japanese and US students (n=40) in order to obtain salient descriptions of anger and shame antecedents. In study 2, experience sampling of Japanese and US students (n=103) yielded a range of daily anger and shame antecedents. From the pool of anger and shame antecedents obtained in studies 1 and 2, a random sample (stratified by gender and origin) of 40 anger and 40 shame antecedents was selected and condensed to short situation descriptions. In study 3, participants (n=160) indicated for most students they know how frequently these situations would occur and how likely they would lead to anger or shame. Japanese and US students perceived situations taken from their own cultural context both as more frequent and as more likely to lead to the associated emotion. While anger situations were perceived as more frequent in the US, shame situations were perceived as more frequent in Japan. Results and implications are discussed from the perspective of a contextualized multi-component model of emotion regulation.

**THE CROSS-CULTURAL PECULIARITIES OF RUMINATION AND ITS CONSEQUENCES** Igor Grossmann<sup>1</sup>, Ethan Kross<sup>1</sup>; <sup>1</sup>University of Michigan, Ann Arbor, USA –

Although abundant findings document a strong negative association between rumination and distress among Westerners, it is unclear whether these findings generalize to other cultures. Integrating research on self-distancing and emotional analysis among Westerners with cultural research on perspective taking, we examined whether the self-reflective practices of Russians vs. Westerners are differentially associated with well-being, and the psychological mechanisms mediating these differences. We hypothesized that reflecting over negative feelings would be associated with less detrimental outcomes in Russians than Westerners because Russians self-distance more when analyzing their feelings. In Study 1 (n=168) we administered two trait measures of rumination (Ruminative Response Scale; Rumination Reflection Questionnaire), as well as a behavioral vignette measure designed to assess cultural differences in rumination. Results indicated that although Russians displayed higher levels of rumination compared to Americans, rumination was less strongly associated with depressive symptoms (BDI scores) among Russians than Americans. In Study 2, participants (n=162) recalled and analyzed an intensely distressing autobiographical anger experience. Subsequently, they indicated the extent to which they analyzed their experience from a self-immersed vs. self-distanced perspective and then rated their level of negative affect and answered a series of questions designed to assess how they construed their experience. Results indicated that Russians experienced less distress and displayed a more adaptive pattern of construals (less episodic recounting of their experience; less blame; more reconstruing) than Americans. In addition, Study 2 revealed how culture leads to these beneficial outcomes– by leading Russians to self-distance more when analyzing their feelings compared to Americans.

**EMOTION REGULATION AS A PASSIVE OR FLEXIBLE COPING STRATEGY? VIEWS FROM SITUATIONAL AND CULTURAL PERSPECTIVES** Cecilia Cheng<sup>1</sup>;

<sup>1</sup>The University of Hong Kong, China – Problem-solving has long been regarded as an active coping strategy that fosters psychological adjustment, whereas emotion-focused coping is generally regarded as a passive strategy that elicits greater distress. This study challenged this

widely held view by putting forward the adaptive aspect of emotion-focused coping in stressful encounters. From a situational perspective, emotion-focused coping may be adaptive when it fits the specific situational demands. From a cultural perspective, this strategy may be related to secondary control, which is valued in collectivistic societies. Participants were 105 Chinese undergraduates selected based on their coping profile (i.e., flexible, active-inflexible, or passive-inflexible). In the experiment, they were instructed to first complete a questionnaire. All of them performed a control task for baseline measures of skin conductance level (SCL) and then an uncontrollable task. Results showed that when handling an objectively uncontrollable stressful task, the active-inflexible group attempted to alter the task outcome, the flexible group tended to use emotion-focused coping, and the passive-inflexible group did not do anything. The active-inflexible group experienced the highest SCL than the other two groups. Use of emotion-focused coping was positively related to secondary control rather than relinquished control. Greater perception of secondary control was related to lower SCL in an uncontrollable situation. These findings provide support for the adaptiveness of emotion-focused coping in the context of uncontrollable stressful situations. It is also noteworthy that problem-solving can heighten stress levels in this type of situations.

**EMOTION-REGULATORY GOALS MEDIATE CULTURAL DIFFERENCES IN EMOTION RESPONDING** Iris B. Mauss<sup>1</sup>, Emily A. Butler<sup>2</sup>; <sup>1</sup>University of Denver, USA, <sup>2</sup>University of Arizona, USA – Cultural contexts tend to influence people's experiential and behavioral but not autonomic physiological responses to emotional situations. Little research has examined how these differences between cultural groups come about and why cultural context shapes some but not all aspects of emotional responses. In the present two studies, we tested the hypothesis that culture affects people's emotion-regulatory goals (here operationalized as the extent to which people value emotion control, ECV), which in turn affect their response to emotional situations to the extent that these responses are amenable to self regulation. Because experience and behavior are more amenable to self regulation than physiological responses, we expected that ECV would mediate cultural differences in experience and behavior but not physiology. We tested our hypotheses in Asian-American (AA) versus European-American (EA) cultural contexts because they provide a relatively clear contrast. We present data from two studies that suggest that AA individuals value emotion control to a greater extent than EA individuals. In addition, AA participants compared to EA participants responded with less anger experience and behavior to a standardized laboratory anger provocation. Groups did not differ in physiological responding. Importantly, differences in experience and behavior were mediated by ECV. These results support the notion that cultural differences in emotional responding are mediated by culturally specific values about emotion, which in turn might be instantiated via value-consistent emotion regulation.

## Symposia Session B7

### SOCIAL IMAGE AND CULTURE

Friday, January 29, 11:15 am - 12:30 pm, Capri Rooms 101-102

Chair: Susan Cross, Iowa State University

Speakers: Young-hoon Kim, Toshie Imada, Patricia M. Rodriguez Mosquera, Susan E. Cross

Social image refers to others' views of us and our perceptions of how much they value us. It encompasses a variety of constructs, such as reputation, honor, and face. How do conceptions of social image and the means of maintaining it vary across cultures? How does threatened social image affect psychological processes across cultures? This symposium brings together papers addressing these questions in multiple cultural contexts and using a variety of paradigms. The papers represent the concept of social image in varied ways, with studies that focus on public knowledge of one's actions (Kim and Imada), devaluation of one's social groups (including one's family, religion, or nationality;

Rodriguez Mosquera), and everyday situations that affect honor (Uskul). The papers also describe diverse effects of social image; they examine consequences for the self (self-evaluation, self-definition, and self-justification), emotional responses, and effects on one's close others. Finally, the papers highlight cultural differences and similarities in the role of social image. In the papers by Kim, Uskul, and Imada, Americans' relative neglect of others' views of them is contrasted with Turkish, Japanese, or Chinese people's concern for social image. Across three cultural groups, Rodriguez Mosquera finds similarities in emotional responses to threatened social image. While addressing the concept of social image from varied perspectives, the papers all point to the importance of this construct for understanding intrapersonal processes and interpersonal behavior in diverse cultural contexts. They highlight cultural differences and similarities in public and private facets of human psychology.

### ABSTRACTS

#### THE JURY AND ABJURY OF MY PEERS: THE ROLE OF PUBLIC REPRESENTATIONS IN DEFINING THE SELF

Young-hoon Kim<sup>1</sup>, Dov Cohen<sup>1</sup>; <sup>1</sup>University of Illinois, Champaign-Urbana – The self is defined and judged differently by people from Face and Dignity cultures (in this case, Hong Kong and the U.S., respectively). Across 3 experiments, Face culture participants absorbed the judgments of other people into their private self-definitions. Particularly important for Face culture participants are public representations – knowledge that is shared and known to be shared about someone. In contrast, Dignity culture participants try to preserve the sovereign self by not letting others define them. In Experiment 1, we examined a role-constrained behavior, using a modified version of Ross et al. (1977) quiz bowl task where the contestant (vs. questioner) looks relatively ignorant. For Face culture participants, the public performance of this ignorant role (looking-dumb) affected their self-definition whereas their private performance of this role (feeling-dumb) did not. For Dignity culture participants, a poor performance either in public or in private affected self-definition. In Experiment 2, we examined the limiting condition of "public". For Face culture participants, what was known to even one other person simply could not be ignored, and as a consequence, such public information was absorbed into one's self-definition to a far greater extent than purely private information. In contrast, for Dignity culture participants, no difference was found between public and private information. In Experiment 3, we examined how public representations come to define the self. Face culture participants absorbed into their self-definition whatever was publicly known and acknowledged to be publicly known about them, whereas Dignity culture participants did not absorb such judgments.

#### WATCHING EYES AND SELF-JUSTIFICATION: DISSONANCE IN VARYING CULTURAL CONTEXTS

Toshie Imada<sup>1</sup>, Shinobu Kitayama<sup>2</sup>; <sup>1</sup>University of Minnesota, <sup>2</sup>University of Michigan – Individuals are expected to justify their choice when the choice is self-threatening. However, because the nature of the self varies across cultures, the conditions in which the choice becomes self-threatening may also vary. In North American, independent cultural contexts, a choice will be self-threatening when it is private and thus experienced as self-expressive. In contrast, in Asian, interdependent cultural contexts, a choice will be self-threatening when it is publicly exposed and, thus, experienced as socially binding. The present work aimed to examine this cross-cultural pattern and its boundary conditions. By unobtrusively inducing an impression of public scrutiny, three studies found support for this analysis. Study 1 found that while Japanese justified their choice more when an impression of social eyes was unobtrusively primed during the choice than when this impression was primed only at a later point, this pattern was reversed for Americans. Study 2 found such contrasting pattern of cultural difference even in the absence of any social eyes as long as a cognitive representation of a face was subtly activated during the choice. Furthermore, Study 3 found that Americans justified their choice only when an observer was perceived as innocuous and non-influential. Together, these findings provide the first unequivocal evidence for the hypothesis

that perceived privacy or publicity of choice interacts with cultural backgrounds of both American and Asian participants to determine the likelihood of choice justification. Implications for culture, self, and dissonance are discussed.

**EMOTIONS AND THE DEVALUATION OF GROUP SOCIAL IMAGE** Patricia M. Rodriguez Mosquera<sup>1</sup>; <sup>1</sup>Wesleyan University – Social image refers to how others view us and how much they value us. One's social image is tied to one's individual self as well as to one's group-based self. Three studies examined emotional responses to the devaluation of group social image. These studies focused on three different types of groups –the family, religious group, national group– and included participants from three different cultural communities. In Study 1, 300 Pakistani participants reported a recent devaluation of their family's social image. In Study 2, 74 Muslim-British participants reported a recent devaluation of their religious group's social image. In Study 3, 80 European-American participants reported a recent devaluation of their identity as an 'American.' Across all studies measures of group identification, emotions (appraisals, intensity of feelings), and motivational tendencies were measured. Findings revealed that three emotions were especially intense in response to the devaluation of group social image: anger, shame, and humiliation. In addition, identification with one's group was a positive and significant predictor of the intensity of these emotions in response to group devaluation. In a similar vein, the more the participants identified with their group, the more they wanted to restore their group's social image. These findings were obtained for all three cultural communities. Implications of the findings for understanding the emotional bases of social image and reasons for observed cross-cultural similarities will be discussed.

**HONOR IN TURKEY AND THE MIDWESTERN US: SOCIAL IMAGE OR PRIVATE CHARACTER?** Ayse K. Uskul<sup>1</sup>, Susan E. Cross<sup>2</sup>; <sup>1</sup>University of Essex, <sup>2</sup>Iowa State University – Although the existence and importance of the concept of honor have been identified in many world cultures, its salience, forms, and associated responses tend to vary considerably. We tested the hypothesis that the extent to which a person's social image is reflected in the concept of honor varies in Mediterranean (Turkish) and Western (Midwestern American) cultures. In Study 1, using the situation sampling method, Turkish participants generated more honor-relevant situations than did Americans; the Turkish-generated situations focused more on close others and involved more references to an audience than did the American situations, pointing to the importance of social image in the Turkish understanding of honor. In Study 2, participants evaluated these situations for their impact on the self and close others. Among Turkish participants, honor-related events were seen as affecting the individual and his/her family equally, whereas for Americans, honor-related situations were viewed as more strongly affecting the individual than his/her family. In Study 3, an analysis of prototypes of honor-related situations revealed that prototypical Turkish situations involved more references to relationships and social image than did prototypical American situations. In summary, honor in Turkey is strongly related to others' views of the person and his/her family (i.e., social image), whereas honor in the US is primarily related to the individual's behavior alone. Thus, when honor is to be protected, Turkish people would place much more emphasis on protection and maintenance of social image than do Americans. The implication of these findings will be discussed for honor-related aggression.

## Symposia Session B8

### THE TWO FACES OF VERBAL MIMICRY: DOES LINGUISTIC SYNCHRONY PREDICT POSITIVE OR NEGATIVE SOCIAL OUTCOMES?

Friday, January 29, 11:15 am - 12:30 pm, Capri Rooms 103-106

Chairs: Matt L. Newman, Arizona State University, and Marlone D. Henderson, University of Texas at Austin

Speakers: Paul J. Taylor, Molly E. Ireland, Lauren E. Scissors, Amy L. Gonzales

Language is inherently social, existing principally for the purpose of communication between two or more people. Consequently, conversations are more than the sum of their discrete parts. However, most social psychological studies of language have analyzed it at the individual level—ignoring joint effects. More recently, a handful of researchers have begun filling this gap by analyzing language at the dyad or group level, focusing specifically on the relationship between verbal mimicry and practical outcomes. In this symposium, four speakers from diverse areas of specialization bring together findings that illuminate both the positive and negative consequences of verbal mimicry. On the positive side, Taylor and colleagues analyzed transcripts from real-life hostage negotiations and divorce mediations, finding that negotiations were more likely to be successful when negotiators consistently mimicked each other's language use. On the negative side, Ireland and Henderson analyzed transcripts of competitive negotiations in the laboratory, finding that dyads tended to argue more and have more trouble reaching agreement when competitors mimicked each other's language use. Finally, Scissors et al. suggest a middle ground, finding that different manifestations of verbal mimicry predict both high and low interpersonal trust in a multi-round online social dilemma game. Similarly, in separate studies, Gonzales and colleagues found that verbal mimicry is related to greater cohesiveness and task performance in work groups and may be used by individuals as an automatic deception strategy in dyads. Together, these findings suggest that verbal mimicry can be a potent predictor of both positive and negative joint outcomes.

#### ABSTRACTS

### LINGUISTIC STYLE MATCHING PREDICTS THE OUTCOME OF CRISIS NEGOTIATIONS

Paul J. Taylor<sup>1</sup>, Sally Thomas<sup>2</sup>, Stacey M. Conchie<sup>2</sup>;

<sup>1</sup>Lancaster University, UK, <sup>2</sup>University of Liverpool, UK – This research examined the relationship between Linguistic Style Matching—the degree to which negotiators coordinate their word use—and negotiation outcome.

Transcripts of dialogue from nine hostage negotiations (Study 1) and twenty divorce mediations (Study 2) were divided into 6 time stages, and interlocutors' dialogue was analyzed across 18 linguistic categories. Correlational analyses showed that successful negotiations were associated with higher aggregate levels of Linguistic Style Matching (LSM) than unsuccessful negotiations. In the hostage negotiations, this result was due to dramatic fluctuations of LSM during unsuccessful negotiations, with negotiators unable to maintain the constant levels of rapport and coordination that occurred in successful negotiations. In the divorce mediations a similar effect was observed, although the differences were confined to earlier stages of the interaction. Further analyses of LSM at the local turn-by-turn level revealed complex but organized variations in behavior across outcomes in both sets of negotiations. In comparison to unsuccessful negotiations, the dialogue of successful negotiations involved greater coordination of turn taking, reciprocation of positive affect, a focus on the present rather than the past, and a focus on alternatives rather than on competition.

### VERBAL MIMICRY IN NEGOTIATION: THE LANGUAGE OF THE DEAL

Molly E. Ireland<sup>1</sup>, Marlone D. Henderson<sup>1</sup>; <sup>1</sup>The University of Texas at Austin –

The present research examined the role of subtle verbal mimicry in competitive negotiation contexts. Across three studies, increased verbal mimicry as indexed by language style matching (LSM; Niederhoffer & Pennebaker, 2002) was negatively associated with the negotiation pro-

cess and outcome. Specifically, Studies 1 and 2 established that increased verbal mimicry was associated with a decreased likelihood of reaching agreement in negotiation. Moreover, increased verbal mimicry was associated with less efficiency (more words and time required) when agreement was reached. Study 3 replicated and extended these results, with self-reported contentiousness found to fully mediate the negative relationship between verbal mimicry and likelihood of reaching agreement. Implications for the use of verbal mimicry as a predictor of negotiation outcomes in relatively more or less competitive negotiations will be discussed.

**TRUST THROUGH TEXT: EXAMINING LINGUISTIC SIMILARITY AND TRUST IN TEXT CHAT** Lauren E. Scissors<sup>1</sup>, Alastair J. Gill<sup>1</sup>, Kathleen Geraghty<sup>1</sup>, Darren Gergle<sup>1</sup>; <sup>1</sup>Northwestern University – This work examines how different forms of linguistic similarity, including mimicry, relate to the establishment of interpersonal trust in a text-chat environment. Pairs of participants played an iterative social dilemma investment game and periodically chatted via Instant Messenger (IM) after every five rounds of investment. Initial results (N = 26 pairs) revealed that, within chat sessions, lexical mimicry was significantly higher for high-trusting pairs than for low-trusting pairs, but that lexical mimicry across chat sessions was significantly higher for low-trusting pairs than for high-trusting pairs. Further inquiry and analysis (N = 62 pairs) examined linguistic similarity at two levels: lexical mimicry and semantic similarity. Results revealed that certain types of mimicry (e.g., emoticon mimicry) and semantic similarity (e.g., similar use of positive emotion words) were associated with high levels of interpersonal trust, while other types of linguistic similarity (e.g., similar use of negative emotion words) were associated with low levels of interpersonal trust. Despite previous research which indicates that mimicry and similarity are positively related to relational development, the current findings suggest that not all similarity is beneficial for the establishment of interpersonal trust.

**USING VERBAL MIMICRY TO PREDICT POSITIVE AND NEGATIVE SOCIAL PROCESSES** Amy L. Gonzales<sup>1</sup>, Jeffrey T. Hancock<sup>1</sup>, James W. Pennebaker<sup>2</sup>, Lauren E. Curry<sup>1</sup>, Saurabh Goorha<sup>1</sup>, Michael Woodworth<sup>3</sup>; <sup>1</sup>Cornell University, <sup>2</sup>The University of Texas at Austin, <sup>3</sup>University of British Columbia, Okanagan, Canada – The degree to which people synchronize their verbal behavior can reveal important information about social dynamics. In one study, the Linguistic Style Matching (LSM) algorithm was introduced as a measure of verbal mimicry based on an automated textual analysis of function words. The LSM algorithm was applied to language generated during a small group discussion in which 70 groups comprised of 324 individuals engaged in an information search task either face-to-face or via text-based computer-mediated communication. As a metric, LSM predicted the cohesiveness of groups in both communication environments, and it predicted task performance in face-to-face groups (Gonzales, Hancock, & Pennebaker, in press). Another study investigated changes in both the liar's and the conversational partner's linguistic style across truthful and deceptive dyadic communication in a synchronous text-based setting. An analysis of 242 transcripts revealed that deceptive conversations were characterized by a higher degree of LSM, particularly when the liar was highly motivated to lie. However, the linguistic patterns in both the liar and the partner's language use were not related to deception detection, suggesting that partners were unable to use this linguistic information to improve their deception detection accuracy (Hancock, Curry, Goorha, & Woodworth, 2008). The results reveal that this type of automated measure of verbal mimicry can be an objective, efficient, and unobtrusive tool for predicting positive and negative features of underlying social dynamics.

## Symposia Session B9

### SURVEY SAYS?: INVESTIGATING THE POTENTIAL AND LIMITS OF SURVEY RESEARCH

Friday, January 29, 11:15 am - 12:30 pm, Capri Rooms 107-110

Chairs: Amanda Snook and David Kenny, University of Connecticut

Speakers: Charles Judd, Amanda Snook, Jon Krosnick, Niall Bolger

Social psychology as a field has been dominated by the use of laboratory experiments with college students. In this symposium, researchers show, in very different ways, the potential and limits of using survey research. Judd and Van Boven show how survey instruments need not be limited to simple questions of opinion. They use survey data to measure not only an individual's perception about an issue but also perceptions of distribution of sentiment among groups and individuals. Snook and Kenny re-analyze several different surveys to investigate Sears' as yet untested hypothesis that bias exists in samples consisting of only college students. Although they do find some differences, they are not as large as might be expected. Krosnick and Yeager describe many highly-cited social psychological studies that were replicated with representative samples of American adults via national surveys. They compare the laboratory effect sizes to the survey effect sizes, and explore the utility of social psychological principles in explaining everyday behavior. Finally Bolger, Shrouf, and Gleason discuss an experiment that compares daily diary data to survey data and found a stronger initial elevation bias with survey data, as opposed to diary data. The symposium emphasizes the importance of survey research as well as discussing its limitations.

#### ABSTRACTS

**MEASURING THE PERCEIVED DISTRIBUTIONS OF POLITICAL SENTIMENTS** Charles Judd<sup>1</sup>, Leaf Van Boven<sup>1</sup>; <sup>1</sup>University of Colorado at Boulder – The attitudes and attributes that one perceives others to possess figure prominently in work on social comparison, stereotyping, and social judgment most broadly. Until recently, survey research has only been able to measure the typical or modal attitudes and attributes that others are perceived to possess. We present a new method for gathering survey data on the perception of the entire distributions of sentiment attributed to groups and individuals. We will demonstrate this procedure and illustrate its utility by examining national survey data collected prior to the 2008 Presidential Elections. Respondents were asked about the perceived distributions of sentiment towards the two candidates, Barack Obama and John McCain, among Americans in general and among Democratic voters and Republican voters. Results reveal attitude projection as well as the projection of attitude polarization, i.e., those with more extreme sentiments project more extremity to others. Additionally, the results reveal clear evidence of ingroup homogeneity: members of each party perceive less variability in sentiments towards the two candidates in their own party than in the opposition party.

**HOW DIFFERENT ARE COLLEGE STUDENTS FROM OTHER ADULT SAMPLES?** Amanda Snook<sup>1</sup>, David Kenny<sup>1</sup>; <sup>1</sup>University of Connecticut – About 70% of published research in social psychology relies on college student samples (Wintre, North, & Sugar, 2001), yet Sears (1986) has argued that college students differ from other adult samples in important ways. He argued that these differences introduce biases into results that rely solely on college student samples. Although Sears provided a compelling theoretical argument that college students differ from other adults in both personality and trait factors, he provided no data to support his claims. The current study uses publicly available, nationally-representative survey data to empirically investigate Sears' claim of differences between college students and other adults. Final analyses included data from over 60,000 participants collected across a 30-year span. A surprisingly small number of differences were found between college students and other adults, and what differences did exist were typically of only small or medium effect size. For example, college students are just as happy as other adults and do not differ on measures of

Big Five personality traits. College students may not be as different as previously thought from other adults.

**PULLING SOCIAL PSYCHOLOGY OUT OF THE LABORATORY, KICKING AND SCREAMING** Jon Krosnick<sup>1</sup>, David Yeager<sup>1</sup>; <sup>1</sup>Stanford University

— During the last 30 years, social psychologists have produced a volume of evidence documenting how college students think and act, mostly in artificially-constructed laboratory settings. An increasing number of studies have posted experiments on websites and collected data from more heterogeneous groups of people, though never of representative samples of any populations to which we wish to generalize. Yet in popular press coverage, social psychological findings are often described as if they generalize not just to some college students or all college students but to all people in all settings. These methods result in potential consumers of our research doubting its validity and generalizability. An obvious implication of this reasoning is that social psychologists should collect data from representative samples of Americans in settings outside of our laboratories. This talk will describe many highly-cited social psychological studies that were replicated with representative samples of American adults via national surveys. We compare the laboratory effect sizes to the survey effect sizes, and we explore the utility of social psychological principles in explaining everyday behavior, such as turning out in the 2008 U.S. Presidential Election and voting for or against Barack Obama. The results obtained using this "new" method for social psychologists is evidence that some of our findings do generalize, some do not, and that unexpected moderating conditions can be observed that call into question some of our most fundamental but as yet untested interpretations of wide-cited findings and presumably widespread social and cognitive phenomena.

**REDUCING BIAS IN SURVEY DATA THROUGH REPEATED MEASUREMENT** Niall Bolger<sup>1</sup>, Patrick Shrout<sup>1</sup>, Marci Gleason<sup>2</sup>; <sup>1</sup>New York University, <sup>2</sup>Wayne State University

— Recall biases in self-report data have led some researchers to advocate using longitudinal survey designs in which participants provide reports of immediate experiences at multiple time points. There is some suggestion in the literature, however, that repeated surveys may lead to other biases: an initial elevation and a subsequent reduction in reports of events and experiences. We examine these effects by comparing the results from different survey designs. In two experiments, we randomly assigned participants approaching an acute stressor (an examination) to a multiple-week daily diary design, a two-wave panel design, and two cross-sectional designs. Results confirmed the operation of an initial elevation in negatively toned variables. Because this effect dissipated quickly in diary designs yet was pervasive in cross-sectional and panel designs, diary designs provided a more accurate picture of the experiences associated with the acute stressor. Cross sectional study designs appear especially vulnerable to initial measurement effects.

**Symposia Session B10**

**EXPERIENTIAL NEEDS AND BEHAVIORAL MOTIVES: DIFFERENT THINGS OR SAME DIFFERENCE?**

SpeFriday, January 29, 11:15 am - 12:30 pm, Capri Rooms 114-116

Chair: Kennon Sheldon, University of Missouri

Speakers: Mark Leary, Ken Sheldon, Richard Ryan, Joy McClure

Although psychological needs and motives provide core explanatory constructs in social-personality psychology, there are troubling ambiguities and even contradictions among different theories of needs and motives. For example, "needs" and "motives" are often used interchangeably, but are they different in reality? Motives might be construed as more-or-less stable dispositions that orient and energize behavior in certain directions, and needs construed as the experiential nutrients that must result from behavior if the individual is to thrive. If so then obviously, needs and motives can diverge; behavioral motives might not aim toward (or satisfy) unmet experiential needs, and unmet experiential

needs might not give rise to relevant behavioral motives. In this symposium Leary will describe his current thinking regarding how needs and motives may differ, discuss the criteria that must be met in order to determine that something is a universal need or motive, and critique the status of several popular need constructs in social and personality psychology. Sheldon will discuss new work construing the Self-determination theory (SDT) needs (autonomy, competence, and relatedness) as motives rather than as experiential requirements, showing that the absence of satisfaction drives behavior whereas the presence of satisfaction rewards it. Ryan will distinguish between "wants" and "needs," showing what can happen when personal wants are incongruent with the evolved needs proposed by SDT. Finally, McClure will discuss research showing that primed deficits in the SDT needs motivate behavior, perhaps in a hierarchical way such that relatedness takes precedence over competence, which takes precedence over autonomy.

**ABSTRACTS**

**NEEDS, MOTIVES, AND THEIR PSYCHOLOGICAL UNDERPINNINGS**

Mark Leary<sup>1</sup>; <sup>1</sup>Duke University

— Needs and motives are widely used as explanatory constructs that identify the impetus behind certain thoughts, emotions, and behaviors. However, ambiguities and inconsistencies in the conceptualization of need and motive have impeded theory and research. This presentation focuses on recurring questions and controversies surrounding needs and motives and offers suggestions for how these issues can be resolved. After discussing distinctions among needs, motives, and related constructs (such as desires, drives, urges, and goals), the talk examines differences between needs and motives that seem to be universal versus those that operate only for some individuals. For example, all normal people appear to have a need to belong, but it is less clear that everyone needs fame, deference, or beauty, as some theorists have proposed. The presentation also discusses the fact that certain needs and motives are exogenous (elicited by situational factors) whereas other are endogenous, (originating internally without external influence) and examines individual differences in the frequency vs. strength of needs and motives. Finally, the talk explores problems in determining whether particular needs or motives serve primarily an intrapsychic or interpersonal function. Some needs and motives (such as cognitive consistency and self-esteem maintenance) have been conceptualized as fundamentally intrapsychic, whereas others (such as the need to belong and the need for power) are viewed as serving interpersonal goals. Recurring controversies with this distinction will be discussed, along with suggestions for future work.

**WHEN NEEDS BECOME MOTIVES: DIFFERENTIAL EFFECTS OF SATISFACTION AND DISSATISFACTION** Ken Sheldon<sup>1</sup>; <sup>1</sup>University of Missouri

— Sheldon will describe recent research showing that the three needs identified by Self-determination theory (SDT)—autonomy, competence, and relatedness—are indeed universally required, in that they mediate the positive effects of a wide variety of predictors upon well-being, in a wide variety of cultures. However, they also appear to be more than required experiences; Sheldon and Gunz (in press) show that unmet SDT needs (i.e., feeling lonely, incompetent, or controlled) evoke desires and corresponding behavioral preferences that might yield the missing experiences. This data also suggests that it may be essential to consider negatively-worded items (i.e. dissatisfaction) separately from positively-worded items (i.e. satisfaction); these are not just reversed psychometric equivalents, as shown in models containing latent dissatisfaction and satisfaction variables as well as latent autonomy, competence, and relatedness variables. Sheldon will also present new data integrating the "needs as motives" and "needs as requirements" perspectives as well as the Atkinsonian motive disposition perspective, showing that people who are lowest in relatedness need-satisfaction increase the most in well-being when they later achieve assigned relationship goals (compared to those low in relatedness who achieve assigned academic goals), a pattern that is especially pronounced when they are high in the need for intimacy as measured by the PRF (and vice

versa for PRF need for achievement). These interactions suggest that particular motive dispositions amplify the effects of satisfying relevant unmet needs, simultaneously supporting both universalist and individual difference perspectives on needs and motives.

**A SELF-DETERMINATION THEORY APPROACH TO NEEDS, WANTS AND THEIR (MIS-)ALIGNMENT** Richard Ryan<sup>1</sup>; <sup>1</sup>University of Rochester – Within self-determination theory (Deci & Ryan, 2000; Ryan & Deci, 2000) basic psychological needs are defined as nutriments that are essential to personality growth, integrity and wellness. The theory more specifically argues that there are at least three basic psychological needs, namely those for autonomy, competence and relatedness. By contrast, from the SDT view, wants are personal desires that can organize motives and the behavior that follows from them, but wants are not identical with needs. Although wants can have an important role in organizing behavior and attaining various satisfactions, when they are incongruent with basic needs, personal wants can lead to poorer mental health and adjustment, even when they are successfully attained. In this talk Ryan will present both experience sampling and experimental data concerning the relations between wants and needs, and he will show the functional outcomes associated with their congruence or misalignment. He will also provide evidence for the SDT-based hypothesis that the development of wants that are incongruent with needs is often the result of need frustrations in development that lead to insecurities, and moreover that the process of aligning needs and wants is facilitated by conditions of autonomy support. Evidence also supports the cross-cultural validity of these claims.

**HORIZONTAL OR HIERARCHICAL PSYCHOLOGICAL NEEDS? USING PRIMING TO COMPARE THE EFFECTS OF NEED THREATS ON AFFECT, COGNITION, AND BEHAVIORAL INTENTIONS** Joy McClure<sup>1</sup>, John Lydon<sup>1</sup>; <sup>1</sup>McGill University – Self-determination theory (Deci & Ryan, 2000) proposes that we have fundamental needs for autonomy, competence, and relatedness; dissatisfaction of these needs is detrimental to well-being, but does it also motivate ameliorative responses? If so, are these processes similar for each need, or do threats to particular needs more readily engender motivational reactions? In a series of studies, we compared the three needs using a threat priming paradigm, and examined affective and cognitive responses to threat as well as downstream behavioral intentions to ameliorate the threat. Study 1 examined possible affective mechanisms, and we found that endorsement of each of the need threat primes was associated with decreases in life satisfaction. In Study 2, we tested whether priming threat would direct cognitive processing, specifically examining how threat to one need affected the accessibility of the other needs in a word-fragment completion task. The accessibility of autonomy was decreased by either threatening competence or relatedness, and the accessibility of competence was decreased by threatening relatedness and increased by threatening autonomy, but the accessibility of relatedness was unaffected by threats to autonomy or to competence. In Study 3, we examined how threat to a need affected intentions to improve that domain. When relatedness was threatened, participants showed an increased intention to buy self-help books on relatedness topics, but this was not true of the other two needs. These findings may indicate that needs lower in the Maslovian (1943) hierarchy are more readily transformed into motives in the face of threat.

## Symposia Session C

Friday, January 29, 2:00 - 3:15 pm

### Symposia Session C1

#### PRESIDENTIAL ADDRESS

Friday, January 29, 2:00 - 3:15 pm, Royale Pavilion 1

Speaker: Jennifer Crocker, University of Michigan

Introducer: Richard Petty, Ohio State University

Psychologists have often claimed that people need self-esteem, and are motivated to pursue it. Does pursuing self-esteem work? That is, when people have egosystem goals, does their own self-esteem increase? Do others view them more positively? Do they reap benefits for mental health, relationships, or self-regulation? Are they more oriented toward learning and growth? I will present evidence that when people pursue self-esteem by trying to get others to recognize their positive qualities, they create the opposite of what they want, at a high price to both themselves and others. Paradoxically, both self-esteem and regard from others increase when people focus not on themselves, but on the well-being of others. These self-transcendent ecosystem goals, focused on supporting the well-being of others but not at the expense of the self, predict improvements in mental health, relationships, and self-regulation, and foster learning and growth orientations. I suggest that egosystem goals activate physiological systems that promote self-preservation, whereas ecosystem goals activate physiological systems that promote species-preservation, or transcendence of narrow self-interest.

### Symposia Session C2

#### THE PERSON AND THE POLITICAL MIND: NEW INSIGHTS FROM RESEARCH ON VALUES, MINDSETS, PERCEPTIONS OF THE NATION, AND GENDER

Friday, January 29, 2:00 - 3:15 pm, Royale Pavilion 2

Chairs: Anat Bardi, Royal Holloway University of London, and Sonia Roccas, The Open University of Israel

Speakers: Anat Bardi, Gerard Saucier, Dennis T. Kahn, I-Ching Lee

The political arena provides a critical context to the study of the interface between the person and society. How do people differ in their approach to societal structures and processes? What are some of the psychological processes that explain these differences? When such individual processes occur en-masse they can enhance or block political decisions that affect the lives of citizens in the entire country. Hence, this symposium will examine individual differences and processes that give rise to Islamophobia, political extremism, willingness to sacrifice one's co-nationals, and support for social hierarchies. The symposium will introduce novel theoretically-based findings on basic psychological processes studied in the context of current political events in various places in the world. Anat Bardi will show that tolerance values can break the link between national British identification and Islamophobia. Gerard Saucier will bring new insights into the mindsets of political extremists. Dennis Kahn will show in the Israeli-Palestinian conflict that people who perceive the nation as a trans-generational entity are more willing to sacrifice their co-nationals to advance their national interests. Finally, I-Ching Lee will present a Meta analysis of gender differences in the support of social hierarchies and will show the way these differences vary meaningfully across nations with different societal characteristics. Together, these new findings will enhance our understanding of the interface between the person and political processes.

## ABSTRACTS

**VALUES BREAK THE LINK BETWEEN NATIONAL IDENTIFICATION AND ISLAMOPHOBIA** Anat Bardi<sup>1</sup>, G. Tendayi Viki<sup>2</sup>; <sup>1</sup>Royal Holloway University of London, <sup>2</sup>University of Kent – Muslims are viewed as a threatening group in Britain. Ingroup identification is typically positively related to prejudice against a threatening outgroup. Hence, national British identification is likely to relate positively to Islamophobia. Yet we propose, for the first time, that valuing tolerance can break this link. People who value tolerance to different beliefs are not likely to translate identifying with their country to exclusion of all members of a seemingly threatening outgroup. A correlational and an experimental study support this proposition. The correlational study found the expected positive relation between national identification and Islamophobia; the latter measured as the wish to exclude Muslims from society. Moreover, tolerance values moderated this link. In those who did not value tolerance, the more they identified with being British the more they wished to exclude Muslims from society. Yet, in those who valued tolerance, there was no such relation. An experimental study using the general population to enhance ecological validity established the causal direction of this interaction. Manipulating security values, which are opposite to tolerance values in the Schwartz (1992) value theory resulted with a positive relation between national identification and Islamophobia, but this relation was not found as a result of manipulating tolerance values. The same pattern of interaction was obtained in comparing the manipulation of tolerance values to manipulating stimulation values, which are unrelated to tolerance or security in the Schwartz value theory, hence served as a control condition. We conclude that tolerance values break the link between national identification and Islamophobia.

**PATTERNS OF THINKING ASSOCIATED WITH PERPETRATORS OF SOCIOPOLITICAL VIOLENCE** Gerard Saucier<sup>1</sup>, Laura Geuy Akers<sup>1</sup>; <sup>1</sup>University of Oregon – Recurrent features of the thinking pattern (or mindset) of those who carry out programs of sociopolitical violence are delineated, discussed, and related to previous research and theory. In a first extensive content analysis, militant extremist groups were selected from a diverse range of continents, cultures, and political and religious orientations. Statements by (and to some degree statements about) these groups were compared, leading to the formulation of 16 themes common to the militant-extremist mindset. Among these themes are perceptions of a crisis involving violations of posited sacred values, along with justifications for violence to remediate such problems. There are indications that such themes are not infrequent in the general population. For example, research participants failed to strongly disassociate themselves from the sentiments and framings found in the fanatical items, which undercuts the notion that militant-extremist thinking represents bizarre ideation. Key themes in this thinking pattern might fit together to construct a potentially compelling narrative, which may be a key part of the ideological appeal of salient militant-extremist groups. We report also on a second, parallel content analysis focusing on the thinking patterns of ideologues who were behind a dozen diverse instances of genocide or state terror. Some of the same themes are present in this second study of sociopolitical-violence perpetrators, although some features of genocide and state terror are necessarily unique to those able to act from the center rather than the periphery of societal power.

**DIACHRONIC GROUP PERCEPTION AND WILLINGNESS FOR INGROUP SACRIFICE: THE ISRAELI-PALESTINIAN CONTEXT** Dennis T. Kahn<sup>1</sup>, Yechiel Klar<sup>1</sup>, Sonia Roccas<sup>2</sup>; <sup>1</sup>Tel-Aviv University, <sup>2</sup>The Open University of Israel – The purpose of this presentation is to introduce the time dimension in the research on group perception. We focus on the extent to which social groups are perceived as Diachronic, i.e. as trans-generational entities, including past and future generations of group members. We examined the utility of this construct in a series of studies focusing on perceptions of one's own national group in the context of a violent conflict. In a first study among Israeli University students (N=103), our

measure of Diachronic Group Perception (DGP) correlated positively with Group Primacy, i.e. an elevated willingness to sacrifice members of the ingroup for the sake of the ingroup itself. Study 2 (N=119) showed that DGP was positively correlated to readiness for indefinite endurance of the sufferings experienced by the ingroup in an intergroup conflict. Furthermore, holding a Diachronic Perception of the Group and supporting Group Primacy was shown to be related to an increased willingness to sacrifice the personal interests of an Israeli soldier (Gilad Shalit) captured by a Palestinian organization (Hamas) for the sake of Israeli national interests. In a third study (N=81), it was found that a religious sample to a larger extent held a Diachronic Perception of the national group, showed a greater degree of Group Primacy and displayed more willingness to endure ingroup suffering as a result of intergroup conflict, as compared to the secular sample.

Furthermore, holding a Diachronic Perception of the Group and supporting Group Primacy was shown to be related to an increased willingness to sacrifice the personal interests of an Israeli soldier (Gilad Shalit) captured by a Palestinian organization (Hamas) for the sake of Israeli national interests. In a third study (N=81), it was found that a religious sample to a larger extent held a Diachronic Perception of the national group, showed a greater degree of Group Primacy and displayed more willingness to endure ingroup suffering as a result of intergroup conflict, as compared to the secular sample.

**A META ANALYSIS OF INDIVIDUAL DIFFERENCES IN THE SUPPORT OF SOCIAL HIERARCHY** I-Ching Lee<sup>1</sup>, Felicia Pratto<sup>2</sup>, Blair Johnson<sup>2</sup>; <sup>1</sup>National Chengchi University, <sup>2</sup>University of Connecticut – The biggest political struggles of the last several centuries have hinged on the question of whether social inequality occurs with the consent of the governed or despite their dissent. The current meta-analysis examined whether socio-structural and psycho-cultural characteristics of societies corresponded with how much gender and ethnic/racial groups differ on their support of social hierarchy. Support of social hierarchy measured by social dominance orientation was found to be associated positively with nationalism, racism, heterosexism, sexism, use of force, conservatism, right-wing authoritarianism, and other beliefs in support of social hierarchy; support for social hierarchy was found to be associated negatively with support for progressive social policies. Robustly, women opposed social hierarchy more than men did, and members of lower-power ethnic/racial groups opposed social hierarchy more than members of higher-power ethnic/racial groups. As predicted by social dominance theory, gender differences were larger, more stable, and less variable from sample to sample than differences between ethnic/racial groups. Both kinds of group differences were larger in societies that were higher on individualism (versus collectivism) and lower on uncertainty avoidance. Specifically, gender difference of support of social hierarchy was found in societies with more gender equality than in societies with less gender equality. Implications for social dominance theory, social role theory and biosocial theory, social identity theory, system justification theory, and relative deprivation theory are discussed.

The biggest political struggles of the last several centuries have hinged on the question of whether social inequality occurs with the consent of the governed or despite their dissent. **Symposia Session C3****SOCIAL PSYCHOLOGY FOR AN ECONOMIC RECESSION: EXAMINING THE EFFECTS OF SOCIOECONOMIC STATUS ON PSYCHOLOGICAL PROCESSES**

Friday, January 29, 2:00 - 3:15 pm, Royale Pavilion 5

Chairs: Natalya C. Maisel, University of California, Los Angeles, and Paul K. Piff, University of California, Berkeley

Speakers: Paul K. Piff, Natalya C. Maisel, Elizabeth Page-Gould, Edith Chen

The current economic recession has placed great demands on adults, children, and families. This symposium expands our understanding of these demands and their potential impact by (1) demonstrating how socioeconomic variables affect psychological and interpersonal processes and (2) examining specific mechanisms through which low-SES individuals in particular are vulnerable to negative health outcomes. The first three papers examine how SES moderates psychological and interpersonal processes. First, Piff, Kraus, and Keltner present experimental evidence that low-SES individuals favor contextual over dispositional explanations for social events, and that this contextual orientation increases altruistic behavior. Second, Maisel, Garvan, Hou, and Karney find, in a large diverse random sample, that the association between acute stress and relationship quality varies by income level, such that relationship quality is more negatively associated with stress for low-SES individuals. Third, Page-Gould, Koslov, and Mendes examine how

SES affects social interactions, observing different physiological responses (threat vs. challenge) when people interact with a low- versus high-SES individual. Complementing this focus on SES as a moderator, the final paper examines a mechanism through which low-SES can lead to negative health outcomes. Chen finds that the association between SES and negative physiological outcomes in children is mediated by increased threat appraisals of the social environment. Together, these papers highlight the need to incorporate SES in models of psychological processes and social interactions. Further, they raise the possibility that models of psychological and interpersonal processes tested exclusively on more affluent individuals may not generalize to low-income individuals.

#### ABSTRACTS

#### TO HAVE AND HAVE-NOT: SOCIOECONOMIC STATUS, CONTEXTUALISM, AND THE GIVING GAP

Paul K. Piff<sup>1</sup>, Michael W. Kraus<sup>1</sup>, Dacher Keltner<sup>1</sup>; <sup>1</sup>University of California, Berkeley – Lower socioeconomic status (SES) is associated with less access to educational and social institutions, increased exposure to environmental threat, and a reduced sense of personal control. Given these constraining life circumstances, low-SES individuals tend to construe the social environment in terms of the social context. We present evidence showing that low-SES individuals are contextual, relative to their upper-SES counterparts. Moreover, we demonstrate a potential prosocial outcome associated with this contextual orientation among low-SES people: altruism. Across several studies, we show that low-SES, and the reduced sense of control this confers, causes people to favor contextualist over dispositional explanations of social events, including economic trends and the emotions of others. Next, we demonstrate that, compared to high-SES individuals, low-SES individuals are more generous toward strangers in an economic game ('dictator game'). Moreover, when interacting with a distressed partner in an experimental setting, low-SES people were more benevolent and helping than high-SES individuals. This pattern was moderated by feelings of compassion: a compassion induction boosted high-SES people's altruism to levels similar to those of low-SES people. We argue that the contextualist worldview shared by low-SES people produces a heightened sensitivity to the needs and concerns of others. Thus, low-SES people, despite having fewer resources, are more compassionate and benevolent toward others in an effort to enhance social bonds and foster egalitarianism.

#### RELATIONSHIP QUALITY IS MORE STRONGLY ASSOCIATED WITH ACUTE STRESS IN LOW-SES THAN HIGH-SES INDIVIDUALS

Natalya C. Maisel<sup>1</sup>, Cynthia W. Garvan<sup>2</sup>, Wei Hou<sup>2</sup>, Benjamin R. Karney<sup>1</sup>; <sup>1</sup>University of California, Los Angeles, <sup>2</sup>University of Florida, Gainesville – Federal policies have targeted the relationships of low-income couples for interventions. Yet the empirical foundation for such interventions is thin, because research on relationships has been conducted primarily on middle-class couples (Karney & Bradbury, 2005). It has been assumed that models of relationships developed in more affluent couples generalize to poorer couples, but low-income couples face more stressors than high-income couples (e.g., McLeod & Kessler, 1990), and may be affected by stress in different ways. In particular, acute stress may be more detrimental for low-income couples, who have fewer resources to cope when a stressor strikes. To examine this hypothesis, the current study tested the moderating effects of income on the association between acute stress and relationship quality on one hand, and acute stress and mental health on the other, in a stratified random sample of 4008 Florida residents that oversampled for low-income participants. Income and subjective financial strain independently moderated the association between acute stress and relationship quality, such that high-income individuals were buffered from the negative effects of acute stress on relationship quality, whereas acute stress was particularly detrimental for low-income couples. Income also moderated the association between acute stress and mental health, such that the association between acute stress and negative mental health was greater for low-income individuals. Controlling for mental health and demographic factors (e.g., race/ethnicity, relation-

ship length) did not affect the findings for relationship quality. Together, these results demonstrate the pressing need to examine how relationship processes vary across diverse samples and contexts.

#### PHYSIOLOGICAL THREAT WHILE COOPERATING WITH LOW-STATUS INTERACTION PARTNERS

Elizabeth Page-Gould<sup>1</sup>, Katrina Koslov<sup>2</sup>, Wendy Berry Mendes<sup>2</sup>; <sup>1</sup>University of Toronto at Scarborough, <sup>2</sup>Harvard University – Psychophysiological research on stigma has demonstrated a tendency for people to respond with cardiovascular patterns consistent with 'threat' when interacting with the socially stigmatized (Blascovich et al., 2001; Mendes et al., 2002). To the extent that low socio-economic status (SES) is a stigmatized identity, we hypothesized that an interaction partner's SES would affect physiological reactions during a cooperative task. Students and adults from the community were invited to the lab in dyads that were matched for age, sex, and race, but were allowed to differ from each other in SES. The participants completed a cooperative task together for bonus money while their cardiovascular responses were continuously monitored. As hypothesized, participants who interacted with a partner who was low in SES exhibited a pattern of cardiovascular responses consistent with physiological threat: increases in vascular constriction and no increase in cardiac output despite having an increase in ventricular contractility. On the flip side, people who interacted with a high SES partner exhibited cardiovascular responses consistent with physiological challenge: vascular dilation and notable increases in cardiac output in tandem with increased ventricular contractility. Furthermore, participants who were paired with high SES partners had significantly greater reductions in respiratory sinus arrhythmia than people paired with low SES partners, suggesting that participants were concentrating harder when working together with a high SES partner. Implications of these findings for social relations and health in the context of the current economic climate will be discussed.

#### SOCIOECONOMIC STATUS AND PHYSICAL HEALTH: PSYCHOBIOLOGICAL PATHWAYS

Edith Chen<sup>1</sup>; <sup>1</sup>University of British Columbia – Low socioeconomic status (SES) is a risk factor for a variety of health problems throughout the lifespan and across both countries with and without universal health care. For example, in childhood, low SES is associated with more severe exacerbations of asthma, the most common childhood chronic illness. However, research investigating the psychobiological mechanisms underlying this relationship has been sparse. Across two studies, we document that low SES is associated with increased production of inflammatory markers relevant to asthma (Th-2 cytokines), as well as at the genomic level, with alterations in bioinformatic indications of transcription factor activity relevant to inflammation. These findings indicate plausible biological pathways that may explain why low SES children are more likely to experience more severe asthma. Furthermore, we document specific psychological processes in children that may be shaped by SES, and which are linked to these biological processes. We hypothesized that because of their life experiences and the environments they grow up in, low SES children develop a tendency toward interpreting the world in a threatening manner, that this tendency is most pronounced during situations that are ambiguous in outcome, and that these threat interpretations have physiological costs. Using a laboratory-based assessment of threat appraisals, we find that threat appraisals statistically mediated the relationship between SES and both inflammatory markers and transcription factor activity. These findings suggest that low SES children perceive their social world in more threatening ways, and that these social perceptions have physiological consequences.

**Symposia Session C4****CONTENDING WITH DISCRIMINATION: PSYCHOLOGICAL, NEUROLOGICAL, PHYSIOLOGICAL, AND BEHAVIORAL CONSEQUENCES OF ATTRIBUTIONAL AMBIGUITY**

Friday, January 29, 2:00 - 3:15 pm, Royale Pavilion 6

Chairs: Jenessa R. Shapiro, University of California, Los Angeles, and Sophie Trawalter, University of North Carolina, Chapel Hill

Speakers: Sophie Trawalter, Naomi I. Eisenberger, Brenda N. Major, Jenessa R. Shapiro

Defying conventional wisdom, research finds that attributing negative treatment or feedback to discrimination protects self-esteem. This symposium offers new insights into the processes and consequences of attributional ambiguity. Specifically, we consider the psychological, physiological, and behavioral consequences of attributing different types of social rejection (e.g., social, academic) to discrimination from the perspective of multiple social groups (e.g., women, racial minorities). First, Trawalter and colleagues explore attributions to discrimination using social cognitive paradigms that permit accuracy testing. Contrary to research suggesting that women are hyper-vigilant to cues of discrimination, they find that female participants are often accurate at detecting discrimination. The next two talks investigate physiological correlates of attributional ambiguity. Using fMRI methodologies, Eisenberger and colleagues find that Black participants who attribute social rejection to discrimination exhibit decreased neural activity in regions associated with social pain (dACC) and increased activity in regions associated with emotion regulation (PFC). Major and colleagues find that minorities who chronically perceive discrimination not only exhibit less physiological threat when attributing negative feedback to discrimination but more physiological threat when they are unable to do so. Finally, Shapiro and colleagues explore interpersonal consequences of making attributions to discrimination. They find that when negative academic feedback is attributionally ambiguous (Black participants receiving feedback from White evaluators), participants are less likely to engage in other harmful self-esteem maintenance strategies, such as prejudice expression. Taken together, these talks shed light on the multiple stages and consequences of making attributions to discrimination, from social cognitive and physiological responses to interpersonal behavior.

**ABSTRACTS****WHEN DISCRIMINATION HAPPENS, WHO NOTICES? STIGMATIZED GROUP MEMBERSHIP AND DISCRIMINATION DETECTION** Sophie Trawalter<sup>1</sup>, Jenessa R. Shapiro<sup>2</sup>, <sup>1</sup>University of North Carolina, Chapel Hill, <sup>2</sup>University of California, Los Angeles – Research finds that stigmatized group members (e.g., racial minorities, women) perceive more discrimination in the world than do non-stigmatized group members (e.g., whites, men). Often, these findings are interpreted to mean that stigmatized group members are “hyper-sensitive” to cues that portend prejudice and discrimination; they see discrimination, sometimes even when it is not really there. In the present work, we examine the extent to which stigmatized group members are accurate at perceiving and detecting discrimination. In Study 1, participants were asked to report the extent to which women are under-represented in several domains (e.g., how many U.S. senators are women?). Results revealed that female participants who believe that discrimination is pervasive were more accurate relative to male participants. In Study 2, participants watched a game of Cyberball played by 3 ostensible players—two men and one woman. Ball tosses were manipulated to be either random (i.e., fair) or non-random (i.e., unfair to the female player). Results revealed that female participants were sensitive to the manipulation; they reported that the game was fairer when the ball tosses were random relative to non-random. In contrast, male participants were not sensitive to the manipulation. Taken together, these studies suggest that women accurately detect discrimination, at least some of the time. Accordingly, these findings challenge the

claim that stigmatized group members are “hyper-sensitive” to prejudice-related cues. Implications, including when and how stigmatized and non-stigmatized group members can reach a consensus regarding the occurrence of discrimination, will be discussed.

**BEING THE TARGET OF RACIAL DISCRIMINATION: AN FMRI STUDY**

Naomi I. Eisenberger<sup>1</sup>, Carrie L. Masten<sup>1</sup>, Eva H. Telzer<sup>1</sup>; <sup>1</sup>University of California, Los Angeles – Two competing accounts have been proposed for understanding the affective consequences of attributing negative social treatment to discrimination. One account suggests that attributing negative treatment to discrimination is distressing because discrimination is due to an internal characteristic of the target that cannot be changed (“my race;” Schmitt & Branscombe, 2002). The other account suggests that attributing negative treatment to discrimination may be self-protective because prejudice is viewed as an external characteristic of the perpetrator (“they are prejudiced;” Crocker & Major, 1989). To disentangle these alternatives, we scanned Black participants as they were ostensibly excluded by Whites to see if attributing negative treatment to discrimination was associated with more or less social pain-related neural activity. After being excluded, participants rated the extent to which they believed they were rejected because of their race. Additionally, participants were videotaped while describing their experience during the game, and, later, naive judges rated each video for negative affect (“observer-rated distress”). Consistent with work demonstrating the ‘pain’ of social rejection, participants with higher observer-rated distress displayed greater activity in social pain-related neural regions (dorsal anterior cingulate cortex), whereas participants with lower ratings displayed greater activity in regions associated with emotion regulation (prefrontal cortical regions). In contrast, the more participants felt that they were excluded because of their race, the less activity they displayed in social pain-related neural regions and the more activity they displayed in regions associated with emotion regulation. Findings support the notion that race-based attributions can be self-protective in situations of negative social treatment.

**WORLDVIEW DISCONFIRMATION IS STRESSFUL** Brenda N. Major<sup>1</sup>, Sarah Townsend<sup>1</sup>, Pamela Sawyer<sup>1</sup>; <sup>1</sup>University of California, Santa Barbara –

I will discuss recent research showing how beliefs about the basis and legitimacy of status differences shape physiological reactions to prejudice among low status groups. Studies show that those who believe status differences are legitimate show a physiological threat response when they must interact with someone who is prejudiced against their group. In contrast, those who believe status differences are illegitimate show a threat response when interacting with others who are not prejudiced. Implications for intergroup relations will be discussed.

**CONVERGING PROCESSES, DIVERGING BEHAVIORS: ATTRIBUTIONAL AMBIGUITY AND PREJUDICE EXPRESSION WITHIN WHITE AND BLACK PERCEIVERS** Jenessa R. Shapiro<sup>1</sup>, Steven L. Neuberg<sup>2</sup>, Stephen Mistler<sup>2</sup>; <sup>1</sup>University of California, Los Angeles, <sup>2</sup>Arizona State University –

Minority groups tend to be chronically aware of the potential for devaluation and negative treatment from the majority group (e.g., Richeson & Shelton, 2007). Thus, on the surface, many may assume that this chronic devaluation by the majority group would lead to an increased likelihood of devaluing other minority groups as a way in which to elevate one’s own (or one’s group’s) self esteem: Prejudice expression can be self-affirming, and as a result, individuals often express prejudice as a self-image maintenance strategy (Fein & Spencer, 1997). However, attributional ambiguity research suggests a very different outcome of devaluation from the majority. That is, negative feedback from outgroup members is often ambiguous, as it can be influenced by prejudices and fail to reflect a genuine evaluation of one’s abilities (Crocker & Major, 1991). The present research examined the role of attributional ambiguity plays in prejudice expression as a self-image maintenance strategy. In one study, White, but not Black, participants evaluated a minority (Native American) job applicant more negatively after receiving negative feedback from a White evaluator. A second study provides support for attributional

ambiguity as driving the evaluative differences between White and Black participants: When the evaluator providing the negative feedback was Black—creating ambiguity for White and not Black participants—White participants no longer differentially evaluated the job candidates, but Black participants did. The present findings highlight the importance of taking a relational approach to intergroup interaction and considering the psychology of both frequently and infrequently stigmatized targets.

## Symposia Session C5

### ACCURATE SELF-KNOWLEDGE

Friday, January 29, 2:00 - 3:15 pm, Royale Pavilion 3-4

Chair: C. Randall Colvin, Northeastern University

Speakers: Erika N Carlson, Elizabeth R Tenney, Lauren J Human, C Randall Colvin

The ancient Greek philosophers declared self-knowledge a virtue and encouraged followers to “know thyself.” Centuries later, theorists associated accurate self-knowledge with mental health, believing it to be a prerequisite for personal growth. Many contemporary psychologists believe that self-knowing promotes well-being; yet researchers have only recently explored the veracity of self-knowledge. This symposium explores the topic of accurate self-knowledge and its psychological outcomes. The speakers present their research on accurate self-knowledge, highlighting methodological challenges and empirical outcomes. In Paper 1, the authors examine the “looking glass self” effect and provide evidence that people accurately know the impressions others have of them. In Paper 2, the researcher explores the conditions under which accurate and distorted self-views are personally adaptive, a refreshing contrast to previous research on this topic. Paper 3 examines a phenomenon related to accurate self-knowledge – people who are judged accurately by others. The researchers show that accurately judged individuals exhibit positive intra- and inter-personal functioning, results that are similar to previous research on accurate self-knowledge. These overlapping results suggest that some people may be “transparent” i.e., self-known and easily judged. Paper 4 contrasts the personality characteristics associated with self-knowing and self-liking. The results indicate accurate self-knowledge is related to communion whereas self-esteem is related to agency. Self-knowledge resides in the mind, but its antecedents and consequences appear to be interpersonal. We hope the symposium will energize others to explore the personal and social consequences of accurate self-knowledge.

#### ABSTRACTS

### **DIFFERENTIAL META-ACCURACY: PEOPLE ARE AWARE OF THE RELATIVE IMPRESSIONS THEY MAKE ON OTHERS**

Erika N Carlson<sup>1</sup>, R. Michael Furr;  
<sup>1</sup>Washington University in St. Louis, <sup>2</sup>Wake Forest University – Previous research suggests that people cannot accurately perceive the relative impressions they create in others (Kenny & DePaulo, 1993), or that differential meta-accuracy is poor. Our research re-evaluates this conclusion by implementing a novel, contextually-differentiated design. Specifically, we assess participants' meta-accuracy for people from different contexts of their real lives (i.e., parents, hometown friends, & college friends). This design is based upon the logic that: a) people tend to behave differently across different contexts, b) interaction partners from different contexts witness these differing behaviors and form differing impressions of a target, which provides a strong “signal” for targets to detect, and c) metaperceptions should be differentiated across contexts because contextual information (e.g., target's behavior or feedback) is also relatively differentiated. In the current study, target participants provided metaperceptions of the Big Five for up to six informants (two per context), and informants described the target by completing an online personality measure. As predicted, actual impressions and metaperceptions were relatively more differentiated across contexts than within contexts, suggesting that our contextually-differentiated approach provided a strong signal for targets to detect in the form of dif-

ferentiated impressions and that targets were aware that they created different impressions on informants across contexts. More importantly, multi-level modeling showed strong, positive effects of differential meta-accuracy for all Big Five traits. In summary, when given meaningful variability in impressions to detect, people can indeed detect the relative impressions they make on others suggesting that people have a greater awareness of their social identity than previously thought.

### **COMPLEX SOCIAL CONSEQUENCES OF SELF-KNOWLEDGE IN INTERVIEW SETTINGS**

Elizabeth R Tenney<sup>1</sup>; <sup>1</sup>University of Virginia – People possess some knowledge of their own strengths and weaknesses, and people are called on to convey this self-knowledge to others in social situations, such as job interviews. Previous research has yielded mixed results regarding whether it is beneficial to possess (and convey) accurate self-knowledge, or whether it is better to be extremely self-confident, regardless of one's actual circumstances (i.e., to self-enhance). One reason for the mixed results could be that results depend on the information that observers possess. It might be beneficial to self-enhance unless observers suspect that someone's positive statements about the self are unfounded. A series of vignette studies supported this prediction. At first participants favored the most self-confident applicants for a job or a spot on a swim team; however, once evidence suggested that the applicants were incorrect about one aspect of their self-report, the confident applicants lost more credit overall than applicants who were less self-confident but better judges of themselves. Thus, it may be beneficial to self-enhance unless people can find out that someone's positive self-views are baseless.

### **ACCURATE SELF-KNOWLEDGE, EXPRESSIVE ACCURACY AND THE RELATIONSHIP TO ADJUSTMENT**

Lauren J Human<sup>1</sup>, Jeremy C Biesanz<sup>1</sup>;  
<sup>1</sup>University of British Columbia, <sup>2</sup>University of British Columbia – Just as accurate self-knowledge is considered important for personal and interpersonal functioning, so too is accurate understanding between individuals. Across a series of round-robin studies involving new acquaintances, we examined whether expressive accuracy – the level of accuracy with which a particular individual is perceived (i.e., the good target) – was associated with adjustment. Expressive accuracy was assessed using multiple different validation measures (self and knowledgeable informant reports) and was indeed associated with personal and interpersonal adjustment. Of note, using the social accuracy model (Biesanz, 2007, 2009) to examine Cronbachian components revealed a deeper complexity in that target adjustment was linked primarily to distinctive accuracy, being perceived in line with one's unique characteristics. Moreover, expressive accuracy, when assessed using self-reports to verify impressions, consistently resulted in stronger relationships with adjustment than expressive accuracy measured with knowledgeable informant reports, indicating that being viewed in line with one's self views is more relevant to adjustment than being viewed in line with close others' views. In short, individuals whose self-views are more accurately perceived by others have higher personal and interpersonal functioning. The conceptual links between knowing oneself and being known by others will be discussed.

### **IS THE OPTIMAL RELATIONSHIP BETWEEN SELF-KNOWING AND SELF-LIKING? CONTRIBUTIONS OF ACCURATE SELF-KNOWLEDGE AND SELF-ESTEEM TO PSYCHOLOGICAL WELL-BEING**

C Randall Colvin<sup>1</sup>;  
<sup>1</sup>Northeastern University – What is the optimal relationship between self-knowing and self-liking? For centuries Western philosophers have argued that to “know thyself” is the ultimate human virtue. In contrast, the psychological literature contains a handful of papers on accurate self-knowledge (ASK) and over 10,000 on self-esteem. Despite this discrepancy, many psychologists believe ASK is an important feature of mental health. The present research evaluated ASK, self-esteem, and their independent contributions to the prediction of psychological well-being. Approximately 100 people participated in the study that collected data from self, friends, parents, interaction partners, and trained coders. To assess ASK, several agreement indices were calculated between partici-

pants' self-ratings of personality and (a) coded behavior and (b) parent ratings -- greater agreement reflected higher self-knowledge. To assess self-esteem, participants completed the Rosenberg, and a real and ideal self Q-sort. The Rosenberg and real-ideal measure were highly correlated; self-esteem was indexed by their composite. Results indicated that ASK and self-esteem were positively correlated ( $r=.54$ ). Partial correlations were conducted to determine the independent contributions of ASK and self-esteem on personality and social behavior. Based on friend, interaction partner, and behavior ratings, ASK (controlling for self-esteem) was related to agreeableness and communion. In contrast, self-esteem (controlling for ASK) was related to low agreeableness and neuroticism. People who possessed high self-esteem and low self-knowledge were perceived to be narcissistic. Finally, ASK and self-esteem made independent and significant contributions to psychological well-being. The answer to the title question? Psychological well-being is maximized when people possess both high ASK and high self-esteem.

## Symposia Session D

Friday, January 29, 3:30 - 4:45 pm

### Symposia Session D1

#### THE PSYCHOLOGY OF STATUS

Friday, January 29, 3:30 - 4:45 pm, Royale Pavilion 1

Chairs: Nir Halevy and Taya Cohen, Northwestern University

Speakers: Taya Cohen, Sebastien Brion, Nir Halevy, Robb Willer

Hierarchy is a fundamental characteristic of social relations. Most groups, organizations, and societies have stratified structures where some group members are conferred with more responsibility and privileges than others. What makes some individuals emerge from social interactions as leaders? What functions does status differentiation serve in groups? Four empirical papers address these two critical questions. Cohen, Livingston and Halevy show that social rather than pro-social individuals are likely to emerge as leaders following small group interactions. That is, individuals put their trust in and bestow leadership on interpersonally engaging group members rather than on group members who genuinely care for the welfare of others. Anderson and Brion focus on the causal path leading from overconfidence to social status. Their research shows that projected overconfidence produces perceptions of competence, which in turn, create enduring high status. Halevy, Chou, Galinsky and Murnighan show that status differentiation may be beneficial for group functioning. Specifically, they show that pay dispersion and status differentiation relate positively to intragroup cooperation and performance in National Basketball Association teams. Finally, Willer shows that groups use status to motivate their members to participate in collective action. His research shows that status serves as a powerful incentive that increases group member motivation to engage in costly group-serving behaviors. The four papers employed diverse methodologies to investigate status dynamics in groups. Taken together, they provide novel insights into the interplay between social perception and social interaction, which underlies the psychology of status.

#### ABSTRACTS

#### WHY PEOPLE LIKE WOLVES IN SHEEP'S CLOTHING: THE FOLLY OF CHOOSING SOCIAL RATHER THAN PROSOCIAL LEADERS

Taya Cohen<sup>1</sup>, Robert Livingston<sup>1</sup>, Nir Halevy<sup>1</sup>; <sup>1</sup>Northwestern University – People describe effective leaders as possessing prosocial traits, such as helpfulness and sincerity. However, in this research we show that when it comes to choosing a leader (i.e. a group member that will control resources), people vote for those judged as social rather than those judged as prosocial. “Social” individuals are interpersonally engaging (e.g., talkative, extra-

verted, high in self-monitoring) whereas “prosocial” individuals promote the welfare of others (e.g., generous, honest, cooperative). In the study, undergraduate students completed self-report and behavioral assessments of personality and engaged in a short group discussion with two other students. After the discussion, participants voted for a leader to control group resources and rated each group member on social (e.g., talkative, extraverted), prosocial (e.g., trustworthy, generous), and dominance traits (e.g., status, power). We found that leadership votes were based on ratings of dominance, which, in turn, were based on ratings of social but not prosocial traits. People may base their inferences of leadership ability on perceptions of social rather than prosocial traits because social traits are more visible—social behavior is easier to observe and recognize than prosocial behavior. Consistent with this reasoning, people who talked more during the group discussion were judged as more social and participants inferred status and power from these judgments of sociability. We argue that it is a folly to vote for social rather than prosocial leaders because social leaders hoarded group resources—they allocated more raffle tickets to themselves than to others—whereas prosocial leaders distributed resources more fairly.

#### OVERCONFIDENCE AND SOCIAL STATUS: WHY THOSE WITH “BIG EGOS” BECOME “BIG WIGS”

Sebastien Brion<sup>1</sup>, Cameron Anderson<sup>1</sup>; <sup>1</sup>University of California - Berkeley – Overinflated egos seem to go hand and hand with high social status. Ask people to describe the typical Wall Street tycoon, political leader, or famous scientist, and they are likely to depict someone with an exaggeratedly positive self-view. Prior research has also confirmed that overconfidence and social status are closely associated. But how does this association emerge? Past work has shown that possessing high social status can lead individuals to become overly confident in their abilities. The current work tested whether overconfidence can also lead to the attainment of higher social status. In three studies of task-focused dyads and groups in laboratory and field settings, we found that overconfident individuals were perceived by others as more competent, and in turn, attained higher status. An experimental manipulation established the causal priority of overconfidence, and a longitudinal study found the effects of overconfidence endured over time. These findings contribute to our understanding of the psychology of status, the consequences of overconfidence, and status distribution systems in groups and organizations.

#### KING OF THE HILL: STATUS DIFFERENTIATION ENHANCES TEAM PERFORMANCE

Nir Halevy<sup>1</sup>, Eileen Chou<sup>1</sup>, Adam Galinsky<sup>1</sup>, J. Keith Murnighan<sup>1</sup>; <sup>1</sup>Northwestern University – Status differentiation is a near-universal phenomenon: In virtually any group, people occupy different positions that are associated with unequal rewards and levels of authority. At the same time, however, status differentiation also varies across different groups. This research focused on the understudied effects of status differentiation on intragroup cooperation and team performance. Theories of team interaction suggest that pay dispersion and status differentiation will both be detrimental to performance. In contrast, we theoretically argue and present data from 282 professional basketball (NBA) teams, which show that pay dispersion and status differentiation relate positively to intragroup cooperation and team performance. In addition, status differentiation mediated the positive effect of pay dispersion on team performance and intragroup cooperation mediated the positive effect of status differentiation on team performance. The results highlight the functionality of status differentiation in teams; they also indicate that structural and dynamic forms of status differentiation enhance team performance through different paths.

#### OVERCOMING THE FREE-RIDER PROBLEM: PROSOCIAL BEHAVIOR EARNS DIVERSE MATERIAL AND SOCIAL REWARDS

Robb Willer<sup>1</sup>; <sup>1</sup>University of California - Berkeley – A classic social scientific puzzle is how groups motivate their members to set aside self-interest and make costly contributions to group efforts. This research presents evidence that status serves as a selective incentive motivating contribution. Contributors to collective action signal their group-oriented motivation and conse-

quently earn diverse benefits from group members – in particular, higher status – and these rewards in turn encourage greater giving to the group in the future. A series of laboratory experiments demonstrates that high contributors to collective action were granted higher status, exercised more interpersonal influence, were cooperated with more, and received gifts of greater value. Follow-up studies replicated these findings while discounting various alternative explanations. Mediation and experimental evidence show that giving to the group mattered because it signaled the individual's underlying motivation to help the group. Further research showed that participants who received status for costly contributions subsequently viewed the group more positively and contributed more as a result. These results demonstrate how the allocation of respect to contributors shapes group productivity and solidarity, offering a solution to the free-rider problem.

## Symposia Session D2

### POSITIVE AND NEGATIVE EVALUATION IN SELF-REPORTED PERSONALITY

Friday, January 29, 3:30 - 4:45 pm, Royale Pavilion 2

Chair: Eric Turkheimer, University of Virginia

Speakers: Leonard Simms, Martin Bäckström, Amber Thalmayer, Erik Pettersson

Although it is well-known that evaluation is an important dimension of personality ratings, the substantive meaning of evaluation as a personality construct remains controversial. Is evaluation a legitimate rotation of the five factor model, a response bias, or the top level of a hierarchical model of personality? This symposium presents data on the validity of evaluation as a component of personality ratings. Simms analyzes data from friendship dyads, showing that variability in ratings can be separated into evaluative and non-evaluative components. Bäckström explores differences that result when evaluative and non-evaluative terms are used as markers of similar constructs. Thalmayer and Saucier explore the cross-cultural structure of evaluation using data from several continents. Pettersson and Turkheimer construct a self-report inventory in which positively and negatively valenced markers of five factor model facets are balanced, deriving a positive-negative dimension on which lexically opposite terms like "reckless" and "timid" load in the same direction. Evaluation has at least two aspects: it is a crucial and nearly universal component of personality ratings of all kinds, but it may not be literally descriptive of actual behavior in the same sense as traditional self-report scales. Reflecting the state of the field at this time, the symposium participants do not entirely agree about the relative importance of these two aspects, so we expect spirited discussion of these fundamental issues in the assessment of personality.

#### ABSTRACTS

### THE IMPACT OF EVALUATION VARIANCE ON THE STRUCTURE OF COMMON LEXICON PERSON DESCRIPTORS

Leonard Simms<sup>1</sup>, William Calabrese<sup>1</sup>, Monica Rudick<sup>1</sup>; <sup>1</sup>University at Buffalo, The State University of New York – The impact of evaluation variance on the structure of personality trait descriptors is an understudied area in the literature. In the factor analytic tradition that resulted in the Big Five model, researchers attempted to control the impact of evaluation by simply excluding dictionary terms that were deemed highly evaluative (e.g., Allport & Odbert, 1936; Norman, 1967). However, it is unlikely that person descriptors represent either wholly evaluative or wholly non-evaluative trait variance. A compelling alternative is that all person descriptors include varying proportions of evaluative and trait variance, the latter of which is most relevant to personality trait structure. In the present study, we examined the factor structure of 519 inclusive common language person descriptors (CL-519; Simms et al., in prep) in a sample of 654 friendship dyads. To study the impact of evaluation on structure, we compared a standard principal factor analysis of the CL-519 to three alternative factoring procedures designed to statistically extract evalua-

tive variance from the response matrix and the resulting factor structures: (a) partialling the first unrotated principal component prior to extracting subsequent factors, (b) partialling the variance associated with Positive Valence and Negative Valence as measured by an external measure, and (c) an ipsatized factor solution based on within-person standardized responses. Standard structural analyses revealed clear evidence of additional factors beyond the Big Five. Moreover, the three alternative methods yielded meaningfully different solutions from the standard solution and from one another. The implications for structural personality research will be considered.

### THE EVALUATIVE DIMENSION AS A SEPARATE FACTOR IN PERSONALITY TESTS

Martin Bäckström<sup>1</sup>; <sup>1</sup>Lund University, Sweden – The evaluative content of personality items, also known as their valence, provokes some subjects more than others to make self-ratings in the direction of social desirability, creating an evaluative dimension. One way to investigate the evaluative dimension is to analyze the difference between ratings of items that have a high level of evaluative content with ratings of items that measure the same dimension but have a lower level of evaluative content. This method was used in a study (N= 600) with two versions of an FFM-inventory, one version with items that were high and one with items that were low in evaluative content. Five variables were created based on the difference between the high and low versions of each scale of the FFM-inventory. To test the hypothesis that the evaluative variables, one for each personality factor, form an independent sixth dimension, the personality variables were analyzed together with parcels created based on the five personality scales of the inventory (the version with low level of evaluative content). As predicted, the evaluative variables formed an independent sixth factor. In addition it was found that the evaluative factor correlated highly with self deception and impression management. The importance of these result for personality measurement will be discussed.

### EVALUATION AS A UBIQUITOUS DIMENSION ACROSS LANGUAGES

Amber Thalmayer<sup>1</sup>, Gerard Saucier<sup>1</sup>; <sup>1</sup>University of Oregon – Dictionaries representing twelve languages, mutually isolated, representing diverse cultural characteristics and language families, from multiple continents, were examined to identify common-denominator concepts for human attributes. The languages included were (from Africa) Maasai, Supyire, Senufo, Khoekhoe, Afar, (from Asia) Mara Chin, Hmong, (from Australia, New Guinea, and Oceania) Wikmungkan, Enga, Fijian, (from the Americas) Inuktitut, Hopi, and Kuna. Each one of the nearly 17,000 person-descriptive terms in these dictionaries was cataloged, and a composite list was examined to determine the content (in terms of English translation) of those human attributes most ubiquitously referenced across languages. No fewer than 21 single-word concepts used to describe persons could be identified in all 12 languages. Findings indicate that some personality-attribute concepts may be as cross-culturally ubiquitous as "basic emotion" concepts, but the content of these ubiquitous concepts does not conform to what would be expected based on the most commonly used contemporary dimensional systems for personality. Based on this and other recent studies by our group, we conclude that the more ubiquitously appearing personality concepts are characteristically decidedly evaluative. We further argue that the content of evaluative descriptors in natural language is not adequately covered by concepts of psychopathology because psychopathology has far from full overlap with (im)morality.

### TIMID AND RECKLESS: COUNTERINTUITIVE PROPERTIES OF THE EVALUATION DIMENSION

Erik Pettersson<sup>1</sup>, Erin Horn<sup>1</sup>, Eric Turkheimer<sup>1</sup>; <sup>1</sup> – The strongest dimension to emerge from a factor analysis of a matrix of personality items is not one of the familiar traits of the Five-Factor Model; instead it is a dimension of evaluation including positive, desirable traits at one end and negative, undesirable traits at the other. To explore the properties of this dimension, we developed 30 quadrupled sets of adjectives for each of the thirty facets from the NEO PI-R describing trait dimensions ranging from low and negative, low and positive,

high and positive, to high and negative (cf. Peabody, 1967). For example, the facet modesty was described by the adjectives conceited, confident, humble, and self-deprecating. Three-hundred-and-seventy participants rated themselves on each of the resulting 120 adjectives. The first principal component of the responses correlated highly with evaluation ratings of the adjectives. Moreover, items of opposite meaning but equal evaluative valence loaded in the same direction on the first principle component. For example, self-deprecating and conceited loaded positively, whereas humble and confident loaded negatively. Although such a dimension may have valid external correlates (Block, 1965), it cannot be a valid representation of the actual behavior of a participant. Therefore, we partialled it from the data matrix using Exploratory Structural Equation Modeling (Asparouhov & Muthen, in press). Results demonstrated that once evaluation is controlled, positive and negative descriptors loaded together on meaningful descriptive factors. We conclude that evaluation more of a reporting bias than a valid descriptive dimension of personality.

### Symposia Session D3

#### THE SCIENCE OF MONEY AND RELATIONSHIPS: WAYS THAT MONEY HELPS AND HURTS INTERPERSONAL FUNCTIONING

Friday, January 29, 3:30 - 4:45 pm, Royale Pavilion 5

Chairs: Peter Caprariello, University of Rochester, and Nicole Mead, Kathleen Vohs, Tilburg University, University of Minnesota

Speakers: Nicole Mead, Scott Rick, Peter Caprariello, Xinyue Zhou

Outside of buyer-seller relationships, there is little theoretical basis for expecting that money would influence interpersonal relationships. Yet conventional wisdom and recent research suggests that money – even thoughts of it – influences how people behave toward others. The papers in this symposium move beyond overly simplistic claims that money necessarily helps or hurts relationships. Instead, they ask more nuanced questions about whether, when, and how money affects interpersonal functioning. The first set of talks discuss how money can strain social relationships. Mead, Caruso, Vohs, and Baumeister show that merely reminding people of money causes them to become self-focused and therefore less likable. Rick, Small, and Finkel present evidence that people tend to marry mates with dissimilar feelings toward spending money. Despite this complementary attraction, opposing attitudes toward spending money decreases marital satisfaction by increasing conflict. The second set of talks focus on how money can enhance interpersonal functioning. Caprariello, Reis, and Göritz not only address basic questions of money and happiness, but also suggest how people should spend money to boost happiness: People are happier spending money on interpersonal experiences than on material goods or even experiences alone. Finally, Zhou, Vohs, and Baumeister demonstrate that activating the idea of money soothes the sting of social rejection. It seems that reminders of money act like a salve to mollify interpersonal hurts. Together these papers shed new light on the beneficial and harmful consequences of (real and imaginary) money for social relationships, providing an interpersonal basis for the science of money.

#### ABSTRACTS

**THERE IS NO “YOU” IN MONEY: REMINDERS OF MONEY HEIGHTEN EGOCENTRISM AND DECREASE LIKABILITY** Nicole Mead<sup>1</sup>, Eugene Caruso<sup>2</sup>, Kathleen Vohs<sup>3</sup>, Roy Baumeister<sup>4</sup>; <sup>1</sup>Tilburg Institute for Behavioral Economics Research, Tilburg University, <sup>2</sup>University of Chicago, <sup>3</sup>University of Minnesota, <sup>4</sup>Florida State University – People have a strong need to be liked and accepted by others because social interdependency facilitated survival and reproduction throughout evolutionary history. Money may have a detrimental effect on the motivation to obtain social acceptance because it enables people to obtain what they want regardless of whether they are well-liked. Six experiments tested whether reminders of money strain social relationships. We predicted that they would because reminders of money reduce motivation to engage in cognitive

and behavioral strategies aimed at social acceptance. Compared to control participants, participants who had been reminded of money were worse at remembering information about a peer (Experiment 1), more likely to assume that others share their opinions (Experiment 2), and less likely to take the perspective of others (Experiment 3). Experiment 4 found that being financially dependent on taking the perspective of others wiped out the effect of money reminders on egocentrism, in (what we believe to be) the first demonstration of how to get people to overcome the deleterious biases elicited by reminders of money. Experiments 5 and 6 showed negative effects of money reminders on actual behavior: Relative to participants not reminded of money, participants reminded of money were perceived as not trying very hard to come across as warm and friendly when meeting new acquaintances, which in turn made them less likable. In short, reminders of money strain social relationships by reducing the motivation to gain social acceptance.

#### FATAL (FISCAL) ATTRACTION: SPENDTHRIFTS AND TIGHTWADS IN MARRIAGE

Scott Rick<sup>1</sup>, Deborah Small<sup>2</sup>, Eli Finkel<sup>3</sup>; <sup>1</sup>University of Michigan, <sup>2</sup>University of Pennsylvania, <sup>3</sup>Northwestern University – Money is a common source of marital conflict. Most research about such conflicts has focused on how couples cope with economic hardship. Yet conflict over money likely exists even for couples not struggling financially. If spouses differ in their feelings toward spending money, they may be vulnerable to conflict over money, independent of financial constraints. We used the Tightwad-Spendthrift scale (Rick, Cryder, and Loewenstein, 2008) to examine whether spouses systematically differ in their feelings toward spending money. The scale assesses the extent to which people experience distress when considering spending money. Spendthrifts spend freely, but wish they could spend less. Tightwads spend little, but wish they could spend more. Although people select mates with traits that are similar to their own, similarity is not a universal principle of mate selection. For instance, people tend to be attracted to mates who possess characteristics similar to those they value in themselves, but dissimilarity tends to be appealing for disliked aspects of the self (Klohnen and Mendelsohn, 1998). Thus, if tightwads and spendthrifts are dissatisfied with their spending behavior, tightwads and spendthrifts should be attracted to one another. Consistent with our hypothesis, two studies, with 458 married adults and 110 married couples, revealed that the correlation between the Tightwad-Spendthrift scores of partners was negative and significant. Also as predicted, spendthrift/tightwad differences diminished marital satisfaction. This effect was mediated by arguments over money. Thus, although people are attracted to mates who feel differently toward spending money, these opposing feelings ultimately diminish marital well-being.

#### TO DO WITH OTHERS OR TO HAVE (OR TO DO ALONE)? THE VALUE OF EXPERIENCES OVER MATERIAL POSSESSIONS DEPENDS ON THE INVOLVEMENT OF OTHERS.

Peter Caprariello<sup>1</sup>, Harry Reis<sup>2</sup>, Anja Göritz<sup>3</sup>; <sup>1</sup>University of Rochester, <sup>2</sup>University of Rochester, <sup>3</sup>University of Erlangen-Nürnberg – How can money be used to enhance one’s own happiness? Recent studies have addressed this question. Van Boven and Gilovich (2003) showed that spending money on experiences makes people happier than spending money on material possessions. We take this finding to the next level by proposing that the key hidden variable in this effect is whether the experience includes another person. Dunn, Aknin, & Norton (2008) showed that spending money on others makes people happier than spending money on themselves. Therefore, the present research tested whether spending money on experiences makes people happy because many people’s experiences naturally include the involvement of others. Hence, the social component of many experiences (e.g., vacationing with others versus vacationing alone) may render them better able to make people happy, relative to material possessions. This also leads to the secondary prediction that experiences with others makes people happier than experiences by oneself. A series of experiments supported these predictions. Experiment 1 showed that when deciding between hypothetical social experiences and material possessions, people chose and said they would be made happier by social experiences.

Moreover, when deciding between material objects and solitary experiences, people chose and said they would be made happier by material objects. The same pattern of preferences was confirmed in a large sample of German respondents who considered actual past purchases (rather than hypothetical purchases). In short, taking into account the relationship context of experiences appears to be key to predicting what kind of monetary purchases best lead to happiness.

**REMINDERS OF MONEY ALTER SOCIAL DISTRESS AND PHYSICAL PAIN** Xinyue Zhou<sup>1</sup>, Kathleen Vohs<sup>2</sup>, Roy Baumeister<sup>3</sup>; <sup>1</sup>Sun Yat-Sen University, <sup>2</sup>University of Minnesota, <sup>3</sup>Florida State University – Money can obviously help when people feel pain, such as to buy cures, creams, or other aids. But can money symbolically help alleviate pain as well? We found that it does, in three experiments that tested whether mere reminders of money lessen the pain of social rejection. Experiment 1 found that people who counted out slips of currency, relative to people who counted out slips of paper, felt less distress over being socially rejected during an online ball-tossing game. Experiment 2 found that people who were socially rejected by a group of peers, compared to people who were not socially rejected, showed signs of desiring money more: They represented coins as larger, offered to trade more nice things (e.g., sunshine, music) to be a millionaire, and gave less of their own money to an orphanage. Experiment 3 showed that reminders of money that people have spent during the past month makes social rejection feel more painful (using the same online ball-tossing game as Experiment 1), compared to being reminded of the weather for the past month. Money thus seems to act as a symbolic inner resource that people can call upon to help them cope with challenges to their interpersonal well-being.

#### Symposia Session D4

### THE NATURE, CAUSES AND CONSEQUENCES OF OBJECTIFICATION

Friday, January 29, 3:30 - 4:45 pm, Royale Pavilion 6

Chairs: Steve Loughnan, University of Melbourne, and Anna Newheiser, Yale University

Speakers: Jeroen Vaes, Anna-Kaisa Newheiser, Jamie L. Goldenberg, Steve Loughnan

To date, research on objectification – treating people as objects – has concentrated on the intrapersonal effects of objectifying the self, while remaining relatively silent on the objectification process itself. However, the field is currently experiencing rapid conceptual and empirical change, with researchers returning to earlier accounts of objectification in order to understand how and why people treat others as objects. The emerging consensus is that objectification consists of a failure to recognize the objectified as fully human. Across a range of international settings, this symposium showcases research from this new perspective on objectification, exploring how and why people objectify others and the consequences of doing so. Four independent, methodologically diverse presentations converge to demonstrate that objectification entails viewing the other as less than fully human. To explore why this might occur, two presentations examine the underlying processes. Vaes, Puvia, and Paladino examine sex differences in the objectification of female targets, arguing that while men are motivated by sexual desire, women are motivated by social distance. Newheiser, LaFrance, and Dovidio investigate why people fail to refrain from objectifying others, finding that males – but not females – underestimate the harmfulness of being objectified. Examining the consequences for the target, Goldenberg and Heflick demonstrate that objectification reduces perceived competence and warmth, leading to decreased public support. Loughnan and Haslam focus on the moral domain, showing that the objectified are viewed as lacking moral status and pain sensitivity. Combined, these studies offer new insight into the nature and negative consequences of objectification.

#### ABSTRACTS

**ARE SEXUALIZED FEMALE TARGETS HUMAN BEINGS? WHY MALES AND FEMALES DEHUMANIZE SEXUALLY OBJECTIFIED WOMEN** Jeroen Vaes<sup>1</sup>, Elisa Puvia<sup>1</sup>, Maria Paola Paladino<sup>2</sup>; <sup>1</sup>University of Padova, <sup>2</sup>University of Trento – Focusing on the dehumanization of sexually objectified targets, the present set of studies measured human associations with male and female objectified and non-objectified targets. Adapting a SC-IAT in Study 1, only sexually objectified female targets were associated less with uniquely human words compared to objectified male and both non-objectified targets. Importantly, both male and female participants showed these dehumanizing results, but likely for different reasons. Hypothesizing that females dehumanize objectified female targets because they see them as a disliked subcategory, Study 2 measured the extent to which female participants saw objectified women as a subcategory and identify with them. Results indicated that only female participants who distance themselves from objectified female targets tend to dehumanize them. Study 3, instead, focused on male participants and tested the hypothesis that sexual attraction lies at the basis of males' dehumanization of objectified female targets. Male participants were either primed with a sex goal or not and their tendency to dehumanize female targets was measured. Importantly, the female targets in this study were not objectified or sexually arousing per se, but could be seen as such as a result of the manipulation. In addition, participants had to select an attractive or a competent female collaborator for an ostensible online mathematical task. Results indicated that only males with an active sex goal dehumanized the female targets and preferred the attractive instead of the competent collaborator. Taken together, these results indicate the opposing motivations that make both males and females dehumanize objectified women.

**OTHERS AS OBJECTS: HOW WOMEN AND MEN UNDERSTAND THE CONSEQUENCES OF OBJECTIFICATION** Anna-Kaisa Newheiser<sup>1</sup>, Marianne LaFrance<sup>1</sup>, John F. Dovidio<sup>1</sup>; <sup>1</sup>Yale University – Research on sexual objectification has identified several negative consequences for objectified women. Little is known, however, about whether people recognize the negative impact objectifying treatment has on others. We examined people's potential underestimation of the negative emotional consequences of being objectified. Because sexual objectification occurs when a person is evaluated primarily based on physical or sexual attributes, we propose that objectifying another person impairs the perceiver's understanding of that person's psychological state. In particular, because men have relatively little personal experience with being objectified, we expected them to be more likely than women to show signs of such limited understanding. In Study 1, participants were either induced to objectify a female target by focusing on her attractiveness, or instead focused on her health. Women were more likely than men to perceive negative emotions in the objectified target. Study 2 examined whether this sex difference could be explained by men's relative lack of motivation to attend to objectified targets' experience. To increase motivation, participants were induced to identify with objectified and non-objectified targets by imagining themselves in the targets' position. Although both sexes reported experiencing more negative and less positive affect after identifying with objectified (vs. non-objectified) targets, the effect was considerably weaker for men. This finding indicates that factors beyond motivation, such as personal experience with being objectified, are likely to be involved in men's relatively poorer understanding of objectified targets' experience. Together, the findings implicate underestimation of the negative impact of being objectified in the perpetuation of sexual objectification.

**WOMEN AS OBJECTS: THE EFFECTS OF APPEARANCE FOCUS ON PERCEPTIONS OF WOMEN'S COMPETENCE, WARMTH, AND HUMANNES** Jamie L. Goldenberg<sup>1</sup>, Nathan A. Heflick<sup>1</sup>; <sup>1</sup>University of South Florida – Few would debate: women are evaluated on the basis of their appearance more so than men. Research has documented intra-psy-

chological consequences for women, however, little empirical attention has been given to how focusing on a woman's appearance affects the way she is perceived by others. We suggest that 1) focusing on a woman's appearance induces perceptions of the woman as an object, whereas focusing on the appearance of men is not similarly objectifying; and 2) objectified individuals should be perceived as less competent, less warm and less fully human. We merge these propositions to hypothesize that focusing on women's, but not men's, appearance should reduce perceptions of their competence, warmth, and humanness. Supporting this, we present finding revealing that when participants focused on the appearance of Sarah Palin or Angelina Jolie, they perceived each woman to be less competent and less fully human (people evaluating Palin's appearance also reported reduced likelihood to vote for the McCain-Palin ticket prior to the 2008 election). We demonstrated the specificity of this phenomenon to perceptions of women by replicating the decreased competence effect in response to focusing on the appearance of Michelle, but not Barack, Obama. In a follow-up to this, we manipulated the attractiveness of the target as well as the gender, and found that women were perceived as less warm when evaluated on the basis of their appearance regardless of their level of attractiveness; but again, perceptions of males were not affected.

#### **OBJECTIFICATION AND DIMINISHED PERSONHOOD: THE DENIAL OF MIND AND MORAL CONCERN TO OBJECTIFIED OTHERS** Steve

Loughnan<sup>1</sup>, Nick Haslam<sup>1</sup>; <sup>1</sup>University of Melbourne – Being objectified means more than simply being viewed in a sexualized manner. It implies that someone's personhood has been diminished or denied and they are instead seen as an object. Philosophers have argued that when people are objectified they are viewed as if they lack the mental states and moral status associated with personhood, but this claim has been largely neglected by psychologists. Three studies investigated how objectification leads to de-personalization, assessed by judgments of mind, competence, and moral concern. Study 1 examined the relationship between objectification and mind attribution, finding that objectified people are viewed as deficient on a range of mental states compared to non-objectified people. In Study 2, objectified women were attributed less mind and were accorded lesser moral concern than non-objectified women. Study 3 replicated the results of the two preceding studies with both male and female targets. Objectified people were denied mental attributes and this led to decreased perceived job competence and lower IQ. Objectified people were also viewed as lacking moral status and as having lesser sensitivity to pain. In short, this research shows that objectified people may be viewed as non-persons; they are denied mind and moral status and seen as possessing lower intelligence, less competence, and decreased capacity for suffering. The implications of these findings for understanding sexism and violence will be discussed.

#### **Symposia Session D5**

#### **UNDERSTANDING IMPLICIT AND EXPLICIT ATTITUDES: EXPLORING THE DUAL-SYSTEMS PERSPECTIVE**

Friday, January 29, 3:30 - 4:45 pm, Royale Pavilion 3-4

Chairs: Michael J. McCaslin, Ohio State University, and Chris Loersch, University of Missouri

Speakers: Robert Rydell, Kate A. Ranganath, Aiden P. Gregg, Michael J. McCaslin

In recent years, dual-process logic has been applied to a wave of new dual-systems models of human thought and behavior. This trend is particularly evident in models of evaluation, and recent research on the topic has sparked debate regarding the formation and expression of attitudes. In particular, some investigators have proposed the existence of relatively independent implicit and explicit attitudes that stem from separate associative and deliberative processing systems, whereas other researchers argue that this distinction is not necessary to account for the current data. In this symposium, we seek to further the discussion of this dual-systems logic by providing new research findings that explore the

formation and possible interplay of implicit and explicit attitudes. First, Rydell will present a dual-systems model that offers an explanation for dissociations between implicit and explicit attitude measures. Then, Ranganath and Nosek will provide an account of how and when evaluative associations generalize to implicit and explicit attitudes. Next, Gregg and Sedikides will explore the nature of implicit and explicit attitudes by examining implicit and explicit self-esteem in relation to narcissism. Finally, McCaslin, Loersch, and Petty will present data showing that implicit and explicit attitude measures can be mutually influenced by associative and deliberative processing. Together, these presentations offer greater understanding of the key factors that impact implicit and explicit attitude formation and the conditions under which different evaluative processes may or may not interact.

#### **ABSTRACTS**

**A SYSTEMS OF EVALUATION MODEL** Robert Rydell<sup>1</sup>; <sup>1</sup>Indiana University – The Systems of Evaluation Model (SEM; McConnell, Rydell, Strain, & Mackie, 2008; Rydell & McConnell, 2006) assumes that people utilize two different mental systems when they evaluate entities: an associative system and a rule-based system. The associative system of evaluation is relevant to understanding how quick and relatively spontaneous evaluations form and function by following the basic principles of similarity and contiguity. The rule-based system fits with a conceptualization of evaluations based on conscious deliberation or syllogistic reasoning, which can reveal quick but resource-dependent changes. In the SEM, systems refer to aspects of the mind that use particular types of information and operating principles to render evaluations, actively or passively. Essentially, each system can be conceived of as an interrelated group of mechanisms that are dedicated to evaluation. Because the two systems differ in their inputs and style of information processing, their outputs can differ. A system approach assumes that two broad groups of processes and mechanisms that operate and serve to disambiguate the attitude object, its features, and its value to (or probable impact on) the perceiver given current environmental constraints and perceiver goals. As evidence for this model, several experiments in which implicit attitude measures are more sensitive to associative forms of information (e.g., subliminal primes, associative cues) and explicit attitude measures are more sensitive to symbolic forms of information will be presented. These experiments demonstrate that utilizing a "systems" model offers a viable account for certain dissociations between implicit and explicit attitude measures.

#### **PROCESSES IN IMPLICIT AND EXPLICIT ATTITUDE GENERALIZATION** Kate A. Ranganath<sup>1</sup>, Brian A. Nosek<sup>2</sup>; <sup>1</sup>Tilburg University, <sup>2</sup>University of Virginia

Attitude transfer is the formation of attitudes toward a novel stimulus based on its associations with other valenced stimuli. Based on distinguishing between associative and propositional processes (Gawronski & Bodenhausen, 2006), implicit evaluations of one stimulus object may generalize to other stimuli through simple associations, despite explicit attitudes to the contrary. In several studies, we used an attitude generalization paradigm to examine distinct influences on the formation of implicit and explicit attitudes. Implicit evaluations of novel individuals readily generalized to new individuals described as belonging to the same group; explicitly, participants resisted such generalization. Days later, both implicit and explicit evaluations of the original individuals generalized to the new individuals. The results suggest that associative links (e.g., shared group membership) are sufficient for implicit attitude generalization, but deliberative logic (e.g., individual group members are not necessarily the same) can reduce explicit generalization-by-association. When knowledge distinguishing who-did-what is unavailable, such as after forgetting, associative knowledge provides the basis of explicit evaluation. We conclude that a simple association linking one individual to another can produce implicit attitude generalization immediately and explicit attitude generalization eventually. We suggest that resisting attitude transfer requires the ability to deliberately refrain from generalization. If there is no such ability, activated associa-

tions play a greater role in explicit judgments. In this way, implicit attitudes might influence explicit attitudes. However, deliberately trying to exert cognitive control might lead to explicit attitudes that influence implicit attitudes.

**EXPLICIT AND IMPLICIT SELF-ESTEEM: CONTINUING CONUNDRUMS OF QUANTITY, QUALITY, AND CONSISTENCY** Aiden P. Gregg<sup>1</sup>, Constantine Sedikides<sup>1</sup>; <sup>1</sup>Centre for Research on Self and Identity, University of Southampton—Self-esteem can be defined as a summary attitude towards self. Hence, it can also be characterized in terms of the distinction between explicit and implicit attitude. Moreover, implicit self-esteem (ISE), variously indexed, has been hypothesized to better reflect, either in isolation or conjunction, the quality or security of self-regard, whereas explicit self-esteem (ESE) has been hypothesized to better reflect the quantity of self-regard, potentially fragile. Using as a starting point our own and others' research into the hypothesis that the narcissistic self-aggrandizement represents a compensation for fragile self-regard, we critically review the expected and observed antecedents, correlates, and consequences of ESE and ISE, and the statistical patterns underlying them. We arrive at the sobering conclusion that, although some isolated findings point to ISE being a significant psychological phenomenon exhibiting discriminant predictive validity, the accumulated empirical record nonetheless contains a critical mass of inconsistencies, anomalies, and problems of interpretation that cast doubt on ISE as the sine qua non of secure self-regard. We emphasize the need for more specific and coherent theoretical accounts of why and how ISE should reflect secure self-regard, and offer one testable model of how, in respect of their relation to narcissism, ISE and ESE can be causally connected but nonetheless dispositionally diverge.

**ATTITUDE DISSOCIATION? THE INTERPLAY OF ASSOCIATIVE AND DELIBERATIVE ATTITUDE PROCESSES** Michael J. McCaslin<sup>1</sup>, Chris Loersch<sup>2</sup>, Richard E. Petty<sup>1</sup>; <sup>1</sup>Ohio State University, <sup>2</sup>University of Missouri—Recently, considerable controversy has surrounded the nature of implicit and explicit attitudes and what is captured by the implicit and explicit measures used to assess them. We present research that examines whether or not different measures of attitudes (i.e., implicit or automatic versus explicit or deliberative) are uniquely sensitive to different bases of attitudes (i.e., associative versus deliberative). Much prior research in which either associative or deliberative processes served as the sole foundation of attitudes revealed that either process could affect both implicit and explicit measures. More recent research in which both kinds of processes operated simultaneously, however, suggested that different attitude measures might reflect independent modes of evaluation (i.e., implicit measures are solely impacted by association-based processes and explicit measures are only affected by deliberative processes). In two studies, we show how either result could occur depending on methodological aspects of the study. For example, with respect to explicit measures, a social judgeability perspective can account for both potential outcomes. The results of our research demonstrate that although implicit and explicit attitude estimates diverge under "natural" conditions, the two converge when efforts to eliminate social judgeability concerns are taken. These findings suggest that some dissociations between implicit and explicit attitude measures occur because individuals are hesitant to report consciously inexplicable "gut feelings" towards certain attitude objects. When social judgeability concerns are reduced, the impact of associative and deliberative processes of attitude formation can be captured by both implicit and explicit measures.

## Symposia Session D6

### BEYOND RECOGNITION: WHAT ARE THE SOCIAL (AND NOT-SO-SOCIAL) FUNCTIONS OF EMOTION EXPRESSIONS?

Friday, January 29, 3:30 - 4:45 pm, Royale Pavilion 7-8

Chairs: Jessica L. Tracy and Azim F. Shariff, University of British Columbia

Speakers: Azim F. Shariff, Arne Ohman, Alexander Todorov, Adam K. Anderson

A large literature has demonstrated that a small set of emotions are associated with distinct, cross-culturally recognized, nonverbal expressions, leading many to conclude that these expressions are evolved. However, surprisingly few studies have asked why emotion expressions might have evolved. Most researchers assume that emotions communicate evolutionarily significant information, but Darwin speculated that these expressions originated not for the purpose of social communication, but rather to promote basic physiological changes. This leads to the question: did emotion expressions evolve to serve social functions? Here, we present the latest work from researchers directly tackling this issue. Shariff and Tracy will present evidence for social functions of two self-conscious emotions, pride and shame, which may communicate shifts in social status even in the face of conflicting contextual information. Ohman and Juth will take a nuanced approach to the longstanding, evolutionary predicated question of whether observers attend more quickly to happy or angry faces in a crowd. Todorov will demonstrate links between the facial-structure dimensions that allow for perceptions of trustworthiness from neutral expressions and that underlie anger and happiness expressions—providing a dimension-based explanatory account of these displays. Anderson will also focus on the dimensional structure of expressions, providing long-awaited empirical support for Darwin's proposition that expressions' original functions are more related to physiological coping than social communication, but have been co-opted to serve a more social purpose. Together, these talks mark the beginning of a new explanatory account of emotion expressions, focused less on what is expressed, and more on why.

## ABSTRACTS

### THE IRREPRESSIBLE COMMUNICATIVE POWER OF THE EMOTION EXPRESSIONS OF PRIDE AND SHAME

Azim F. Shariff<sup>1</sup>, Jessica L. Tracy<sup>1</sup>; <sup>1</sup>University of British Columbia—If emotion expressions are evolutionary rooted (at least in part) in social communication, then it is likely that humans developed a pair of complimentary adaptations - one to display distinct and universally recognizable expressions, and another to 'read' the meaning of these displays in others. Here, we present evidence for both abilities, using the emotions of pride and shame as examples. Theorists have long noted similarities between the pride and shame nonverbal expressions, in humans, and the dominance and submission displays found throughout the animal kingdom. We show that individuals indeed tightly associate status with pride and shame displays, and that these expressions are integral to the social communication of high and low status, respectively. First, humans around the world—including congenitally blind individuals who have never seen others' emotion expressions—reliably display pride and shame expressions in response to status-relevant situations such as personal success or failure. Second, observers respond to these expressions by implicitly and unavoidably granting or withdrawing social status accordingly, and the pride expression, in particular, is a stronger status signal than any other emotion expression examined, including anger and happiness. Moreover, these implicit status judgments occur and influence decision-making even when observers are confronted with explicitly contradictory contextual information about the expresser's status. These findings demonstrate the irrepressible communicative power of the pride and shame displays, and suggest that these emotion expressions may have evolved to influence important social judgments as powerfully as rational knowledge of the situational context.

### CONDITIONS FOR PREFERENTIALLY ATTENDING TO AN ANGRY FACE IN A CROWD

Arne Ohman<sup>1</sup>, Pernilla Juth<sup>1</sup>; <sup>1</sup>Karolinska Institute—From a Darwinian perspective, it makes eminent sense that humans should more quickly direct their attention to an angry than to a happy face in a crowd of faces. An angry face conveys a potential threat, which may call for an immediate action, whereas a happy face invites social interaction and acceptance, which is less demanding in terms of urgent action. The empirical support for this "angry superiority effect", however, is very mixed. Therefore, we developed and tested a novel theory to reconcile

opposing findings in the literature on visual search for emotional target faces among neutral distractor faces. We predicted and found that the nature of the distractor stimuli was very important, with overall better search performance when distractors were redundant (i.e., “familiar”, because they were drawn from a small rather than large stimulus set). This effect interacted with target gender and target emotion. Female happy target faces were always more quickly detected than female angry target faces. Similarly, a happy target face advantage was obtained with male target faces when the distractors were non-redundant. However, more rapid detection of angry than happy target faces was observed with male targets and redundant distractors. Thus, our results demonstrate that claims of an anger superiority effect in visual search for faces are empirically valid, but only under circumscribed boundary conditions. From a social perspective, it is interesting to note that these boundary conditions included male targets in the context of familiar faces—a common situation for interpersonal violence.

### **THE FUNCTIONAL BASIS OF EVALUATION OF FACES ON SOCIAL DIMENSIONS** Alexander Todorov<sup>1</sup>, Chris Said<sup>1</sup>, Nikolaas Oosterhof<sup>1</sup>;

<sup>1</sup>Princeton University—People reliably and automatically make personality inferences from facial appearance despite little evidence for their accuracy. Using data-driven methods, we show that the two primary dimensions for social evaluation of faces are valence/trustworthiness and power/dominance. We argue that these evaluations reflect attempts to infer the intentions of the person. Specifically, the valence dimension maps onto inferences about the person’s harmful intentions and determines approach/avoidance decisions. The dominance dimension maps onto inferences about the person’s ability to cause harm. Here, we present three independent lines of evidence that inferences along the valence dimension from emotionally neutral faces are based on similarity to emotional expressions signaling approach/avoidance behavior. First, using a variant of reverse correlation, we created a computer-generated imagery model of face valence/trustworthiness. Exaggerating faces along this dimension in the positive direction produced faces expressing happiness. Exaggerating faces in the negative direction produced faces expressing anger. Second, using a vision classifier trained to identify basic emotional expressions, we show that the probabilities of categorizing emotionally neutral faces as angry or happy predict trait inferences related to the valence dimension of face evaluation. Third, using dynamic emotional faces, we show that congruent changes in face trustworthiness intensify the perception of emotions of anger and happiness. For example, anger is perceived as more intense when expressed by an untrustworthy face and, particularly, when the expression of emotion is accompanied by a change from a trustworthy to an untrustworthy face (i.e., moving from features resembling happy to features resembling angry expressions).

### **FACIAL EXPRESSION FORM AND FUNCTION** Adam K. Anderson<sup>1</sup>;

<sup>1</sup>University of Toronto—Facial expressions are instrumental in communicating one’s internal emotional state and in regulating social interactions. Over 130 years ago, Darwin hypothesized that emotional expressions originate in a less appreciated functional role—to modify preparedness for perception and action. We examined whether the specific appearance of emotion facial expressions may originate in their potential for altering sensory systems whose receptors reside on the face, in the service of regulating sensory input. Our results provide evidence for this thesis and two of Darwin’s evolutionarily derived principles of emotional expressive behavior: 1) “serviceable associated habits” or “function”—whereby specific facial expressions originate in patterns of movement serving adaptive functions for the expresser, and 2) “antithesis” or “form”—whereby emotions with opposite functions are opposites in physical configuration. Our second thesis is that, despite these origins, facial expressions have been co-opted, maintained, and further shaped for their more primary role as social signals. First, with regard to the reception of facial signals, we draw upon opponent coding (similar to color perception) to show how oppositions in facial expression structure are mirrored in perceiver’s brains. Second, with regard to the sending of facial signals, we

show how expressions of moral disgust in response to unfair social exchanges originate from a primitive facial response to the rejection of bad tastes. These convergent sources of evidence demonstrate that facial expressions may have a sensory-functional origin, but this function has critically extended from the physical to the social environment.

### **Symposia Session D7**

#### **THE ORIGINS, PREDICTORS, AND MODERATORS OF RELIGIOUS BELIEFS AND INVOLVEMENT**

Friday, January 29, 3:30 - 4:45 pm, Capri Rooms 101-102

Chairs: Joni Sasaki and Heejung Kim, UC Santa Barbara

Speakers: Azim Shariff, Kristin Laurin, Joni Sasaki, Adam Cohen

Considering its scope of influence, research on religion is vastly underdeveloped in psychology. However, recent empirical investigations have made notable progress towards a more nuanced understanding of why people are religious and how religion impacts people’s lives. The speakers of this symposium will contribute their unique perspectives on the origins, predictors, and moderators of religious beliefs and involvement. Norenzayan and Shariff will begin the session by addressing the prevalence of belief in a supernatural deity and regional variations in religiosity from a cultural evolutionary perspective. They will also demonstrate some of the benefits and consequences of religious involvement. In the second talk, Laurin, Kay, and Moscovitch will build on their work showing that belief in a controlling God can compensate for a lack of personal control. Specifically, they will present research findings showing that anxiety from threats to personal control can predict greater belief in a controlling God, but that this increase in belief can be eliminated using a misattribution of arousal procedure. The third talk, by Sasaki and Kim, will show how the effects of religion can be moderated by culture. Using a cultural psychological perspective, their research will demonstrate how the impact of religion on personal control may be more relevant for people from individualistic cultures. In the fourth talk, Cohen will show that the relationship between religiosity and political alignment is moderated by race. Each presentation will address important questions about the universal versus culture-specific implications of religious belief and involvement.

#### **ABSTRACTS**

#### **THE CULTURAL EVOLUTION OF RELIGIOUS INVOLVEMENT** Ara

Norenzayan<sup>1</sup>, Azim Shariff<sup>1</sup>; <sup>1</sup>University of British Columbia—Religions have existed in all societies throughout recorded history. Even in modern societies, only a small proportion of the world denies the existence of a supernatural deity. In this talk, we review experimental and cross-cultural evidence that links religion to prosocial tendencies. We present a cultural evolutionary account of why religion is so prevalent, why it remains more pronounced in certain regions of the world than others, and why the spread of atheism faces considerable challenges. In addition, we will present data showing that the same religious involvement that ties people together lead to an entangled combination of ingroup altruism and outgroup conflict.

#### **GOD IN A RANDOM WORLD: RELIGIOUS BELIEF AND THE THREAT OF PERCEIVED DISORDER** Kristin Laurin<sup>1</sup>, Aaron Kay<sup>1</sup>, David Moscovitch<sup>1</sup>;

<sup>1</sup>University of Waterloo—The need to feel personal control over the events in our lives is a widely documented human need. The satisfaction of this need is said to protect people from the psychologically stressful perception that the world is random. However, beliefs about personal control cannot always be uniformly high: most people’s everyday life contains at least some experiences, such as missing an appointment due to a late bus, or receiving an unexpected visit from a friend, that highlight the ways in which they do not have personal control. Recent research we have conducted suggests that beliefs in the existence of a controlling God can compensate for fluctuating personal control beliefs: when feelings of personal control are threatened, participants increase their endorsement

of a controlling God. In this presentation, we describe evidence documenting the extent to which this process is motivated, and driven by attempts to down-regulate the arousal or anxiety associated with perceptions of randomness. That is, we present studies testing the hypothesis that threats to perceived order engender anxiety and that attempts to cope with this anxiety produce increased beliefs in a controlling God. These studies demonstrate that (i) the anxiety associated with threats to personal control predict subsequent beliefs in a controlling God and (ii) providing participants an opportunity to misattribute feelings of arousal to a placebo pill eliminates the effects of control threat on belief in a controlling God.

**AT THE INTERSECTION OF CULTURE AND RELIGION: A CULTURAL ANALYSIS OF THE EFFECT OF RELIGION ON CONTROL** Joni Sasaki<sup>1</sup>, Heejung Kim<sup>1</sup>; <sup>1</sup>University of California, Santa Barbara – Research suggests that religion helps people maintain a sense of control in difficult situations, but little is known about how culture may influence the effects of religion. Given that people from individualistic cultures, such as European Americans, are more motivated towards personal agency and control than people from collectivistic cultures, such as East Asians, the current research examines the interaction of culture and religion on control. In Study 1, participants were either primed with religion or not and were observed during a mild distress situation. Results showed that priming religion influenced acts of personal control for European Americans but not Asians/Asian Americans. Using daily diary methodology, Study 2 showed that religious coping was associated with personal control for European Americans but not East Asians, and religious coping predicted more social coping for both cultural groups. In Study 3, a content analysis of mission statements on church websites showed that while themes of personal agency (e.g., spiritual growth, inclusion of diverse members) were more prevalent on American church websites, themes of relationships (e.g., close relationships within the church, social activities with other church members) were more prevalent on Korean church websites. Taken together, our findings suggest that the functions and implications of religion may vary for individuals depending on their cultural background.

**RACE AS A MODERATOR OF THE RELATIONSHIP BETWEEN RELIGIOSITY AND POLITICAL ALIGNMENT** Adam Cohen<sup>1</sup>; <sup>1</sup>Arizona State University – Religiosity, especially religious fundamentalism, is often assumed to have an inherent connection with conservative politics. We propose that the relationship varies by race in the United States. In Study 1 race moderated the relationships between religiosity indicators and political alignment in a nationally representative sample. The effect replicated in a student sample with more reliable measures (Study 2). Among both Black and Latino Americans the relationship between religiosity and conservative politics is far weaker than it is among White Americans, and it is sometimes altogether absent. In Study 3, a tradition-focused view of religion was found to more strongly mediate the link between religiosity and political attitudes among Whites than it did among Blacks and Latinos. We argue that the relationship between religiosity and political alignment is best understood as a product of cultural-historical conditions associated with group memberships.

## Symposia Session D8

### PROHIBITIONS AND PUNISHMENTS: IMPLICATIONS FOR MORAL PSYCHOLOGY

Friday, January 29, 3:30 - 4:45 pm, Capri Rooms 103-106

Chairs: Sana Sheikh and Ramila Usoof-Thowfeek, University of Massachusetts Amherst

Speakers: Sana Sheikh, Fiery Cushman, Ramila Usoof-Thowfeek, Kevin M. Carlsmith

Punishment is a phenomenon central to morality: People often feel justified, and even obligated, to punish those who have violated moral prohibitions. Indeed, punishment of prohibited behavior lies at the very

foundation of maintaining social order, a central motivation underlying morality. In light of its significance to the study of moral psychology, the current symposium brings together four programs of research that examine the complex, yet inextricable relations between moral prohibitions and punishment. Examining the dimensions of prohibitions and punishments provides a richer understanding of moral conduct, informing areas ranging from the socialization of prohibitions to the use of torture as retributive punishment for moral violators. Specifically, we ask: Do people adhere to prohibitions to avoid punishing outcomes? Are prohibitions socialized through authoritarian, punitive parenting, and are they associated with particular moral emotions (Sheikh)? When violated, are the subsequent punishments strongly influenced by the transgressor's intentions or by the outcomes alone (Cushman)? And what is the role of the prohibition "do no harm" when deciding on an appropriate punishment for its violation? How does effortful processing change automatic reactions to violations of prohibitions (Usoof-Thowfeek)? Recent work has found that punishment is motivated by retribution rather than utilitarian concerns; which of these motives underlie the use of torture? Is the desire to use torture driven by the effectiveness of the technique or by the (im)moral status of the transgressor (Carlsmith)?

## ABSTRACTS

**MORAL PROHIBITIONS, AUTHORITARIAN PARENTING, AND FEELINGS OF SHAME** Sana Sheikh<sup>1</sup>, Ronnie Janoff-Bulman<sup>1</sup>; <sup>1</sup>University of Massachusetts Amherst – From a self-regulatory perspective, prohibitions reflect a motivation to inhibit immoral, punishing outcomes. Janoff-Bulman, Sheikh, and Hepp (2009) have found that prohibitions ("should nots"), but not prescriptions ("shoulds"), are avoidance-motivated, related to the Behavioral Inhibition System and increase after threat situational primes. I present four studies that examine the socialization and emotional implications of a self-regulatory perspective on prohibitions. Early, punitive interactions with parental figures may in fact socialize prohibitions; in particular, authoritarian parenting may restrict immoral behavior through the threat of punishment, but not foster socially valuable, prescriptive behaviors. Studies 1 and 2 find that adhering to prohibitions and making proscriptive moral judgments are both positively related to having punitive, authoritarian parents. However, authoritarian parenting is not associated with adherence to prescriptions or making prescriptive moral judgments. Prohibitions also incur distressing emotions when violated: Because shame is related to an avoidance-orientation, where higher shame-proneness is associated with the Behavioral Inhibition System (Study 3), transgressing a prohibitive rule is likely to incur more shame (Study 4) than other non-avoidance moral emotions, such as guilt. Overall, a motivational perspective on morality informs both the socialization of prohibitions and the self-evaluative consequences following their transgressions.

**ACCIDENTAL OUTCOMES GUIDE PUNISHMENT IN A "TREMBLING HAND" GAME** Fiery Cushman<sup>1</sup>, Anna Dreber<sup>1</sup>, Ying Wang<sup>1</sup>, Jay Costa<sup>2</sup>; <sup>1</sup>Harvard University, <sup>2</sup>Stockholm School of Economics – How do people reward and punish accidents? We explore this question in a two-player economic game where allocations are made with a "trembling hand": that is, intentions and outcomes are sometimes mismatched. Player 1 allocates \$10 between herself and Player 2 by rolling one of three dice. One die has a high probability of a selfish outcome, another has a high probability of a fair outcome, and the third has a high probability of a generous outcome. Based on Player 1's choice of die, Player 2 can infer her intentions. However, any of the three die can yield any of the three possible outcomes. Player 2 is given the opportunity to respond to Player 1's allocation by adding to or subtracting from Player 1's payoff. We find that Player 2's responses are influenced substantially by the accidental outcome of Player 1's roll of the die. Comparison to control conditions suggests that in contexts where the allocation is at least partially under the control of Player 1, Player 2 will hold Player 1 accountable for unintended outcomes. In addition, Player 2's responses are influenced by Player 1's intention. However, Player 2 tends to modulate his responses substan-

tially more for selfish intentions than for generous intentions. This novel economic game provides new insight into the psychological mechanisms underlying social preferences for fairness and retribution.

**HARM AND COGNITIVE PROCESSING: WHAT MATTERS WHEN PUNISHING MORAL TRANSGRESSIONS?** Ramila Usoof-Thowfeek<sup>1</sup>, Ronnie Janoff-Bulman<sup>1</sup>; <sup>1</sup>University of Massachusetts Amherst – Morality

ensures social order and cohesion by preventing people from over-benefiting the self and punishing those who engage in violations of such prohibitions. The nature and the severity of the punishment, however, can depend on several factors. Prior research on morality, for example, has shown that responses to moral transgressions may depend on the type of infringement in question. In two studies we focused on cognitive processing and harm as factors that would impact the nature and severity of punishments. The differential impact of automatic and deliberative processing on outcomes is evidenced by a large body of research in several areas of social psychology. However, in moral psychology research has typically focused on one or the other. In these studies automatic and deliberative processing were manipulated to assess their impact on people's responses to moral transgressions. We also examined how the presence or absence of harm of others affected punishments. Both studies involved instances of serious academic dishonesty that clearly over-benefited the self, but in Study 2 the violation also harmed others. In Study 1 deliberative judgments were more lenient than automatic judgments, whereas in Study 2 the reverse was observed. It appears that under controlled processing harm produces "augmentation" of automatic punishment responses, while its absence is likely to result in "discounting" of these more intuitive reactions. These studies provide evidence of the divergence in moral judgments created both by differences in cognitive processing and the presence and absence of harm.

**THE FINE LINE BETWEEN INTERROGATION AND RETRIBUTION** Kevin M. Carlsmith<sup>1</sup>, Avani M. Sood<sup>2</sup>; <sup>1</sup>Colgate University, <sup>2</sup>Princeton University – The

use of harsh interrogation techniques on terrorism suspects is typically justified on utilitarian grounds. The present research suggests, however, that those who support such techniques are fuelled by retributive motives. An experimental study conducted with a broad national sample of U.S. residents found that the desire for harsh interrogation is largely isomorphic with the desire to punish, and that both effects are mediated by the perceived moral status of the target, but not the perceived effectiveness of the interrogation. Results are discussed with regard to retributive justice and the national policy on interrogation and torture.

**Symposia Session D9**

**A PRIMER ON SOCIAL NEUROSCIENCE METHODS FOR CONSUMERS AND PRACTITIONERS: ENDOCRINOLOGY, GENETICS, AND NEUROIMAGING**

Friday, January 29, 3:30 - 4:45 pm, Capri Rooms 107-110

Chairs: Elliot Berkman and Matthew Lieberman, UCLA

Speakers: Pranjal Mehta, Baldwin Way, Eddie Harmon-Jones, Elliot Berkman

There has been an explosion over the last years of research using neuroscience methods to address social psychological questions. These include neuroimaging methods such as electroencephalography (EEG) and functional magnetic resonance imaging (fMRI), endocrine measures such as cortisol and testosterone, and genetic assessments such as single nucleotide polymorphisms. The social neuroscience toolkit is broad and expanding rapidly, and as a consequence it is difficult to stay apprised of recent methodological developments and controversies. This is especially true for the vast majority of social psychologists who do not usually use these techniques. This symposium will provide an overview of several common neuroscience methods for both social psychologists and social neuroscientists. Presenters will describe how neuroscience methods are used in social psychology, highlight key strengths and weaknesses of each, and discuss statistical approaches for each method and how those statistics impact interpretation. Finally, presenters will

describe developing methods that are likely to be common in the near future. Harmon-Jones will present analysis of EEG data including event-related potentials and localization. Way will discuss how genetic data (e.g. polymorphisms) are collected and analyzed, and how (and how not) to interpret the relationship between genetic data and behavior. Mehta will review how endocrine measures are assessed and interpreted, and discuss several common misunderstandings. Berkman will highlight new analytic techniques for fMRI data and discuss how to relate these data to behavioral and personality measures. Together, these talks will provide critical information for social psychologists to be more informed consumers of social neuroscience research.

**ABSTRACTS**

**SOCIAL ENDOCRINOLOGY: BRIDGING BEHAVIORAL ENDOCRINOLOGY AND SOCIAL-PERSONALITY PSYCHOLOGY** Pranjal Mehta<sup>1</sup>; <sup>1</sup>Columbia

University – Social endocrinology is an emerging interdisciplinary field that combines theories and methods from behavioral endocrinology and social-personality psychology. This talk provides an overview of the social endocrinology approach for psychologists and social neuroscientists. In particular, I will (1) discuss several common myths about hormones and behavior; (2) evaluate the strengths and challenges of social endocrinology by comparing it to other approaches in social neuroscience and psychology; (3) show how social endocrinology research designs can be used to address questions of interest to personality psychologists, social psychologists, and social neuroscientists; and (4) provide practical methodological and statistical guidelines for those who are interested in incorporating hormone measurements into their own research programs. I draw on recent empirical studies on the roles of testosterone and cortisol in personality and social behavior. I conclude that social endocrinology can provide unique insights into nearly all areas of social and personality psychology.

**A GENETICS PRIMER FOR SOCIAL PSYCHOLOGISTS: CONCEPTS, METHODS, AND ISSUES OF STUDY DESIGN** Baldwin Way<sup>1</sup>; <sup>1</sup>University of

California, Los Angeles – With recent technological developments in molecular biology, genetic techniques have become increasingly accessible to psychologists. This ability to assess individual differences at the genetic level has great promise for facilitating understanding of basic social psychological processes. Yet, because many psychologists do not have a strong background in genetics or biochemistry, the terminology used by geneticists may seem like a foreign language. The aim of this presentation is to provide an introductory guide to help navigate this foreign territory. Thus, the nature of genes, genetic variation, neurochemistry, and their effects upon neurotransmission will be introduced using the serotonin and opioid neurotransmitter systems as illustrative examples due to their role in regulating sensitivity to the social environment. In addition to this basic background, methodological considerations for the design of effective studies will be discussed.

**ELECTROENCEPHALOGRAPHIC METHODS IN SOCIAL AND PERSONALITY PSYCHOLOGY** Eddie Harmon-Jones<sup>1</sup>; <sup>1</sup>Texas A&M University – I

will review electroencephalographic (EEG) methods, which have been used in a number of research areas within social and personality psychology. The underlying physiological basis for EEG will first be described, and comparisons to other neuroimaging measures will be noted. Specific steps involved in collecting and processing EEG data will be reviewed. Frequency analyses (e.g., alpha power) and temporal analyses (event-related potentials; ERPs) will also be described. The use and psychological meaning of frequency oscillations and ERPs in social and personality psychology will be reviewed, along with recent research examples. New developments in EEG will also be covered, including the psychological meaning of relationships among frequency bands of activity, event-related desynchronization, coherence, source localization, and simultaneous recording of EEG and other neural measures (e.g., fMRI). In the end, advantages and disadvantages of EEG methods in comparison to other neural measures will be discussed.

### BEYOND THE NEW PHRENOLOGY: ADDRESSING SOCIAL PSYCHOLOGICAL QUESTIONS USING FMRI

Elliot Berkman<sup>1</sup>, Matthew Lieberman<sup>1</sup>; <sup>1</sup>University of California, Los Angeles – Until recently, scientists seeking to understand the neural systems involved in social, cognitive, affective, or personality processes were limited to a handful of analytic techniques. Though they have yielded important insights, these techniques nonetheless address only a small set of the questions, such as which neural regions are involved in a given task. Social neuroscientists are now beginning to capitalize on alternative analytic techniques that allow us to more directly address social psychological questions. We will present three such techniques: (1) region of interest analysis to compare neural activity on the same task between groups (e.g. to examine cultural differences); (2) between- and within-subjects correlations to examine the relationship between neural activity and individual differences, behavior, and subjective experience (e.g. to investigate the underpinnings of cognitive dissonance); and (3) functional connectivity analysis examining a network of brain regions to test dynamic models of cognitive or affective processes (e.g. to test competing models of emotion regulation). For each technique, we will explain which psychological questions it addresses (and which it does not), how it is typically implemented, discuss common analytic strategies, and give an example of how it has been used in recent research to fruitfully address social psychological questions.

### Symposia Session D10

#### EXISTENTIAL EPISTEMOLOGY: THE SCIENCE OF MOTIVATED KNOWLEDGE CONSTRUCTION

Friday, January 29, 3:30 - 4:45 pm, Capri Rooms 114-116

Chair: Joshua Hart, Union College

Speakers: Sheldon Solomon, Zachary Rothschild, Nathan Heflick, Jessica Tracy

One of contemporary psychology's major intellectual contributions has been to challenge the assumption, previously held by behavioral economists, that human beings are purely rational (let alone accurate) information processors (e.g., Kahneman & Tversky, 1981). Knowledge acquisition, far from being a process of objective data-gathering, is strongly influenced not only by imperfections in cognitive machinery (e.g., decision-making heuristics and memory fallibility), but also by emotional and motivational factors. Frequently, people's "knowledge" about reality reflects the way they would like it to be as much as the way it ostensibly is. This symposium showcases innovative new research highlighting the influence of existential concerns – that is, the potential for anxiety posed by humans' awareness of their own vulnerability and mortality – on knowledge construction. Solomon will present evidence that death reminders skew information processing by increasing people's preference for information that confers a sense of meaning and order; Rothschild, Landau, and Sullivan will present research showing that ambiguity regarding personal value poses a threat that people cope with by seeking out clearly quantified representations of their worth; Heflick, Goldenberg, and Hart will present studies concerning the "why" and "how" of afterlife beliefs, suggesting that dualistic thinking is an existentially motivated and necessary condition for belief in an afterlife; and finally, Tracy, Hart, and Martens will present a series of findings suggesting that existential concerns underlie the currently popular (and to scientists, startling) interest in intelligent design theory, and corresponding skepticism about evolutionary theory.

#### ABSTRACTS

**EXISTENTIAL EPISTEMOLOGY** Sheldon Solomon<sup>1</sup>; <sup>1</sup>Skidmore College – "...the longing for immortality, is it not the primal and fundamental condition of all...human knowledge?" --Miguel de Unamuno, *Tragic Sense of Life* According to terror management theory (TMT; Greenberg, Pyszczynski, & Solomon, 1986), the uniquely human awareness of death gives rise to potentially paralyzing terror, which is assuaged through cultural

worldviews that infuse the world with meaning. This has important implications for epistemology; specifically: people generally prefer knowledge and beliefs that satisfy existential needs over those that accurately reflect the nature of reality. This presentation will consist of an historical overview of "existential epistemology" starting with Plato's Allegory of the Cave (and including Nietzsche, Spengler, Peirce, and Fox News commentator Glenn Beck ["Believe in something. Even if it's wrong."]) in support of the claim that from a psychological perspective, being sure is more important than being right – followed by empirical evidence that subtle reminders of death increase (a) primacy effects; (b) reliance on representative information; (c) preference for interpersonal balance, and viewing the world as just and benevolent; while (d) decreasing the aesthetic appeal of abstract art devoid of apparent meaning.

#### I AM A PERSON OF VALUE, P < .05: EPISTEMIC AMBIGUITY AND THE QUANTIFICATION OF SELF-ESTEEM

Zachary Rothschild<sup>1</sup>, Mark Landau<sup>1</sup>, Daniel Sullivan<sup>1</sup>; <sup>1</sup>University of Kansas – Research shows the importance of self-esteem in quelling existential concerns, but has not yet addressed self-esteem's epistemic dimension: How do people know they are valuable when standards of value are often ambiguous? Drawing on clinical and existential perspectives, we propose that ambiguous self-esteem standards pose an existential threat that people minimize by relying on quantitative indices of self-esteem (e.g., number of cars, mates, publications), which afford more certain self-evaluations than qualitative indices (e.g., friendly interactions). If this is true, people faced with ambiguous (vs. clear) standards in an esteem-relevant performance context should express greater belief in and liking for quantitative over qualitative performance feedback, even when neither feedback type affords opportunities for social comparison or self-enhancement. This effect should be specific to individuals dispositionally high in personal need for epistemic structure (PNS). In Study 1, participants completed a visual intelligence test with ambiguous vs. clearly defined performance standards (controlling for performance level feedback) and then rated the extent to which quantitative and qualitative feedback on a separate intelligence task accurately represented their abilities. As hypothesized, high-PNS participants in the ambiguous standards condition preferred quantitative feedback, in contrast to participants in the other conditions. Study 2 conceptually replicated this effect and furthermore showed that it was mediated by self-esteem certainty but not overall self-esteem level.

#### FEAR OF DEATH AND BODY-SELF DUALISM: THE WHY AND HOW OF AFTERLIFE BELIEF

Nathan Heflick<sup>1</sup>, Jamie Goldenberg<sup>1</sup>, Joshua Hart<sup>2</sup>; <sup>1</sup>University of South Florida, <sup>2</sup>Union College – Afterlife beliefs have existed in virtually every culture throughout history. Why do people develop these beliefs, and how are they constructed? We propose that fear of death provides the why, and body-self dualism, that is, construing the self as distinct from the body, is the how. Specifically, mortality salience (MS) should increase the desire to believe in immortality; however, actual belief requires dualistic thinking. Three studies supported these hypotheses about the epistemology of believing – and not believing – in an afterlife. In Study 1, MS increased body-self dualism among individuals high in spirituality, and lowered dualism among individuals low in spirituality. In Study 2, MS increased belief for participants who were primed to think of themselves dualistically, but lowered belief for people primed to think of their physical bodies. In Study 3, MS reduced afterlife belief among participants concurrently undergoing an experience (a foot massage) that increased awareness of the physical self. In Studies 2 and 3, MS increased the desire to believe in an afterlife, but actual belief depended on both MS and dualism. These findings thus identify a motivation and mechanism by which people sustain (or do not sustain) afterlife beliefs.

**DEATH AND SCIENCE: THE EXISTENTIAL UNDERPINNINGS OF BELIEF IN INTELLIGENT DESIGN AND DISCOMFORT WITH EVOLUTION** Jessica

Tracy<sup>1</sup>, Joshua Hart<sup>2</sup>, Jason Martens<sup>1</sup>; <sup>1</sup>University of British Columbia, <sup>2</sup>Union College – Although it is disputed by almost all evolution scientists, intelligent design theory (IDT) has received considerable support from the general public, educators, and elected officials, who argue that it should be taught alongside evolutionary theory (ET). The present research examined the psychological origins of belief in IDT and corresponding antagonism toward ET. Specifically, we tested whether this ideology might be partially accounted for by IDT's provision of an explanation of life's origins that is framed in scientific language, but that, unlike ET, promises to buffer existential anxieties by suggesting that life was intentionally created and is therefore meaningful. In four studies, a diverse range of student and non-student participants (total N=1,575) were randomly assigned to be exposed to mortality salience or dental pain (control) primes, after which they read a passage about ET and/or a passage about IDT, both excerpted from leading proponents of each theory. Participants then rated their belief in the theories and liking of the passages' authors. Across all studies, mortality salience increased acceptance of IDT and/or rejection of ET. In Study 4, some participants additionally read a passage by Carl Sagan arguing that naturalism can be a source of transcendent meaning; among these participants, effects reversed, such that mortality salience led to greater acceptance of ET and rejection of IDT. These findings suggest that the effect of mortality salience on belief in IDT and ET is due to a tendency to seek transcendent meaning when existential threats are activated.

symposium presents four approaches to exploring the functions of STIs. Laura Kressel's studies show that judging whether causal relations exist between trait and behavior words (adjectives and verbs) shows the same reaction time asymmetry as judging causal relations between other causes and effects, and that this asymmetry correlates with forming STIs. So isolated traits function as causes of behavior. SoYon Rim shows that STIs function as abstractions about people from their behavior. Therefore, consistent with construal level theory, STIs are more likely when the people are more distant in space or time, and when perceivers have an abstract mindset. Tania Ramos shows that STIs function as expectancies about people, with predictable effects on the processing of and memory for subsequent behavioral information. Randy McCarthy also shows that STIs function as expectancies about people, by looking at their predictions of future behavior – predictions that do not rely on behavioral or valence similarities. These findings suggest STIs from behaviors function as implicit causal concepts, providing a basis for abstractions, expectancies, and predictions.

**ABSTRACTS****ISOLATED PERSONALITY TRAITS FUNCTION AS CAUSES OF BEHAVIORS** Laura Kressel<sup>1</sup>, Jim Uleman<sup>1</sup>; <sup>1</sup>New York University – Person-

ality traits can be descriptive or causal concepts. As descriptive concepts, traits summarize people and their behavior. As causal concepts, traits explain behavior and enable predictions. Study 1 tested the hypothesis that traits and behaviors are causally (not associatively) linked, and thus function primarily as causal concepts. Participants completed a "relation recognition task," making rapid causal judgments of 128 word pairs, including 32 trait-action pairs. Previous research used this paradigm to demonstrate that causal and associative links have different representations. Nonsocial causal pairs produced asymmetric reaction times for detecting causal relations, depending on word order. People identified concepts as causally related more quickly when they appeared in a predictive sequence (cause?effect) than in a diagnostic sequence (effect?cause). Fenker, Waldmann & Holyoak, (2005) hypothesized that role mapping facilitates causal judgments in the predictive sequence because it matches the typical experiential order of cause-effect events (causes always precede effects). However traits are never observed but are inferred after behavioral observations. Nevertheless, if traits and behaviors are causally linked, participants may respond more quickly to pairs in a predictive sequence (e.g. clumsy?stumble) than a diagnostic sequence (e.g. blush?shy). Participants did just that. Results suggest that traits function, primarily, as causal concepts. They also suggest that this asymmetry reflects mental links, not experiential order. Follow-up studies demonstrate that the meaning of traits is at least partially determined by perceivers' functional mindset at the time social stimuli are encountered.

**SPONTANEOUS TRAIT INFERENCE AND CONSTRUAL LEVEL THEORY: PSYCHOLOGICAL DISTANCE INCREASES NONCONSCIOUS TRAIT THINKING** SoYon Rim<sup>1</sup>, Jim Uleman<sup>1</sup>, Yaacov Trope<sup>1</sup>; <sup>1</sup>New York University –

Can psychological distance affect how much perceivers form spontaneous trait inferences (STI) from others' behaviors? On the basis of construal level theory (CLT) which posits that distant (vs. near) entities are represented more in terms of their abstract, global, and decontextualized features, we predicted that perceived distance would increase the tendency for perceivers to draw spontaneous trait inferences from behavioral information about actors. In 2 experiments, participants learned about people who were perceived as being distant or proximal to the self, and STI formation was subsequently assessed. We found that perceivers were more likely to form STIs about distant vs. near actors from the same behavioral information. These findings generalized across two distance dimensions: space and time. In addition, we found that priming individuals to adopt a high-level (vs. low-level) construal mindset also resulted in increased STI (Experiment 3). In sum, psychological distance facilitates STI formation, and this occurs via high-level construal of actors and their behaviors. Our findings shed light on the function of

**Symposia Session E**

Friday, January 29, 5:00 - 6:15 pm

**Symposia Session E1****CAMPBELL AWARD ADDRESS****ENVY UP AND SCORN DOWN: HOW COMPARISON DIVIDES US**

Friday, January 29, 5:00 - 6:15 pm, Royale Pavilion 1

Recipient: Susan T. Fiske, Princeton University

Introducer: Peter Glick, Lawrence University

Americans both recognize and minimize class distinctions. In our supposedly classless society, Main Street is pitted against Wall Street. Lazy freeloaders are pitted against honest working people. Elites are pitted against the deserving poor. People constantly compare themselves with other people. This is natural. Even dogs and chimps do it. But comparisons make us envy those above us and scorn those below us. Comparison divides us and depresses us. So why do we persist? Can this possibly be good? Can we get beyond compare? More optimistically, perhaps we can harness comparison for good.

**Symposia Session E2****PERSONALITY TRAITS AS IMPLICIT CAUSAL THEORIES ABOUT PEOPLE**

Friday, January 29, 5:00 - 6:15 pm, Royale Pavilion 2

Chair: Jim Uleman, New York University

Speakers: Laura Kressel, SoYon Rim, Tania Ramos, Randy J. McCarthy

Personality traits can function many ways: as causal explanations for behavior within persons, as descriptions persons or behaviors on one occasion, or as descriptions of frequent behaviors. Explicit traits' functions are usually clear from their conversational context. But when trait concepts are activated implicitly, do they have identifiable functions or properties? Spontaneous trait inferences (STIs) occur unintentionally and outside of awareness, and implicitly activate trait concepts. This

trait inferences. Trait inferences are functional for psychologically distant actors because they allow perceivers to transcend the constraints of the specific context and inform predictions about the actors when details of the situation may no longer be relevant.

**THE NEED FOR COHERENCE: HOW PREVIOUS ACTOR'S BEHAVIORS INFLUENCE SPONTANEOUS TRAIT INFERENCES** Tania Ramos<sup>1</sup>, Leonel Garcia-Marques<sup>2</sup>, David L. Hamilton<sup>3</sup>, Mario Ferreira<sup>2</sup>; <sup>1</sup>ISCTE, Lisbon, <sup>2</sup>University of Lisbon, <sup>3</sup>University of California, Santa Barbara – Recent data have shown that the spontaneous trait inferences (STIs) are inhibited by associating inconsistent stereotypes with actors (Wigboldus, Dijksterhuis, & Van Knippenberg, 2003). Our goal was to explore whether STIs work in line with more general coherence requirements. If that is the case, STIs should not only be influenced by stereotypes, but also by previous behavioral information about the actor. In our studies, pairs of behaviors were presented about the same actor. Our hypothesis was that STIs will be less likely to occur from a behavior when it is preceded by an inconsistent than by a consistent behavior. In study 1, participants were asked to recall second behaviors of each pair with either implied traits or first behaviors given as cues. We predicted that traits would be better cues than first behaviors for consistent pairs. In opposition, first behaviors would be better cues than traits for inconsistent pairs. Results confirmed our predictions. In order to prove the online nature of these effects, in study 2 we used the recognition probe paradigm. After the presentation of the second behavior, the implied trait was presented and participants should indicate whether the trait was included in the previous sentence. As expected, fewer errors were observed when the behavior was preceded by an inconsistent behavior. By showing that STIs are influenced by the presentation of merely one previous behavior, our results inform us about the occurrence conditions of STIs, and generally support a flexible view of the STI process.

**PEOPLE'S BEHAVIOR PREDICTIONS SUGGEST PRIOR SPONTANEOUS TRAIT INFERENCES** Randy J. McCarthy<sup>1</sup>, John J. Skowronski<sup>1</sup>; <sup>1</sup>Northern Illinois University – One consequence of making inferences about others is that they can be used to make predictions about others' subsequent behaviors. Hence, the fact that people can make such predictions after exposure to trait-implicative behaviors can be an indicator of spontaneous inference-making. Three studies explored this possibility. The first study was primarily designed to develop new stimuli for the behavior prediction studies. Nonetheless, results from that study replicated prior research demonstrating in a savings paradigm that spontaneous inferences were made from behavior. It also demonstrated that the presence of discounting information in the descriptions seemed to eliminate evidence of such inferences. Studies 2 and 3 explored the extent to which exposure to trait-implicative and non-implicative behaviors prompted perceivers predicted that actors would perform new behaviors. Study 2 used a matching task that asked perceivers to pair actors with the future trait-relevant behaviors that they thought each actor would perform. Study 3 used a trait rating task that asked perceivers to directly judge the likelihood that and actor would perform trait-relevant behaviors. Results from both studies suggested that spontaneous trait inferences formed in an initial exposure to trait-implicative behavior caused people to make behavior predictions that were consistent with the trait implications of the original behavior. These effects did not occur when behaviors were rendered non-trait-implicative by the inclusion of discounting information. Results could not be explained by processes involving behavior-to-behavior extrapolation, or by generalization from evaluative impressions that might have been formed from exposure to the initial behavior.

## Symposia Session E3

### COGNITIVE UNDERPINNINGS OF ATTACHMENT REPRESENTATIONS: EXAMINING RELEVANT KNOWLEDGE STRUCTURES

Friday, January 29, 5:00 - 6:15 pm, Royale Pavilion 5

Chair: Bulent Turan, University of California, San Francisco

Speakers: Leonard M. Horowitz, Amanda M. Vicary, Bulent Turan, Gulenbaht Algac

This symposium presents a new approach for examining the cognitive structure of attachment representations: Four papers operationalize and examine relational knowledge structures that are abstract and detailed. Using methods of cognitive psychology, two knowledge structures are examined: (a) indicators of a supportive partner; and (b) the secure-base (attachment) script. The papers show how these detailed knowledge structures help people to process incoming information and how they are related to each other and to attachment security. The first paper describes a task for assessing each person's knowledge of the indicators (predictors) of a supportive partner; it shows that the degree of knowledge predicts performance on a relevant laboratory task. The second paper examines the independent roles of knowledge of indicators of supportiveness and attachment style in (a) recognizing and choosing behaviors that lead to a harmonious relationship, and (b) recognizing whether or not a partner is being supportive. The third paper examines the accessibility of the secure-base script using animated film clips. The paper shows that having access to the secure-base script is related to (a) the way a person processes attachment-relevant information, (b) self-reported attachment styles, and (c) a person's ability to predict an elderly relative's end-of-life health care wishes. The fourth paper relates the accessibility of the secure base script to a person's attachment security assessed by two different methods (Adult Attachment Interview and the Experiences in Close Relationships). Together these papers suggest that these knowledge structures are important in understanding attachment processes and interpersonal competency in attachment relationships.

#### ABSTRACTS

### A PROTOTYPE OF INDICATORS AS A KNOWLEDGE STRUCTURE: ASSESSING KNOWLEDGE ABOUT A PARTNER'S SUPPORTIVENESS

Leonard M. Horowitz<sup>1</sup>; <sup>1</sup>Stanford University – Prototype methodology has been used to identify indicators for predicting whether a potential partner will be supportive. A false recognition study demonstrated that this knowledge affects information processing in predictable ways. Then the prototype of indicators was used to assess individual differences in knowledge and motivation. The resulting measure, the Knowledge of Indicators (KNOWI) Task, applies signal detection methods to provide two indices: (a) KNOWI-accuracy, which assess each participant's ability to discriminate good from poor indicators (knowledge of indicators), and (b) KNOWI-readiness, which assesses each participant's tendency to regard all indicators as good predictors. (The readiness index correlates significantly with objective measures of the strength of communal motivation.) The two indices obtained from the KNOWI Task (assessing accuracy and motive strength) predicted performance on a relevant laboratory task. Participants interacted with a confederate who described a problem revealing subtle cues that another person will not be supportive. High-scoring participants on the KNOWI-accuracy recognized the cues more readily. In addition, the statistical interaction between KNOWI-accuracy and KNOWI-readiness was significant: Superior knowledge (assessed by KNOWI-accuracy) led to superior performance only when motivation (assessed by KNOWI-readiness) was high. A final study extended the laboratory findings to everyday life using experience sampling methodology. Motivated and knowledgeable people (people with high scores on both KNOWI-accuracy and KNOWI-readiness) more often sought support from partners at times of distress.

### **WHO RECOGNIZES AND CHOOSES BEHAVIORS THAT ARE BEST FOR A RELATIONSHIP? THE SEPARATE ROLES OF KNOWLEDGE, ATTACHMENT, AND MOTIVATION**

Amanda M. Vicary<sup>1</sup>; <sup>1</sup>University of Illinois at Urbana-Champaign – Why do people not always behave in ways that are best for a relationship? One reason may be that some people do not know whether a specific behavior is relationship-enhancing or relationship-detrimental. A second reason is that even when people know the relationship-enhancing behavior, they may not choose it. The present research first identified factors that influence whether a person knows and actually chooses relationship-enhancing options. Participants made relationship decisions in several “Choose Your Own Adventure” dating story-tasks by choosing between two options at each of 20 points throughout the computerized stories. One option was always the relationship-enhancing option; the other option was detrimental to the relationship. Study 1 included two experimental conditions: Participants were either asked to identify the relationship-enhancing option or to report which option they would actually choose. Individuals with better knowledge of indicators of supportiveness (assessed by KNOWI-accuracy) were more likely to identify relationship-enhancing behaviors, but not more likely to actually choose them. Secure individuals and individuals strongly motivated to have supportive relationships (assessed by KNOWI-readiness) were more likely to identify and to choose relationship-enhancing options, which is an important factor in developing supportive relationships. Another important factor in developing supportive relationships is having a supportive partner. Thus, Study 2 addressed the question: “Who is able to recognize whether a partner is supportive or not?” Partner supportiveness was manipulated: The fictitious partner was either supportive or non-supportive. Individuals with better knowledge of indicators of supportiveness were better at recognizing whether a partner was supportive or not.

### **ACCESSIBILITY OF THE SECURE-BASE SCRIPT SHAPES PROCESSING OF ATTACHMENT INFORMATION**

Bulent Turan<sup>1</sup>; <sup>1</sup>University of California, San Francisco – The notion of scripts developed by cognitive psychologists is used to examine an important knowledge structure concerning attachment relationships. The secure-base script concerns the sequence of events when an attachment figure comforts a distressed partner. Accessibility of this script should (a) help people to process relevant information, and (b) affect behaviors, cognitions, and emotions in attachment-relevant situations. Studies 1 and 2 assessed the degree to which participants recognized the abstract structure of the script: Participants watched animated film clips in which geometric figures depicted the secure-base script, and were asked to describe the animations. Participants who recognized the script were more likely to (a) see a common theme in different animations, (b) later recall more details of the animations, (c) include more elements in describing the animations, and (d) create better organized stories. Thus, recognizing the secure-base script enables people to process information concerning secure-base support, which should shape how they interpret supportive efforts of partners and make global judgments about partners. As expected, recognizing the secure-base script was associated with better knowledge of indicators of supportiveness and attachment avoidance was negatively related to both knowledge structures. In Study 3, surrogate decision makers were asked to predict end-of-life health care wishes of their elderly relatives; whether their elderly relatives would prefer life-saving painful medical procedures or wish to optimize the quality of their remaining lives. As hypothesized, surrogate’s accuracy in predicting their elderly relatives’ wishes depended on (a) surrogates’ ability to recognize the secure-base script, and (b) surrogates’ attachment security.

### **ATTACHMENT SECURITY AND HAVING ACCESS TO THE SECURE-BASE SCRIPT**

Gulenbaht Algac<sup>1</sup>, Arzu Goncu<sup>1</sup>, Yavuz Erten<sup>1</sup>, Ercan I Alp<sup>2</sup>, Bulent Turan<sup>3</sup>; <sup>1</sup>Bilgi University, Istanbul, Turkey, <sup>2</sup>Bogazici University, Istanbul, Turkey, <sup>3</sup>University of California, San Francisco – Why do some people have easy access to the secure-base script whereas others do not? Do people learn the secure-base script as children in their relationships with their par-

ents? We hypothesized that people who have a secure representation of attachment relationships have had many experiences with the secure-base script. This familiarity should lead to easier access to the secure-base script in adulthood. Adults with a secure attachment should therefore be more likely to recognize the abstract form of the secure-base script when they see it. Two different methods were used to assess adult participants’ attachment security: (a) Adult Attachment Interview (AAI), an interview method focusing on childhood experiences to assess participants’ representation of attachment relationships, and (b) Experiences in Close Relationships (ECR), a self-report measure assessing representations of romantic relationships in adulthood. Participants’ ability to recognize the abstract structure of the secure-base script was assessed using animated film clips in which geometric figures depicted the secure-base script. Participants with a secure state of mind with respect to attachment assessed with the AAI were more likely to recognize the secure-base script in the animations compared to participants with either type of insecure state of mind (preoccupied or dismissing). The avoidance dimension of the ECR (but not the anxiety dimension) was also associated with a reduced likelihood of recognizing the secure-base script in the animations. In brief, a deficit in recognizing the secure-base script was found to be related to attachment insecurity measured in two different ways (interview and self-report).

### **Symposia Session E4**

### **DIFFERENT ASPECTS OF ESSENTIALISM: LOOKING ACROSS RACE, STATUS, RELIGION, AGE, AND SEXUAL ORIENTATION**

Friday, January 29, 5:00 - 6:15 pm, Royale Pavilion 6

Chair: Negin R. Toosi, Tufts University

Speakers: Japinder Dhesi, Negin R. Toosi, Matthew Christian Jackson, Ross D. Avilla

Essentialism is the belief that there is a deep, underlying, and oftentimes intangible essence that defines a human category. In this symposium, we explore essentialism as it relates to different types of social identities: social status, religion, race, age, and sexual orientation. By exploring essentialism as it relates to these various categories, we can gain insights about the nature of essentialism and its effect on intergroup relations, prejudice and stereotyping. Across four presentations, we explore the factors that influence essentialism and investigate looming questions, such as: Do differences in social status lead to essentialist thinking (Dhesi & Prentice)? What elements of religious identity may lead other people to essentialize and stereotype that identity (Toosi & Ambady)? What are the consequences of racial outgroup dehumanization on an essentialized category such as childhood (Jackson & Goff)? Are essentialist beliefs about sexual orientation in some part due to the perceived tolerance of those beliefs (Avilla)? Taken together, these programs of research shed light on additional questions, exploring what specific social factors affect the relationship between essentialism and prejudice, and what holds true in outcomes of essentialism regardless of the particular human category being investigated.

### **ABSTRACTS**

### **DO STATUS DIFFERENCES TRIGGER ESSENTIALIST THINKING?**

Japinder Dhesi<sup>1</sup>, Deborah A. Prentice<sup>2</sup>; <sup>1</sup>London School of Economics, <sup>2</sup>Princeton University – Representations of many social categories are characterized by essentialist thinking – that is, people see category members as sharing deep, non-obvious properties that make them the kinds of things they are. What triggers essentialist thinking? Previous research has shown that categories that carry information about social status are more likely to be essentialized. However, the causal direction of this relationship remains unclear. The present research examined the possibility that status differences trigger essentialist thinking. We adapted a paradigm utilized in earlier studies of gender and essentialism. Participants completed a test that purportedly measured an unfamiliar psychological attribute: their perceptual style. After receiving predetermined feedback

about their standing on this attribute, they were assigned to either the high-status role of boss or the low-status role of subordinate for an upcoming task. Finally, they completed several measures of their beliefs about their perceptual style, including a measure of essentialist beliefs. We administered this test under several different conditions. In the critical condition, two participants completed the test in the same experimental session and learned they had different perceptual styles. Subsequently one participant was assigned to the role of boss and the other to the role of subordinate. Participants in this condition, where differences in perceptual style were correlated with status differences, expressed stronger essentialist beliefs than did participants who completed the experiment alone or under conditions in which status and perceptual style were uncorrelated. These results support the claim that people essentialize attributes that distinguish between individuals along status lines.

**ESSENTIALIST BELIEFS ABOUT RELIGIOUS IDENTITIES** Negin R. Toosi<sup>1</sup>, Nalini Ambady<sup>1</sup>; <sup>1</sup>Tufts University – As a social identity, religion is unique because it contains a spectrum of choice. In some religious communities, individuals are considered members by virtue of having parents of that background, and religion, culture, and ethnicity are closely intertwined. Other faith communities actively invite people of other backgrounds to join, expecting individuals to choose the religion that best fits their personal beliefs. This aspect of choice may influence beliefs about the essentialist nature of religious identity. In our first study, we examine college students' perceptions of eight different religious identities and several filler groups by asking them to rate these groups on a number of traits associated with essentialism. As expected, there were significant differences between religious groups in the degree to which they were essentialized. In our second study, participants learned about a fictional religious group whose membership was determined by birth or by choice, then rated the group on essentialized traits and completed a stereotyping measure. Results showed that individuals essentialized and applied physical but not personality stereotypes more when group membership was described as being by birth than by choice. Furthermore, participants' self-reported religious identity formation also influenced the degree to which they essentialized the fictional group. Implications for interfaith relations as well as directions for future research are discussed.

**THE ESSENCE OF INNOCENCE: CONSEQUENCES OF DEHUMANIZING OUTGROUP CHILDREN** Matthew Christian Jackson<sup>1</sup>, Phillip Atiba Goff<sup>1</sup>; <sup>1</sup>University of California, Los Angeles – It is difficult for most people to imagine a truly evil child. So much so that innocence, it seems, is an essential characteristic of childhood. Data across three studies suggests that not only is childhood an essentialized category—with innocence and the need for protection essentialized traits—but that a consequence of intergroup dehumanization is the denial of childhood (and its attendant traits) to outgroups. Specifically, three studies demonstrate that the dehumanization of Black children obscures oft-essentialized characteristics of children, such as innocence and the right to protection. Study 1 provides evidence that children are seen as an essentialized category, and demonstrates the perception that there exists a need to protect the innocent, whether the targets be animals or children. In Study 2, presenting children as criminal suspects led undergraduate observers to overestimate the age of Black (but not White) youth and prescribe harsher penalties for the Black suspects—denying Black youth their childhoods and the protections it might afford them. Study 3 demonstrated similar patterns in police officers, which lead to increased violence directed towards Black youth, relative to White youth, in real-world policing contexts. Taken together, these data suggest the importance of essentialized childhood, dehumanization, and intersectional approaches to the study of intergroup conflict.

**THE EFFECT OF PREJUDICE ON ESSENTIALIST BELIEFS: CONTRADICTING AN ATTRIBUTIONAL EXPLANATION** Ross D. Avilla<sup>1</sup>; <sup>1</sup>University of California, Davis – Essentialism, as it pertains to prejudice, refers to beliefs that the stigmatized characteristics of an outgroup are inborn, immutable, and uncontrollable. Essentialist beliefs have been shown to negatively correlate with many different forms of prejudice, including prejudice against those who are homeless, obese, and gay. Past research has tended to favor an “attributional explanation” of this relationship—that prejudice against a given outgroup is least justifiable, and consequently least likely to be held, if that group's stigma is perceived as being outside of their control. Contrary to this explanation, Hegarty has recently posited a “symbolic explanation”—that individuals endorse essentialist beliefs about a given group to the extent that the perceived tolerance of those beliefs matches the individuals' level of tolerance toward that group. Given that essentialist beliefs have been shown to be more negatively related to prejudice against sexual minorities than any other group, two studies were conducted examining essentialist beliefs about gay men. The first study demonstrated that participants' relative endorsement of essentialist beliefs could be altered simply by manipulating the perceived tolerance of those beliefs, supporting a symbolic over attributional explanation of the relationship between essentialist beliefs and prejudice. However, due to several shortcomings of both the manipulation and sample, this relationship was not found to be moderated by participants' preexisting level of sexual prejudice. A second study was conducted to remedy these shortcomings. The two studies, as well as their implications for popular prejudice reduction strategies, will be discussed.

### Symposia Session E5

#### TRAINING COMMITTEE SYMPOSIUM

#### GIVING THEM WINGS TO FLY: ADVICE FOR SOON-TO-BE, NEW, AND ESTABLISHED FACULTY IN THE TRAINING OF GRADUATE STUDENTS

Friday, January 29, 5:00 - 6:15 pm, Royale Pavilion 3-4

Chairs: Jamie Arndt, University of Missouri, and Michael D. Robinson, North Dakota State University

Speakers: David Funder, Thomas D. Gilovich, Jennifer Crocker, Jeff Greenberg

The SPSP Training Committee is sponsoring a symposium focused on providing guidance on the mentoring of graduate students. As we anticipate, start, and continue along our careers, we're confronted with numerous challenges surrounding the mentoring of graduate students. These are important issues given our students represent the future of the field, yet we're often only exposed to the strategies of our own mentors or those in the departments from which we get our degrees; rarely is the practice of mentoring featured in our own training. The Training Committee is excited to present four distinguished mentors in areas pertaining to both personality and social psychology who will offer for consideration their views on such key aspects of graduate mentoring as: How does one nurture the scholarly growth and possibilities for career success among one's students? How does one establish a constructive relationship in which critical feedback can be delivered and used as a springboard for development? How and when should training be tailored to the specific strengths and weaknesses of the individual? The symposium is intended to educate and inform not only soon-to-be and new faculty, but also those who seek ways to improve in the vital task of graduate mentoring. The symposium is structured to provide ample opportunity for audience questions.

#### ABSTRACTS

#### THE SEVEN SECRETS OF TRAINING HIGHLY SUCCESSFUL GRADUATE STUDENTS

David Funder<sup>1</sup>; <sup>1</sup>University of California, Riverside – Seven tips to success in training psychology graduate students so they can begin their career on the right track. You can train your students to: (1) Go to

meetings and network every way they can. Treat SPSP as a business trip and never miss a chance to join a colloquium speaker for lunch or dinner. Don't forget that their fellow graduate students at other universities will be their life-long colleagues. (2) Avoid "working at home." It is surprising how much one can get done sitting in an office with nothing to do but work. Plus, people in their department will learn who they are. (3) Find ways to delegate research tasks to others (such as undergraduate assistants). Good working relationship between graduate and undergraduate students can and should be mutually beneficial. (4) Collaborate with fellow students as well as with faculty. A major research project cannot be a one-person production. (5) Talk with their advisor – a lot. Regular lab meetings can be particularly valuable, but whatever the format, constant contact is a must. (6) Don't get bogged down with what doesn't matter – being busy is not the same thing as being productive. Being a good TA and departmental citizen are worthy activities, and will be praised – don't forget this is not why they went to graduate school, and will be very little help in getting a job. (7) Do research all the time – from the first day on campus to the last, and beyond.

#### **THE CRITICAL ROLE OF TRUST IN GRADUATE STUDENT MENTORING**

**Thomas D. Gilovich<sup>1</sup>; <sup>1</sup>Cornell University** – Conflict mediators are taught over and over to "trust the process" – to let the mediation unfold rather than quickly encourage a solution that comes more from the mind of the mediator than the disputants. The same can be said of graduate student mentoring. All students are different and each must find and develop his or her own strengths to maximize long-term success. Rather than impose on each student a one-size-fits-all template of what makes a good scientist, it is important to develop and trust a set of training experiences (that is, a sound curriculum) and trust that those experiences, and the independent bent of mind that comes with working through them, will lead to the outcome that both parties seek. This talk will discuss this and various other places in which trust is critical to successful graduate student mentoring.

#### **GIVING CONSTRUCTIVE FEEDBACK** Jennifer Crocker<sup>1</sup>; <sup>1</sup>University of Michigan

– Giving positive feedback to graduate student advisees – or anyone for that matter – is easy, because people like to hear good news. Giving negative feedback, on the other hand, is hard, because it can be upsetting to the recipient, to the relationship, and consequently to the provider of feedback. It is tempting to become a "booster," praising accomplishments and overlooking issues and difficulties until they accumulate or become too severe to overlook. But being a booster does not serve the needs of graduate students to learn and evolve as psychologists, nor does it serve the needs of the advisor or the program. Boosters can create a "love, love, love, hate" dynamic when problems are neglected for too long. The challenge for both positive and negative feedback is to make it constructive, so it supports, inspires, and leads to growth. I will describe a collaborative process for giving both positive and negative feedback that involves identifying the student's most important strengths and weaknesses (i.e., those that will have the greatest impact on the students' professional success, as defined by the student), and provides a structure for the student to evolve, holding both student and advisor accountable.

#### **MENTORING GRAD STUDENTS: NO SIZE FITS ALL** Jeff Greenberg<sup>1</sup>; <sup>1</sup>University of Arizona

– There are some general principles to good mentoring and fostering growth toward a successful career in social and personality psychology, and I will briefly suggest some of those (e.g., First Do No Harm). But a key one I will focus on is Flexibility. Because each grad student has different strengths and weaknesses and a different personality, mentoring should always be customized to the needs, skills, personality, and goals of the individual. Patience is an important aspect of this flexibility, because different students develop various competencies at different rates. I will provide specific examples to illustrate ways mentoring can be customized to the individual student, depending on variables such as work ethic, self-confidence, sociability, and idealism.

### **Symposia Session E6**

#### **BIASES IN PROCESSING SOCIAL CUES: LINKS TO EARLY AVERSIVE EXPERIENCES AND FUNCTIONING ACROSS THE LIFESPAN**

Friday, January 29, 5:00 - 6:15 pm, Royale Pavilion 7-8

Chair: Karin G. Coifman, Columbia University

Speakers: W. John Curtis, Sarah E. Romens, Karin G. Coifman

There is now considerable evidence demonstrating the role that emotion processing plays in adaptive social interaction and the development of supportive relationships (e.g. Keltner & Haidt 2001). Moreover, there is a growing literature demonstrating a link between particular impairments in emotion processing and deficits associated with both mood and severe personality pathology (Keltner & Kring, 1998; Kring, 2008). Recently, a compelling body of work on the harmful effects of childhood maltreatment and neglect on the developing brain, has suggested that the effect of early aversive experiences on the ability to process emotion in social cues may increase the risk for social and emotional impairment throughout the lifespan (see Pollak, 2009). This symposium will present evidence for biases in attention to social cues in high risk samples at three distinct points in the lifespan: infancy, adolescence and adulthood. First, Curtis presents evidence for early maltreatment effects on neural correlates of facial expression processing in 9-month old infants. Then, Romens and Pollak will present evidence demonstrating the importance of the interaction between maltreatment and cognitive vulnerability factors (namely, rumination and cognitive style) when evaluating attention to emotional expressions in adolescents. Finally, Coifman et al. present data in adults with severe personality disorders in order to show a link between the basic recognition of emotional expressions and biases in the perception of daily interpersonal interactions with others.

#### **ABSTRACTS**

#### **AN EVENT-RELATED POTENTIAL (ERP) STUDY OF PROCESSING OF AFFECTIVE FACIAL EXPRESSIONS IN INFANTS WHO HAVE EXPERIENCED MALTREATMENT** W. John Curtis<sup>1</sup>; <sup>1</sup>University of Kentucky

– The ability to recognize basic emotion expressions from facial affect displays is critical for the development of adaptive functioning (Sroufe, 1996). However, aberrations in recognition of discrete affects can exert a deleterious impact on numerous areas of socio-emotional development, including parent-child attachment relationships, emotion regulatory abilities, and peer relations (Cole et al., 2004). Moreover, abnormalities in recognition of facial expressions have been associated with many childhood and adult mental disorders (Izard & Harris, 1995). This research investigated the effects of maltreatment during the first 6 months of life on neural correlates of processing facial expressions of emotion at 9 months of age. Event-related potentials (ERPs) elicited while infants viewed pictures of models posing angry, happy, and neutral facial expressions were examined. ERPs represent scalp-derived changes in brain electrical activity obtained by averaging segments of the electroencephalogram synchronized to stimulus presentation. ERPs are one of few ways to directly study brain activity in healthy infants and provide millisecond-level temporal resolution of neural functioning. Differences in ERP waveforms between groups of 19 maltreated and 28 high risk non-maltreated infants were compared. The maltreated infants manifested greater Nc waveform amplitude while viewing happy facial expressions ( $F(2, 220) = 3.63, p < 0.05, \eta^2 = 0.076$ ). The Nc waveform is believed to represent relative stimulus novelty. Thus, this finding indicates that maltreated infants perceived happy facial expressions as more novel than angry, suggesting a lack of early experience with positive facial expressions. Implications for development of emotion recognition and psychopathology will be discussed.

### **ATTENTION TO SOCIAL EMOTIONAL INFORMATION IN MALTREATED ADOLESCENTS AT RISK FOR DEPRESSION**

Sarah E. Romens<sup>1</sup>, Seth D. Pollak<sup>1</sup>, <sup>1</sup>University of Wisconsin – Child maltreatment has been linked to significant disruptions in attention and emotion regulation, and alterations in attention to social emotional cues confer risk for psychopathology. The current study seeks to bridge research on attention to social emotions in maltreated adolescents with research on cognitive vulnerability to depression, a disorder of emotion regulation. Here, we examine how maltreated adolescents attend to emotional stimuli and relate attentional patterns to established cognitive risk factors for depression (negative cognitive style and rumination). Participants were maltreated and non-maltreated adolescents ages 11-13. Participants completed an emotional dot probe task that included happy, sad, and angry faces paired with neutral faces at baseline, after a sad mood induction, and after a delay period. Maltreated adolescents with a negative cognitive style showed a bias toward sad faces after the sad mood induction, and maltreated children with a high tendency to ruminate showed a bias toward sad faces after the delay. In contrast, non-maltreated adolescents and adolescents low in negative cognitive style and rumination showed no sad bias. Maltreated adolescents also showed a bias toward angry faces at baseline, but not after sad mood induction. Maltreated adolescents who have a negative cognitive style or who ruminate showed heightened attention toward sad stimuli immediately and well after the experience of a sad mood, respectively. Altered attentional processes for social emotional cues for these individuals may contribute to disruption in emotion regulation in an interpersonal context, and confer particular vulnerability to depression.

### **SENSITIZATION TO NEGATIVE EMOTIONAL EXPRESSIONS AND INTERPERSONAL DYSFUNCTION IN ADULTS WITH BORDERLINE AND AVOIDANT PERSONALITY DISORDERS**

Karin G. Coifman<sup>1</sup>, Kathy R. Berenson<sup>1</sup>, Eshkol Rafaeli<sup>2,3</sup>, Geraldine Downey<sup>1</sup>; <sup>1</sup>Columbia University, <sup>2</sup>Barnard College, <sup>3</sup>Bar-Ilan University – Borderline Personality Disorder (BPD) is often associated with instability and rapid deterioration of relationships despite frantic efforts to maintain attachments to others. In contrast, Avoidant Personality Disorder (APD) is characterized by pervasive and self-undermining avoidance of interpersonal situations and exposure to rejection. Although there is compelling evidence linking BPD with aversive experiences in childhood (e.g. Bradley, Jenei, & Westen, 2005; Crawford et al, 2009) and corresponding theories and data relating to APD (Benjamin 1996; Eggum et al, 2009), not every individual who struggles with these experiences develops severe psychopathology, and not every individual with PDs reports the same early aversive experiences. As such, the pattern of dysfunction that characterizes the adult relationships of individuals with PDs may be explained by cognitive-affective processes through which sensitization to negative emotional expressions in others leads to biased perceptions of social cues. In this investigation we compared the ability of adults with BPD (N=38) or APD (N = 30) with adult healthy controls (N=39) in their ability to recognize prototypical facial expressions of happiness, fear, sadness, and anger in 2 facial emotion recognition paradigms (FER). We examined performance on the FER tasks in relation to a 21-day experience sampling diary in which they reported 5 times daily on interpersonal experiences. The results indicated that individuals with PDs marked by high sensitivity to interpersonal rejection demonstrated significant biases in the recognition of negative emotional expressions and that these biases were linked to perceiving abandonment and rejection in their daily interactions with others.

## **Special Session B**

### **Saturday, January 29, 8:15 - 9:30 am**

#### **Special Session B1**

### **APA TASK FORCE REPORTS: AIDING, ADVANCING, AND APPLYING RESEARCH**

**Saturday, January 30, 8:15 - 9:30 am, Capri Rooms 103-106**

**Chair:** Steve Breckler, Director of the APA Science Directorate

**Speakers:** Steve Breckler, Susan Saegert, Brenda Major, Monica Biernat, Eileen Zurbiggen, Janet Swim

One service the American Psychological Association (APA) does for the psychology community is to support task force reports that summarize topics of interest to psychologists. Several reports have been produced recently that are likely to be of interest to social psychologists. In this Symposia Steve Breckler (Director of the APA Science Directorate) will describe the formation and function of task force reports. The purpose, major conclusions and/or policy recommendations, and resultant use of five reports covering the following topics will be presented: Psychology and Social Economic Status (Susan Saegert, Vanderbilt University), Psychological Impacts of Abortion (Brenda Major, UC Santa Barbara), IRBs (Monica Biernat, University of Kansas), Sexualization of Girls (Eileen Zurbiggen, UC Santa Cruz), and Psychological Dimensions of Climate Change (Janet Swim, The Pennsylvania State University). A 20 to 25 minute discussion will follow the presentations.

#### **Special Session B2**

### **SOCIAL PSYCHOLOGY IN THE SERVICE OF NATIONAL SECURITY: COLLABORATION OPPORTUNITIES IN SUPPORT OF THE FEDERAL SECURITY CLEARANCE SYSTEM**

**Saturday, January 30, 8:15 - 9:30 am, Capri Rooms 107-110**

**Chairs:** Bryan Castelda and John Capps, Office of the Director of National Intelligence, Special Security Center

**Speakers:** Eric L. Lang, Bryan A. Castelda, Verónica Benet-Martínez, Cynthia L. Pickett

## **Symposia Session F**

### **Saturday, January 30, 9:45 - 11:00 am**

#### **Symposia Session F1**

### **HOW PSYCHOLOGICAL PROCESSES SHAPE CULTURE**

**Saturday, January 30, 9:45 - 11:00 am, Royale Pavilion 1**

**Chair:** Jonah Berger, University of Pennsylvania

**Speakers:** Todd Gureckis, Yoshihisa Kashima, Eytan Baskshy, Jonah Berger

While psychologists have long recognized the important role that culture plays in shaping psychological processes, there has been less attention to the reciprocal processes, or how psychological processes might shape culture. Ideas diffuse rapidly, first names wax and wane in popularity, and videos, news, and information spread virally over the internet. But why do certain cultural items spread contagiously while others languish? And how might psychological processes operating at the individual level shape these collective cultural outcomes? This symposium brings together emerging research that explores the psychological foundations of culture, or how cognition, emotion, and other psychological aspects drive the popularity and transmission of cultural tastes. Gureckis and Goldstone, for example, investigate the interdependence between

individual decision making and collective outcomes, showing how the popularity of first names over time are shaped by individual level cognitive processes as well as social influence. Kashima and Blavin demonstrate how social influence strategies affect the type of information people share, examining how normative and informational influence determine whether people transmit stereotype consistent or inconsistent information. Bakshy and colleagues address the ongoing debate about the importance of source characteristics in diffusion, testing whether characteristics of the initial adopters predict how much something spreads. Berger and Milkman explore what makes things viral, looking how emotion and other shared psychological processes affect which articles make the New York Times Most-Emailed List. Taken together, these diverse perspectives shed light on how psychological processes shape collective outcomes and suggest exciting future directions for this emerging area of research.

#### ABSTRACTS

##### **HOW YOU PICKED A NAME FOR YOUR CHILD: UNDERSTANDING THE RELATIONSHIP BETWEEN INDIVIDUAL DECISION-MAKING AND COLLECTIVE OUTCOMES**

Todd Gureckis<sup>1</sup>, Rob Goldstone<sup>2</sup>; <sup>1</sup>New York University, <sup>2</sup>Indiana University – Cultures are obviously made up of individuals, but to what degree can aggregate patterns of social and cultural change be understood as arising from individual decision processes? We examine the interdependence between individual and group behavior surrounding a somewhat arbitrary, real-world decision: selecting a name for one's child. Using a historical database of the names given to children over the last century in the United States, we find that naming choices are influenced by both the frequency of a name in the general population, and by its "momentum" in the recent past in the sense that names which are growing in popularity are preferentially chosen. This bias toward rising names is a recent phenomena: in the early part of the 20th century, increasing popularity of a name from one time period to the next was correlated with a decrease in future popularity. However, more recently this trend has reversed. We present a number of computational simulations that detail how individual decision-making strategies, played out in a large population of interacting agents, can explain these empirical observations as a type of "emergence". The view we adopt is that cognition acts as a kind of "cultural filter" which, along with processes of social influence, help to determine the spread of ideas. Indeed, individual cognitive capacities for change detection, the encoding of frequency in memory, and biases towards novel stimuli appears to interact with the behavior of other decision makers to determine the distribution and dynamics of cultural tokens.

##### **HOW SOCIAL INFLUENCE STRATEGIES IMPACT IMPLICIT CULTURAL TRANSMISSION**

Yoshihisa Kashima<sup>1</sup>, Nikola Balvin<sup>2</sup>; <sup>1</sup>University of Melbourne, <sup>2</sup>University of Queensland – Implicit cultural transmission is a process by which cultural information is transmitted without the sender's explicit intention to do so. One way to explore this is offered by Bartlett's (1932) serial reproduction method, where information is transmitted from a first person to a second person, who in turn transmits it to a third person, and so on in a chain of communication. Past research has largely shown that implicit cultural transmission tends to reproduce culture: people tend to pass on information consistent with cultural stereotypes (SC) more than information inconsistent with them (SI) over serial reproduction chains. In this research, we began to ask a second generation question, that is, what if we try to modify culture by deploying normative and informational social influence strategies? A narrative about an Aboriginal Australian man was transmitted through three-person serial reproduction chains. Participants in one condition received a social scientific report about the circumstances of Aboriginal Australians (informational social influence), but those in the other condition did not. Within each condition, half the chains received information about positive community attitudes towards Aboriginals (normative influence); the other chains did not receive this information. Although the normative influence tended to reduce the transmission of negative SC information

in the absence of the informational influence, it tended to exacerbate the transmission of negative SC information in its presence. This research provides a cautionary remark about an unexpected and potentially negative effect of combining two well intentioned social influence strategies on implicit cultural transmission.

##### **SOURCE EFFECTS IN SOCIAL CONTAGION**

Eytan Baskshy<sup>1</sup>, Sharad Goel<sup>2</sup>, Jake Hofman<sup>2</sup>, Winter Mason<sup>2</sup>, Duncan Watts<sup>2</sup>; <sup>1</sup>University of Michigan, <sup>2</sup>Yahoo! Research – Psychological research on social influence has identified certain source characteristics that have a positive effect on influence (e.g., authority, credibility, likability, etc.) Research often assumes the individuals who possess these source characteristics are "opinion leaders" who have a disproportionate effect on whether a cultural item, such as a product or idea, diffuses in a population. Moreover, it has been suggested that one can identify these individuals simply by observing their local position in the social network. Subsequent work (Watts & Dodds, 2007) has contested this hypothesis and suggested that the individual may be less important in affecting the size of a cascade than global network features such as their proximity to easily persuaded individuals. In this work we examine three online social networks—an instant messenger client, a photo sharing website, and a microblogging site—and measure the spread of influence (e.g., shared URLs) across these networks. In all three cases we identify the initial adopters to determine if there are any identifiable attributes, or characteristics, which predict the number of people who ultimately adopt. In general, we find that most things are not "viral", and do not spread at all, regardless of who initiates the diffusion. However, the local network structure of the initial adopter has a very small but reliable effect on the prediction of the subsequent size of the adoption cascade, indicating that there is marginal value in identifying the "well-connected" individuals for the diffusion of culture.

##### **VIRALITY, CULTURAL SELECTION, AND CULTURAL SUCCESS**

Jonah Berger<sup>1</sup>, Katy Milkman<sup>1</sup>; <sup>1</sup>University of Pennsylvania – People often share news, opinions, and information with those around them, but why are certain cultural items shared more than others? We investigate whether shared psychological processes (i.e., emotion) shape what spreads by examining the virality of articles from one of the world's most popular newspapers: The New York Times. Because the Times covers a wide range of topics and reaches over 20 million readers, it is an ideal venue for examining what types of content are frequently shared. The Times continually reports which of its articles have been emailed most frequently in the last 24 hours, and we examine whether there is a link between psychological characteristics of articles and whether they make the New York Times' most emailed list. Analysis of over 7,500 articles (using both manual coding and textual analysis) shows that mind-opening or awe-inspiring articles are more viral. Practically useful, surprising, positive, and affect-laden articles are also more likely to make the most emailed list. These relationships are robust to controlling for a host of other factors including external drivers of attention (e.g., where articles appear in the physical paper and online), writing style (e.g., complexity), and author fame. In contrast to theories suggesting exchange is driven by economic value, these findings suggest the important role of deepening social connections. People not only share to encourage reciprocity but also to strengthen social bonds. Further, the magnitudes of these relationships are considerable and support the notion that shared psychological processes act as a selection mechanism on culture.

#### Symposia Session F2

##### **PANEL DISCUSSION: FORGING CONNECTIONS BETWEEN SOCIAL MEDIA AND SOCIAL/PERSONALITY PSYCHOLOGY**

Saturday, January 30, 9:45 - 11:00 am, Royale Pavilion 2

Chairs: Samuel D. Gosling, University of Texas, Austin, and Kate Niederhoffer, Dachis Corporation

Speakers: Cameron Marlow, Matthew Hurst, Winter Mason

Social media (e.g., Facebook, Boing Boing, Twitter, Flickr, Yelp, Digg) are playing an increasingly prevalent role in daily social life. Every action taken on a social media platform is performed by a psychological being trying to satisfy some kind of psychological need—that is, individuals use social media to meet their emotional, social, attitudinal, cognitive, behavioral, and identity needs. As a result, social media platforms provide abundant untapped opportunities for social/personality psychologists to engage in collaborative research using datasets that are unparalleled in size, scope, and ecological validity. Moreover, social media companies offer opportunities for consultation and employment. Yet, connections between social media providers and social/personality researchers are virtually non-existent. This panel discussion will serve to provide an overview of the realm of social media and to initiate a dialogue between social media providers and social/personality psychologists. Panelists will base their discussion on three core questions: (1) What kinds of data and research opportunities are available to researchers and what needs to be done to initiate research projects? (2) What questions would the social media companies like addressed by social/personality psychologists? and (3) what job and consultation opportunities are available? Time will be set aside for questions and discussion from the audience.

#### ABSTRACTS

**CAMERON MARLOW** Cameron Marlow<sup>1</sup>; <sup>1</sup>Facebook – Cameron Marlow will speak from his experience at Yahoo and Facebook.

**MATTHEW HURST** Matthew Hurst<sup>1</sup>; <sup>1</sup>Microsoft Research – Matthew Hurst will speak from his experience at Microsoft Research

**WINTER MASON** Winter Mason<sup>1</sup>; <sup>1</sup>Yahoo! Research – Winter Mason will talk from his experience at Yahoo! Research

#### Symposia Session F3

##### SELF-REGULATION IN RESPONSE TO REJECTION AND SOCIAL THREAT

Saturday, January 30, 9:45 - 11:00 am, Royale Pavilion 5

Chair: Maire Ford, Loyola Marymount University

Speakers: Geraldine Downey, Peggy Zoccola, Maire Ford, Anett Gyurak

Generally rejection or conditions of social-evaluative threat (which signal the potential for rejection) are aversive experiences. However, there is variability in the ways that individuals process and respond to rejection and social-evaluative threat (SET). Certain patterns of processing and responding to rejection/SET are associated with maladaptive outcomes, whereas other patterns are associated with some degree of resilience in the face of rejection/SET. Recent research indicates that the ability to self-regulate may play a key role in shaping responses to rejection/SET by overriding potentially harmful patterns of processing and responding. Speakers in this symposium will discuss the role that self-regulatory processes play in shaping a variety of responses to rejection/SET and the impact that this can have on personal and interpersonal wellbeing. Distinct methodological approaches will be discussed which allow for an integrative, multi-level analysis of the relationship between rejection/SET and self-regulation. Speakers will discuss the components of regulatory competency, the neural infrastructure that facilitates regulation ability, and the role that self-regulatory failure plays in driving a variety of maladaptive responses to rejection/SET. These responses range from extreme pathological responses to more common (yet still highly impactful) cognitive, physiological, and health-related responses. Individual differences that impact self-regulation ability will also be discussed as well as implications for health and wellbeing.

#### ABSTRACTS

**A SELF-REGULATORY PERSPECTIVE ON DISTINCT PATHOLOGICAL RESPONSES TO REJECTION** Geraldine Downey<sup>1</sup>, Kathy Berenson<sup>1</sup>, Eshkol Rafaeli<sup>2</sup>; <sup>1</sup>Columbia University, <sup>2</sup>Barnard College – We have previously delineated how rejection experiences can sensitize people to respond to rejection in self-defeating ways, extreme forms of which are captured in Borderline (BPD) and Avoidant (APD) Personality Disorder. BPD entails desperate efforts to connect to others and intense reactions to rejection including inappropriate anger, impulsive and self-injurious behavior, and extreme fluctuations in mood and identity. APD entails extreme social inhibition and reluctance to risk exposure to rejection. We propose that while rejection sensitivity is common to both disorders, they involve distinct regulatory difficulties reflecting differences in the need to avoid punishment and to attain reward as well as in competency in regulating impulsive responses. BPD is characterized by the destabilizing need to both avoid punishment and attain rewards, often in impulsive ways that suggest impaired ability to delay gratification. By contrast, APD is characterized by an exaggerated need to avoid punishment and a low need for reward – a motivational configuration that facilitates social inhibition. Regulatory competency involves specific competencies for controlling attention, thoughts, affects and behavior in the immediate situation to further long-term goals. We predict that BPD involves lower competency in these aspects of executive control than APD. Preliminary support for these predictions comes from a comparison of persons with APD, BPD, or without psychopathology who completed lab assessments of relevant aspects of executive functioning and goal strength (sensitivity to reward and punishment, delay of gratification, attentional control, behavioral inhibition, and adaptation to changing contingencies), and a daily diary monitoring distinctive symptoms of these disorders.

**RUMINATION AND SALIVARY CORTISOL IN THE CONTEXT OF SOCIAL-EVALUATIVE STRESSORS** Peggy Zoccola<sup>1</sup>; <sup>1</sup>University of California, Irvine – For some, a stressor's psychological and physiological influence ceases upon removal; for individuals who ruminate, the effects may persist. In two studies, we tested whether rumination moderated the cortisol stress response in the context of social-evaluative threat (SET). In study one, we investigated whether ruminating on a laboratory stressor predicts elevated cortisol, and whether rumination levels depend on the stressor's evaluative nature. Eighty-nine participants performed speeches in front of evaluative panels (SET) or in one of two non-explicitly evaluative conditions. State rumination was associated with increased cortisol across all conditions, and the SET condition elicited more state rumination than other conditions. In study two, we tested whether trait rumination moderates the cortisol response to a SET stressor and whether trait and state rumination predicted cortisol levels during later stressor recall. Fifty-nine participants performed speech and math tasks in front of evaluative panels (SET) and two weeks later completed recall interviews in either supportive or unsupportive contexts. Trait rumination was associated with greater cortisol reactivity and delayed recovery in response to the stressor. It also predicted greater cortisol reactivity during later stressor recall, but only for males in the unsupportive recall interview. Males who scored high on trait rumination and also ruminated in the two weeks following the stressor had the greatest reactivity to the unsupportive recall. Together, the findings suggest that those who engage in high levels rumination may be at risk for prolonged cortisol responses to stressors, and that SET stressors may be particularly like to elicit ruminative thought.

**INDIVIDUAL DIFFERENCES IN HEALTH-RELATED BEHAVIORAL REGULATION FOLLOWING REJECTION** Maire Ford<sup>1</sup>, Nancy Collins<sup>2</sup>; <sup>1</sup>Loyola Marymount University, <sup>2</sup>University of California, Santa Barbara – Prior research shows that rejection and related social-evaluative threats can tax an individual's self-regulatory resources and leave him/her vulnerable to poor personal and interpersonal outcomes. This effect is especially pronounced for certain individuals who are highly sensitive to

rejection. These individuals are more likely to exhibit a chronic tendency to experience self-regulation failure in the face of rejection and as a result they are vulnerable to poor psychological and interpersonal outcomes. However, little is known about what effect this self-regulation failure may have on health-related outcomes. Because self-regulation plays such an important role in motivating many health behaviors we sought to extend this area of research. In this talk we will discuss findings from a daily diary study that investigated the effects of real-life rejection on participants' self-reported self-regulatory ability and on daily health behaviors (e.g., eating behaviors and drug use). We will present findings indicating that rejection does impact perceived self-regulatory ability as well as health behaviors. Additionally, we will discuss factors that put some individuals at greater risk for self-regulation failure following rejection, thereby increasing the likelihood that they will engage in harmful health-related behaviors. These findings suggest that the effects of self-regulatory ability extend beyond psychological and interpersonal outcomes, but they also serve to impact one's vulnerability to poor health related outcomes following rejection. This places individuals who are sensitive to rejection (and who are more likely to experience self-regulation failure following rejection) at risk for poor short-term and long-term health outcomes.

**INDIVIDUAL DIFFERENCES IN REGULATION OF RUMINATIVE RESPONSES TO REJECTION - A JOINT fMRI AND DAILY-DIARY INVESTIGATION** Anett Gyurak<sup>1</sup>, Christine Hooker<sup>2</sup>, Özlem Ayduk<sup>1</sup>; <sup>1</sup>University of California, Berkeley, <sup>2</sup>Harvard University – Excessive rumination might exacerbate the negative effects of social rejection experiences in close relationships. However, research evidence suggests that individual differences in the ability to engage regulatory control after interpersonal rejection might attenuate the negative effects typically associated with social rejection. This talk will review findings from a joint fMRI and daily-diary investigation that indicates that low recruitment of the lateral prefrontal cortex in response to an affective challenge in the scanner predicts an increase in rumination following a real-life relationship conflict among dating couples. This suggests that the LPFC may serve to control ruminative tendencies in response to social rejection. Furthermore, evidence is discussed that individual differences in self-reported attentional control similarly buffer otherwise vulnerable low self-esteem individuals from ruminative thinking after a relationship conflict. Collectively, these findings suggest that regulatory processes may lower ruminative tendencies following interpersonal rejection, and offer an avenue for intervention research. Implication for affective neuroscience and clinical research are discussed.

#### Symposia Session F4

### SPSP DIVERSITY AND CLIMATE COMMITTEE SYMPOSIUM - A MULTI-STAGE APPROACH TO UNDERSTANDING INTERGROUP CONTACT: CHALLENGES AND POTENTIAL SOLUTIONS

Saturday, January 30, 9:45 - 11:00 am, Royale Pavilion 6

Chairs: Tamar Saguy, Interdisciplinary Center (IDC) Herzliya, and Tessa West, New York University

Speakers: Michael Inzlicht, Michael Norton, Tamar Saguy, Tessa West

Traditionally, the focus of research on intergroup contact has been on when contact is effective for improving intergroup relations and how contact reduces prejudice. Less is known, however, about the psychological processes associated with the various stages of intergroup encounters, from the pre-interaction phase, through the initial interaction phase, to the progression of interactions over-time. Using neurological, behavioral, and longitudinal approaches, this symposium examines psychological processes associated with various stages of intergroup encounters. Focusing on the pre-interaction phase, Inzlicht and Gutsell use EEG and ERP methods to demonstrate basic affective processes that underlie low levels of empathy directed towards outgroup, compared to ingroup, members, and methods of improving out-group directed empathy. Norton and colleagues demonstrate that when an opportunity for an

intergroup encounter exists, people choose to “opt out” of an interaction so as to not appear prejudiced; a phenomenon termed racial paralysis. Saguy and Dovidio examine the content that group members choose for the initial stage of intergroup interactions. They show that when a possibility for change in status relations exists, group members strategically direct attention to topics that can potentially advance their group goals. Moving to the progression of interactions over time, West and colleagues show that prior interracial contact improves accuracy in perceptions of roommates' anxiety over time, which in turn promotes cross-group friendship development. Taken together, the research presented in this symposium demonstrates challenges that occur at different stages of intergroup encounters, and offers insights into how to improve intergroup interactions.

#### ABSTRACTS

### EMPATHY CONSTRAINED: EVIDENCE THAT NEURAL SYSTEMS UNDERLYING EMPATHY ARE UNRESPONSIVE TO OUTGROUPS, BUT THAT APPROACH BEHAVIORS HELP

Michael Inzlicht<sup>1</sup>, Jennifer Gutsell<sup>1</sup>; <sup>1</sup>University of Toronto – The abilities to identify with others and to overlap the self with the others play a pivotal role in empathy. Here, we propose that empathy is bounded, with the neural system underlying empathy less responsive to outgroups than ingroups. We also propose, however, that empathy can be increased by active efforts, including efforts to conceptually approach the outgroup. Using electroencephalographic (EEG) oscillations and event-related-potentials (ERPs) as an index of empathy and its underlying neural processes, we predict that people will be unlikely to (1) experience vicarious emotions when watching the outgroup in pain, (2) mentally simulate the actions of the outgroup, and (3) associate the self with outgroups. Importantly, we also predict that (4) training in embodied approach behaviours could reduce electrocortical differentiation of the self from the outgroup. In Studies 1 and 2, we found that participants showed similar neural activation patterns when feeling sad or taking action as when they observed ingroup members feeling sad or taking action. In contrast, participants did not show these same activation patterns when observing outgroup members, and even less so the more they were prejudiced. In Study 3, we found that participants demonstrated electrocortical differentiation between the self and outgroup, but that this differentiation attenuated after outgroup-approach training. These findings provide evidence from brain activity for the concept of bounded empathy: Empathy may be restricted to close others and may not extend to outgroups, unless active efforts are taken to associate the self with the outgroup thereby increasing self-outgroup overlap.

### RACIAL PARALYSIS: THE IMPACT OF COLORBLINDNESS ON INTERRACIAL RELATIONS

Michael Norton<sup>1</sup>, Malia Mason<sup>2</sup>, Joseph Vandello<sup>3</sup>, Andrew Biga<sup>3</sup>, Rebecca Dyer<sup>2</sup>; <sup>1</sup>Harvard Business School, <sup>2</sup>Columbia Business School, <sup>3</sup>University of South Florida – Imagine stepping onto a crowded subway car and finding two seats remaining, each next to a similarly dressed man: one White, the other Black. We suggest that in such situations, individuals may choose to forgo either seat and remain standing, rather than risk the appearance of bias. Four studies demonstrate this “racial paralysis” – the tendency to opt out of cross-race decisions, even when the strategy proves costly. While Whites were quite willing to choose which of two White individuals was more likely to be class valedictorian or to have committed a violent crime, they were less likely to admit having a preference between a White and Black person (Study 1). Study 2 used fMRI to examine the mechanism underlying this tendency, revealing greater recruitment of the lateral orbitofrontal cortex – a region implicated in inhibiting instinctively preferred but contextually inappropriate responses – when making cross-race decisions. Study 3 examined the strength of this preference to opt out: Though Whites were willing to forgo a small (\$1) incentive to avoid choosing, they overcame their reluctance to choose when given a sufficient (\$5) incentive. Finally, Study 4 explored the effectiveness of this strategy, demonstrating that both Whites and non-Whites see opting out as an

effective means of appearing unbiased. Studies 3 and 4 together suggest that the costs of forgoing choosing may be outweighed by the social benefits that opting out confers. We discuss the impact of inhibiting preferences on the quality of interracial relations.

**PUTTING CONTACT IN CONTEXT: THE STRATEGIC VALUE OF DISCUSSING POWER AND COMMONALITIES IN INTERGROUP INTERACTIONS** Tamar Saguy<sup>1</sup>, John Dovidio<sup>2</sup>; <sup>1</sup>Interdisciplinary Center (IDC) Herzliya, <sup>2</sup>Yale University

Members of advantaged and disadvantaged groups bring different goals and preferences to intergroup encounters. Research has demonstrated that whereas disadvantaged group members prefer to discuss topics related to group-based inequality (i.e., power), advantaged group members prefer intergroup discussions that are focused on cross-group commonalities. The present research investigated whether these different preferences are actually strategic, that is, reflect goals for advancing status (among disadvantaged groups) or maintaining status (among advantaged groups). We hypothesized that if group-based preferences for the content of contact are indeed strategic, they would be more pronounced when intergroup relations are unstable and illegitimate. Under these conditions, group members perceived a possibility for change in the status hierarchy. In Experiment 1, group status was manipulated along with the stability and legitimacy of the status relations. As expected, disadvantaged group members' desire to address power was most pronounced when the status relations were unstable and illegitimate. This was explained by heightened motivation for social change. Advantaged group members showed a tendency to increase the desire to address commonalities when the status relations were unstable and illegitimate. In Experiment 2, involving only members of advantaged groups, goals regarding changing or sustaining the power differences were directly manipulated. When the goal was to sustain power, the desire to address commonalities was particularly pronounced, and when the goal was to change power, the desire to discuss power was particularly pronounced. These findings point to the strategic value of discussing power and commonalities in intergroup contact.

**A NEW BENEFIT TO INTERRACIAL CONTACT: USING OLD FRIENDS TO IMPROVE COMMUNICATION BETWEEN NEW FRIENDS ACROSS THE RACIAL DIVIDE** Tessa West<sup>1</sup>, Adam Pearson<sup>2</sup>, John Dovidio<sup>2</sup>; <sup>1</sup>New York University, <sup>2</sup>Yale University

Interracial interactions rank among the more stressful of everyday experiences in contemporary society. Within these interactions, minority and majority group members face communication challenges that promote misunderstandings and distrust, and hinder the development of close personal relationships across the racial divide. Understanding factors that promote effective communication between racial groups is crucial for improving race relations. Nevertheless, little is known about the processes through which group members understand one another's experiences as interactions unfold, and the accuracy of these assessments – processes that are likely to contribute to effective communication. The present research demonstrates that prior interracial contact improves communication between Whites and minorities via its effects on over time changes in perceptual accuracy. Randomly assigned college roommates indicated their perceptions of their own and their roommates' feelings of anxiety and of friendship formation, twice a week during the first six weeks of the semester. For Whites, the more cross-race friendships they had prior to moving in with their outgroup roommate, the more accurate they became in the perceptions of their roommates' anxiety over time. For racial minorities, cross-race friendships did not moderate accuracy in their perceptions of their Whites' roommates' feelings of anxiety; all minorities increased in accuracy over time. For both Whites and minorities in interracial dyads, increases in accuracy of perceptions of anxiety were associated with greater perceptions of friendship formation, and with greater roommates' perceptions of friendship formation. These results demonstrate the benefits of prior interracial contact in the context of developing cross-race friendships.

**Symposia Session F5**

**WHERE AM I? CULTURAL PRODUCTS AND SELF-EXPERIENCE**

Saturday, January 30, 9:45 - 11:00 am, Royale Pavilion 3-4

Chair: Jean Twenge, San Diego State University

Speakers: Beth Morling, Batja Mesquita, Tugçe Kurtis, Jean Twenge

Where is the self located? Common understandings place the foundations of self and identity within the person, often in the architecture of the brain. But another perspective proposes that these apparently internal structures of self and identity are also embedded in the everyday worlds in which we live. Self-experiences are reflected in cultural products such as music, advertisements, TV shows, naming practices, and holiday celebrations. Four presentations apply this perspective to different aspects of self and identity that are shaped by, and in turn, shape, a variety of cultural products. Beth Morling presents meta-analyses of cultural products (e.g., advertisements, books) from East Asian and North American settings that reflect individualism and collectivism. Batja Mesquita presents two studies showing that representations of emotion in TV shows from Japanese and American contexts correspond to individuals' self-reports of their emotion. Tugçe Kurtis, presents three studies that show how social identity (national glorification) and collective memory (silence about genocide of Indigenous Peoples) are embedded in holiday commemoration practices associated with American Thanksgiving. Jean Twenge presents four studies from large databases showing a cultural shift over time toward greater individualism in American society not only in self-report measures, but also in external structures such as song lyrics and naming practices. Together these presentations suggest a "more social" psychology that locates the foundations of self and identity not only in internal brain architecture, but also in socially constructed affordances (e.g., practices, material artifacts, and behavioral models) of everyday cultural worlds.

**ABSTRACTS**

**MEASURING CULTURAL DIFFERENCE BY QUANTIFYING BOTH PRODUCTS AND PEOPLE** Beth Morling<sup>1</sup>, Marika Lamoreaux<sup>2</sup>; <sup>1</sup>University of Delaware, <sup>2</sup>Georgia State University

Cultural psychology is, most famously, the study of how "culture and psyche make each other up" (Shweder, 1989). Increasingly, the research of cultural psychologists has exemplified this definition. Researchers have captured cultural differences not just in people's emotions, cognitions, and self-reports, but also in tangible, public representations of culture. These "cultural products" include advertisements, song lyrics, websites, religious texts, and aggregated public behaviors such as walking speed or helpfulness. We collected and meta-analyzed studies in which cultural differences were measured via cultural products. East Asian cultural products were more collectivistic and less individualistic than North American cultural products, and these effect sizes were significantly larger than those found in meta-analyses of self-reports on the same dimensions. We also analyzed results for other values and dimensions (such as power distance, positivity, hedonism, focus on modernity, and use of an explicit message); effect sizes varied, depending on dimension, region, and nation. We will speculate on the complexity of the results, recommend other ways to conduct research on cultural products, and explain why cultural products should continue to be an important element of cultural psychology research.

**CULTURAL MODELS IN THE MIND AND IN THE WORLD: THE EXAMPLE OF CONFLICT** Batja Mesquita<sup>1</sup>, Ishani Banjeri<sup>2</sup>, Mayumi Karasawa<sup>3</sup>; <sup>1</sup>University of Leuven, <sup>2</sup>Indiana University, <sup>3</sup>Tokyo Women's Christian University

Two studies tested the hypothesis that representations of emotions differ across cultures reflective of the cultural models of self and relationships in which they occur. Moreover, we tested the idea that these models can be found both in the mind and in the world. Both studies focused on emotion representations in conflict situations in North American and Japanese contexts. In a first study, North American and Japanese narratives of emotions were content analyzed. North American emotions in

conflict situations reflected independent models of self and relating, emphasizing the (increased) separation between the respondent and the offender (e.g., blaming, feeling rejected), whereas Japanese narratives underlined the interdependence of respondent and offender (e.g., taking the perspective of the offender, doing nothing). In the second study, we presented American and Japanese respondents with one of two clips taken from either a popular North American or a Japanese television show. The clips had been rated as representative of the theme of conflict, as well as anger-provoking by an independent sample of North American and Japanese respondents. In a free recall task, both same-culture and other-culture respondents recalled unique features of the cultural emotion model represented by each clip; however, the culture-specific elements of the emotion model were recalled by a greater proportion of same-culture than other-cultural respondents. Together the studies suggest that cultural models of emotions are reflected by cultural artifacts, but that these artifacts are particularly powerful to people from these cultural contexts.

#### **THANKSGIVING COMMEMORATIONS AS CULTURAL TOOLS FOR COLLECTIVE SELF-GLORIFICATION** Tugçe Kurtis<sup>1</sup>, Glenn Adams<sup>1</sup>, Michael Yellow Bird<sup>1</sup>; <sup>1</sup>University of Kansas

A cultural psychology perspective emphasizes that the structure of self and identity is not limited to brain architecture, but also resides in socially constructed affordances inscribed in everyday worlds. Building on this idea, three studies examined how holiday practices serve as cultural affordances for the experience of collective self. In particular, we investigated how silence about genocide in commemoration of American Thanksgiving both reflects and promotes national self-glorification. In Study 1, we analyzed presidential Thanksgiving proclamations and observed that glorification themes were more frequent in proclamations that failed to mention Indigenous Peoples than proclamations that did mention indigenous peoples. In Study 2, we asked White undergraduates to rate 3 different proclamations; ratings of liking, relevance, and recommendation were much lower for a genocide-mentioning proclamation than genocide-silencing proclamations, especially when national glorification concerns were high (as individual difference measure or via experimental manipulation). In Study 3, we manipulated exposure to different Thanksgiving commemorations and observed that national glorification scores and tendencies to reproduce silence were weaker for participants exposed to a genocide-mentioning commemoration than participants exposed to genocide-silencing commemorations. Overall, results suggest that silence about genocide in Thanksgiving commemorations serves as an "intentional world" for the production of national selves. Silence about genocide in Thanksgiving commemorations not only materializes (or "makes real") self-glorifying beliefs and desires (e.g., about American greatness), but also carries a psychological charge that—regardless of individual intention or awareness—directs experience toward nation-glorifying ends (e.g., "loyal" citizens prepared to kill or die for homeland).

#### **CULTURAL PRODUCTS, BEHAVIOR, AND SELF-REPORTS ACROSS TIME: GENERATIONS AS CULTURE** Jean Twenge<sup>1</sup>; <sup>1</sup>San Diego State University

Culture differs not only across regions but across time. Four large datasets examine how changes in cultural products and self-reports reflect increasing cultural individualism in the United States. First, we examined the lyrics of popular songs between 1980 and 2007. The use of first-person singular pronouns (I, me) and antisocial behavior increased and that of collective pronouns (we, our) and social interactions decreased. In the second study, an analysis of the given names of 325 million Social Security card holders between 1880 and 2007 showed that, over time, fewer people received common names. For example, 40% of boys received one of the 10 most common names in the 1940s; by 2007, less than 10% did. Thus parents have increasingly favored names that would help children stand out rather than fit in. Two additional studies show that self-reports also reflect these cultural shifts. Narcissistic personality traits, a type of hyper-individualism, increase among generations of American college students between 1982 and 2009 in three

analyses; confounding by campus explains why some previous studies found no change. These increases mirror trends in cultural products and behaviors such as increases in plastic surgery, surging levels of debt, larger houses, and increased interest in fame and celebrities. Finally, data from the Monitoring the Future survey of high school students demonstrates significant changes consistent with individualism, such as increases in materialism, high expectations, desire for leisure, more flexible views of social rules, and lack of trust.

#### **Symposia Session F6**

#### **IMPULSE AND REFLECTION: UNDERSTANDING BEHAVIOR AND MOVING BEYOND THE IMPLICIT-EXPLICIT DISTINCTION**

**Saturday, January 30, 9:45 - 11:00 am, Royale Pavilion 7-8**

**Chairs: Michael Haefner and Kees van den Bos, Utrecht University**

**Speakers: Fritz Strack, Michael Haefner, Kees van den Bos, Charles S. Carver**

Many recent dual-systems models stress the fact that human behavior is determined by a joint function of impulse and reflection. The bulk of research inspired by these models, however, often sticks to the dissociation of implicit and explicit attitude measures and the situational factors leading to their dissociation. It is the aim of the present symposium to move beyond this practice and to investigate impulsive and reflective behavior beyond the comparison of implicit and explicit attitudes. In doing so, we clarify the processes underlying the distinction between impulse and reflection. Furthermore, we substantiate the impulse-reflection distinction by new empirical findings across various domains. Thus, this symposium shows why dual-systems models provide a useful vantage point on surprisingly diverse aspects of behavior. Specifically, Fritz Strack will provide a thorough theoretical overview of recent dual-systems models, with a particular focus on the prediction of behavior and the role of feelings. This analysis will be backed up by empirical findings across different domains. Next, Michael Häfner will investigate whether and how flexible impulsive sexual behavior can be, and what potential underlying processes are driving this flexibility. Then, Kees van den Bos will present research showing how important it is to distinguish between impulsive and reflective processes in order to better understand complex phenomena as the just world belief. Finally, Charles Carver will discuss how variation in serotonergic function relates to the two systems and to psychological and behavioral variability, ranging from normal to impulsive aggression and depression.

#### **ABSTRACTS**

#### **THE DUAL DETERMINATION OF JUDGMENT AND BEHAVIOR** Fritz

Strack<sup>1</sup>, Roland Deutsch<sup>1</sup>; <sup>1</sup>University of Wuerzburg – While most dual-systems or dual-process models are about human thinking and judgment formation, only a few of them address behavior. For both subject domains, however, they typically contrast automatic and controlled mechanisms. In addition, behavioral theories juxtapose rational or cold and emotional or hot processes. The Reflective-Impulsive Model (RIM) attempts to integrate these components in a dynamic fashion with the aim to explain their influence on human thoughts and actions. Specifically, behavioral schemata are assumed to be elicited by input from two mental systems with different operating principles, which are interacting at various stages of the processing. Feelings play a role in both systems either as input into reflective judgments or as facilitating or inhibiting conditions in impulsive operations. The postulated mechanisms are illustrated with findings from different domains such as intuitive judgments and self-regulation.

#### **MOTIVATED EROTIC COGNITION: ON THE FLEXIBILITY AND CONTEXT-DEPENDENCY OF IMPULSIVE SEXUAL BEHAVIOR** Michael Haefner<sup>1</sup>,

Roland Deutsch<sup>2</sup>, Beate Seibt<sup>3</sup>; <sup>1</sup>Utrecht University, <sup>2</sup>University of Würzburg, <sup>3</sup>Centro de Investigação e Intervenção Social (CIS), ISCTE Lisbon – Evolutionarily inspired research on the processing of sexual opportunities has typically highlighted stable differences such as gender differences and

downplayed the role of dynamically changing motives and situational affordances. We argue and demonstrate, however, that taking dynamically changing motives into account eclipses gender differences in the processing of sexual cues, rendering the automatic regulation of sexual behavior even more adaptive. In particular, we demonstrate that spontaneous motivational tendencies towards sexual opportunities are not only determined by the gender of the perceiver but, independently, also by the state of sexual deprivation the perceiver is actually in (Study 1). Furthermore, we demonstrate that also salient social norms interact with the gender of the perceiver in the prediction of the impulsive responses to sexual opportunities (Study 2). Taken together, these findings do not only highlight the considerable flexibility of impulsive (sexual) behavior, but may also help to disambiguate the equivocal role deprivation previously played in the literature on sexual behavior. Specifically, the present findings suggest that sexual deprivation can have a direct (absolute) and an indirect (relative) influence on behavior and that both pathways follow different rules.

**ON ASSOCIATIVE LINKS AND PROPOSITIONAL REASONING PROCESSES: DIFFERENT ROUTES TO VICTIM BLAMING** Kees van den Bos<sup>1</sup>, Marjolein Maas<sup>1</sup>; <sup>1</sup>Utrecht University – The paper by Kees van den Bos and Marjolein Maas will examine why people may blame innocent victims of robbery or sexual assault. The authors propose that in experiential mindsets associative links are formed between the victim and the negative event. As the creation of such links is independent of explicit beliefs, people in experiential mindsets produce negative reactions to the victim largely independent of their just world beliefs. Rationalistic mindsets, however, instigate propositional and consistency-based reasoning. For people who strongly endorse just world beliefs (such as people who have strong predispositions to believe that the world is just or whose just world beliefs have been threatened strongly), learning about an innocent victim creates a logically inconsistent system of beliefs. This inconsistency can be resolved by blaming the victim. For people who only weakly endorse just world beliefs, there is no inconsistency in the first place and therefore no need to blame the victim.

**DUAL-PROCESS MODELS AS CONCEPTUAL TOOL: CONCEPTUALIZING SEROTONERGIC FUNCTION** Charles S. Carver<sup>1</sup>; <sup>1</sup>University of Miami – The serotonin system has been studied for decades. Variation in serotonergic function relates to psychological and behavioral variability of several sorts, including vulnerability to psychological disorders ranging from impulsive aggression to depression. Dual-process models suggest a way to conceptualize these effects of serotonergic function: Specifically, serotonergic function may influence the balance of influence between the lower-order system that responds quickly to cues of the moment and the higher-order system that responds reflectively and planfully. That is, low serotonergic function seems to enhance the influence of the lower-order system, whereas higher serotonergic function seems to enhance the influence of the higher-order system. This hypothesis has a number of implications, both for normal variation in personality and for views of disorder. This presentation will address some of those implications. A core underlying theme is that the dual-process model provides a useful vantage point on surprisingly diverse aspects of behavior.

## Symposia Session F7

### THE SELFISH ORIGINS OF SELFLESSNESS: INTEGRATING EVOLUTIONARY, ECONOMIC, AND PSYCHOLOGICAL MODELS OF HELPING & COOPERATION

Saturday, January 30, 9:45 - 11:00 am, Capri Rooms 101-102

Chairs: Vladas Griskevicius, University of Minnesota, and Noah Goldstein, UCLA

Speakers: Douglas Kenrick, Noah Goldstein, Paul Van Lange, Vladas Griskevicius

Altruism, cooperation, and helping are studied across disciplines, and there have been several interesting controversies about why people

behave in self-sacrificing ways. The papers in this symposium present new theory and research bridging work on economic game theory, the social psychology of helping, and evolutionary approaches to cognitive decision-making. Using laboratory studies, formal modeling, and field experiments, the papers converge on the novel idea that self-sacrifice is often in a person's self-interest – that selflessness is ultimately selfish in the evolutionary sense. Drawing on recent connections between economics and evolutionary theory, Kenrick, Sanabria, Sundie, & Killeen propose an elaboration of game theory. They show that incorporating factors such as reproductive value and kinship into game theory can turn competition into cooperation. Bridging evolutionary theory with social psychological work on reciprocity, Goldstein, Griskevicius, Mortensen, & Cialdini examine the workings of reciprocity when strangers provide favors not to us, but to our kin or close others. They find that we inherit the social debts of close others – as if we ourselves were the recipients of the initial favor. Van Lange, Klapwijk & Reinders Folmer examine how reciprocity and generosity can promote cooperation, finding that generosity can function to build trust by enhancing reputation. Finally, Griskevicius, Tybur, & Van den Bergh examine how purchasing “green” products can be construed as altruistic. They find that self-sacrificing to help the environment is associated with status. This symposium highlights a new wave of helping and cooperation research that bridges evolutionary, economic, and psychological perspectives.

## ABSTRACTS

### GAME THEORY AND SOCIAL DOMAINS: HOW FITNESS INTERDEPENDENCIES TRANSFORM STRATEGIC DECISIONS

Douglas Kenrick<sup>1</sup>, Federico Sanabria<sup>1</sup>, Jill Sundie<sup>2</sup>, Peter Killeen<sup>1</sup>; <sup>1</sup>Arizona State University, <sup>2</sup>University of Houston – Drawing on recent connections between economics and evolutionary theory, we propose an elaboration of game theory with important implications for social psychology. Classical economic models predict that people facing decisions to cooperate or compete will routinely make choices favoring themselves over others. Evolutionary theory suggests factors such as kinship and reproductive value that should modify strategic decisions, sometimes manifesting as cooperative or even altruistic behavior. Siblings, for example, should be invested in one another's payoffs since on average they share half their genes. Parents and children have similar genetic interests, but differ in future reproductive potential. We present a general model incorporating such differential biases as quantifiable weights in strategic decisions, and work out several examples of formal implications for cooperative games. We review empirical data consistent with this model. This model demonstrates how biases formerly considered qualitative and idiosyncratic can be translated into quantitative and objective influences on strategic decision-making that vary systematically across social contexts. This work parallels developments in evolutionary biology, anthropology, and economics. We discuss ways in which social psychologists could become more centrally involved in this interdisciplinary conversation.

### VICARIOUS RECIPROCITY: INHERITING THE SOCIAL DEBTS OF CLOSE OTHERS

Noah Goldstein<sup>1</sup>, Vladas Griskevicius<sup>2</sup>, Chad Mortensen<sup>3</sup>, Robert Cialdini<sup>3</sup>; <sup>1</sup>UCLA, <sup>2</sup>University of Minnesota, <sup>3</sup>Arizona State University – Psychologists, economists, and evolutionary theorists all note that cooperation and helping is strongly influenced by reciprocity. But whereas we feel obligated to return favors provided for us directly, might we feel equally obligated to return favors that are provided to our kin or other individuals with whom we feel psychologically close? Evolutionary theory suggests that factors such as kinship and friendship should produce a certain overlap between our own actions and those of close others, suggesting that we might inherit the social debts incurred by close others, even when we ourselves are not recipients of any favor. A series of laboratory and field experiments examined this possibility. Findings showed that social debts are indeed passed on from psychologically close others to us. Furthermore, we are motivated to act on these obligations to pay back the favor-doer – almost as if we ourselves were the direct recipients of the favor. In contrast with previous explanations for indirect reciproc-

ity, which suggest that individuals who engage in indirect reciprocity are driven to do so to enhance their reputations and gain status, the findings from the current investigation suggest that vicarious reciprocity norms are internalized, operating even when their behavior is anonymous. Finally, an additional field experiment found that we feel the need to repay strangers who perform favors not only for close others, but also those who do favors for organizations and causes with which we identify.

#### **WHY GENEROSITY EXISTS AMONG STRANGERS: A THEORETICAL CHALLENGE FOR ECONOMISTS AND PSYCHOLOGISTS**

**Paul Van Lange<sup>1</sup>, Anthon Klapwijk<sup>1</sup>, Chris Reinders Folmer<sup>1</sup>, <sup>1</sup>VU University Amsterdam** – Can generosity promote cooperation? Past research on economic games between non-strangers suggests that generosity (behaving more cooperatively than another person) elicits greater levels of cooperation than reciprocity (behaving as cooperatively as another person). Generosity is especially effective in economic games when there is some kind of “noise” – when people every now and then make an idiosyncratic mistake or misunderstanding (e.g., arriving too late for an appointment due to an unforeseen traffic jam). A key question that remains unanswered, however, is whether generosity may be functional in our interactions with strangers, whom we are unlikely to meet again. After some disagreement, economists and psychologists now exhibit similar levels of optimism, suggesting that a mechanism of indirect reciprocity – reciprocity that is communicated by third parties via reputation – may promote cooperation (i.e., reputation-based cooperation). Our experiments examined whether indirect generosity may outperform indirect reciprocity in its ability to cope with “noise” in economic games among strangers. Results revealed that noise undermined cooperation and impressions of benign intent. Yet, such undermining effects of noise were substantially weaker or even absent when strangers behaved in a generous (versus reciprocal) manner. These findings add credence to the claim that the ultimate functions of generosity may be rooted in building trust that may even take place among strangers through communicating about one another’s behavior. Our findings help explain why people often do help strangers, and underscore the importance of trusting communities in coping with noise and misunderstandings.

#### **GOING GREEN TO BE SEEN: STATUS, REPUTATION, AND CONSPICUOUS CONSERVATION**

**Vladas Griskevicius<sup>1</sup>, Joshua Tybur<sup>2</sup>, Bram Van den Bergh<sup>3</sup>, <sup>1</sup>University of Minnesota, <sup>2</sup>University of New Mexico, <sup>3</sup>Rotterdam School of Management** – Why do people behave altruistically toward strangers? Biologists and behavioral ecologists have observed that human and non-human altruism might function as a “costly signal” associated with status. A person who incurs a cost to himself for the benefit of others may be signaling that he can afford to incur this cost. We used a costly signaling framework to examine why people purchase pro-environmental “green” products. We argue that buying such products can be construed as altruistic, since green products often cost more and are of lower quality than their conventional counterparts, but green goods benefit the environment for everyone. Because altruism might function as a costly signal associated with status, we examined how activating status motives influenced desire for green products. Findings across three experiments showed that activating status motives led people to choose green products over more luxurious non-green products. For example, status motives led people to choose a pro-environmental car with few features over a more luxurious but less-environmentally friendly vehicle. Two additional findings supported the notion that altruism can function as a costly signal: (1) Status motives increased desire for green products when shopping in public, but not in private; and (2) status motives increased desire for green products when green products cost more, but not less, than non-green products. The studies together demonstrate experimentally the links between altruism, reputation, and status. The findings also suggest that status competition can be a useful tool for promoting pro-environmental behavior.

### **Symposia Session F8**

#### **FREE WILL, MORAL ACTION, AND MORAL RESPONSIBILITY**

**Saturday, January 30, 9:45 - 11:00 am, Capri Rooms 103-106**

**Chairs: Yoel Inbar, Harvard University, and David Pizarro, Cornell University**

**Speakers: Joshua Greene, Yoel Inbar, Joshua Knobe, Jonathan Schooler**

What does it mean to say that a person acted ‘freely’? Is free will necessary for the notion of moral responsibility? In this symposium we bring together four researchers who in recent years have made a great deal of progress toward answering these questions from a psychological perspective, and whose findings are beginning to paint a consistent picture of how the concept of free will influences moral judgment and behavior. Greene and Paxton, using brain imaging techniques, give us a plausible method for measuring how much will is exerted in any given decision, and demonstrate (rather surprisingly) that the exertion of will seems to play a larger role in deciding to act dishonestly than in deciding to resist temptation and act honestly. But while immoral acts may often involve such clear exertions of the will, what of cases in which an infraction is committed but free will appears absent or reduced? Inbar and Knobe both provide evidence that people who lack freedom are indeed seen as being less responsible (a finding Knobe shows is not limited to Western cultures). However, this connection is more tenuous than many assume – under certain conditions individuals are very willing to ascribe responsibility despite a clear lack of freedom. Finally, Schooler provides additional evidence for the connection between freedom and responsibility by showing that undermining belief in free will also undermines belief in moral responsibility, and that this opens the door for individuals to engage in morally questionable behaviors they would not have engaged in otherwise.

#### **ABSTRACTS**

#### **WILL OR GRACE? PATTERNS OF NEURAL ACTIVITY ASSOCIATED WITH HONEST AND DISHONEST MORAL DECISIONS**

**Joshua Greene<sup>1</sup>, Joseph Paxton<sup>1</sup>, <sup>1</sup>Harvard University** – What makes people behave honestly when confronted with opportunities for dishonest gain? Research on the interplay between controlled and automatic processes in decision-making suggests two hypotheses: According to the “Will” hypothesis, honesty results from the active resistance of temptation, comparable to the controlled cognitive processes that enable the delay of reward. According to the “Grace” hypothesis, honesty results from the absence of temptation, consistent with research emphasizing the determination of behavior by the presence or absence of automatic processes. To test these hypotheses, we examined neural activity in individuals confronted with opportunities for dishonest gain. Subjects undergoing functional magnetic resonance imaging (fMRI) gained money by accurately predicting the outcomes of computerized coin-flips. In some trials, subjects recorded their predictions in advance. In other trials, subjects were rewarded based on self-reported accuracy, allowing them to gain money dishonestly by lying about the accuracy of their predictions. Many subjects behaved dishonestly, as indicated by improbable levels of “accuracy.” Our results support the Grace hypothesis. Individuals who behaved honestly exhibited no additional control-related activity (or other kind of activity) when choosing to behave honestly, as compared to a control condition in which there was no opportunity for dishonest gain. In contrast, individuals who behaved dishonestly exhibited increased activity in control-related regions of prefrontal cortex, both when choosing to behave dishonestly and on occasions when they refrained from dishonesty. Levels of activity in these regions correlated with the frequency of dishonesty in individuals.

#### **AMPLIFIER OR ATTENUATOR? DIVERGENT EFFECTS OF REDUCED CONTROL ON MORAL EVALUATION**

**Yoel Inbar<sup>1</sup>, Clayton Critcher<sup>2</sup>, David Pizarro<sup>2</sup>, <sup>1</sup>Harvard University, <sup>2</sup>Cornell University** – The notion of control is central to our conception of freely willed action – I cannot be said to have done something freely if I had no choice to do otherwise (Frankfurt,

1971). Therefore, according to many any philosophical (Clarke, 2003) and psychological (Shaver, 1985; Weiner, 1991) theories of moral responsibility, reduced control over an action should attenuate moral blame or praise. Here, we show that this is not always the case: Reduced control can act as a moral amplifier or attenuator, depending on the inferences drawn regarding the actor's underlying character and intentions. In Study 1, we identify two distinct types of reduced control—rashness and emotionality—and find that people rate behaviors reflecting rashness as more reliable indicators of character than behaviors reflecting emotionality. If rash actions are especially reliable indicators of character, praise and blame should be amplified for rash acts, which we demonstrate in Study 2—people who act positively are praised more, and those who act badly are condemned more, when they do so rashly. Further, we show that this moral amplification effect is driven by assessments of the actor's underlying character. Conversely, in Study 3 we show that blame is attenuated, but praise is not, for actions performed while extremely emotional. Again, this attenuation effect is again driven by people's assessment of the actor's underlying character.

#### **INTUITIONS ABOUT FREE WILL: A DUAL-PROCESS THEORY** Joshua

**Knobe<sup>1</sup>; <sup>1</sup>Yale University**—The traditional philosophical debate over free will has focused on a deceptively simple question. If our actions are completely determined, can we still be morally responsible? Though philosophers typically approach this question with complex arguments and distinctions, it seems that ordinary people also find the question deeply puzzling and mysterious. Our aim, therefore, was to engage in an empirical study of people's ordinary understanding of free will. Five studies revealed that people arrive at radically different judgments depending on which sort of cognitive process they apply. When we introduced manipulations designed to trigger more abstract, theoretical reasoning, most participants (86%) said that no one could be morally responsible for actions that were entirely determined. By contrast, when we introduced manipulations designed to trigger immediate affective reactions, most participants (72%) said that it actually was possible to be morally responsible even for actions that were determined. A subsequent cross-cultural study demonstrated the robustness of this effect. Participants in Hong Kong, India, Colombia and the United States all showed the same pattern of responses, with no significant cross-cultural differences. Drawing on these experimental results, we argue that the classic philosophical debate over free will actually reflects a tension between two different cognitive mechanisms within each individual. People's capacity for abstract, theoretical reasoning draws them toward one answer, their capacity for immediate, affective reactions draws them toward another, and their ultimate conclusion depends in part on which of these cognitive processes they apply in the moment of decision.

#### **THE CONSEQUENCES OF BELIEVING IN FREE WILL** Jonathan Schooler<sup>1</sup>;

<sup>1</sup>University of California, Santa Barbara—Recent evidence suggests that people's beliefs about free will can be at least temporarily altered by exposure to arguments that free will is merely an illusion. Moreover, exposure to anti-free will sentiments has both negative and positive effects on people's moral judgments. On the down side, being encouraged to think of free will as an illusion increases people's propensity to cheat and decreases their prosocial behavior. On the upside, priming determinism also leads to reduced retributivism in context of doling out punishment. These findings suggest that people's beliefs about free will, while unstable, nevertheless have a significant impact on their moral behaviors and attitudes.

### **Symposia Session F9**

#### **OUTDOORS PSYCHOLOGISTS: ADVANCING SOCIAL PSYCHOLOGICAL THEORY AND EXPERIMENTAL METHODS IN THE FIELD**

**Saturday, January 30, 9:45 - 11:00 am, Capri Rooms 107-110**

**Chairs:** Elizabeth Levy Paluck, Princeton University, and Ruth Dittmann, Yale University

**Speakers:** Ruth K. Dittmann, Robert B. Cialdini, Laura G. Barron, Glenn Adams

This symposium is stimulated by Robert Cialdini's recent call to improve academic psychology by using field research (Cialdini, 2009). Social psychologists who have stepped outside the laboratory for various epistemological and substantive reasons will present research and discuss challenges and benefits of advancing social psychological theory through field research. Presentations will consider challenges like the capability of field research to access cognitive variables and mediation of major findings, the status of the field in relationship to the laboratory, and the extent to which working in the field inhibits a researcher's control over independent variables or limits overall productivity. The presentations will also underscore benefits, such as the capacity to capture a variety of demand-free behavioral outcomes, produce findings with immediate relevance to everyday human activity, and generate unique advances in psychological theory. Paluck and Dittmann introduce these issues, illustrated by recent findings and experiences drawn from field experimental research programs on interethnic conflict and discrimination. Subsequent empirical presentations analyze the significance of naturalistic behavioral measures as reliable predictors of political attitudes (Cialdini), the relationship between ethnic identification and discrimination in real world hiring situations as compared to laboratory simulations (Barron, King, & Hebl), and the lessons of participant-observation field research for understanding the laboratory as a culturally specific context (Adams & Stocks). By communicating the range of motivations for and dividends from field research, the panel aims to raise the value assigned to field research in academic psychology.

#### **ABSTRACTS**

#### **WAS IT WORTH IT? FIELD EXPERIMENTS AND OTHER WAYS TO SPEND YOUR TIME OUTSIDE THE LABORATORY** Ruth K. Dittmann<sup>1</sup>, Elizabeth Levy Paluck<sup>2</sup>; <sup>1</sup>Yale University, <sup>2</sup>Princeton University—

An overview of motivations for conducting field research highlights empirical and theoretical dividends unique to the field, along with challenges that can discourage potential field researchers. Two recent experiments illustrate benefits and drawbacks. An experiment in American retail stores measuring changes in discrimination throughout customer-cashier interactions illustrates the value of assessing behavioral indicators without demand characteristics and as they unfold in real-time. It also points to challenges, such as achieving consistency and control in naturalistic settings, and advantages, such as using as natural variation in settings to enable analysis of effect size heterogeneity across different conditions. An experiment in Southern Sudan that modified a real world democracy-promotion radio program to measure the effect of narrative vs. educational media and group discussion vs. naturalistic "chatting" demonstrates the feasibility of using multiple independent variables and experimental mediation analysis in the field. It also highlights possibilities for funding and partnership with non-academic organizations, along with its attendant political and logistical challenges. For very different reasons, each experiment was "worth" a departure from the laboratory, and together the two illustrate the range of motivations for taking a field experimental approach.

#### **LITTERING AS A COVERT MEASURE OF POLITICAL ATTITUDES: MESSY BUT CLEAN** Robert B. Cialdini<sup>1</sup>; <sup>1</sup>Arizona State University—

Two experiments were performed to test the usefulness of littering as an unobtrusive measure of attitude. In the first experiment, choice of presidential candidate in a national election was assessed. Results demonstrated that

the tendency to retain vs. litter a handbill supporting a given candidate was significantly related to the tendency to vote for that candidate. In a second experiment, the sensitivity of littering as a nonreactive measurement technique was tested against a standard interview procedure. Opinions toward topics with high or low social desirability were assessed by both measurement techniques. Results showed equivalence between the techniques when assessing responses with low levels of social desirability; however, when the responses were laden with social desirability, attitudes measured by the interview technique were skewed in the socially desirable direction relative to those measured by the littering technique.

**MANIFESTING ONE'S ETHNIC IDENTIFICATION: LIABILITY IN THE LAB BUT STRATEGY IN THE FIELD?** Laura G. Barron<sup>1</sup>, Eden B. King<sup>2</sup>, Michelle Hebl<sup>1</sup>; <sup>1</sup>Rice University, <sup>2</sup>George Mason University – While its value is often lauded, social psychological research rarely relies upon field methods; the overwhelming majority of contemporary research is conducted on individual laboratory subjects. One area of research in which ecological validity may be questioned is intergroup relations. The current research considers the generalizability of recent laboratory findings that suggest that ethnic identification can lead to negative evaluations of ethnic minorities (Kaiser & Pratt-Hyatt, 2009) by studying face-to-face interactions in contexts wherein impression management concerns are particularly salient: the workplace. In a field experiment, Black, Hispanic, and Irish individuals applied for 221 retail jobs with or without visible displays of their ethnic identification. Specifically, they wore one of three hats (a blank hat, a “Black [Hispanic, Irish] Student Association” hat, or a “Black [Hispanic, Irish] and Proud” hat) while interacting with a store manager and applying for a job. We recorded both formal and interpersonal forms of discrimination (see Hebl, Foster, Mannix, & Dovidio, 2002). Contrary to evidence in the lab (Kaiser & Pratt-Hyatt, 2009), expression of ethnic identification reduced interpersonal forms of discrimination. These findings underscore the importance of social context in intergroup behaviors, highlight the benefits and challenges of leaving the laboratory and conducting field research, and point to the need for more field studies in social psychological research (see also Cialidini, 2009).

**LABORATORY EXPERIMENT AND FIELD RESEARCH: A CULTURAL PSYCHOLOGY ANALYSIS** Glenn Adams<sup>1</sup>, Eric Stocks<sup>2</sup>; <sup>1</sup>University of Kansas, <sup>2</sup>University of Texas, Tyler – Viewed in broad scientific perspective, the discipline of social psychology suffers from an almost fetishistic obsession with laboratory experiments. A cultural-psychological analysis, especially when informed by the practice of participant-observation field research, helps to illuminate problems with this emphasis. These problems are not limited to issues of external validity: for example, the common criticism that people who typically report for laboratory experiments constitute an unrepresentative foundation upon which to build a general social science; or that “knowledge” from laboratory experiments may not generalize well to other environments, including those more typical of human history and ecology. In addition, these problems include issues of internal validity: whether the typical account of experimental results adequately explains what happens inside the experimental context. Inspired by the 20th anniversary of Shweder's (1990) classic paper (“Cultural Psychology: What is it?”), the first part of this presentation considers implicit assumptions that raise issues for interpretation of the typical laboratory experiment: perhaps most important, belief in the atomistic separation of person and context that both (a) locates the structure of mind in self-contained, ontologically prior individuals and (b) treats the laboratory as a culture-transcendent space. Building on this analysis, the second part of the presentation draws upon a program of participant-observation field research in West African settings to consider how ecologically grounded, experimental methods can play an important role as part of a broader (and arguably more empirical), culture-conscious social psychology.

## Symposia Session F10

### EMBODIED MOTIVATION: IMPLICATIONS OF BODY FEEDBACK FOR FUNDAMENTAL PROCESSES UNDERLYING MOTIVATED ACTION

Saturday, January 30, 9:45 - 11:00 am, Capri Rooms 114-116

Chairs: Nils B. Jostmann and Jens A. Förster, University of Amsterdam

Speakers: Jens A. Förster, Simone Schnall, Nils B. Jostmann, Dennis R. Proffitt

The aim of the symposium is to promote an integrative perspective on embodiment research and motivation science, which are two influential but still largely separated areas of psychological investigation. An important concern of embodiment research is to understand how bodily states including facial expression, muscle contraction, or posture influence people's cognitive and affective reactions. The symposium brings together research that addresses the implications of such feedback for motivated behavior. Jens Förster argues that theories on embodiment and attitudes cannot fully explain effects of bodily cues on behavior. In his studies showing an influence of head movements on task persistence, he demonstrates that in case of high goal commitment bodily cues have a direct influence on behavior, whereas in case of low commitment, meta-cognitive processes drive effects. Simone Schnall and her colleagues provide evidence that coherence between emotional and bodily reactions has motivational benefits because coherence decreases cognitive costs in ongoing tasks. Nils Jostmann and his colleagues show that people use body feedback to establish the value of an issue. They found that holding a heavy weight influences what people find important and whether they are willing to invest cognitive effort. Dennis Proffitt demonstrates that people's estimations of distances depend on body feedback (e.g., heart rate) that signals the energetic consequences of goal-directed action. The research presented in the symposium strongly suggests that body feedback has important implications for a number of core motivational variables including commitment, task persistence, value, effort, and distance.

## ABSTRACTS

**DIRECT AND META-COGNITIVE INFLUENCES OF EXPRESSION PATTERNS ON BEHAVIOR: MODERATION BY INTEREST, DISTANCE, AND DECISION PHASE** Jens A. Förster<sup>1</sup>; <sup>1</sup>University of Amsterdam – Bodily cues can influence attitudes either directly or via self-validation mechanisms. To illustrate, valenced head movements can directly intensify the value of objects, such that for example nodding enhances liking of chocolate and head shaking reduces liking of medication. Alternatively, expression patterns can be used as information with respect to the confidence with which one holds an attitude. Thus, head shaking may reduce confidence with respect to negative attitude objects, leading to opposite effects (e.g., medication is not so bad). The two processes identified to explain embodiment effects on attitudes may be useful to explain effects on behavior. However, for behavior, a moderating influence of goal commitment is suggested. Commitment increases with interest, goal proximity, and whether one has yet decided or not to do it. If commitment is high, direct influences are expected; if commitment is low, bodily cues serve as information for one's confidence in doing the activity. We examined head shaking, nodding and a control group and varied interest (high vs. mild; Study 1), decision phase (pre- versus post-decisional phase; Study 2), and goal proximity (a year from now, today; Study 3), between participants. Consistently, we found direct effects of expression patterns on persistence of doing an activity when commitment was relatively high (i.e., highly interesting goals, proximal goals, and when participants were in a post-decisional phase). However, bodily cues were used for self-validation when commitment was relatively low (mildly interesting goals, distal goals or when participants were in a pre-decisional phase).

### MOTIVATIONAL CONSEQUENCES OF AFFECTIVE INCOHERENCE: WHEN AFFECTIVE CONCEPTS AND EMBODIED REACTIONS CLASH

Simone Schnall<sup>1</sup>, David B. Centerbar<sup>2</sup>, Gerald L. Clore<sup>3</sup>; <sup>1</sup>University of Cambridge, <sup>2</sup>University of Massachusetts, <sup>3</sup>University of Virginia – Both in science and in everyday life our actions typically validate the appropriateness of our cognitions. For example, finding yourself smiling validates the appropriateness of a positive concept that became accessible in a situation, whereas finding yourself frowning does not. Such confirmation or disconfirmation of affective thoughts by embodied reactions is an important way in which mind and body interact to motivate behavior. We examined how affective expressions, feelings, and actions function as such confirmation and disconfirmation of affective mental content. We expected that affective coherence, namely compatibility of affective concepts and embodied reactions, facilitates the pursuits of processing goals. By contrast, incompatibility between affective concepts and embodied reactions disrupts such processing goals. In five studies, participants were first primed with happy or sad concepts, and then experienced embodied affective cues. In Studies 1 and 2, the embodied reactions were approach (arm flexion) and avoidance (arm extension). In Study 3, the embodied reactions were feelings of mood induced by listening to happy or sad music. In Studies 4 and 5, the embodied reactions involved flexing the muscles involved in smiling and frowning. In all studies, coherence between affective concepts and embodied affective experiences motivated better recall of a story than affective incoherence. We propose that the experience of experiential affective cues serves as evidence of the appropriateness of affective concepts that come to mind. Presumably, affective coherence has motivational benefits because it allows proceeding with a given action (e.g., pursuing a cognitive goal), whereas incoherence incurs cognitive costs.

### VALUE FROM WEIGHT: HOLDING A HEAVY WEIGHT INFLUENCES IMPORTANCE JUDGMENTS AND COGNITIVE EFFORT INVESTMENT

Nils B. Jostmann<sup>1</sup>, Daniël Lakens<sup>2</sup>, Thomas Schubert<sup>3</sup>; <sup>1</sup>University of Amsterdam, <sup>2</sup>Utrecht University, <sup>3</sup>ISCTE, Lisbon – Recently, the notion of value as a core motivational variable has received new attention. The value of an object or activity relates in part to its perceived importance (Higgins, 2008). Importance, in turn, is metaphorically linked to weight: Important matters carry more weight than unimportant matters. The present research examines whether the concept of importance is grounded in bodily experiences of holding a heavy weight. We conducted three studies in which participants provided judgments of importance while they held either a heavy or a light clipboard. Holding a heavy clipboard increased judgments of monetary value (Study 1) and made participants consider receiving voice in decision-making procedures to be more important (Study 2). Because people are more likely to invest cognitive effort in elaborating about issues that they find important rather than unimportant, we conducted an additional study to test whether holding a heavy weight causes more elaboration. In line with our predictions, holding a heavy compared to a light clipboard led to more elaboration as indicated by greater polarization between strong versus weak arguments, and greater confidence in participant's judgments (Study 3). Taken together, these findings show that the experience of weight influences how people establish the importance of an issue and how much cognitive effort they are likely to invest.

### PERCEPTION VIEWED AS A PHENOTYPIC EXPRESSION

Dennis R. Proffitt<sup>1</sup>; <sup>1</sup>University of Virginia – Visual experience relates the optically-specified environment to people's ever-changing phenotype, which consists of their morphology, physiology, and behavior. Within near space, apparent distances are scaled with morphology, and in particular, to the extent of an actor's reach. For example, we have found that the apparent distance to targets becomes foreshortened when a person holds a tool, which makes previously out of reach targets reachable. For large environments, such as fields and hills, spatial layout is scaled by changes in physiology – the bio-energetic costs of walking relative to the bio-energetic resources currently available. When appropriate, behavioral perfor-

mance scales apparent size; for example, our studies have shown that baseballs look larger when a batter is hitting well. To assess the underlying physiological mechanisms that scale large spatial layouts, we investigated distance perception, before and after exhausting exercise. Two groups of competitive bicyclists rode a stationary bike for 45 minutes. One group was given a carbohydrate drink, whereas the other was given a non-caloric one. Measures of heart rate, energy expenditure, oxygen uptake, and blood glucose were taken throughout the exercise. Predicted changes in apparent distance were associated, not only with the drink manipulation, but also with individual differences in energy expenditure, fitness, heart rate, and blood glucose. This study shows that distance perceptions are closely coordinated with body feedback about the energetic costs and opportunities of performing goal-directed behavior.

## Symposia Session G

Saturday, January 30, 11:15 am - 12:30 pm

### Symposia Session G1

#### "GIMME FIVE!" TACTILE COMMUNICATION AND ITS PROSOCIAL CONSEQUENCES

Saturday, January 30, 11:15 am - 12:30 pm, Royale Pavilion 1

Chairs: Michael W. Kraus, University of California, Berkeley, and Christopher Oveis, Harvard University

Speakers: Matthew J. Hertenstein, Christopher C. Nocera, Christopher Oveis, Michael W. Kraus

Tactile communication, or physical touch, is the most highly developed sense at birth, and preceded language in the evolutionary history of the human species (Burgoon, Buller, & Woodall, 1996). Physical touch is fundamental to the social functioning of both human and non-human species (Harlow, 1958), and yet, its form and functions have remained largely understudied. In this symposium, we use four unique perspectives to explore the communicative functions of physical touch and its prosocial consequences for individuals and whole social groups. First, Hertenstein employs a basic emotions perspective, showing that prosocial emotions (e.g., love, gratitude) are accurately signaled and perceived between strangers in a laboratory setting. Second, through nonconscious priming methods Nocera, Ackerman, and Bargh show that people form impressions of others based on their sensory experiences touching unrelated physical objects. Third, Oveis uses a thin-slicing framework to assess how physical touch in family photographs and in brief interactions between romantic partners predicts later well-being and relationship satisfaction. Finally, Kraus, Huang, and Keltner explore the group functions of touch by assessing the impact of celebratory touch (e.g., high fives, fist bumps) on team performance in a longitudinal study of behavior during professional basketball games. Together, these papers suggest that touch (1) is a fundamental aspect of communication between people, (2) is used as a tool for forming impressions of others, (3) has soothing functions in times of stress, (4) and promotes healthy group functioning in families, teams, and romantic couples.

#### ABSTRACTS

#### TOUCH COMMUNICATES PROSOCIAL EMOTIONS

Matthew J. Hertenstein<sup>1</sup>; <sup>1</sup>Depauw University – Touch as been described as the most fundamental means of contact with the world and most straightforward of all sensory systems (Geldard, 1960). Despite the importance of touch in several key domains of social life, its role in the communication of emotion, particularly prosocial emotions, has received little attention compared to the face and voice. Indeed, one finds virtually no mention of the tactile modality in reference works in the field of affective science (Lewis, 2008). To help address this gap, we conducted a study to test

whether distinct emotions, particularly prosocial emotions, can be communicated via touch. To test this hypothesis, one participant who was designated the encoder (i.e., the person who touched the other) entered the lab to find the decoder (i.e., the person who was touched) blindfolded. The decoder could not see the encoder, nor were the participants allowed to talk or make any sounds. Eight emotion words were displayed serially to the encoder and s/he was instructed to touch the decoder to communicate each of the emotions via touch. After each trial, the decoder chose which emotion s/he thought the encoder communicated. For the first time in the literature, our results indicated that touch reliably communicated four prosocial emotions—happiness, love, gratitude, and sympathy—without confusion. Moreover, specific tactile behaviors were identified for the communication of each emotion. These findings will be discussed in the context of evolutionary theory, as well as the differentiated nature of the tactile system compared to the face and voice.

#### **NONCONSCIOUS PRIMING EFFECTS OF TOUCH IN IMPRESSION FORMATION**

**Christopher C. Nocera<sup>1</sup>, Joshua M. Ackerman<sup>2</sup>, John Bargh<sup>3</sup>;** <sup>1</sup>Harvard University, <sup>2</sup>MIT Sloan School of Management, <sup>3</sup>Yale University — Research on priming effects has typically focused on activating concepts or goals outside of conscious awareness through exposure to words, images or actions. Actual physical experiences with objects may also act as primes insofar as they map onto psychological constructs (e.g., through metaphors). Building off work on metaphor priming, we investigated the role of incidental sensory touch cues on impression formation. In several studies, we show that experiences with different degrees of weight, texture and hardness, although ostensibly irrelevant to the focal task, influence subsequent judgments people make about others. For instance, participants who evaluated a job candidate while holding a heavy clipboard, relative to a light one, judged the candidate to be a stronger applicant and more serious about obtaining the job. Within a second study, participants evaluated an ambiguous social interaction between two people as being more argumentative and competitive after completing a puzzle task featuring pieces with a rough surface compared to pieces with a smooth surface. Such effects are consistent with the metaphoric association of heaviness with importance and coarseness with being rude and boorish. We discuss the role of haptic experiences in influencing impressions in everyday life, and consider the developmental process through which metaphors might be constructed on the basis of physical experience.

#### **THIN SLICES OF TOUCH REVEAL AFFECTIVE STYLE AND RELATIONSHIP DYNAMICS**

**Christopher Oveis<sup>1</sup>;** <sup>1</sup>Harvard University — Two studies investigate the claim that affiliative touch serves as a reliable indicator of affective style in children and romantic couples. In Study 1, using classroom and family photographs, smile intensity and tactile contact were assessed in 91 kindergartners and their families. Classroom photographs depicted children posing their most intense smiles, and family photographs depicted children and their families posing together in an unstructured manner. Consistent with claims that discrete forms of touch communicate positive emotion, warm touching between family members in the home, but not the overall amount of touching behavior between family members, was positively correlated with children's positive emotional displays in the classroom. In Study 2, 69 romantic couples participated in a series of videotaped laboratory conversations concerning peak experiences of love, sacrifices made for one another, and times of great distress. Participants then provided daily reports of emotional events, relationship-relevant emotions, and relationship satisfaction for the next 14 days after the initial conversations. Affiliative touching behavior during laboratory conversations was correlated with relationship satisfaction and pro-social emotion. Context-specific forms of prosocial touch were associated with domain-specific enhancements in relationship quality. Taken together, these studies suggest that discrete forms of touch may transmit positive emotion between parents and children and between romantic partners, and point to the utility of touch as an indicator of affective style and relationship satisfaction.

#### **TACTILE COMMUNICATION, TRUST, AND PERFORMANCE IN GROUP COMPETITION: AN ETHOLOGICAL STUDY OF THE NBA**

**Michael W. Kraus<sup>1</sup>, Cassy Huang<sup>1</sup>, Dacher Keltner<sup>1</sup>;** <sup>1</sup>University of California, Berkeley — Tactile communication, or physical touch, serves many social functions that include soothing others in times of stress, communicating specific emotions, and promoting inferences of warmth and trust between people (Williams & Bargh, 2008). Based on this research, we predicted that in group competition, touch would be more likely during moments of heightened competition, and that touch would increase both individual and group performance. In an ethological study, we observed basketball games from the National Basketball Association (NBA) during the 2008-2009 regular season, and coded the occurrence and duration of touch behavior between players during those games. Performance was based on efficiency measures of player and team play that are highly correlated with team season wins (Berri, Schmidt, & Brook, 2007). Consistent with hypotheses, touch was more likely when games were most competitive, and early season touch led to greater performance for individuals as well as teams later in the season. Moreover, this effect held independent of status, preseason expectations, and immediate performance in the game coded for touch. Finally, touch enhanced team performance by increasing the trust shown between teammates, as rated by observers. Taken together, the results imply that high-performing groups or teams obtain success because they engage in forms of physical contact that foster cooperation. This research highlights the importance of tactile communication in other group settings that include business settings, political organizations, and classrooms.

#### **Symposia Session G2**

##### **KEYNOTE PANEL**

#### **THE ROLE OF GENETICS IN PERSONALITY AND SOCIAL PSYCHOLOGY**

**Saturday, January 30, 11:15 am - 12:45 pm, Royale Pavilion 2**

**Chairs:** William Fleeson, Wake Forest University, and Serena Chen, University of California, Berkeley

**Panelist:** Frances A. Champagne, Columbia University,

#### **Gene-Environment Interplay and the Transgenerational Impact of the Social Environment**

**Panelist:** Steve Cole, David Geffen School of Medicine at UCLA,

#### **Social regulation of gene expression in humans**

**Panelist:** Robert F. Krueger, Washington University,

#### **Genes and Environments in Personality and Social Psychology: Some Reflections on Scientific Strategies**

**Panelist:** Eric Turkheimer, University of Virginia,

#### **A Null Model for the Genetics of Complex Human Behavior**

Research and theoretical innovations are rapidly generating new Paradigms or investigating the role of genetics in personality and social psychology. The SPSP 2010 Keynote Panel showcases several of these innovative and exciting paradigms. You may find that your current conceptions about genetics are substantially broadened, altered, and perhaps even challenged, by the panel's insights. A significant period of time after the talks is reserved for open discussion.

#### **Symposia Session G3**

#### **THE BIOLOGY OF THE ATTACHMENT BOND**

**Saturday, January 30, 11:15 am - 12:30 pm, Royale Pavilion 5**

**Chair:** Paul Eastwick, Texas A&M University

**Speakers:** Paul Eastwick, Lisa Diamond, Peter Gray, James Coan

The attachment-behavioral system works adaptively in adulthood to form and maintain pair-bonds between romantic partners. For this reason, attachment theory has proven to be a valuable perspective on adult romantic relationships and has sparked many insights about how relationships affect humans' health and well-being. Now, scholars are seek-

ing a more complete understanding of the function of the attachment bond (and, by extension, social bonds in general) by examining attachment processes in conjunction with other aspects of human physiology. These four talks will explore how hormonal, genetic, and metabolic factors interface with the attachment-behavioral system. Eastwick and Finkel hypothesize that attachment bonds should refocus the effects of women's ovulatory adaptations toward the purpose of protecting and strengthening the bond, and two studies offer support for their predictions. Diamond finds that, although the sex of lesbian and bi-sexual women's primary attachment figures differ (i.e., women and men, respectively), both groups of women report increased sexual attraction to women when ovulating versus not ovulating. Gray focuses primarily on men, reviewing links between testosterone and fatherhood and presenting new data on genetic predictors of marital status and reproductive outcomes among Kenyan pastoralist men. Finally, Coan applies his Social Baseline Model to attachments among same-sex couples and finds that participants are differentially likely to conserve metabolic resources depending on the proximity of their romantic partner. Not only is the attachment-behavioral system a critical component of the mating psychology of *Homo sapiens*, it affects—and is affected by—various features of our underlying biology.

#### ABSTRACTS

**THE EVOLUTIONARY ARMISTICE: ATTACHMENT BONDS MODERATE THE FUNCTION OF OVULATORY CYCLE ADAPTATIONS** Paul Eastwick<sup>1</sup>, Eli Finkel<sup>2</sup>; <sup>1</sup>Texas A&M University, <sup>2</sup>Northwestern University — During the course of human evolution, attachment bonds evolved between adult mating partners to encourage increased investment, especially paternal investment, in offspring. However, previously existing adaptations that foster intersexual conflict could have threatened attachment bonds; therefore, attachment processes should have evolved the ability to mute or refocus the effects of such adaptations in order to protect the bond. Indeed, ovulatory adaptations, such as women's tendency to be attracted to symmetrical extra-pair partners when fertile, predate adult attachment processes in the primate psyche by several million years and frequently foster intersexual conflict (e.g., by confusing paternity). Therefore, attachment processes may refocus the effects of ovulatory adaptations in a manner that promotes intersexual cooperation. Two studies offer support for this prediction by demonstrating that attachment bonds moderate the function of ovulatory cycle adaptations. Among women who were weakly bonded to their romantic partners, fertility was associated with an increased desire for an extra-pair sexual liaison. But among women who were strongly bonded to their partners, fertility was actually associated with reduced desire for extra-pair sex. In addition, to the extent that women were bonded to a partner, fertility predicted their use of sexual contact to foster an emotional connection with him. These results (a) suggest that attachment bonds between sexual partners may have cultivated an "evolutionary armistice" by managing the effects of older, conflict-promoting adaptations and (b) highlight the utility of combining traditional adaptationist theorizing with a phylogenetic perspective that considers the time course of events within the hominid lineage.

**ATTACHMENT, SEXUAL ORIENTATION, AND CHANGES IN SEXUAL MOTIVATION DURING OVULATION: EVIDENCE FOR DIFFERENTIATION BETWEEN ATTACHMENT AND SEXUAL DESIRE** Lisa Diamond<sup>1</sup>; <sup>1</sup>University of Utah — We investigated whether motivation for same-sex sexual contact was related to ovulatory estrogen levels in women with consistent versus inconsistent patterns of same-sex desire and same-sex attachment over a 10-year period. Twenty women, all of whom have been providing detailed data on their sexual behavior, romantic relationships, and sexual identities every 2 years since 1995, completed daily diaries assessing sexual motivation and provided 10 days of salivary estrogen samples. Women who had consistently identified as lesbian or who had consistently identified as bisexual since 1995 showed increased motivation for sexual contact with women during the ovulatory peak in

estrogen than when not ovulating. Yet despite showing similar shifts in same-sex desire, these two groups had notably divergent patterns of same-sex and other-sex romantic attachment. Specifically, bisexuals had been more predominantly romantically attached to men over the previous 10 years (and were more likely to be currently romantically attached to a man) whereas lesbians had been more predominantly romantically attached to women over the past 10 years (and were more likely to be currently romantically attached to a woman). The findings provide evidence that the orientation of a woman's sexual desires, here operationalized in terms of the predominance of her same-sex versus other-sex sexual motivation during peak fertility, may diverge sharply from her current and prior experiences with emotional attachment to women versus men.

**HORMONES, PAIR BONDS, AND PARENTING: EVOLUTIONARY AND CROSS-CULTURAL PERSPECTIVES ON MEN** Peter Gray<sup>1</sup>; <sup>1</sup>University of Nevada, Las Vegas — Human reproductive physiology and anatomy are consistent with a recent evolutionary history of slightly polygynous reproductive unions along with low sperm competition. The hominin fossil and archeological evidence suggests this pattern of reproductive unions, also entailing long-term bonds and paternal care, arose in the genus *Homo*. Here, we consider the hormonal correlates of human male long-term partnerships (i.e., marriage). Because the endocrine system helps attune an organism's behavior to its social context, it is reasonable to expect, as in other vertebrates, that human male involvement in long-term partnerships as well as paternal care impact men's hormonal profiles. To date, the most conclusive evidence for this proposal is that men involved in long-term partnerships and/or paternal care commonly have lower testosterone levels than unpartnered men. This has been observed in at least ten North American studies as well as at minimum six international samples (e.g., Beijing, China). However, in some cases lower testosterone levels are only found among fathers rather than partnered men without children. Researchers have only begun to investigate the effects of male pair bonds and paternal care on other hormones such as oxytocin, vasopressin, or cortisol, and I briefly review what these other studies have found. For example, a recent study implicated vasopressin 1a receptor polymorphisms in Swedish male pair bonding outcomes, though colleagues and I did not find links between vasopressin 1a receptor polymorphisms and marital status or reproductive output among Kenyan pastoralist men. I conclude with some points about methodological challenges and directions for future research.

**THE CONSERVATION OF METABOLIC RESOURCES VIA ATTACHMENT AND SOCIAL PROXIMITY** James Coan<sup>1</sup>; <sup>1</sup>University of Virginia — In humans, social influences on the regulation of emotion are in many cases unconditional and often powerful. The Social Baseline Model of emotion regulation suggests the human brain's first and most robust strategy for regulating emotion is via social proximity and interaction. It draws on the principle of Economy of Action, which states that to survive, organisms must over time consume more energy than they expend. One of the methods by which the brain is capable of managing energy expenditure is via alterations in sensory perception that aid in decision-making about the deployment of available resources. The Social Baseline Model proposes that social proximity, particularly to attachment figures, modifies the perception of available resources, which in turn governs how resources are deployed and utilized. It also proposes that humans are hard-wired to "assume" the presence of other humans, particularly those with whom we are familiar. Thus, when familiar others are perceived to be absent, humans normatively respond with increased vigilance for signs of threat and, when threats do arise, respond to those threats with greater intensity. In other words, when humans are alone, they deploy more personal resources in anticipation of coping with environmental challenges. This talk will review recent evidence for the conservation of neural resources, especially those dedicated to emotion and the regulation of emotion, as a function of social proximity. Implications for social and medical policy will be described in the context of recent work in our laboratory on same-sex romantic couples.

**Symposia Session G4****BEYOND PARTICULARISM IN THE STUDY OF INTERSECTIONAL IDENTITIES: BUILDING AND TESTING GENERAL THEORIES OF IDENTITY INTERSECTIONALITY**

Saturday, January 30, 11:15 am - 12:30 pm, Royale Pavilion 6

Chairs: Valerie Purdie-Vaughns, Columbia University, and Richard P. Eibach, University of Waterloo

Speakers: Margaret A. Thomas, Ram Mahalingam, Isis H. Settles, Valerie Purdie-Vaughns

Discussion of Sotomayor's appointment to the Supreme Court focused on the candidate's statement that a "wise Latina" brings a valuable perspective to the judiciary. Although Sotomayor's statement was about ethnicity and gender, commentators took it as a statement about ethnicity alone. This episode illustrates a disregard of intersectionality that is pervasive. Social science often approaches social identities in isolation rather than intersectionally. When intersectionality is studied, researchers take a particularistic approach, documenting unique experiences of narrowly defined intersectional groups, or they limit their focus to investigating whether people with multiple subordinate-group identities (e.g., black women) are more disadvantaged than those with single subordinate-group identities (e.g., black men). This symposium brings together psychologists working to develop more general models of intersectionality. First, Thomas and Goff draw on models of person perception to demonstrate that ethnic identities are often gendered, leading to predictable errors in categorization judgments. Second, Mahalingam and colleagues use cognitive developmental theories of essentialism to study social psychological factors that influence awareness of the dynamics of intersectionality and privilege. Third, Settles and colleagues draw on models of occupational and gender identity to examine whether incongruent identities affect the psychological well being of female scientists. Finally, Purdie-Vaughns and colleagues test the hypothesis that people with intersecting subordinate-group identities are perceived as non-prototypical members of their identity groups and this non-prototypicality renders them relatively "invisible" in social representations. Together these presentations bring intersectionality into mainstream social psychology, highlighting the relevance of general models of intersectionality to theories of identity and prejudice.

**ABSTRACTS**

**A NEW TRADITION: INTERSECTIONALITY IN PERSON PERCEPTION AND INTERGROUP CONFLICT** Margaret A. Thomas<sup>1</sup>, Phillip Goff<sup>2</sup>; <sup>1</sup>Alfred University, <sup>2</sup>University of California, Los Angeles – Traditional approaches to person perception and group-based stereotyping tend to treat race and gender as if each occurs in the absence of the other. Five studies support the notion that, contrary to traditional approaches, examining the intersections of race and gender is crucial to understanding person perception and intergroup conflict. In Study 1, participants imagined a "person," who was "Black," "White," "Asian," or unspecified, then indicated the gender of the person they imagined. Participants reliably imagined Blacks as males and Asian as females, leading us to hypothesize that some races may be strongly gendered (i.e. Black = male, Asian = female). Study 2 lent support to this hypothesis: participants rated Black women as more masculine and Asian men as more feminine than same-gender targets of other races. In Studies 3 and 4 participants mis-categorized Black women as men at significant rates while gender errors for White women and all men were minimal. Misperceiving gender was correlated with racial stereotypicality for Black women, such that the more "Black" women appeared, the more "masculine" they seemed – rendering them less attractive. Finally, data from Study 5 suggest that racial stereotypes may apply more to gender-prototypical group members (i.e. Black males and Asian females) than to gender-aprototypical group members (i.e. Black females and Asian males). Taken together, this research suggests that intersectional approaches to social psychology

may be necessary to reveal both hidden harms of intergroup conflict (i.e. the social construction of Black women as unattractive) and to reveal basic person perception processes.

**PRIVILEGE, POWER AND REPRESENTATIONS OF SOCIAL CLASS: AN INTERSECTIONALITY PERSPECTIVE** Ram Mahalingam<sup>1</sup>, Melissa Sanders<sup>1</sup>, Jennifer Yim<sup>1</sup>; <sup>1</sup>University of Michigan – Critical race theorists have proposed an intersectionality perspective to examine how the intersecting social identities we embody (e.g., race, ethnicity, social class, gender and sexuality) simultaneously affect our lives (Crenshaw, 2008; Shields, 2008). In this presentation, we review 3 studies that investigate how consciousness of this intersectionality relates to essentialist beliefs about privileges and legitimizing ideologies. Several researchers have noted that essentialist representations of social categories positively relate to legitimizing ideologies (Hirschfeld, 1996; Mahalingam, 2006). We test the hypothesis that intersectional awareness negatively relates to essentialist beliefs and legitimizing ideologies. In Study 1, we analyzed final reflection papers written by students who participated in a semester-long intergroup dialogue course. Twenty-five percent of students displayed awareness of identity intersectionality. We documented three qualitatively different stages of intersectional awareness. In Study 2 we studied whether awareness of male and white privileges was positively related to intersectional awareness in a college sample. Privileged group members (males and upper middle-class students) were low on both privilege awareness and intersectional awareness. Social Dominance Orientation was negatively related to intersectional awareness. In study 3 we used an intersectionality board game to examine whether creating a personal narrative that incorporates intersecting identities increased one's intersectional awareness in comparison to a control group who played the board game without a personal narrative for their characters. Qualitative and quantitative findings support that creating a personal narrative indeed led to increased intersectional awareness. These studies together illustrate the significance of studying social identities in an intersectionality framework.

**DOES GROUP IDENTIFICATION HELP OR HARM? THE MODERATING ROLE OF IDENTITY CHANGE IN IDENTITY-THREAT OUTCOMES FOR WOMEN IN SCIENCE** Isis H. Settles<sup>1</sup>, William A. Jellison<sup>2</sup>, Jennifer S. Pratt-Hyatt<sup>1</sup>; <sup>1</sup>Michigan State University, <sup>2</sup>Quinnipiac University – Holding multiple identities can produce identity interference, which occurs when the expectations of one identity interfere with the performance of another identity. The current research examines identity centrality, or the psychological importance of an identity, as a moderator of the relationship between identity interference and decrements in performance. This is the first longitudinal study to examine whether the centrality (importance) of two identities (woman and scientist) plays a buffering or exacerbating role in the relationship between identity-related disruptions (i.e., woman-scientist interference) and psychological well-being. The present research involved a study of 128 female scientists who were students at Time 1 (T1); and two years later (T2), 51% had transitioned to science-related jobs whereas 49% remained students. Results revealed that identity interference was related to lower psychological well-being two years later for women who became less identified as women, but they were unrelated for women who increased their level of gender identification. In addition, identity interference was related to poorer perceptions of science performance two years later for women who became less identified as scientists. However, for women who increased their level of scientist identification, T1 identity interference and T2 science performance perceptions were unrelated. Contrary to predictions, change in scientist centrality did not moderate the relationship between T1 identity interference and T2 psychological well-being, and change in the centrality of the woman identity did not moderate the negative effect of T1 identity interference on T2 perceived science performance. These results suggest important domain-specific effects of identification with different groups.

**HOW INTERSECTIONALITY SHAPES PROTOTYPICALITY: THE INTERSECTION OF ANDROCENTRISM, ETHNOCENTRISM, AND**

### **HETEROCENTRISM IN DEFINING PROTOTYPES OF GENDER, RACE, AND SEXUAL CATEGORIES**

Valerie Purdie-Vaughns<sup>1</sup>, Richard P. Eibach<sup>2</sup>, Ruth Dittmann<sup>3</sup>; <sup>1</sup>Columbia University, <sup>2</sup>University of Waterloo, <sup>3</sup>Yale University – Androcentrism defines the prototypical person as male, ethnocentrism defines the prototypical person as white, and heterocentrism defines the prototypical person as heterosexual. The intersection of ethnocentrism and androcentrism makes the prototypical gay person a white male. The intersection of ethnocentrism and heterocentrism makes the prototypical woman a white heterosexual. And the intersection of androcentrism and heterocentrism makes the prototypical nonwhite person a heterosexual male. Consequently, nonwhite women should be seen as nonprototypical women and nonprototypical ethnic minorities. Similarly, lesbians should be seen as nonprototypical women and nonprototypical gay people. We tested this intersectional nonprototypicality hypothesis in a series of studies. For example, in an archival study of national magazine covers we found that nonwhite women were significantly underrepresented, relative to population proportions, both on covers depicting women and covers depicting nonwhite people. Another study involved asking participants to explain differences within oppressed groups. Since prototypical persons define the group norm, nonprototypical persons should tend to be the focus of explanations when people attempt to explain differences within groups. Indeed, we found that black women were the focus when participants attempted to explain differences between black men and women and when they attempted to explain differences between black and white women. Similarly, lesbians were the focus when participants attempted to explain differences between lesbian and heterosexual women and when they attempted to explain differences between lesbians and gay men. The nonprototypicality that people with intersecting disadvantaged identities experience may make them vulnerable to having their interests marginalized by policymakers and advocates.

### **Symposia Session G5**

#### **NEW INSIGHTS INTO SOCIAL EVALUATION BIASES: FROM BRAIN TO BEHAVIOR**

Saturday, January 30, 11:15 am - 12:30 pm, Royale Pavilion 3-4

Chair: Jennifer S. Beer, University of Texas at Austin

Speakers: David Dunning, Jason P. Mitchell, Constantine Sedikides, Jennifer S. Beer

Illusions pervade both the social-cognition and visual systems. Vision scientists argue that optical illusions belie an elegant visual system that promotes efficiency rather than costly precision. In contrast, the illusions that pervade social judgments have often been used to illustrate ‘cognitive shortcomings’ in social environments. Do these cognitive shortcomings arise because people (a) actively distort information or (b) use heuristic shortcuts for the social targets they know best? In this symposium, new insight into the mechanisms driving social-evaluation biases is provided through complementary pairings of the latest behavioral research and neural research. Dunning shows that biased predictions of future behavior arise when people fail to make appropriate associations between their past selves and future selves. Are self-representations of past behavior actively suppressed or not drawn upon in the first place? Mitchell presents a series of fMRI studies that suggest self-representations are not drawn upon when making future predictions for the self. Sedikides provides new insight into the robust effect of alternate information-processing on reducing bias in social evaluations. Do alternate approaches to evaluations deepen heuristic processing or combat active distortions of relevant information? Beer presents a series of fMRI studies showing that positively-biased social evaluations are reduced (rather than increased) by cognitive control. These talks suggest a heuristic nature for the biases that pervade judgments of self and well-known others. Perhaps the social cognition system, like the visual system, is built for efficiency and the resources needed for precision are only executed in particular contexts and for unfamiliar social targets.

### **ABSTRACTS**

#### **ARE PEOPLE BETTER SOCIAL PSYCHOLOGISTS THAN SELF-PSYCHOLOGISTS?**

David Dunning<sup>1</sup>, Erik G. Helzer<sup>1</sup>; <sup>1</sup>Cornell University – Recent work on the “holier than thou” phenomenon suggests that people are overly optimistic about their own behavior but not when forecasting others. Two studies investigated why. Our guiding hypothesis was that people give too much weight to their own agency (e.g., intentions, plans, and aspirations) in self-prediction and discount too much the predictive value of their past behavior. In predicting peers, people largely avoid these tendencies. In the first study, participants predicted their own performance in an upcoming exam after providing relevant information, as did a peer after reviewing the same information. Participants proved too optimistic in their self-predictions, relative to peer predictions. This undue optimism arose because participants focused too much on their own agency, giving too much weight to their target score than did a peer. Participants also discounted past performance too much, relative to peers. These tendencies, in addition, appeared to be related to wishful thinking. Participants set higher target scores and discounted past performance in self-prediction—two tendencies related to error—to the extent that the class was important. In a second study, participants were given chances to win money by predicting the exam score of a peer or by having a peer predict the participant’s own exam score. Participants uniformly wanted to know about past test performances over target score when predicting a peer. However, when it came to having a peer predict them, participants were more likely to pass on information about their target score than information about their past.

#### **DIFFERENTIAL SELF-OTHER ACTIVITY IN VENTROMEDIAL PREFRONTAL CORTEX PREDICTS SHORTSIGHTED MONETARY DECISIONS**

Jason P. Mitchell<sup>1</sup>, Jessica Schirmer<sup>1</sup>, Daniel L. Ames<sup>2</sup>, Daniel T. Gilbert<sup>1</sup>; <sup>1</sup>Harvard University, <sup>2</sup>Princeton University – People often make shortsighted decisions to receive small benefits in the present rather than large benefits in the future, that is, to favor their current interests over those of their future selves. In two studies using functional magnetic resonance imaging, we demonstrated that people make such myopic choices because they tend to think of their future selves not as they think of their present selves, but as they think of other people. Participants showed reduced activity in a set of brain regions associated with thinking about the self (e.g., the ventromedial prefrontal cortex) when they thought about their future selves rather than their present selves, and the magnitude of this reduction in neural activity was strongly correlated with the shortsightedness of participants’ monetary decisions. These findings suggest that shortsighted intertemporal choices result from a failure to engage in sufficiently self-referential processing when considering the experience of one’s future self.

#### **DO STRONG CUES OVERRIDE SELF-ENHANCEMENT?**

Constantine Sedikides<sup>1</sup>, John Skowronski<sup>2</sup>; <sup>1</sup>University of Southampton, UK, <sup>2</sup>Northern Illinois University – Self-enhancement (e.g., self-favoring judgments) are spontaneous, pervasive, and powerful. In four experiments, we set out to understand whether strong internal cues (e.g., priming) can override self-enhancement. In the first three experiments, some participants read a story describing ambiguously mean behaviors performed by another person. Other participants read the story and imagined that they performed the behaviors. Results showed that: (a) Exposure to a conceptual priming manipulation caused assimilation effects in actor meanness judgments, regardless of whether the actor was self or other, (b) neither tasks designed to heighten self-concept accessibility, or to threaten the self, moderated the effects of conceptual meanness primes on self-meanness judgments, and (c) this lack of moderation occurred despite considerable evidence of self-enhancement effects elsewhere in self-judgments. A fourth experiment examined the extent to which priming affected interpretations of real self or other behavior. Results were consistent with the idea that priming altered event interpretation and subsequent judgments, but also suggested that judgments were influenced by self-

enhancement motivation. The findings have implications for theorizing in personality and self-knowledge acquisition

### **REDUCED COGNITIVE CONTROL SUPPORTS POSITIVITY BIASES IN SOCIAL EVALUATION** Jennifer S. Beer<sup>1</sup>, Brent L. Hughes<sup>1</sup>; <sup>1</sup>University of Texas at Austin

— We tend to view ourselves and our close others through rose-colored glasses. Although behavioral research has shown that encouraging alternate information-processing corrects these biases, it remains unclear why these manipulations are effective. Is accuracy promoted because encouraging alternate processing elaborates on heuristics used to evaluate the self and close others? From this perspective, bias should be reduced by cognitive control. Or is accuracy promoted because alternate processing makes it difficult to perpetuate the cognitive control needed to emotionally regulate perceptions of the self and close others? In this case, bias should be supported by cognitive control mechanisms. Although mental load is often used to understand the extent to which a process involves cognitive control, people can overlearn cognitive control making it resilient to mental load. Another potential avenue for resolving these two perspectives is to examine the underlying neural systems of accuracy and bias in social evaluation. In a series of four fMRI studies, we found support for the view that bias results from heuristic processing because bias is reduced by activation in neural regions associated with cognitive control. Regardless of whether bias was operationalized as a “better than average” effect, a discrepancy between self-evaluation and actual task performance, or an overclaiming index, bias was reduced by recruitment of the orbitofrontal cortex and dorsal anterior cingulate cortex. Therefore, the neural systems that mediate social-evaluations parallel the neural systems involved in a broader class of judgment biases arising from heuristic processing (e.g., framing effects) rather than studies of emotion regulation.

namely, because power alters how people perceive, present, and manage the self. Finally, they posit the provocative notion that, beyond attracting narcissists, positions of power might actually \*lead\* to narcissism—a sobering possibility that ought to be examined more closely in future research.

### **ABSTRACTS**

### **POWER AND OVERCONFIDENT DECISION MAKING** Nathanael J. Fast<sup>1</sup>, Niro Sivanathan<sup>2</sup>, Adam D. Galinsky<sup>3</sup>, Nicole D. Mayer<sup>4</sup>; <sup>1</sup>University of Southern California, <sup>2</sup>London Business School, <sup>3</sup>Northwestern University, <sup>4</sup>University of Illinois, Chicago

— The recent global economic meltdown—considered the worst financial crisis since the Great Depression—occurred, in part, because powerful actors in financial and government institutions made poor decisions in the face of information that would guide them to do otherwise. The present set of findings offer one possible explanation for these actors’ departure from sound, rational decision making: Feeling powerful leads to overconfidence. Moving beyond research showing that power enhances perceived outcome control (Fast, Gruenfeld, Sivanathan, & Galinsky, 2009), four studies showed that power causes people to systematically overestimate their actual abilities to perform well on a variety of tasks. This link between power and overconfidence was robust, emerging regardless of whether the power was operationalized with a dispositional measure (Study 1), an experiential prime (Study 2), a measure of power in the workplace (Study 3), or random assignment to power roles in the laboratory (Study 4). Further, this power-overconfidence link persisted even when participants were offered financial incentives to be accurate (Studies 3 and 4). In addition, and consistent to the notion that illegitimacy blocks power’s activation of the behavioral approach tendencies (Lammers, Galinsky, Gordijn, & Otten, 2008), perceived legitimacy moderated the power-overconfidence effect (Study 4). In sum, results indicate that power leads to overconfidence among decision makers, so long as they feel they deserve their power. Implications for research on power, the self, and decision making will be discussed.

### **POWER LEADS TO CHARISMA** Senia Maymin<sup>1</sup>, Francis J. Flynn<sup>1</sup>; <sup>1</sup>Stanford University

— Charisma is often thought of as a source of power, an idea that is prevalent in both the popular and scholarly literatures. However, while many have posited that charisma leads to power, no research has examined the potential for the opposite relationship. Building on recent findings regarding the psychological effects of power, two studies examined this possibility. Results indicate that power can, indeed, lead to charisma. In one study, high-power actors were rated by participants as being more charismatic than actors with low-power. This was significant both on a one-item charisma measure and on the 20-item Conger-Kanungo charisma scale (Conger, Kanungo, Menon, & Mathur, 1997). In a second study, participants were primed with either high-power or low-power making a sales pitch about a food product to a listener (who was unaware of the presenter’s level of power). As predicted, being primed with power showed the tendency for presenters to be rated as being more charismatic than presenters who were not primed with power. Taken together, these studies suggest that power increases individuals’ capacity to adopt self-presentation styles that will be perceived as charismatic. Not only do participants tend to assume that high-power actors are charismatic, which can lead to self-fulfilling tendencies, but feeling powerful allows people to present themselves more charismatically as well. Implications for research on power, leadership, and charisma are discussed.

### **POWER AND REDUCED SENSITIVITY TO SIGNIFICANT OTHERS** M. Ena Inesi<sup>1</sup>, Kimberly Rios Morrison<sup>2</sup>; <sup>1</sup>London Business School, <sup>2</sup>The Ohio State University

— Recent research suggests that power decreases interpersonal sensitivity in a variety of ways. Compared to those not in positions of power, power holders objectify and stereotype others more and take their perspectives less. These effects have been demonstrated not only within the context of a power relationship but also in unrelated contexts

## **Symposia Session H**

**Saturday, January 30, 2:00 - 3:15 pm**

### **Symposia Session H1**

### **POWER AND THE (NARCISSISTIC) SELF: THE EFFECTS OF POWER ON SELF PERCEPTION, SELF PRESENTATION, GOALS FOR THE SELF, AND ETHICAL DECISION MAKING**

**Saturday, January 30, 2:00 - 3:15 pm, Royale Pavillion 1**

**Chairs:** Nathanael J. Fast, University of Southern California, and Senia Maymin, Stanford University

**Speakers:** Nathanael J. Fast, Senia Maymin, M. Ena Inesi, Jennifer R. Overbeck

Building on recent advances in the power literature, this symposium explores the transformative effects of power on the self. Four papers indicate that power leads to a variety of tendencies that are commonly associated with narcissism. Fast and colleagues show that power fosters overconfidence in the self, leading to irrational—and financially costly—decision making. Maymin and Flynn show that power increases people’s abilities to display charisma as well as to be perceived as charismatic by others. Inesi and Morrison demonstrate that power buffers people from being influenced by significant others, leaving them freer to pursue their own goals. Finally, Overbeck and colleagues demonstrate that power leads to egocentric ethical decision making; specifically, powerful decision makers tend to draw on their own conceptions of what is right and wrong, rather than considering how their decisions will affect others. Taken in concert, these closely interrelated lines of research offer several important contributions. First, by placing the study of power squarely on the self, they point the power literature in a new direction, setting the stage for mutually beneficial interactions between the literatures on power and the self. Second, they offer novel answers to the question of why power holders tend to be action-oriented and disinhibited—

(i.e., with those outside the power relationship). These disparate effects suggest that power may fundamentally alter the way people think about and act on relationships, both inside and outside the situation of power. In particular, power may decrease individuals' sensitivity to the activation of non-conscious relational schemas. Relational schemas are mental representations that an individual develops regarding the goals, attitudes and values that a significant other holds for him or her. When reminded of the significant other outside of conscious awareness, the individual is normally more likely to act on and express goals, attitudes and values that are consistent with the relational schema, in order to maintain the relationship. However, we predict that power holders should be less likely than those not in power to act on a significant other's goals when reminded of him or her. We test this prediction using several different significant others (i.e., mothers, grandparents, romantic partners) and goals (i.e., achievement, conservatism, healthy eating). Across four experiments, we show not only that those in power are less likely to assimilate to the goals and attitudes of a significant other, but also that they may be more likely to react against these goals and attitudes.

**I KNOW WHAT'S BEST FOR YOU (AND EVERYONE): POWER, SELF-CENTERED ETHICAL REASONING, AND THE COST OF NOT "GRAPPLING"** Jennifer R. Overbeck<sup>1</sup>, Leigh Plunkett Tost<sup>2</sup>, Abbie Wazlawek<sup>3</sup>; <sup>1</sup>University of Southern California, <sup>2</sup>Duke University, <sup>3</sup>Columbia University – Do powerful and powerless people use different ethical reasoning? And, if so, is powerholders' ethical reasoning style related to the common perception that "power corrupts"? We conducted three short studies to examine these issues. Studies 1 and 2 asked high- and low-power participants to respond to classic "lifeboat problem" ethical questions, and found that high-power respondents were more likely to use deontological reasoning—that is, to be guided by a sense of absolute principles—whereas low-power respondents were more likely to use consequentialist reasoning—that is, weighing costs and benefits of different options. The two studies used different operationalizations of power (experiential priming via personal essay in Study 1; implicit priming via word completion in Study 2), providing convergent evidence for the effect and dismissing an explanation based on self-justification motives. In Study 3, participants read short vignettes describing several ethical decisions made by two company owners. One owner was consistently deontological and one was consistently consequentialist, but both made equal numbers of ethical and unethical decisions. Participants reported greater interest in working for the consequentialist boss, and judged him more positively. Together, our results suggest that powerful people's ethical reasoning reflects a relatively fixed perspective in which powerholders feel entitled to judge (Leyens, Yzerbyt, & Schadronek, 1992) based on an internal preference (e.g., Overbeck, Tiedens, & Brion, 2006). This is perceived by lower-power observers, though, as a failure to properly grapple with the issues and stakeholders involved, and as a result the powerholders are judged negatively for their reasoning.

## Symposia Session H2

### BLOCK AWARD ADDRESS

**Saturday, January 30, 2:00 - 3:15 pm, Royale Pavilion 2**

**Recipient: Paul T. Costa, Jr., National Institute of Aging**

**Introducer: David C. Funder, University of California, Riverside**

This talk celebrates the contributions of the Five-Factor Model (FFM) of personality traits to a variety of research areas, ranging from molecular genetics to cross-cultural studies. I will focus on three areas: (1) Longitudinal studies of the broad factors and specific facets that have refined our understanding of trait stability and change over the life-span. (2) The interface between personality and health, specifically the association between traits and health risk/protective behaviors, physiological biomarkers of disease, and longevity. And (3) application of the FFM framework to psychiatric disorders and the FFM as an alternative approach to assessing and treating DSM personality disorders.

## Symposia Session H3

### BALANCING CLOSENESS AND DISTANCE IN INTIMATE RELATIONSHIPS

**Saturday, January 30, 2:00 - 3:15 pm, Royale Pavilion 5**

**Chairs: Gertraud Stadler and Niall Bolger, Columbia University**

**Speakers: Gertraud Stadler, Masumi Iida, Benjamin R. Karney**

Balancing closeness and distance in relationships is a common challenge. Usually closeness between intimate partners is viewed as desirable and has been the focus of many studies. However, distance may also be important in protecting and maintaining relationships, especially in times of stress (Repetti, 1992). Previous research on distance in intimate relationships is limited and has mostly highlighted its negative effects. This symposium brings together three perspectives on studying couples' psychological and physical distance, highlighting the potential for the positive and protective effects of distance. The first presentation shows that people may want space from a partner as a desired means of support in stressful situations. The second presentation demonstrates that spouses' well-intended efforts in chronic disease management can undermine closeness in their relationships: When spousal influence is experienced as pressure it can create tension in the relationship. The third presentation looks at the long-term effect of physical distance on relationship closeness and duration. All three studies present longitudinal data that allow the researchers to examine how closeness and distance affect relationships over time. The first two studies include the perspective of both partners and use daily diary methods. The third study illustrates the real-world relevance of studying physical distance and how partners maintain closeness in spite of physical distance.

#### ABSTRACTS

### "GIVE ME SPACE" AS A DESIRED WAY OF SUPPORT IN RELATIONSHIPS ACROSS QUESTIONNAIRES, DAILY DIARIES, AND LABORATORY SUPPORT DISCUSSIONS

Gertraud Stadler<sup>1</sup>, Niall Bolger<sup>1</sup>, Kenzie Snyder<sup>1</sup>, Sarah Burns<sup>1</sup>, Alexandra Suppes<sup>1</sup>, Jamil Zaki<sup>1</sup>, Patrick E. Shrout<sup>2</sup>; <sup>1</sup>Columbia University, <sup>2</sup>New York University – Wanting space from a partner may be a more common desire in stressful situations than previously thought. The current study investigated dyadic support processes in couples, and coded if individuals wanted space from their partner when distressed. Three hypotheses were tested: (1) Individuals might want space from their partner when distressed. (2) Individuals who report wanting space from their partner when distressed have lower relationship satisfaction. (3) More men want space from their partner when distressed than women. Participants (n = 193 in 97 couples) reported their dyadic support processes in questionnaires and 183 participants filled out daily diaries. A subsample of 40 couples also participated in support discussions in the lab. The current study supported the hypotheses: One in four male partners and one in twenty female partners mentioned wanting space when distressed. Participants who wanted space under stress perceived less support from their partners and others, evaluated support as less beneficial when they reported receiving it, and sought less support overall than participants who did not report wanting space. This pattern held for both emotional and practical support in the diaries. Similar results were found in laboratory support discussions. These results provide a new perspective on the interplay between individual and dyadic coping.

### SPOUSES' INVOLVEMENT IN CHRONIC DISEASE MANAGEMENT IMPACTS DAILY RELATIONSHIP EVALUATIONS

Masumi Iida<sup>1</sup>, Mary Ann Parris Stephens<sup>1</sup>, Melissa M. Franks<sup>2</sup>, Karen S. Rook<sup>3</sup>, James K. Salem<sup>4</sup>; <sup>1</sup>Kent State University, <sup>2</sup>Purdue University, <sup>3</sup>University of Irvine, <sup>4</sup>SUMMA Health System – Spouses are most often the source of support and control in patients' adherence to medical recommendations in a variety of chronic conditions; however, little is known about the consequences of caregiving spouses' behaviors on the quality of the marital relationship. In this electronic diary study (N = 129 couples), we examined various ways spouses are involved with the management of their diabetic partners'

daily dietary choices over 24 days. We focused on spouses' support (i.e., efforts to reinforce patients' ongoing dietary adherence), persuasion (i.e., efforts to convince or motivate patients to stick to the diabetic diet) and pressure (i.e., efforts to force or coerce patients to improve dietary adherence) as they effect patients' daily evaluations of the relationship (relationship tension and enjoyment). On the days when spouses provided support, patients' reported greater relationship enjoyment and less relationship tension. In contrast, on the days when spouses engaged in pressure efforts, patients reported greater relationship tension, but spousal support was not associated with patients' relationship enjoyment. Spousal persuasion was not associated with either relationship tension or enjoyment. Taken together, these findings suggest that spousal support improves the quality of partner interactions, whereas spouses' attempts to pressure patients to adhere to dietary regimen may negatively impact the quality of partner interactions.

**DISTANT BUT STABLE: THE UNEXPECTED EFFECTS OF DEPLOYMENT ON MILITARY MARRIAGES** Benjamin R. Karney<sup>1</sup>, John S. Crown<sup>2</sup>; <sup>1</sup>UCLA, <sup>2</sup>RAND Corporation – When partners in intimate relationships are separated by long distance, their relationships tend to fray and are at increased risk for dissolving. Since 2001, spouses in military marriages have had to endure lengthy periods of long distance, as deployments to the conflicts in Iraq and Afghanistan have been more frequent and lengthier than at any other time since the birth of the all volunteer military in 1973. How have these separations affected the stability of military marriages? To address this question, the analyses described here drew from the personnel records and deployment histories for the entire population of the United States military to estimate the effects of time deployed in the Global War on Terror on the subsequent risk that a military couple will dissolve their marriage. Contrary to expectations, time deployed was associated with reduced risk of marital dissolution for most of the military, and longer time deployed was associated with greater reductions in risk. Moreover, the benefits of deployment were greater for younger couples and couples with children. Explanations for these findings focus on the circumstances under which separations can benefit couples: when the separation serves a shared common value, when the separation is perceived as an investment in the post-separation future, and when supportive communities and institutions are available. Consistent with these explanations, deployments had the greatest positive effects on marriages with the most to gain from enduring the separation.

#### Symposia Session H4

### HOW WE FEEL ABOUT 'THEM': EMOTIONAL RESPONSES TO OUTGROUPS' PLEASURES AND PAINS

Saturday, January 30, 2:00 - 3:15 pm, Royale Pavilion 6

Chair: Mina Cikara, Princeton University

Speakers: Max Weisbuch, Matteo Forgiarini, Mina Cikara, Wilco Van Dijk

How do people respond to outgroup targets' suffering? A cursory reading of the emotion, empathy, and mirror neuron literatures might leave one with the impression that people automatically feel pity or empathy in response to seeing another person in distress. Recent developments in intergroup and emotions research suggest otherwise: People frequently fail to empathize and sometimes even feel pleasure at others' pain. This symposium highlights research on how group membership influences reactions to others' positive and negative experiences. Weisbuch presents research which shows that ingroup members' emotional displays elicit congruent affect (e.g., ingroup joy is positive), whereas outgroup members' emotional displays elicit affective divergence (e.g., outgroup joy is negative). Forgiarini demonstrates that white participants show reduced skin conductance response to black targets' as compared to white targets' pain and that this pattern correlates with implicit race bias. Cikara discusses the neural correlates of Schadenfreude—pleasure at others' misfortunes—in the context of the Red Sox/Yankees rivalry, with an emphasis on the implications of these systems for perpetuation of

conflict. Finally, van Dijk shows that Schadenfreude is motivated in part by a desire to maintain and enhance a positive evaluation of the self. Pleasure at another's pain can perpetuate conflict and prevent reconciliation, so understanding its emotional dynamics can improve interpersonal and intergroup functioning.

#### ABSTRACTS

**AFFECTIVE DIVERGENCE** Max Weisbuch<sup>1</sup>, Nalini Ambady<sup>1</sup>; <sup>1</sup>Tufts University – Extant theory suggests that targets' emotion expressions automatically evoke similar affect in perceivers. Yet in most studies supportive of such "emotion contagion," the group memberships of targets and perceivers are held constant. In contrast to this approach and drawing from ecological theories of social perception, we argue that the self-relevant meaning ("signal") of an emotion expression cannot be isolated from social identity. Group membership should provide a functionally limiting condition to emotion contagion by specifying the signal of the expressed emotion. Specifically, ingroup fear and ingroup joy likely signal danger and safety, respectively, for the perceiver—consequently, emotion contagion should result. Conversely, outgroup fear and outgroup joy signal relative strength (safety) and weakness (danger), respectively, for the perceiver—consequently, perceivers' affective responses should diverge from those of expressers. Across several studies, affective responses to facial, vocal, and verbal emotion were congruous with same-group emotion expressions but diverged from other-group emotion expressions. These effects held for racial, political, and sports groups, for subliminal as well as supraliminal emotion stimuli, and with reaction-time, paraverbal, and self-report measures of affect. Additional evidence suggested that perceivers' felt dominance and fear played important roles in these effects. These data support a signal-value model in which emotion expressions signal environmental conditions.

**RACISM AND INDIFFERENCE TO THE PAIN OF OTHER PEOPLE** Matteo Forgiarini<sup>1</sup>, Marcello Gallucci<sup>1</sup>, Angelo Maravita<sup>1</sup>; <sup>1</sup>University of Milano-Bicoccaforgiar@wjh.harvard.edu – Empathy is the ability to understand and share the feelings and thoughts of other people. One of the main sources of empathic feelings is the pain experienced by other human beings. Empathy for others' pain, in turn, regulates behavior among individuals and social groups. Feeling other people's suffering triggers prosocial behavior, which promotes helping and encourages cooperation. With two different experiments we investigated the existence of a racial bias in the empathic reaction to other people's pain. Empathic reactions were measured via Skin Conductance Responses (SCR) to observed video stimuli showing human subjects experiencing either harmless or painful somatosensory stimuli. We provide, for the first time, experimental evidence that automatic, physiological reactions to other people's pain depend on the race of the person in pain. The first experiment showed that Caucasian observers reacted to pain suffered by African people significantly less than to pain of Caucasian people. In a second experiment we replicated the effect and we showed that the reduced reaction to the pain of African individuals is also correlated with the observers' individual implicit race bias. Our data suggest that the attitude towards other races may involve automatic and physiological reactions. Such a fundamental racial differentiation may bias complex activities and judgments over and beyond human consciousness. An assessment of other people's pain, in fact, is a necessary skill in many human activities, from medical decisions, rescue operations, police intervention, policy making and, in extreme circumstances, use of physical force and punishment.

**RED SOX V. YANKEES: FMRI INVESTIGATION OF PAIN AND PLEASURE RESPONSES TO A RIVAL GROUP'S OUTCOMES** Mina Cikara<sup>1</sup>, Matthew Botvinick<sup>1</sup>, Susan Fiske<sup>1</sup>; <sup>1</sup>Princeton University – Because competitive groups' misfortunes imply own-group's relative gain, outgroups' misfortunes can engender pleasure. Pleasure at others' misfortunes, Schadenfreude, may inhibit empathy toward groups in need, at best allowing indifference toward their suffering, and at worst facilitating

active harm. In the current fMRI study, 10 Red Sox and 6 Yankees fans watched baseball plays featuring their favored teams and rivals playing one another and a neutral third team, the Orioles. After each play, participants reported pleasure, anger, and pain in response to the play's outcome. Favored team-success, rival-failure, and rival-failure against the neutral team (pure Schadenfreude) all elicited significantly more pleasure than the control condition (Orioles v. Blue Jays). Favored-team-failure and rival-success elicited significantly more anger and pain than the control condition. Regions of the ventral striatum—putamen, nucleus accumbens—were activated by 'pleasurable' baseball plays as compared to the control; putamen activation correlated with subjective ratings of pleasure. Also, activation in anterior cingulate cortex and insula—regions part of a well-established pain network—corresponded to "painful" baseball plays; insula activation correlated with subjective ratings of pain, but not anger. These results suggest that evolutionarily old brain systems, which also respond selectively to more basic reinforcers and punishments (e.g., juice, pain, respectively), may have adapted to integrate information about rewards as abstract as favored group-identity and positive or negative outcomes in intergroup competition. This is the first study of which we are aware to investigate the neurobiological correlates of group-identity based pleasure and pain.

#### **EXPERIENCING SCHADENFREUDE: THE SELF-ENHANCING PROPERTIES OF ANOTHER'S MISFORTUNE**

Wilco Van Dijk<sup>1</sup>, Jaap Ouwkerk<sup>1</sup>, Guido van Koningsbruggen<sup>2</sup>, Yoka Wesseling<sup>1</sup>; <sup>1</sup>VU University Amsterdam, <sup>2</sup>Utrecht University—The aim of the present research was to provide empirical support for the contention that a desire to maintain and enhance a positive evaluation of the self constitutes an underlying motive for Schadenfreude. Findings of two series of studies are in line with our contention. Results of the first series of studies showed that low self-esteem participants experienced more Schadenfreude than high self-esteem participants, and participants who had received negative performance feedback experienced more Schadenfreude than participants who had received positive feedback or no feedback. Moreover, participants in a "double whammy" situation—the combination of low self-evaluation and negative performance feedback—were especially likely to experience Schadenfreude toward another's misfortune. In the second series of studies, results showed that participants' experienced Schadenfreude was positively related to their self-enhanced feelings. Moreover, findings showed that low self-esteem participants who had an opportunity to self-affirm experienced less Schadenfreude than those who had no opportunity to self-affirm. Thus, another's misfortune may provide people with an excellent opportunity for self-enhancement. People's painful feelings of inferiority may be lifted and their feelings of self-worth may be reaffirmed, since the misfortunes of others emphasize their relative good position, and this self-enhancing aspect of downward comparison enables them to derive pleasure from it. That is, people might not be pleased by another's misfortune per se, but the misfortune yields Schadenfreude because it satisfies their concern to maintain and enhance a positive evaluation of the self.

#### **Symposia Session H5**

#### **DO I BELONG HERE? IDENTIFYING FACTORS THAT FORTIFY VS. ATTENUATE WOMEN'S SENSE OF BELONGING IN STEREOTYPICALLY MASCULINE ACADEMIC AND PROFESSIONAL DOMAINS**

Saturday, January 30, 2:00 - 3:15 pm, Royale Pavillon 3-4

Chairs: Jane Stout and Nilanjana Dasgupta, University of Massachusetts, Amherst

Speakers: Jennifer Steele, Lisa Rosenthal, Jane Stout, Christine Logel

Although the number of women in influential professional roles has been rising over the past few decades, change has been slow and the representation of women in these roles still pales in comparison to that of men. At face value, it seems that women are given the same opportuni-

ties to pursue jobs and roles that are typically held by men; why then don't more women pursue them? The current symposium brings together four lines of research that address this question. Collectively, these research programs examine (a) how girls' and women's sense of belonging in stereotypically masculine academic and professional domains develop from childhood to adulthood, (b) environmental cues that influence women's motivation to pursue and persist in these domains, and (c) interventions that women might use in identity-threatening environments to strengthen their sense of belonging. Specifically we address the questions: When in development do young girls begin to demonstrate knowledge that their gender is negatively stereotyped in influential and esteemed careers, such as math and science (Steele)? Among young women who do pursue higher education in math and science, how does social support and identity influence their likelihood of continuing on that career path (Rosenthal)? When entering the workforce, what sort of common linguistic practices subtly ostracize women in professional environments and what impact does this have on their self-concept (Stout)? And when women do find themselves in identity-threatening environments, what strategies can they use to bolster their sense of belonging and eliminate threat-based deficits in performance (Logel)?

#### **ABSTRACTS**

#### **THE DEVELOPMENT OF MATH=MALE: IMPLICIT ACADEMIC STEREOTYPING IN YOUNG CHILDREN**

Jennifer Steele<sup>1</sup>, Amanda Williams<sup>1</sup>; <sup>1</sup>York University—Why are there fewer women than men pursuing and succeeding in prestigious careers in math and science? We argue that gender stereotypes, particularly implicit stereotypes, provide a continuing, yet in many ways "hidden" barrier to women's advancement in these domains. Building on emerging evidence that implicit gender stereotypes about math and science predict adults' interest and performance in these domains (Kiefer & Sekaquaptewa, 2008; Nosek et al., in press), in the present research we examined when these automatic associations develop and whether individual differences in implicit stereotyping predict children's orientation towards and performance in these domains. Participants included 147 predominantly White children in middle to late elementary school (Mage = 10 years; Study 1) and 103 children in early elementary school (Mage = 7 years; Study 2). Although we found little evidence of a relationship between implicit stereotyping and either orientation or performance in our child samples, we found that by middle elementary school (Mage = 9 years) children had acquired an implicit math-gender stereotype that did not correspond to their explicit beliefs (Study 1). In addition, we provide some initial data to suggest that this bias might begin to emerge in the early elementary school years (Study 2). These findings suggest that much like evaluative systems (Dunham et al., 2008), category-based associations about academics emerge early in life and may remain relatively stable into adulthood. The theoretical and practical implications and potential consequences for future generations of budding female scientists will be discussed.

#### **IDENTITY COMPATIBILITY AND SOCIAL SUPPORT PROMOTE WOMEN'S ENGAGEMENT IN STEM DURING THE COLLEGE TRANSITION**

Lisa Rosenthal<sup>1</sup>, Bonita London-Thompson<sup>1</sup>, Marci Lobel<sup>1</sup>, Sheri Levy<sup>1</sup>; <sup>1</sup>Stony Brook University—The underrepresentation of women in science, technology, engineering, and mathematics (STEM) fields has long been linked to gender discrimination in STEM environments. Building on prior work, we developed an Academic and Social Engagement (ASE) Model that highlights psychosocial factors within STEM environments that affect women's pursuit of STEM careers. The Model proposes that college women will experience greater engagement and persistence in STEM when they perceive greater compatibility between being a woman and being a STEM major, and when they have greater social support. Because the college transition is a critical period when students typically question their abilities, fit, and potential for success, this project tested the ASE model among female STEM majors across the transition (questionnaire before classes began [background], daily diary during the first

three weeks of college, and questionnaire at beginning of spring semester [spring follow-up]). Regression analyses at background and spring follow-up revealed that women reporting greater perceived compatibility between their gender and STEM, and greater support from close others, also reported greater sense of belonging in STEM at both time points. Hierarchical linear modeling analyses on the daily diary data revealed that within individuals, on days that women reported greater perceived compatibility between their gender and STEM, and on days when women reported feeling more supported, they also reported greater sense of belonging in STEM. Consistent with the ASE model, these findings suggest that during the college transition, social support and identity compatibility are key ingredients of women's STEM engagement.

**WHEN HE DOESN'T MEAN YOU: GENDER-EXCLUSIVE LANGUAGE AS OSTRACISM FOR WOMEN** Jane Stout<sup>1</sup>, Nilanjana Dasgupta<sup>1</sup>; <sup>1</sup>University of Massachusetts, Amherst – Three experiments investigated whether a common linguistic practice, the use of masculine gender-exclusive language to refer to men and women, subtly ostracizes women and threatens their sense of belonging in professional environments. Gender-exclusive language, which neglects references to one gender, is consistent with Williams's (2007) definition of ostracism: "being ignored or excluded....without excessive explanation or explicit negative attention." In Study 1, women and men read a description of a work environment that used either masculine gender-exclusive language (We usually know a good employee when we see him) or gender-inclusive language (him or her). Women experienced a lower sense of belonging and less motivation to pursue the job when they read gender-exclusive versus gender-inclusive language; men's responses did not vary by language. Study 2 replicated these findings in a face-to-face mock job interview. Study 3 covertly videotaped women's nonverbal behavior during a mock job interview to assess their online affective reactions. Results showed nonverbal negative affect over the course of the interview in the gender-exclusive condition versus gender-inclusive and gender-neutral conditions. Moreover, stronger nonverbal negative affect predicted less motivation to pursue the job in the gender-exclusive condition but not in the gender-inclusive or gender-neutral conditions. Together, these findings suggest that linguistic ostracism, although subtle, is an aversive experience for women and leads them to avoid or leave professional contexts in which the language is used.

**AN INTERVENTION TO IMPROVE VULNERABLE STUDENTS' GRADES BY ADDRESSING UNCERTAINTY ABOUT SOCIAL BELONGING** Christine Logel<sup>1</sup>, Gregory M. Walton<sup>1</sup>, Jennifer Peach<sup>2</sup>, Stephen J. Spencer<sup>2</sup>; <sup>1</sup>Stanford University, <sup>2</sup>University of Waterloo – The present study tested two interventions to reduce belonging uncertainty and to raise the academic performance of engineering students, especially among female engineers, a group that is underrepresented and negatively stereotyped. One treatment was designed to change students' attributions for negative experiences in engineering that could otherwise undermine their sense of belonging in the field. The second was designed to teach students to affirm personally important values in times of stress and threat (see Cohen et al., 2007), and thereby raise their sense of belonging. Results showed that among engineering majors with fewer women, end-of-term grades of women in the control condition were significantly lower than men's. However, in the treatment conditions, women's grades were equal to men's. Discussion addresses the role of belonging in achievement, and mechanisms by which social-psychological interventions have long-term effects on school performance.

## Symposia Session H6

### THE DIFFERENTIATION OF POSITIVE EMOTIONS: RECENT ADVANCES IN THEORY AND RESEARCH ON POSITIVE EMOTIONS

Saturday, January 30, 2:00 - 3:15 pm, Royale Pavilion 7-8

Chairs: Michele M. Tugade, Vassar College, and Leslie D. Kirby, Vanderbilt University

Speakers: Craig A. Smith, Michelle N. Shiota, Michele M. Tugade, Anthony H. Ahrens

Both traditional and contemporary theories of emotions tend to propose a general function of positive affect. This symposium examines the distinct motivational and adaptative functions served by different positive emotions, and considers the implications of these functions for cognitive, behavioral, and psychosocial outcomes. Smith and Kirby present research from a multi-site study, showing that a broad range of positive emotions can be uniquely characterized based on profiles of appraisals, motivations (emotivational goals) and behaviors. These findings indicate that there is considerable differentiation among positive emotional states, both in terms of antecedents and consequences. Shiota offers evolutionary accounts of multiple positive emotions, emphasizing their distinct fitness-enhancing functions, and presents research addressing the differing effects of these emotions on cognitive outcomes such as persuasive message processing, stereotyping, and creativity. Tugade & Morrow investigate the distinct qualities of positive emotions, considering whether they differentially help or hinder the stress response. Their findings reveal that select positive emotions function differently with respect to coping and problem-solving. Some people are better able to differentiate amongst positive emotions, thereby gaining from the informational value provided by these unique experiences. Ahrens & McIntosh discuss individual differences in the ability to differentiate amongst positive emotions, showing that this ability is associated with beneficial outcomes in mental and physical health. Together, these papers highlight the multiple ways that positive emotions can be differentiated from one another, as well as the consequences of this differentiation for personal and interpersonal functioning.

#### ABSTRACTS

**PLEASURE IS COMPLICATED: ON THE DIFFERENTIATION OF POSITIVE EMOTIONAL EXPERIENCE** Craig A. Smith<sup>1</sup>, Leslie D. Kirby<sup>1</sup>; <sup>1</sup>Vanderbilt University – Most major theories of emotion posit the existence of only one or two distinct positive emotional states (happiness and often interest) in contrast to a much broader array of distinct negative states (e.g., sadness, anger, guilt, fear, disgust, etc.). However, there are some indications of more differentiation among positive states than these theories suggest. We report the results of a multi-site study (N = 285) that examines this potential differentiation across a broad range of positive states (awe, challenge/determination, contentment, gratitude, happiness, hope, interest and pride), by comparing not only the appraisals associated with these states, but also their associated motivational tendencies ("emotivational goals,") and enacted behaviors, using a new instrument – the Emotivational Goals and Enacted Behavior Scale (EMGEBS) – developed for this purpose. Each participant recalled and described a single past experience associated with one of the targeted emotions, and then rated their appraisals, felt emotions, emotivational goals and enacted behaviors during the remembered experience. Although the emotion ratings were substantially intercorrelated, each targeted emotion demonstrated distinctive, statistically reliable relations with at least one appraisal and at least one emotivational goal and/or enacted behavior -- even after controlling for the variance attributable to both the other emotions and the other variables in the predictor set. Thus each emotion demonstrates a unique profile that sets it apart from the other positive emotions, indicating considerable differentiation among positive emo-

tions. The likely significance of the observed differentiation in terms of the adaptational functions served by positive emotions will be discussed.

**I KNOW WHAT I WAS FEELING, BUT WHAT WAS I THINKING?: AN EVOLUTIONARY APPROACH TO STUDYING POSITIVE EMOTIONS AND COGNITION** Michelle N. Shiota<sup>1</sup>; <sup>1</sup>Arizona State University – In recent decades, a rich body of work has documented the implications of positive affect for a wide range of cognitive processes. The theme emerging from these findings is that positive affect promotes rosy, heuristic-based, flexible and creative thinking with enhanced emphasis on the “big picture.” However, an evolutionary perspective – defining emotions as superordinate neural programs integrating cognitive, physiological, and behavioral elements to facilitate a fitness-enhancing response to prototypical elicitors – suggests the existence of multiple positive emotions with differing functions, and therefore somewhat differing effects on cognition. Theorists have begun to offer functional accounts of several positive emotions, such as reward-focused enthusiasm, contentment, pride, attachment love, nurturant love, amusement, and awe. This talk presents recent data addressing the implications of different positive emotions for cognitive processes such as creativity, stereotyping, persuasive message processing, and product evaluation. Findings support the proposal that particular positive emotions activate cognitive processes and biases that facilitate the appropriate fitness-enhancing response, while inhibiting processes and biases likely to interfere with the appropriate response. Theoretical and methodological implications for future research on positive emotion are discussed.

**WHERE POSITIVE EMOTIONS MEET AND WHERE THEY DIVERGE: THE EFFECTS OF DISTINCT POSITIVE EMOTIONS ON COPING AND PROBLEM-SOLVING** Michele M. Tugade<sup>1</sup>, Jannay Morrow<sup>1</sup>; <sup>1</sup>Vassar College – It is well-established that positive emotions are important for coping with stress. Newer research indicates a need to investigate the distinct qualities of positive emotions and consider whether they differentially help or hinder the stress response. This talk focuses on how, when, and why distinct positive emotions are important for coping and problem-solving. In one study, we tested whether specific positive experiences influence how people confront stressors. After being induced to experience one of eight positive emotions (awe, challenge/determination, contentment, gratitude, happiness, hope, interest, or pride), participants reported their general coping tendencies. Activating select positive emotions differentially influenced people’s perceptions of which coping strategies to employ. In addition, individuals who differentiate more amongst positive emotions use more adaptive coping strategies. In another study, we examined whether and how different positive emotions are useful for problem-solving following a stressor. Research shows that positive emotions facilitate flexible thinking; yet, it may be premature to argue that all positive emotions function the same way. Immediately after being induced to experience anxiety, participants were randomly assigned to experience one of five positive emotions (challenge/determination, contentment, gratitude, interest, or pride). Participants then completed a mental-set-switching task. Except for challenge, all positive emotions facilitated mental-set-switching. When feeling challenged, people may be less likely to abandon established modes of thought, especially if a strategy is working. In contrast, when experiencing other positive emotions, people may explore and discover alternative strategies. We discuss the shared as well as goal-specific mechanisms underlying positive emotions in coping and problem-solving.

**DISTINGUISHING OUR PLEASURES: PEOPLE VARY IN THEIR DIFFERENTIATION OF POSITIVE EMOTIONS** Anthony H. Ahrens<sup>1</sup>, Elizabeth M. McIntosh<sup>2</sup>; <sup>1</sup>American University, <sup>2</sup>Mental Health Center of Boulder County, Colorado – Distinct emotions, including positive emotions, prepare people to engage in distinct behaviors. The ability to differentiate between distinct positive emotions should, then, help people more effectively match their emotion-prepared behaviors to their current contexts. We examined correlates of individual differences in the ability to distinguish between positive emotions. In a first study, participants reported their

likely emotions (including gratitude, happiness, pride, and relief) in response to hypothetical scenarios involving favorable events. For each individual, we calculated the average intercorrelation of these emotions across the scenarios. Those who differentiated more reported lower fear of emotions and were higher in the mindfulness facet of acceptance without judgment. After controlling for initial health symptoms, the tendency to differentiate also marginally predicted lower health symptoms two weeks later. In a second study, we developed a measure of the tendency to differentiate between a wider range of positive emotions. Participants imagined themselves in vignettes, each designed to elicit a particular positive emotion, including awe, challenge/determination, contentment, gratitude, happiness, hope, interest, and pride. Once again, the average within-participant intercorrelation of emotion ratings served as the measure of differentiation. Differentiation between these eight emotions was positively correlated with the mood repair subscale of the Trait Meta-Mood Scale (Salovey et al., 1995) and with measures of emotional well-being and social functioning. It was negatively correlated with measures of physical pain and the degree to which one’s health interferes with one’s activities. Differentiation of positive emotion appears to be adaptive and might arise from ongoing attention to emotional experience.

## Symposia Session I

### Saturday, January 30, 3:30 - 4:45 pm

---

#### Symposia Session I1

#### UNITED AND DIVIDED WE STAND: ON THE COLLECTIVE AND PERSONAL FUNCTIONS OF CONFORMITY AND DISSENT

Saturday, January 30, 3:30 - 4:45 pm, Royale Pavilion 1

Chairs: Kimberly Rios Morrison, The Ohio State University, and Dominic J. Packer, Lehigh University

Speakers: Carsten K. W. De Dreu, Jolanda Jetten, Dominic J. Packer, Kimberly Rios Morrison

Exciting new research that takes a functional approach to conformity and dissent is changing the ways in which psychologists think about these behaviors. This symposium highlights an international array of research, addressing how conformity and dissent affect group outcomes and serve functions at collective and personal levels of identity. De Dreu shows that positive effects of dissent on group creativity and innovation extend beyond the laboratory to real-world organizations, and identifies conditions under which dissent helps versus hurts collective outcomes. Challenging traditional perspectives which predict conformity [dissent] to be greater among prototypical [peripheral] group members, Jetten finds that peripheral members are often more likely than prototypical members to exhibit conformity in strategic efforts to improve their position within the group. Packer further investigates the role of collective identification in dissent, and presents evidence that strongly identified members are willing to express dissent when they believe that doing so will benefit their group. Packer also explores effects of personality traits on dissent, observing greater dissent among individuals high in both openness and conscientiousness, independent of their level of collective identification. Morrison investigates the utility of dissent for personal identity, showing that minority opinion expression is a means by which individuals can restore the self-concept in the face of uncertainty. Taken together, this research highlights the diversity of personal and collective functions served by conformity/dissent, and invites renewed consideration of how individuals manage their identities within groups.

## ABSTRACTS

**WHEN DISSENT DOES (NOT) HELP GROUP CREATIVITY AND INNOVATION** Carsten K. W. De Dreu<sup>1</sup>; <sup>1</sup>University of Amsterdam – There is some evidence that expressing (minority) dissent stimulates targets to engage in divergent thinking, increases their cognitive flexibility, and thus facilitates individual as well as group creativity and innovation. Much of this work has been limited to ad hoc groups in laboratory settings, begging the question of how expressing dissent in ongoing groups where members share a history and a future affects the dissenter as well as his or her targets. Furthermore, almost without exception this past work focused on the main effect of dissent on creativity, and did not address conditions that constrain or facilitate the putatively positive effects of dissent. This presentation considers these two issues. On the basis of a series of (un)published studies it examines implications for expressing dissent in organizational teams, such as project, decision-making, and top management teams. These works reveal that the positive functions of dissent generalize beyond the artificiality of the laboratory, and additionally highlight when and why dissent helps or hinders group creativity and innovation.

**KEEPING UP APPEARANCES: THE STRATEGIC AND CONDITIONAL NATURE OF PERIPHERAL GROUP MEMBERS' LOYALTY EXPRESSIONS** Jolanda Jetten<sup>1,2</sup>, Matthew J. Hornsey<sup>1</sup>; <sup>1</sup>University of Queensland, <sup>2</sup>University of Exeter – Social psychologists have made important advances in understanding group behavior, particularly that of established or “prototypical” group members. Though less often investigated, newcomers or “peripheral” group members are potentially more intriguing because their behaviors have proven to be more difficult to predict compared to those of more established members. Peripheral group members display a variety of group behaviors, ranging from high involvement and group commitment to inaction or even disloyalty and deviance. We present a range of studies examining the strategic nature of newcomers' loyalty expressions. We first examined the hypothesis that people will strategically portray the self as being more group-influenced the more junior they feel within the group. We found among social psychologists that ratings of self-conformity by group members were greater the lower status the participant. Other studies provided evidence for the argument that junior members were partly driven by a need to endear themselves to other group members. For instance, junior group members described themselves as more conformist than senior members when they were addressing an ingroup compared to an outgroup audience and they rated themselves as more conformist when they were led to believe their responses were public than when responses were private. A final study showed though that there are limits to newcomers' strategic behavior. We found among female rugby players that newcomers were more sensitive to what the social context affords in determining the utility and costs of expressing group loyalty – their loyalty expressions were strategic, but also conditional.

**THE INFLUENCE OF SOCIAL IDENTITY AND PERSONALITY VARIABLES ON DISSENT: COLLECTIVE IDENTIFICATION, AND OPENNESS TO EXPERIENCE X CONSCIENTIOUSNESS** Dominic J. Packer<sup>1</sup>; <sup>1</sup>Lehigh University – Recent research suggests that two broad psychological factors are necessary for group members to dissent: the capacity to form alternate perspectives on group issues, and the motivation to publicly express them. This presentation will examine the influence of social identity and personality variables on these factors and their role in dissent. With respect to the influence of social identities, I will argue that adopting a collective sense of self (self-categorizing) is not antithetical to forming certain types of alternate perspectives on group issues, and that collective identification may motivate their articulation. As such, Studies 1 and 2 found that identification with a group increased members' vigilance with respect to group-related problems and motivated expression of dissenting opinions when normative opinions were perceived to be collectively-harmful (measured and manipulated). With respect to the

influence of personality variables, openness to experience may predispose individuals toward the formation of alternate perspectives, while conscientiousness may motivate expression of deviant opinions once they have been formed. Studies 3 and 4 evidenced this interactive pattern, such that expressions of dissent were greatest among individuals high in both openness and conscientiousness. These data also allowed for investigation of relationships between members' levels of identification with a group and their personality traits. Identifying with a group did not suppress (or enhance) the influence of these traits, indicating that personal and social identity level variables can operate independently of one another. Implications for the self-categorization process and collective decision-making will be discussed.

**COMPENSATORY NON-CONFORMITY: SELF-UNCERTAINTY INCREASES MINORITY OPINION EXPRESSION** Kimberly Rios Morrison<sup>1</sup>, S. Christian Wheeler<sup>2</sup>, Dale T. Miller<sup>2</sup>; <sup>1</sup>The Ohio State University, <sup>2</sup>Stanford University – Based on recent findings that self-uncertainty leads people to claim conviction in other areas of their lives, and that minority (more so than majority) opinions foster clarity of the self-concept, the present studies tested whether minority opinion expression increases after one's self-certainty is called into question. In Study 1, participants induced to feel self-uncertain dissented from others' preferences for modern art paintings more often than did those induced to feel self-certain. In Studies 2a and 2b, adult participants high (but not low) in self-esteem indicated a greater willingness to express dissent within their organization after completing a manipulation of self-uncertainty, relative to self-certainty or self-irrelevant uncertainty. In Study 3, self-uncertainty and high self-esteem led participants to report their minority opinions on controversial political issues more quickly, controlling for several indicators of attitude strength. In Study 4, the relationship between self-uncertainty and minority opinion expression was found to be strongest among participants high in explicit but low in implicit self-esteem, who tend to react to uncertainty about the self in defensive ways. These results suggest that minority opinion expression can function as a compensatory response to self-uncertainty, particularly for individuals (i.e., those with high explicit and low implicit self-esteem) who are willing to protect the self-concept even when doing so is interpersonally risky. Implications for how to increase the expression of dissent in groups and organizations, as well as the strategies that people use to cope with uncertainty about the self, are discussed.

## Symposia Session I2

**REDRAWING THE BIG PICTURE: FROM PERSONALITY DATA (BACK) TO PERSONALITY THEORY**

Saturday, January 30, 3:30 - 4:45 pm, Royale Pavilion 2

Chair: Daniel Cervone, University of Illinois at Chicago

Speakers: Daniel Cervone, Peter Kuppens, Sander Koole, Gerald Matthews

The study of personality, in its recent era, has featured two classes of advances: large-scale databases have described stable individual differences and intra-individual patterns of coherence in personal functioning, and broad meta-theories have outlined principles within which specific explanatory theories of personality architecture and functioning might be formulated. The next challenge for personality science, then, is to capitalize on these empirical advances while formulating the explanatory theories. Speakers in each of the four presentations of this symposium pursue this challenge. One presentation (Cervone & Caldwell) applies principles of knowledge representation in social cognition to questions of personality structure and dynamics, and the explanation of patterns of cross-situational coherence. The second (Kuppens & Van Mechelen) uses appraisal theories of emotion as a foundation for explaining variability and consistency in emotional response. The third (Koole) employs personality systems interactions theory to understand mechanisms of personality functioning whose distinctness is revealed by dissociations among measures of individual differences. The fourth (Matthews, Panigamban, Guznov, Kustubayeva) demonstrates how multiple contextual-

ized cognitive processes in stress, appraisal, and coping cohere as a result of their bearing on a common adaptive goal. The complementarity among these findings and explanatory theories suggests that contemporary models of cognitive and affective dynamics can successfully advance the goal pursued by the "classic" personality theorists of the 20th century, namely, to formulate theoretical models of personality structure and dynamics that explain the distinctive patterns of emotion and action of the individual.

#### ABSTRACTS

##### **EXPLAINING PERSONALITY COHERENCE FROM THE BOTTOM UP: APPLYING THE KAPA MODEL OF PERSONALITY ARCHITECTURE**

**Daniel Cervone<sup>1</sup>, Tracy L. Caldwell<sup>2</sup>**; <sup>1</sup>University of Illinois at Chicago, <sup>2</sup>Dominican University – Investigators have long acknowledged that processes of knowledge and meaning construction are central to personality dynamics. Challenges for the personality psychologist are to convert this insight into a well-formulated model of personality architecture, to develop methods to assess the structure and dynamics identified by that model, and to use this framework to recapture the phenomenon of cross-situational coherence in personality functioning. An additional challenge is that, based on established data on individual profiles of response, theory and assessment methods must attend to idiosyncrasy in personality organization that manifests itself in both consistency and variability in experience and action. One effort to meet these challenges is the Knowledge-and-Appraisal Personality Architecture (KAPA) model (Cervone, 2004). We present recent findings that apply the model to diverse domains, including the identification of cross-situational consistency in everyday social behavior (Orom & Cervone, 2009), coping with urges to use addictive substances (Cervone et al., 2008), and formulating strategies of interpersonal behavior (Caldwell, Cervone, & Rubin, 2008). In this presentation, we present novel results that underscore the need to move beyond – or, perhaps, "under" – the study of behavioral expressions of personality. This is compelled by equifinality: different structures and organizations in personal belief systems give rise to similar patterns of consistency and variability in experience and action.

##### **TOWARDS AN UNDERSTANDING OF INDIVIDUAL DIFFERENCES IN EMOTIONAL EXPERIENCE**

**Peter Kuppens<sup>1</sup>, Iven Van Mechelen<sup>2</sup>**; <sup>1</sup>University of Leuven and University of Melbourne, <sup>2</sup>University of Leuven – Research evidence as well as everyday observation tell us that people can display very different emotional reactions, even in response to the same event. Alternatively, one person can react emotionally very similar to seemingly very different events. Based on appraisal theories of emotions, a theoretical framework is offered to account for both the observed variability and consistency in emotional responding. Appraisal theories of emotions view appraisals, the subjective evaluations we make of our circumstances in relation to our own goals, well-being, and coping potential, as the interface between objective events and people's emotional responses to them. For example, we may become happy because an event signals that a goal has been reached, or we may become angry when we perceive someone as having treated us unfairly. Individual differences in emotional responding can therefore arise from individual differences in how people appraise their circumstances, and from individual differences in how these appraisals are associated with specific emotions. The study of both sources is needed to arrive at an in-depth understanding of variability in emotional experience. We review recent research that addresses the nature and relative contribution of the two sources of individual differences, and discuss the parallels between this framework and advances in contextualized personality psychology.

##### **DRAWING THE BIG PICTURE FROM DISSOCIATIONS IN PERSONALITY FUNCTIONING**

**Sander Koole<sup>1</sup>**; <sup>1</sup>Free University Amsterdam – Modern personality psychology has by and large emphasized consistencies across different measures and behaviors. In this presentation, I advocate the opposite strategy, in which inconsistencies or dissociations between measures and behaviors are taken seriously. I highlight the fruitfulness

of this dissociation approach in three different domains. First, I consider dissociations between implicit and explicit measures of personality, along with recent studies showing that these dissociations can be reduced through mindfulness meditation (Koole, Govurun, Chang, & Gallucci, in press). Second, I consider dissociations between individual differences in emotional sensitivity versus individual differences in emotion regulation (Koole, 2009), and discuss evidence that especially the latter individual differences can be improved through training (Koole & van Bommel, in preparation). Third, I consider dissociations between intention and action, which have emerged from studies showing that individuals who are prone to maintain their intentions activated in working memory (so-called "state-oriented individuals") are relatively inefficient in implementing these intentions (Koole & Kuhl, 2007; Jostmann & Koole, 2007). Dissociations between personality measures have important theoretical implications, because they point to separable but interacting mechanisms of personality functioning. A general theory of these mechanisms is personality systems interactions theory (Kuhl, 2000; Kuhl & Koole, 2004), which provides an integrative perspective on the functional architecture of personality.

##### **PERSONALITY TRAITS AND EMOTION: A COGNITIVE-ADAPTIVE PERSPECTIVE**

**Gerald Matthews<sup>1</sup>, April Rose Panganiban<sup>1</sup>, Svyatoslav Guznov<sup>1</sup>, Almira Kustubayeva<sup>2</sup>**; <sup>1</sup>University of Cincinnati, <sup>2</sup>Kazakh National University – Personality trait models, such as the Five Factor Model, are now more widely accepted than ever, but the psychological basis for traits remains elusive. Notably, despite the heritability of traits, theories relating traits to general brain arousal or motivation systems have had only limited success. Although traits are often substantially correlated with other broad-based constructs including self-beliefs, coping and emotion, correlations between traits and individual neural and cognitive processes are typically small in magnitude. The search for small numbers of 'master-processes' that control trait expression may be misguided. Instead, traits are distributed across numerous specific processing components. This viewpoint might call into question the coherence of traits as meaningful psychological constructs. The cognitive-adaptive theory of personality (Matthews, 2008) claims that traits derive coherence from individual differences in adaptation. Traits signal that the individual is adapted to specific human social environments, so that the multiplicity of separate neural and cognitive biases linked to the trait serve a common adaptive goal. ('Adaptations' here include both innate and learned elements). I will illustrate this perspective on personality traits by discussing data on personality and emotion obtained in controlled performance-testing environments. Relationships between traits, including neuroticism and extraversion, and emotion dimensions are substantially dependent upon cognitive stress processes of appraisal and coping. Much of the variance in these processes reflects situational factors, but they are also sensitive to systematic trait influences. Thus traits do not directly represent individual differences in emotionality, as sometimes claimed, but more subtle biases in contextualized cognitive processes.

#### Symposia Session I3

##### **A BIOPSYCHOSOCIAL MODEL OF THREATS TO SOCIAL BELONGING: PERSPECTIVES FROM ACROSS THE SPECTRUM OF SOCIAL PSYCHOLOGY.**

**Saturday, January 30, 3:30 - 4:45 pm, Royale Pavilion 5**

**Chairs:** Lisa M. Jaremka and Nancy L. Collins, UC Santa Barbara

**Speakers:** Lisa M. Jaremka, Sally S. Dickerson, Vivian Zayas, Daan Scheepers

Threats to social belonging (i.e. threats to social acceptance and/or value) are a powerful driving force behind a myriad of psychological and behavioral outcomes. While often conceptualized within the interpersonal domain, threats to social belonging actually come in a variety of forms, ranging from interpersonal rejection to social-evaluative threat to group-based threats. As Smart Richman and Leary (2009) point out in a recent review, these threats are fundamentally similar at their core

because they all jeopardize an individual's inclusionary status. Although much is known about the psychological consequences of threats to social belonging, the relationship between threats to social belonging and physiological processes is less well understood. Accordingly, this symposium aims to understand the physiological correlates of threats to social belonging by unifying research examining these threats from diverse content areas not typically studied under the same overarching umbrella. The talks begin with Dickerson examining the specific components of social-evaluative threat, a specific type of threat to social belonging, that elicit the release of the stress hormone cortisol. Next, using event-related potentials, Zayas demonstrates that interpersonal rejection stimuli affect early stage information processing in the brain. Scheepers reveals that a group-based threat to social belonging influences cardiovascular responses, with individuals with high levels of group-based resources exhibiting an adaptive pattern of responding and individuals with low levels of group-based resources exhibiting a maladaptive pattern of responding. Finally, Jaremka shows that receiving social support moderates the body's response to a threat to social belonging by increasing positive rumination and cognitions.

#### ABSTRACTS

##### **SOCIAL SUPPORT MODERATES PHYSIOLOGICAL RESPONSES TO SOCIAL EVALUATIVE THREAT** Lisa M. Jaremka<sup>1</sup>, Heidi S. Kane<sup>1</sup>, Nancy L. Collins<sup>1</sup>;

<sup>1</sup>UC Santa Barbara – In recent years, it has become clear that social-evaluative threats – such as giving a speech in front of an evaluator – elicit a reliable increase in the stress hormone cortisol. According to social self-preservation theory (Dickerson & Kemeny, 2004), these types of situations activate the physiological stress response because they threaten a basic human need for social status, esteem, and inclusion. While it is evident that social-evaluative threats result in increased cortisol levels, little is known about the personal or interpersonal factors that might moderate this response. Because social evaluative threats are rooted in a threat to social belonging, we reasoned that social support from a significant other may reduce the threat and attenuate cortisol reactivity. To test this hypothesis, we brought couples into the lab and asked one member (our participant) to give a videotaped speech in front of an evaluator. Shortly before and after the speech, participants in the experimental group received a supportive note from their romantic partner who was in a room across the hall; participants in the control group did not receive any notes. To ensure that each participant received the same support, the notes were copied by romantic partners from pre-written templates piloted for supportiveness. Results indicate that participants who received supportive notes from their partner had lower cortisol levels during and after the speech than control group participants. In addition, the relationship between received support and cortisol was partially mediated by the extent to which participants reported more positive thinking.

##### **SOCIAL-EVALUATIVE THREAT: IDENTIFYING THE ELEMENTS ASSOCIATED WITH CORTISOL REACTIVITY** Sally S. Dickerson<sup>1</sup>; <sup>1</sup>UC Irvine – Humans

have a fundamental need to belong and be socially accepted by others; situations which jeopardize this central goal are viewed as profound threats, capable of eliciting emotional, physiological, and behavioral responses. One type of threat to social belonging/acceptance is social-evaluative threat, in which the self could be negatively judged by others. Social-evaluative threat has been theorized to elicit specific emotional and physiological responses, including increases in the self-conscious emotions and cortisol activity. A series of studies now support this premise; acute laboratory stressors with social-evaluative threat have triggered robust increases in cortisol, while equivalent laboratory stressors without this explicit social-evaluative component have not elicited changes in this physiological parameter. Further, participants in social-evaluative conditions have reported greater levels of post-stressor shame and other self-conscious emotions compared to those in non-evaluative contexts. However, there have not been differences for other negative emotions (sadness, anger, fear). Current work focuses on identifying the

specific elements of the social-evaluative context that trigger cortisol changes, as well as the cognitive and emotional responses that may be driving these effects. Delineating the specific social components that are capable of eliciting cortisol reactivity is important, as persistent or chronic activation of this physiological system could have implications for mental and physical health.

##### **NEURAL RESPONSES TO PARTNER REJECTION CUES** Vivian Zayas<sup>1</sup>, Yuichi Shoda<sup>2</sup>, Walter Mischel<sup>3</sup>, Lee Osterhout<sup>2</sup>, Melissa Takahashi<sup>2</sup>;

<sup>1</sup>Cornell University, <sup>2</sup>University of Washington, <sup>3</sup>Columbia University – People are highly sensitive to cues that may signal a threat to their need to belong. Given the importance of close relationships, an especially pernicious threat is rejection, real or imagined, by significant others. Most studies on interpersonal rejection have focused on downstream processes, such as attributions, appraisals, and coping strategies, speaking to how individuals magnify or diminish initial automatic responses to threat cues. However, little is known about neural responses in the early automatic-stage processing of threats to social belonging, which are implicated in the etiology and course of anxiety and mood disorders. With the aim of addressing this crucial gap, we used event-related potentials (ERP) to assess normative responses in early-stage processing of partner rejection cues, and examined how these neural responses may be linked to individual differences in adult attachment. We focused on the N400 ERP component, which reflects the amount of semantic processing prompted by a target. When participants were primed by attachment-related contexts (e.g., “If I turn to my partner, my partner will be”), rejection words (“dismissing”) elicited greater N400 amplitudes than accepting words (“supporting”). Analyses involving nonattachment primes suggest that these findings were not simply caused by the valence of the targets; the brain responds differentially to cues of partner rejection versus acceptance in under 300 ms. Moreover, these early-stage neurophysiological responses were heightened or dampened as a function of individuals' adult attachment; women characterized by high anxiety and low avoidance showed the greatest N400 amplitudes in response to partner rejection (vs. acceptance) cues.

##### **GROUP-BASED REJECTION AS CHALLENGE AND THREAT: THE INFLUENCE OF GROUP IDENTIFICATION** Daan Scheepers<sup>1</sup>;

<sup>1</sup>Leiden University – Threats to social belonging can stem from a variety of sources: From interpersonal rejection to threats to social identity (the part of identity derived from group membership; Tajfel & Turner, 1979) such as negative inter-group comparisons and being the target of stigma and discrimination. Although some have argued that people who are highly identified with their group are most “hurt” by group-threatening information, there is little direct evidence for this proposition as threat has seldom been directly measured. In the current work we provide an alternative account. Based on conceptualizations of groups as “resources” and group identification as a buffer against stress (Haslam & Reicher, 2006) we propose that high identifiers will respond with a challenge motivational state to group-threatening information. Following the biopsychosocial model (Blascovich, 2008) we used cardiovascular (CV) markers of challenge (low vascular resistance, high cardiac performance) and threat (high vascular resistance, low cardiac performance) in our research. Across three studies examining minimal (Study 1) and real (Study 2 and 3) groups and manipulations (Study 1) and measurements (Study 2 and 3) of identification it was found that high identifiers responded with CV-responses indicative of a challenge motivational state to negative feedback about their group (e.g., students receiving negative information about their university). Low identifiers, by contrast, responded with CV-responses indicative of threat to such information. Results are discussed in terms of “social identity as a resource”, the benefits of a biopsychosocial approach for the psychology of social identity and inter-group relations, and implications for health.

## Symposia Session I4

**THE AGE OF OBAMA: A NEW ERA OF RACE RELATIONS, OR A NEW ERA OF MODERN RACISM?**

Saturday, January 30, 3:30 - 4:45 pm, Royale Pavilion 6

Chair: Clayton R. Critcher, Cornell University

Speakers: Cheryl R. Kaiser, Clayton R. Critcher, Eugene M. Caruso, Carlos David Navarrete

Given the United States' regrettable history with race, the election of the first African American president carried with it a poignant optimism for egalitarianism in America. In making sense of any seismic event (e.g., The historic Obama victory), people must make accommodations in their own belief systems that allow them to assimilate this new piece of information. This symposium explores ways in which accommodating and assimilating this success story may have negative implications for perceptions of African Americans. Using diverse samples and methods, Kaiser and colleagues found that people accommodate Obama's victory by seeing less racism in society, thereby leading people to waver in their support for social justice policies. Critcher et al. find that people accommodate African Americans who have succeeded in stereotypically White domains by assuming that continued disparities between Whites and Blacks must be due to Blacks' own lack of effort. Even though people explicitly reject this accommodation strategy, such belief shifts happened unintentionally nonetheless. Caruso and colleagues found that those who like Obama assimilate him into the category White, even at a basic perceptual level—those who like [dislike] him believe that a picture that has been artificially lightened [darkened] better represents him. Navarrete et al. found that women at peak fertility were more likely to support Obama, but only to the extent that they categorized him as more White than Black. In combination, this research suggests that more must be known about how social progress can be achieved without prompting responses that may undermine it.

## ABSTRACTS

**THE IRONIC CONSEQUENCES OF OBAMA'S ELECTION: DECREASED SUPPORT FOR SOCIAL JUSTICE POLICIES**

Cheryl R. Kaiser<sup>1</sup>, Benjamin J. Drury<sup>1</sup>, Kerry E. Spalding<sup>1</sup>, Sapna Cheryan<sup>1</sup>, Laurie T. O'Brien<sup>2</sup>; <sup>1</sup>University of Washington, <sup>2</sup>Tulane University – Has Barack Obama's rise to the presidency led Americans to believe that racism is less of a problem today than it has been in the past and that there is less need for policies that address racial inequalities in the United States? We examined whether Obama's candidacy and subsequent election reduced Americans' perceptions of a need for policies that address racial inequalities in the United States. In an experimental study conducted prior to the election, participants primed with Obama reported less support for policies that address racial inequalities (e.g., affirmative action) compared to participants primed with McCain or those in a no prime control condition. Further, in a longitudinal study conducted in the weeks prior to and after the election, participants increased their perception that racism is less of a problem in the US today than in times past and they also expressed less support for policies designed to address racial inequality after the election compared to prior to the election. Finally, data from public opinion polls with representative independent samples of Americans revealed that Americans reported that racism was a more serious problem for Blacks in the ten months preceding the election compared to the week after the election. Given the continued prevalence of racial disparities in virtually all aspects of American society, these results raise troubling implications for the status of policies aimed at eliminating racial injustice.

**IF HE CAN DO IT, SO CAN THEY: EXPOSURE TO SUCCESSFUL BLACK EXEMPLARS UNINTENTIONALLY SHIFTS EXPLANATIONS FOR RACIAL DISPARITIES**

Clayton R. Critcher<sup>1</sup>, Jane L. Risen<sup>2</sup>, Melissa J. Ferguson<sup>1</sup>; <sup>1</sup>Cornell University, <sup>2</sup>University of Chicago, Booth School of Business – With Jim Crow part of America's recent memory, the election of Barack

Obama was, for many, an inspirational symbol. Past research on social comparison has found that successful comparison targets offer hope and inspiration about what is possible. But in an insidious twist, might this symbol of what is possible lead people to increasingly blame disadvantaged African Americans for their own plight? When explicitly asked, participants rejected this logic, presumably recognizing that the success of a single exemplar is not informative of the forces operating on African Americans as a whole. But are everyday social perceivers such cautious attributional and inductive reasoners? Three studies used a two-part paradigm in which participants were first exposed to famous people in a supposedly unrelated recognition task before providing their opinions about race-related issues. Both liberals and conservatives who were incidentally exposed to successful African Americans (e.g., Obama, Brown president Ruth Simmons) subsequently stated that there was less racial discrimination in America and also blamed the Black community for Black-White socioeconomic disparities. These changes were not observed when people were exposed to Blacks who had succeeded in stereotypically African American domains (e.g., Diana Ross). Finally, this effect appears to be unintentional, given that participants who intentionally thought about the meaningfulness of such exemplars for race-related issues did not show the effect. The pattern of results across the studies suggests that casual (everyday) exposure to successful Black exemplars can ironically lead people to de-emphasize the scope and influence of discrimination on African Americans.

**HOW RED AND BLUE SEE BLACK AND WHITE: POLITICAL IDEOLOGY, PERCEIVED SKIN TONE, AND VOTING BEHAVIOR**

Eugene M. Caruso<sup>1</sup>, Nicole L. Mead<sup>2</sup>, Emily Balcetis<sup>3</sup>; <sup>1</sup>University of Chicago, Booth School of Business, <sup>2</sup>Florida State University, <sup>3</sup>New York University – People tend to view members of their own political party more favorably than members of the competing party. Being part of such ideological groups can trigger basic motivational and cognitive processes to evaluate one's fellow group members positively, particularly when the information under consideration is ambiguous. Because of the ambiguity surrounding Barack Obama's racial identity, we predicted that political orientation would even affect people's visual representations of his skin tone in a manner consistent with their desire to evaluate him positively or negatively. We expected people's biased visual representations of Obama to reflect nonconscious associations with race, whereby people tend to associate being American with being White (Devos & Banaji, 2005) and being White with being good (Smith-McLallen, Johnson, Dovidio & Pearson, 2006). In three studies, we presented participants with photographs of Barack Obama in which his skin tone was artificially lightened or darkened. Liberal participants consistently rated the lightened photographs of Barack Obama as more representative of him than the darkened photographs, whereas conservative participants showed the opposite pattern. Furthermore, the extent to which people rated lightened photographs as representative of Obama predicted their voting intentions and actual voting behavior in the 2008 Presidential election. This effect persisted even when controlling for political orientation and racial attitudes. No such effects were found for evaluations of John McCain, an unambiguously White candidate. These results suggest that people alter their visual representations of ambiguous others in ways that support their own preexisting beliefs and shape their decisions in a consequential context.

**FERTILITY AND RACE PERCEPTION PREDICT POLITICAL SUPPORT FOR BARACK OBAMA**

Carlos David Navarrete<sup>1</sup>, Michael L. Mott<sup>1</sup>, Joseph Cesario<sup>1</sup>, Melissa M. McDonald<sup>1</sup>, Robert Sapolsky<sup>2</sup>; <sup>1</sup>Michigan State University, <sup>2</sup>Stanford University – Research shows that women more positively evaluate targets evincing cues of high male genetic quality as a function of fertility across the menstrual cycle. Recently, a link between fertility and anti-Black race bias has also been documented, an effect that is argued to serve a sexual coercion avoidance function. Here we demonstrate that both effects can be operative in one target, if the male exemplar displays cues of both high genetic quality, and is categorized as belonging to a dangerous out-group. In Study 1, we found that the inten-

tion to vote for Barack Obama in the months preceding the 2008 election increased as a function of conception risk across the menstrual cycle among college women. We replicated the effect in Study 2, finding voting preference and "liking" for Obama increased as a function of conception risk across a broad demographic sample of American women. Importantly, we also found that the relationship between voting preference and conception risk is greatest among women who perceived him as closer to the race category "White," than "Black," whereas the opposite was true among women who perceived him as more "Black" than "White." These findings integrate two threads within menstrual cycle research on positive and negative evaluations of men, and extends them to shed light on a female-specific political psychology--one that speaks to the question of whether mental representations of Barack Obama may be cognitively processed as belonging to the category "White" among his political supporters.

### Symposia Session I5

#### WHAT'S SO SPECIAL ABOUT THE SELF? OR IS THERE ANYTHING SPECIAL AT ALL?

Saturday, January 30, 3:30 - 4:45 pm, Royale Pavilion 3-4

Chairs: Kurt Peters and Bertram Gawronski, University of Western Ontario  
Speakers: Marret K. Noordewier, Allen R. McConnell, Kenneth G. DeMarree, Kurt R. Peters

The self has traditionally been treated as a unique topic of study within psychology. Due to the centrality of the self in human life and its apparent complexity, it has often been suggested that the self must be understood on its own terms and that researchers should distinguish between self-related and non-self-related aspects of cognition. Such a distinction suggests that the self might be particularly difficult to study, since it requires unique theories about its structure and operation that do not generalize to cognition as a whole. The talks gathered in this symposium suggest that basic principles of information processing can indeed be fruitfully applied to the study of the self. Noordewier and Stapel revisit the debate between self-consistency and self-enhancement motives and conclude that salient self-views, which influence the affective response to positive or negative feedback, might be seen as a particular type of expectancy. McConnell and Brown suggest that self-knowledge is organized into context-specific stores in associative memory, implying that the influence of the self-concept on behavior can be understood in terms of general principles of memory-based information processing. DeMarree, Morrison, Wheeler, and Petty show that theories about the nature and consequences of ambivalence from the attitudes literature can inform investigations of ambivalence in self-views, revealing how structural aspects of the self-concept can moderate sensitivity to environmental influences. Finally, Peters and Gawronski apply the basic principles of activation and validation to the processing of knowledge about the self to shed light on the dynamics of self-construal.

#### ABSTRACTS

**WHEN FAILURE FEELS BETTER THAN SUCCESS: SELF-SALIENCE, SELF-CONSISTENCY, AND AFFECT** Marret K. Noordewier<sup>1</sup>, Diederik A. Stapel<sup>1</sup>,  
<sup>1</sup>Tilburg University – People like self-consistent feedback because it induces feelings of predictability and control, but they like self-enhancing feedback because it induces positive self-worth. What determines whether consistency or enhancement motives will predominate people's affective responses? In a series of studies, we show that in addition to processing resources, self-salience is a crucial determinant. Participants were confronted with positive or negative feedback, while cognitively busy or not. Self-knowledge salience was manipulated using different methods, such as increasing the salience of people's chronic positive/negative self-views (self-esteem salience) or inducing positive/negative self-views. With salient self-knowledge, people's primary responses (i.e., under load) are consistency-driven (people with negative self-views feel better after negative feedback than after positive feedback, whereas peo-

ple with positive self-views feel better after positive feedback than after negative feedback) and controlled responses are enhancement-driven (positive feedback feels better than negative feedback, regardless of self-consistency). Without salient self-knowledge, however, this pattern reverses: Because relevant self-conceptions have to be retrieved from memory, self-consistency responses are more resource demanding than self-enhancement responses. Interestingly, the self-salience findings are comparable to our previous research on expectancy disconfirmation, where we showed that primary responses to the unexpected are driven by the consistency of the outcome and controlled responses are driven by the valence of the outcome. This commonality might be taken to imply that salient self-views are represented as self-expectancies, with similar consequences as other type of expectancies.

#### SELF-CONCEPT REPRESENTATION AND ITS IMPLICATIONS IN THE MULTIPLE SELF-ASPECTS FRAMEWORK

Allen R. McConnell<sup>1</sup>, Christina M. Brown<sup>2</sup>,<sup>1</sup>Miami University,<sup>2</sup>Saint Louis University – How is self-knowledge organized in memory and what are the implications? To address this question, we describe our research exploring the Multiple Self-aspects Framework (MSF). The MSF assumes that one's self-concept is organized around self-aspects, which represent context-specific knowledge about individuals (e.g., one's roles, goal selves, relational identities). Each self-aspect is associated in memory with specific attributes (e.g., traits, behaviors, physical characteristics). Thus, self-aspects and their associated attributes form a network of self-knowledge. Based on this particular representational structure, the MSF offers a number of specific predictions that have been borne out in recent work. For example, it anticipates the degree to which self-relevant feedback (e.g., failing an exam) impacts overall affect (e.g., less positive mood) based on how the particular self-aspect in question (e.g., one's student self-aspect) is represented in the network of self-knowledge. Moreover, it predicts when such feedback will influence evaluations of unrelated self-aspects (e.g., one's dating self-aspect). In addition to accounting for how self-relevant feedback is experienced, research based on the MSF has shown that "chronic attributes" are not "always on," but rather are quite context-dependent in nature. Finally, the MSF makes a number of predictions for how self-regulation occurs, revealing that goals are pursued differently based on the confluence of situational factors and one's self-concept structure. In sum, the current work illustrates the importance in understanding how the self is represented in memory for understanding a number of important outcomes, ranging from the experience of self-relevant feedback to attaining one's goals.

#### SIMILARITIES AND DISSIMILARITIES IN SELF AND ATTITUDE STRUCTURE: AMBIVALENCE AND SELF CHANGE

Kenneth G. DeMarree<sup>1</sup>, Kimberly Rios Morrison<sup>2</sup>, S. Christian Wheeler<sup>3</sup>, Richard E. Petty<sup>2</sup>,<sup>1</sup>Texas Tech University,<sup>2</sup>Ohio State University,<sup>3</sup>Stanford University – Ambivalence, or the simultaneous presence of positive and negative reactions to an object, has been useful for understanding attitude-related phenomena, such as the stability of an attitude in response to influence attempts. However, the effect of ambivalence on self-concept stability has only recently been examined. In the current investigation, we tested whether ambivalence moderates self-change in response to subtle environmental influences. Specifically, we predicted that people whose targeted self-beliefs were structurally ambivalent would be most likely to respond to a subtle change induction. We examined both evaluative ambivalence (conflicting self-evaluations) and trait ambivalence (conflicting self-views regarding traits). Using self-esteem conditioning and out-group stereotype priming, we found that people became more susceptible to subtle change inductions as their structural self-ambivalence increased. Notably, these effects held on structural ambivalence, but not on meta-cognitive ambivalence or self-certainty, and were obtained even when dominant self-views were inconsistent with the change induction. These additional findings suggest that the effects were not due to a conscious motivation to reduce inconsistency, and that the structural inconsistency alone was sufficient to produce the observed malleability. Additional studies extended these findings to other structural features of self-per-

ceptions, including discrepancies between actual and desired self-views. Together the results suggest that basic concepts of attitude structure can provide insight into the structure of the self-concept and self-evaluation.

**AN ACTIVATION/VALIDATION MODEL OF SELF-CONSTRUAL** Kurt R. Peters<sup>1</sup>, Bertram Gawronski<sup>1</sup>; <sup>1</sup>University of Western Ontario – While previous research has generally focused on important aspects of the content and organization of the self-concept, relatively less is known about how the self-concept comes to be defined. In other words, how do people arrive at a working definition of themselves, and how can we understand this dynamic process? By applying the basic cognitive principles of activation and validation during information processing, we propose a model of self-construal that captures the dynamic interplay of autobiographical knowledge, desired self-perceptions, and epistemic processing goals. Essentially, the model describes a process in which the implications of activated self-associations in memory are tested for consistency with the current contents of the working self-concept. If these implications are validated, they will be incorporated into the working self-concept in the form of changed self-beliefs; otherwise, they will be rejected and leave the working self-concept unchanged. A first experiment is reported that provides evidence for a “bottom-up” route of self-construal, in which self-associations activated directly in memory feed into and change the working self-concept. A second experiment provides evidence for an alternative, “top-down” route of self-construal, whereby motivation to possess particular self-views biases the activation and validation of self-associations in memory. Finally, novel aspects of self-construal derived from the model will be discussed as directions for future research.

### Symposia Session I6

#### ACHIEVING SUSTAINABLE HAPPINESS: PATHWAYS AND PITFALLS

Saturday, January 30, 3:30 - 4:45 pm, Royale Pavilion 7-8

Chair: Lara Aknin, University of British Columbia

Speakers: Barbara L. Fredrickson, Elizabeth W. Dunn, Julia K. Boehm, Lara B. Aknin

Most people want to be happy beyond the immediate present, but previous research implies that efforts aimed at increasing happiness may be doomed to fail because people readily adapt to changes in their environment. Going beyond past debates about whether happiness can be lastingly increased, however, this symposium brings together researchers whose work highlights some of the situational and dispositional factors that enable or undermine the achievement of sustainable gains in well-being. To begin, Barbara Fredrickson will present research identifying two phenotypic markers that predict whether individuals continue to practice loving-kindness meditation and experience hedonic benefits over the long term. Secondly, Elizabeth Dunn will discuss research suggesting that wealth may undermine the ability to savor positive emotions and life experiences. Third, Julia Boehm will present data showing that individuals' cultural background shapes the effectiveness of interventions designed to increase happiness. Finally, Lara Aknin will discuss research suggesting that a positive feedback loop may exist between happiness interventions and well-being, such that people who experience the highest levels of well-being after a happiness boosting activity are more likely to engage in similar behavior again. Taken together, this symposium will encompass data collected from five cultures using a variety of measures—from biological assessments to behavioral observations—in order to illuminate the stepping stones and stumbling blocks that lie on the route to sustainable well-being.

### ABSTRACTS

#### PHENOTYPIC MARKERS OF SUSTAINED POSITIVE BEHAVIOR CHANGE WITH ATTENDANT POSITIVE EMOTIONAL CONSEQUENCES

Barbara L. Fredrickson<sup>1</sup>; <sup>1</sup>University of North Carolina at Chapel Hill – Some people are more likely than others to maintain the positive behaviors that facilitate long-term gains in well-being. Two plausible phenotypic markers for sustained positive behavior change have emerged within our recent research: positive emotional reactivity (PER) early in the intervention and respiratory sinus arrhythmia (RSA) measured at resting baseline. Study 1 was a one-year follow-up survey of participants who learned loving-kindness meditation (LKM) to increase daily experiences of positive emotions, and thereby build personal resources, reduce depressive symptoms, and increase life satisfaction. One year after receiving LKM training, many participants continued to practice meditation, and those who did reported more positive emotions, greater life satisfaction and physical health than those who stopped or never meditated. Participants showing a rapid positive emotion response to LKM were more likely to continue meditating than those with a delayed response, suggesting that positive emotion reactivity predicts the ability to adopt and benefit from new skills. Study 2 replicated Study 1 with additional laboratory-based physiological measures. Respiratory sinus arrhythmia not only predicted positive emotional reactivity to LKM, but also predicted the extent to which meditation had become a habit one-year later. The heritable trait of positive emotional reactivity is hypothesized to predispose individuals to sustained positive behavior change because it forecasts the development of incentive salience for the newly adopted behaviors, which motivates repeat behavior at nonconscious levels. The heritable biomarker of RSA, an index of heart rate variability, may additionally predispose individuals to successful behavior maintenance because it reflects stable self-regulatory capacity.

#### MONEY GIVETH, MONEY TAKETH AWAY: WEALTH UNDERMINES SAVORING ABILITY

Elizabeth W. Dunn<sup>1</sup>, Jordi Quoidbach<sup>2</sup>, K.V. Petrides<sup>2</sup>, Moira Mikolajczak<sup>3</sup>; <sup>1</sup>University of British Columbia, <sup>2</sup>University of Liège, Belgium, <sup>3</sup>Université catholique de Louvain, Belgium – Achieving lasting happiness depends, in part, on the ability to savor the small joys of daily life, such as sunny days, cold beers, and chocolate bars. We hypothesized that wealth—which opens the door to a wide range of peak experiences, from luxury travel to fine dining—may undermine savoring ability. Indeed, just thinking about wealth may increase perceived access to extremely enjoyable experiences, potentially introducing the risk that the small pleasures of everyday life will be taken for granted. The present study provides the first evidence that money impairs people's ability to savor everyday positive emotions and experiences. In two very different cultural contexts (Cuba and Belgium), wealthier individuals reported lower savoring ability. Moreover, the negative impact of wealth on savoring undermined the positive effects of money on happiness. Supporting the causal influence of money on savoring, experimentally exposing participants to a reminder of wealth produced the same deleterious effect on savoring as did actual individual differences in wealth. Finally, moving beyond self-report, participants exposed to a reminder of wealth spent less time savoring a piece of chocolate and exhibited reduced enjoyment of it. The present research supplies evidence for the previously untested notion that having access to the best things in life may actually undercut the ability to reap enjoyment from life's small pleasures. Thus, our work suggests that money—which is commonly viewed as an important stepping stone to happiness—may also serve as a stumbling block.

#### COMPARING THE EFFECTIVENESS OF HAPPINESS-ENHANCING STRATEGIES IN ANGLO AMERICANS AND ASIAN AMERICANS

Julia K. Boehm<sup>1</sup>, Sonja Lyubomirsky<sup>1</sup>; <sup>1</sup>University of California, Riverside – Increasing evidence suggests that certain interventions to increase happiness can be effective. However, one critical issue has yet to be addressed: are happiness interventions equally effective for people from cultures other

than Western societies? Differences between individualist and collectivist cultures suggest that people from individually oriented societies may benefit more from interventions to enhance well-being than people from collectivist societies. To investigate this issue, community-dwelling Anglo Americans and predominantly foreign-born Asian Americans were randomly assigned either to express optimism ( $n = 89$ ), convey gratitude ( $n = 85$ ), or generate a list of their experiences over the past week ( $n = 91$ ; i.e., control group). Participants engaged in their assigned activities once a week for six weeks. Results indicated that those people in the optimism and gratitude conditions reported enhanced well-being relative to the control condition. Moreover, Anglo Americans in the treatment conditions demonstrated larger improvements in well-being when compared with Asian Americans in the same conditions, and all participants in the control condition. Thus, despite beginning the intervention with equivalent levels of well-being, Anglo Americans appeared to benefit more than Asian Americans from expressing optimism and gratitude. These results are consistent with the notion that the emphasis individualist cultures place on self-improvement and personal agency bolstered the efforts of Anglo Americans to become happier. By contrast, the de-emphasis on individual goals and self-focus by collectivist cultures diminished the happiness-enhancing strategies for Asian Americans.

#### **IS THERE A FEEDBACK LOOP BETWEEN PROSOCIAL SPENDING AND HAPPINESS?: EVIDENCE FROM CANADA AND UGANDA**

Lara B. Aknin<sup>1</sup>, Michael I. Norton<sup>2</sup>, Claire Ashton-James<sup>3</sup>, Paul Nyende<sup>4</sup>, Imelda Kemeza<sup>5</sup>, Elizabeth W. Dunn<sup>1</sup>, Robert Biswas-Diener<sup>6</sup>; <sup>1</sup>University of British Columbia, <sup>2</sup>Harvard Business School, <sup>3</sup>University of Groningen, <sup>4</sup>Makerere University, <sup>5</sup>Mbarara University of Science and Technology, <sup>6</sup>Center for Applied Positive Psychology – Are the people who experience the highest levels of well-being after a happiness-increasing intervention more likely to practice the same behavior again? Our results reveal that a positive feedback loop exists between spending money on others (prosocial spending) and happiness across two vastly different cultures (North America and Africa), such that prosocial spending increases happiness, and higher levels of happiness encourage prosocial spending. In Study 1, fifty-one participants were randomly assigned to reflect on a previous purchase made for themselves or someone else before rating their happiness. Participants were then given money and asked to decide whether to spend the windfall on themselves or someone else. As expected, participants assigned to recall other-oriented purchases felt happier and, the happier participants felt, the more likely they were to spend the windfall on others. In Study 2, the same basic study design was replicated in both Uganda and Canada. Notably, the analyses reveal consistent findings across these two diverse cultures: participants assigned to reflect upon a previous prosocial purchase were happier, and higher levels of happiness, in turn, predicted a future willingness to engage in prosocial spending. Thus, taken together, these two studies provide strong cross-cultural support for a feedback loop between prosocial spending and happiness. Our results further support the notion that individuals who benefit most from engaging in happiness increasing interventions are more likely to engage in these behaviors again.

#### **Symposia Session I7**

#### **SEX, STATUS, POWER AND PENALTIES FOR GENDER DEVIANCE: NEW DIRECTIONS IN BACKLASH RESEARCH**

**Saturday, January 30, 3:30 - 4:45 pm, Capri Rooms 101-102**

**Chairs:** Corinne Moss-Racusin, Rutgers University, and Victoria Brescoll, Yale University

**Speakers:** Laurie A. Rudman, Corinne A. Moss-Racusin, Victoria L. Brescoll, Peter Glick

When people disconfirm gender stereotypes, they risk social and economic penalties (i.e., backlash) for violating established “gender rules” (e.g., Rudman, 1998). Backlash toward gender deviants limits human

potential and reinforces gender stereotypes. Although considerable evidence demonstrates backlash effects, moderators and mediators have been less investigated. This symposium presents novel research on the intersection of sex, status, and power as predictors of backlash toward atypical women and men. First, Rudman et al. introduce the status incongruity hypothesis (SIH), which posits that gender deviants encounter backlash because stereotype violations threaten the existing gender hierarchy. Accordingly, backlash toward agentic women is explained by perceived violations of female proscriptions (breaking the “dominance rule”) rather than female prescriptions (breaking the “communality rule”). Second, Moss-Racusin et al. extend previous research by employing the SIH to account for backlash toward atypical (i.e., modest) men, who suffer penalties due to perceived violations of both (high status) male agency prescriptions and (low status) male proscriptions against weakness. Third, Brescoll and Okimoto find that backlash toward female politicians depends on their perceived power-seeking, and is linked to moral outrage. Finally, Glick et al. investigate female power in the form of sexual attractiveness, finding that appearance-based backlash against female employees’ hinges upon their job status. Specifically, only high-status career women are penalized when dressed in a “sexy” manner. Taken together, these findings point to backlash as a means by which the gender hierarchy is upheld, and illuminate the mediators, moderators, and scope of backlash toward gender deviants.

#### **ABSTRACTS**

#### **PREJUDICE TOWARD FEMALE LEADERS: BACKLASH EFFECTS AND STATUS-RELATED GENDER STEREOTYPES**

Laurie A. Rudman<sup>1</sup>, Julie E. Phelan<sup>1</sup>, Corinne A. Moss-Racusin<sup>1</sup>, Sanne Nauts<sup>2</sup>; <sup>1</sup>Rutgers University, <sup>2</sup>Radboud University Nijmegen – Agentic female leaders risk social and economic penalties (i.e., backlash effects; Rudman & Glick 1999; 2001) that hinder women’s progress. Although violating female stereotypes is a likely cause of backlash, the exact nature of the violation is unknown. The status incongruity hypothesis (SIH) proposes that backlash stems from perceived violations of female dominance proscriptions, rather than female communality prescriptions. Four studies supported the SIH. Study 1 presents a survey revealing that female proscriptions align with status-enhancing traits reserved for leaders and men, whereas female prescriptions are status neutral. Studies 2-3 used videotaped or live confederates to demonstrate that backlash toward agentic women is mediated by exaggerated perceptions of dominance rather than insufficient communality. In other words, agentic female leaders are penalized for violating dominance proscriptions, rather than for violating “niceness” prescriptions. In Study 4, women randomly assigned to a leadership role were sabotaged more than comparable male leaders, but only when female leaders were high (not low) in leadership aptitude. In other words, women’s ability to wield power was more important than the status of her assigned role for predicting backlash. In concert, the findings suggest that female dominance proscriptions pose a significant barrier to gender equality by promoting a double standard for power and authority.

#### **WHEN MEN BREAK THE GENDER RULES: STATUS INCONGRUITY AND BACKLASH TOWARD MODEST MEN**

Corinne A. Moss-Racusin<sup>1</sup>, Julie E. Phelan<sup>1</sup>, Laurie A. Rudman<sup>1</sup>; <sup>1</sup>Rutgers University – Adherence to masculine norms and stereotypes has been linked to negative consequences for men, suggesting that liberating men from the bonds of traditional masculinity would be beneficial (Courtenay, 2000; Pollack, 1998). However, when people deviate from stereotypic expectations, they often encounter backlash (i.e., social and economic penalties; Heilman, Wallen, Fuchs & Tamkins, 2004; Rudman, 1998). A total of 232 participants viewed one of four identically-scripted videotapes of male and female job applicants behaving modestly on an interview, and then indicated their reactions to the applicant. Results demonstrated backlash in the form of prejudice toward modest (i.e., atypical) men, in that the male applicants were less liked than their female counterparts. Of greater importance, this effect was reliably mediated by the male applicants’ perceived violation of sta-

tus-related stereotypes (Rudman, Phelan, Moss-Racusin & Nauts, 2009). Modest men were overcharged with male proscriptions linked to low status (e.g., weakness) and underrated on agentic male prescriptions linked to high status (e.g., confidence and leadership ability). By contrast, communal traits that are largely neutral in status were not an explanatory factor in backlash. These findings suggest that perceived status violations underscore backlash, pressuring men to conform to masculine norms and stereotypes that limit their human potential.

#### **THE PRICE OF POWER: POWER-SEEKING AND BACKLASH AGAINST FEMALE POLITICIANS** Victoria L. Brescoll<sup>1</sup>, Tyler Okimoto<sup>1</sup>; <sup>1</sup>Yale University

— In two experimental studies, we examined the effect of power-seeking intentions on backlash toward women in political office. We hypothesized that a female politician's career progress may be hindered by the belief that she seeks power, as this desire for dominance may violate proscribed expectations for women and thereby elicit interpersonal penalties. In Study 1 we examined respondents' choice between equivalently-described male versus female political candidates, examining the extent to which perceptions of each candidate's power-seeking intentions affect this choice. In Study 2, we further unpack this process by examining voting preferences as a function of direct manipulations of power-seeking intentions and target gender, while also examining the mediating role of perceived communality, agency, competence, and moral-emotional reactions toward male and female politicians. In both studies, the presentation of the target politician was done via a realistic (yet fictional) website for a state senator. Results suggested that voting preferences for female candidates were negatively influenced by her power-seeking intentions (actual or perceived), but that preferences for male candidates were unaffected by power-seeking intentions. These differential reactions were partly explained by the perceived trait violations implied by women's power-seeking intentions, resulting in lower perceived competence and feelings of moral outrage. These findings illuminate one potential source of gender bias in politics.

#### **EVALUATIONS OF SEXY WOMEN IN LOW AND HIGH-STATUS JOBS** Peter Glick<sup>1</sup>, Sadie Weber<sup>1</sup>, Cathryn Johnson<sup>1</sup>, Heather Branstiter<sup>1</sup>; <sup>1</sup>Lawrence University

— The use of sexuality may be another factor that can elicit backlash toward women in high status positions. While physical attractiveness may benefit both men and women at work, women who combine high status with a sexy appearance may be rejected as gaining power illegitimately. In a 2 (Target's Occupation: low versus high status) x 2 (Target's Appearance: conservative versus provocative attire) experimental study, 28 male and 38 female undergraduates evaluated a female target. Depending on random assignment, participants (a) read information indicating that the target was a manager or a receptionist and then (b) viewed a videotaped interview in which the target was dressed in sexy or business-like attire. The content of the target's answers was held constant, as was her demeanor and overall physical attractiveness. Participants exhibited more negative affect toward the sexily attired manager and rated her as less competent than the neutrally attired manager. The tendency to derogate the provocatively dressed manager's competence was fully mediated by emotional reactions toward her. By contrast, the sexy (versus conservative) attire manipulation had no effect on emotions toward or competence ratings of the receptionist. These findings suggest that a sexy self-presentation harms women in high, but not low, status jobs.

#### **Symposia Session I8**

#### **A NEW LOOK ON AUTOMATIC BEHAVIOR: MODULATION, INTEGRATION AND CONSEQUENCES**

Saturday, January 30, 3:30 - 4:45 pm, Capri Rooms 103-106

Chairs: Kai Jonas, University of Amsterdam, and Joseph Cesario, Michigan State University

Speakers: Kai Jonas, Joseph Cesario, Chris Loersch, Dirk Smeesters

Research on automatic behavior can look back on impressive findings, yet recently the picture has been becoming broader and is in need of integration. New prime-behavior effects, such as response behavior towards categories, have been found and new theoretical models were proposed. This symposium reflects complexity of automatic behavior, its modulation and consequences. The first two papers reveal individual and ecological influences on automatic behavior. Jonas and Sassenberg show that consciously activated individual goals are able moderate category specific response activations. The paper by Cesario and Jonas moves a step further, from individual to contextual influences. They show that ecological differences, such as being alone or in a group context, impacts on the type and quality of the activated automatic behavior after social category priming. The paper by Loersch and Payne presents an integrative model that provides insight into the interplay of motivation and cognitive activation effects to explain the so far disjunct lines of prime to perception, behavior and goal effects. Consequences of previous automatic behavior being acted out on subsequent behavior and cognitive processes have not yet been analyzed. This is the topic of the final paper by Smeesters, Wheeler & Liu. They address this by utilizing imitation behavior as a determinant for subsequent processes, such as similarity processing. In sum, the symposium reveals the current state of the art on automatic behavior research moving on from establishing effects to more comprehensive models of modulating conditions and the consequences of automatic behavior.

#### **ABSTRACTS**

#### **GOALS AS MODERATORS OF AUTOMATIC RESPONSE PRIMING** Kai

Jonas<sup>1</sup>, Kai Sassenberg<sup>2</sup>; <sup>1</sup>University of Amsterdam, <sup>2</sup>Knowledge Media

Research Institute Tübingen — Until recently, automatic behavior was only

analyzed and understood as a cognitive activation process, not being further influenced by other processes, such as motivation. Cesario, Plaks and Higgins (2006) proposed the very general notion that interaction motivation influences whether you show imitative or response-type automatic behavior. Yet, interacting with a member of a social category can be relevant to attain one's specific goals above and beyond simple interaction motivation. Thus, automatically activated response behavior (ARP, Jonas & Sassenberg, 2006) can become a means to a specific individual goal attainment. Here, we test whether ARP is moderated by specific activated individual goals (e.g. "being just", or "staying safe"). In Study 1, matching behavior response targets (e.g. punishing or ignoring) were activated faster following a perpetrator prime (vs. a control prime) in a lexical decision task depending on activated goals (justice vs. security). Study 2 shows that mere concept activation isn't, but a salient goal is needed to elicit these effects. Based on the post fulfillment inhibition findings for goals and related means, Study 3 shows that attained goals do not activate the corresponding response to a social category prime, yet unattained goals do. Taken together, the research presented shows the potential of individual goals to act as a moderator on the selection of automatic response behavior activation. Thus, motivation does not only play a role in modulating imitation vs. response activation after categorical primes, but is even able to moderate which specific response is automatically activated after categorical primes.

#### **ECOLOGICAL INFLUENCES ON CONSTRUCT ACCESSIBILITY** Joseph

Cesario<sup>1</sup>, Kai Jonas<sup>2</sup>; <sup>1</sup>Michigan State University, <sup>2</sup>University of Amsterdam —

Ecological influences remain absent from nearly all models of automatic social behavior. Current models cannot accommodate ecological effects, such as whether a person is primed in an enclosed space vs. an open field, or whether a person is primed alone vs. surrounded by others. The motivated preparation model (Cesario, Plaks, & Higgins, 2006), however, does predict the influence of such variables as they define for the actor what I can and cannot do to interact effectively with a primed target. In line with this, prior work (Cesario et al., 2009) found that participants primed with aggressive targets (young Black males) responded with either aggression or distancing, depending on which behavior was allowed by the situation in which the participant was behaving (an

enclosed booth vs. an open room). The current research shows that ecological influences extend to the level of construct accessibility, with one's nonconscious assessment of perceived resources influencing which action tendencies become activated in response to a prime. Participants completed a lexical decision task with riot-related or obedience-related target words; target words were preceded by either the prime police or a control prime. Participants completed the task either alone or in the presence of ingroup members, whose shared membership had been made salient. Results showed that the presence of ingroup members (vs. alone) increased the accessibility of riot-related words in response to police primes only. This effect was not observed when the ingroup connection was not salient, indicating that the effects reflect resource assessment, not mere presence.

**THE SITUATED INFERENCE MODEL OF PRIMING: HOW A SINGLE PRIME CAN ALTER PERCEPTION, GOALS, AND BEHAVIOR** Chris Loersch<sup>1</sup>, B. Keith Payne<sup>2</sup>; <sup>1</sup>University of Missouri, <sup>2</sup>University of North Carolina, Chapel Hill

A single priming induction can elicit a variety of consequences. It can change construal of another individual, drive new behaviors, or initiate effortful goal striving. Although each of these effects has been explained by unique mechanisms, we have recently proposed a model which accounts for all with a single mechanism. According to this Situated Inference Model, primes often do not cause default effects, but instead make the primed concept more accessible. This accessible construct becomes capable of producing an observable priming effect when it is misattributed to one's natural response to some aspect of the situation. Once this occurs, the prime-related mental content can serve as information for answering whatever implicit question or concern is afforded by the situation. Because different situations afford very different implicit questions, the inferred meaning of these prime-related cognitions can vary greatly. In particular, the general construct accessibility resulting from a single prime tends to produce construal priming when people are focused on another person or object. In such cases, the basic implicit question is "Who/What is that?" If a person is instead focused on their current behavioral options, the implicit question "What will I do?" will be presented. In this case, behavior priming will result. And finally, if a person attempts to determine their current motivational state, this will afford the implicit question "What do I want?" The result is goal priming. This talk will outline the model and then describe two studies that provide evidence for its central predictions.

**THE IMPACT OF MIMICRY ON SIMILARITY PROCESSING** Dirk Smeesters<sup>1</sup>, S. Christian Wheeler<sup>2</sup>, Jia Liu<sup>3</sup>; <sup>1</sup>Erasmus University Rotterdam,

<sup>2</sup>Stanford University, <sup>3</sup>University of Groningen – Mimicry occurs spontaneously and ubiquitously in interactions between individuals, and is a form of social feedback. Being mimicked by another person signals interpersonal harmony and affiliation. Not being mimicked, on the other hand, signals a need for individuation and interpersonal distance. Whereas most research has examined the effects of mimicry on behavioral and attitudinal outcomes, the present research explores how mimicry impacts cognitive processing. Because mimicry signals similarity and congruity, being mimicked (versus not being mimicked) could instigate similarity processing of subsequently encountered stimuli. This hypothesis was tested in several studies. The findings of these studies showed that being mimicked (versus not being mimicked) leads to (a) perceiving two pictures as more similar, (b) generating more similarities between both rather similar stimuli (television shows) and rather dissimilar stimuli (a shark and a dog), (c) slower response latencies in detecting differences between two pictures, (d) categorizing different stimuli in fewer categories, and (e) attributing more characteristics from a significant other to a new person. A final study showed that this mimicry-induced similarity processing can also affect subsequent behavior. In this study, participants were mimicked or not before being primed with extreme exemplars (e.g., Einstein). Unmimicked participants exhibited behavioral contrast from the exemplars, replicating previous research, but mimicked participants exhibited behavioral assimilation. This set of

studies adds to our understanding of the impact of social interactions (specifically, mimicry) on subsequent cognitive processing.

**Symposia Session I9**

**THE DYNAMIC SOCIAL MIND**

Saturday, January 30, 3:30 - 4:45 pm, Capri Rooms 107-110

Chairs: Melissa Ferguson and Mike Wojnowicz, Cornell University

Speakers: William A. Cunningham, Mike Wojnowicz, Jonathan B. Freeman, Robin R. Vallacher

How do social psychological mental states emerge from complex interactions within the mind? For example, how do the memories underlying stereotypes, attitudes, and self-esteem dynamically fluctuate over hundreds of milliseconds and result in a coherent behavioral response? Researchers in this symposium are addressing these questions using the interdisciplinary framework of dynamical systems. Will Cunningham explains how repeated cycles of mental processing gradually produce reflective attitudes from initial automatic evaluations. Mike Wojnowicz analyzes hand movement trajectories to find evidence for continuous temporal dynamics in the generation of explicit attitudes. Jon Freeman finds evidence for dynamic continuity in person perception - categorical inferences about another person's race and gender - by analyzing hand movement trajectories alongside event-related potentials (ERPs). Robin Vallacher discusses how psychological systems seek stable states, illustrating the phenomenon with the dynamics of self-esteem.

**ABSTRACTS**

**THE ITERATIVE REPROCESSING MODEL: A MULTILEVEL FRAMEWORK FOR ATTITUDES AND EVALUATIONS** William A. Cunningham<sup>1</sup>; <sup>1</sup>The Ohio State University

Dual-process models of attitudes highlight the fact that evaluative processes are complex and multifaceted. Nevertheless, many of these models typically neglect important interactions among processes that can contribute to an evaluation. We have recently proposed a multilevel model informed by neuroscience in which current evaluations are constructed from relatively stable attitude representations through the iterative reprocessing of information. Whereas initial iterations provide relatively quick and dirty evaluations, additional iterations accompanied by reflective processes yield more nuanced evaluations and allow for phenomena such as ambivalence. Importantly, this model predicts that the processes underlying relatively automatic evaluations continue to be engaged across multiple iterations, and that they influence and are influenced by more reflective processes. That is, automatic evaluations are crucial for survival, but conscious self-reflection enables the formulation of nuanced evaluations to serve long-term goals. To operate effectively, both automatic and reflective evaluative processes need to integrate stored representations from previous experience (attitudes) with current contexts and goals, but contexts and goals have a more prominent role in reflective evaluation. In this talk, I will describe the Iterative Reprocessing Model at the computational, algorithmic, and implementational levels of analysis (Marr, 1982) to more fully characterize its premises and predictions that should inform social-cognitive and cognitive-neuroscientific accounts of evaluation.

**THE SELF-ORGANIZATION OF EXPLICIT ATTITUDES** Mike Wojnowicz<sup>1</sup>, Melissa Ferguson<sup>1</sup>, Michael Spivey<sup>2</sup>, Rick Dale<sup>3</sup>; <sup>1</sup>Cornell University,

<sup>2</sup>University of California at Merced, <sup>3</sup>University of Memphis – How do minds produce explicit attitudes over several hundred milliseconds? Speeded evaluative measures have revealed implicit biases beyond cognitive control or subjective awareness, yet mental processing may culminate in an explicit attitude that feels personally endorsed and corroborates voluntary intentions. We argue that self-reported explicit attitudes derive from a continuous temporally dynamic process, whereby multiple simultaneously conflicting constraints self-organize into a meaningful mental representation. As our participants reported their explicit (like vs. dislike) attitudes towards white versus black people, we recorded stream-

ing  $x, y$  coordinates from their hand-movement trajectories. We found that when participants reported positive explicit attitudes toward black people, rather than white people, their hand movement paths exhibited greater curvature toward the dislike response. Moreover, these trajectories were characterized by precisely the movement disorder and competitive velocity profiles predicted under the assumption that the deliberate attitudes were emerging from continuous interactions between multiple simultaneously conflicting constraints.

#### **DYNAMIC CONTINUITY IN REAL-TIME PERSON PERCEPTION** Jonathan

**B. Freeman<sup>1</sup>, Nalini Ambady<sup>1</sup>; <sup>1</sup>Tufts University** – Social categorization and stereotyping have important implications. Applying a dynamical systems framework, we argue that perceiving others involves simultaneously active representations that continuously fluctuate over time. Moreover, we propose that these representations can continuously build into action. We demonstrate this across 4 studies using a novel computer mouse-tracking method and event-related brain potentials (ERPs). Participants' hand movements were measured in real-time (using the streaming  $x, y$  coordinates of the computer mouse) while they categorized the sex of sex-typical and sex-atypical faces (Study 1), categorized the race of race-typical and race-atypical faces (Study 2), and gender-stereotyped sex-typical and sex-atypical faces (Study 3). In all cases, for atypical faces, hand movements were spatially attracted to the opposite sex/race-category or opposite gender-stereotype continuously across construal. Moreover, as atypicality linearly increased, the hand was increasingly more attracted to the opposite response. Interestingly, different category cues had different dynamic patterns of influence over real-time processing. In Study 4, we measured ERPs while participants used their hands to categorize the sex of sex-typical and sex-atypical faces. The specific pattern of N170, N300/N400, and LRP results revealed that the motor cortices continuously received accumulating information about the target's sex and prepared for action while sex-category knowledge was still gradually evolving in parallel. Together, these findings demonstrate the dynamic continuity in person perception.

#### **IRONIC COHERENCE: THE EMERGENCE OF MULTI-STABILITY IN PSYCHOLOGICAL SYSTEMS** Robin R. Vallacher<sup>1</sup>; <sup>1</sup>Florida Atlantic

**University** – All psychological systems are characterized by a tendency toward progressive integration. Individual cognitive elements (thoughts, feelings, perceptions) in the mental system exert mutual influence to promote the emergence of higher-order mental states such as attitudes, beliefs, impressions, and self-appraisals. These states, in turn, function as new elements that are subject to yet higher-order integration (e.g., values, social judgments, self-concepts). In a social system, in turn, independent agents influence one another to promote the emergence of social norms, customs, collective identities, and ideologies. The emergence of higher-order states by means of self-organization provides coherence and stability for the system, enabling it to resist contradictory information and external threats. When resistance entails the suppression or avoidance of perturbing influences, however, the rejected elements are susceptible to the same press for integration that created the favored coherent state. Over time, then, self-organization in service of coherence can result in a multi-stable system consisting of two conflicting attractors that vie for prepotence in shaping the trajectory of personal and collective experience. When a system is at one of these attractors, it can display remarkable stability, maintaining coherence in the face of disconfirmatory information or threatening events. When a threshold of perturbing influence is reached, however, the system may demonstrate a sudden and dramatic change to the previously latent attractor. The emergence of coherence in a psychological system thus has the ironic effect of creating the seeds of its undoing. This scenario is illustrated in the context of recent research on the dynamics of self-esteem.

#### **Symposia Session I10**

#### **HOW TO SURVIVE SIN CITY: THE ROLE OF COGNITIVE CONTROL IN FIGHTING TEMPTATION**

**Saturday, January 30, 3:30 - 4:45 pm, Capri Rooms 114-116**

**Chairs: Wilhelm Hofmann, Würzburg University, and Lotte Van Dillen, Utrecht University Netherlands**

**Speakers: Wilhelm Hofmann, Brandon Schmeichel, Lotte Van Dillen, Reinout Wiers**

The present symposium is concerned with how internal self-control conflicts between visceral factors (i.e., temptations) on the one hand and people's control goals (restraint) on the other hand are mentally represented, processed, and solved (for better or worse). One special focus will be on the role of cognitive resources which appear to affect both the emergence as well as the control of cravings and desires. For example, executive attention, the capacity to direct one's attention to specific tasks or targets, is positively related to impulse regulation in the service of self-regulatory goals (Hofmann & Friese), whereas low working memory capacity is associated with more impulsive behavior. Secondly, we will take a closer look at the conditions under which reductions in cognitive resources impair or, somewhat paradoxically, benefit self-regulatory success (Schmeichel & Vohs, Van Dillen & Papies). A third focus is on how self-regulatory conflict resolution can be improved both in the short and in the long run. Exciting new avenues in this regard are the re-training of impulsive action tendencies (Wiers & Rinck) or the long-term improvement of cognitive resources. However, the effectiveness of such improvements with regard to self-regulatory success has not been examined thus far. In the symposium, findings from a variety of domains of appetitive behaviors will be related to these important research questions that go beyond a one-dimensional model of cognitive control by suggesting a more complex interplay of cognitive resources, regulatory goals, and psychological states than hitherto assumed.

#### **ABSTRACTS**

#### **WORKING MEMORY CAPACITY AND THE CONTROL OF DESIRE-DRIVEN ATTENTION AND IMPULSES** Wilhelm Hofmann<sup>1</sup>, Malte Friese<sup>1</sup>; <sup>1</sup>University

**of Würzburg, <sup>2</sup>University of Basel** – How is the control of tempting impulses possible? We present evidence from a series of studies showing that working memory capacity (WMC) is crucial for resisting everyday temptations. Specifically, we investigated the extent to which WMC moderates the influence of immediate affect towards temptations on attention and self-regulatory behavior in the domains of sexuality, alcohol, and eating. In Study 1, it was found that men's viewing time of erotic stimuli is more strongly related to immediate affect for low rather than high WMC individuals. A second study using eye-tracking methodology revealed that WMC was involved both with regard to the allocation (time to first fixation) and maintenance (average fixation duration) of attention to alcoholic beverages as compared to control stimuli. Studies 3 and 4 from the eating domain show that WMC also moderates the translation of immediate affect toward specific food (sweets) into explicit on-line evaluations while tasting the food and into actual consummatory behavior. Taken together, the present results yield strong support for the notion that immediate affective reactions to tempting stimuli can have a powerful influence on desire-related attention, thoughts, and behavior and that WMC is needed in order to inhibit these bottom-up influences in accordance with higher-order self-control goals.

#### **LOW LEVELS OF MENTAL CONSTRUAL AND EGO DEPLETION CAN IMPROVE SELF-CONTROL** Brandon Schmeichel<sup>1</sup>, Kathleen Vohs<sup>1</sup>; <sup>1</sup>Texas

**A&M University, <sup>2</sup>University of Minnesota** – The present investigation departs from previous research on the sources of success at self-control by testing the hypothesis that psychological states that routinely hasten self-control failure can in fact contribute to self-control success. Two psychological states known to undermine self-control were tested: a low

level of mental construal and ego depletion. In two experiments, participants in these states outperformed their counterparts on a stop-signal task—a canonical self-control task involving response inhibition. Moreover, an additional experiment found that ego depletion causes participants to move toward a low level of mental construal. We propose that when attending closely to the immediate stimulus environment is necessary for self-control success (as is the case in the stop-signal task), a low level of construal or ego depletion will contribute to self-control success. Conversely, when transcending the immediate environment is necessary for self-control success (as is the case in delay of gratification and emotion regulation paradigms, for example), these same psychological states will contribute to self-control failure. The current findings connect two major self-control theories, construal level theory and strength theory, and provide a more nuanced view of when, why, and how people succeed and fail at self-control than the one-size-fits-all approaches currently proposed by construal level and self-control strength theories.

**TURNING A BLIND EYE TO TEMPTATION: TASK LOAD REDUCES ATTENTION BIAS TO MOTIVATIONALLY SALIENT CUES** Lotte Van Dillen<sup>1</sup>, Belle Derks<sup>1</sup>, Esther Papies<sup>1</sup>; <sup>1</sup>Utrecht University, <sup>2</sup>Leiden University, <sup>3</sup>Utrecht University – Motivationally salient cues have always been assumed to automatically capture attention. In this presentation, we will argue that attention to motivationally salient cues may be fast and unintentional, but that this attention bias requires cognitive resources. We will discuss both behavioral and neuropsychological (EEG) findings that demonstrate the moderating impact of cognitive load on the preferential processing of motivationally salient cues. Participants performed a speeded spatial categorization task with neutral and motivationally salient stimuli, i.e. threatening faces (Study 1), desirable food items (Study 2), and attractive opposite-sex faces (Study 3). During the categorization task, cognitive load was varied such that participants either maintained one digit (low load), or eight digits (high load). In all three studies, there was attentional interference of motivationally salient cues, such that participants were slower to categorize motivationally salient stimuli than neutral stimuli. However, high cognitive load completely eliminated this attention bias. In addition, in Study 1, participants' brain responses reflecting the allocation of attention were greater in response to angry versus happy faces, but again, only when concurrent task load was low. Finally, in Study 2 and Study 3, individual differences in attentional control skills, as well as deprivation state, predicted participants' attention bias to motivationally salient cues, but only under low and not under high task load conditions. The present findings suggest that performing a demanding task might thus serve as an important strategy to escape from the captivating powers of the threats and lures that may hamper everyday self-regulation.

**RE-TRAINING AUTOMATIC APPROACH TENDENCIES IN HEAVY DRINKERS AND ALCOHOLICS** Reinout Wiers<sup>1</sup>, Mike Rinck<sup>1</sup>; <sup>1</sup>University of Amsterdam, <sup>2</sup>Radboud University Nijmegen – Research has demonstrated that relatively automatic processes are important in the etiology and maintenance of addictive behaviors. Even though a problem drinker may consciously know that heavy drinking is harmful, alcohol-related stimuli catch the eye (attentional bias), activate memory associations and a motivational tendency to approach the substance (review: Wiers, et al., 2007). We recently developed a test to assess automatic approach tendencies for alcohol (Wiers, et al., 2009). In this test participants react to the format of a picture (e.g. pull landscape pictures, push portrait pictures) by pulling or pushing a joystick. The size of the presented picture changes upon this movement (grows bigger after pulling, and smaller after pushing). Here we present data from two studies that attempted to re-train automatic approach tendencies. The first was done in heavy drinking students (n = 42), the second in alcoholic patients (n = 201). In the first study, half of the participants were trained to pull alcohol pictures (approach alcohol condition), and the other half to push alcohol pictures (avoid alcohol condition). We found generalized effects of this manipulation (e.g. effects on approach-avoid IAT using words). We also found an effect on drinking behavior in a taste-test, with heavy drinkers who

were successfully trained to push alcohol drinking less beer than heavy drinkers who were successfully trained to pull alcohol. In the clinical study, we successfully re-trained alcoholics to push alcohol away and we found generalized effects (IAT). We are currently following the alcoholics up regarding long term treatment success.

## Symposia Session J

Saturday, January 30, 5:00 - 6:15 pm

### Symposia Session J1

#### WORKING TOGETHER OR TEARING EACH OTHER DOWN: HOW MEMBERS OF LOW STATUS GROUPS TREAT THE INGROUP

Saturday, January 30, 5:00 - 6:15 pm, Royale Pavilion 1

Chair: Kerry Spalding, University of Washington

Speakers: Laurie O'Brien, Dina Eliezer, Grace Lau, Kerry Spalding

In spite of the plethora of work examining how members of high status groups thwart the advancement of members of low status groups, there is little research investigating whether members of low status groups support or fail to support ingroup members and what factors might determine whether they choose to support or harm the ingroup. The speakers in this symposium investigate how members of low status groups expect to be treated by one another, how they actually treat one another, and what factors influence whether they support other ingroup members. First, O'Brien examines how members of lower status groups respond when they are rejected by an ingroup hiring manager. Her research shows that Latinos perceive more discrimination and feel more betrayed when rejected by an ingroup (Latino) hiring manager compared to Whites rejected by an ingroup (White) hiring manager. Second, Eliezer demonstrates how women behave more harshly toward women than men who speak up about workplace discrimination. Third, Lau shows that when women are reminded of their group membership they take pride in rather than feel threatened by a successful female competitor. Finally, Spalding shows that women in powerful positions who identify with the ingroup are more likely to support ingroup members whereas women who are weakly group identified harm the ingroup. These four presentations provide new data, insight, and theory explaining when and why members of low status groups sometimes work together in competitive contexts and sometimes tear one another down.

#### ABSTRACTS

#### INGROUP REJECTION AND PERCEIVED DISCRIMINATION AMONG MEMBERS OF LOW STATUS AND HIGH STATUS GROUPS

Laurie O'Brien<sup>1</sup>, Brenda Major<sup>2</sup>, Stephanie Simon<sup>2</sup>, Alison Blodorn<sup>1</sup>; <sup>1</sup>Tulane University, <sup>2</sup>University of California, Santa Barbara – When people from low status groups achieve powerful positions within organizations dominated by higher status groups, members of their ingroup sometimes criticize them as disloyal to their group. The present research examines how people evaluate the actions of powerful people who make hiring decisions that benefit an outgroup member at the expense of an ingroup member. In Study 1, Latino and White Americans studied the employment decisions of an ingroup member who recommended hiring an outgroup member instead of an equally qualified ingroup member. Compared to Whites, Latinos were more likely to perceive discrimination when rejected by an ingroup job applicant in favor of an outgroup applicant. In Study 2, Latino applicants rejected by an ingroup (Latino) manager were more likely to perceive discrimination and feel betrayed than Whites rejected by an ingroup (White) manager. In Study 3, Latino applicants who were rejected for a job by an ingroup member were more likely to perceive discrimination if they had been primed with the ingroup loyalty norm than if they had not been primed. In Study 4, a loy-

ally prime increased perceptions of discrimination among Latinos reviewing the employment decision of a Latino manager who rejected a Latino candidate, but did not affect perceptions of discrimination among Latinos reviewing the decision of a Latino manager who rejected a White candidate. These studies suggest that loyalty norms may affect evaluations of decisions made by members of low status groups who succeed in organizations dominated by the high status group.

**IT'S NOT YOUR FAULT: EVALUATIONS OF INGROUP VERSUS OUTGROUP MEMBERS WHO ACKNOWLEDGE DISCRIMINATION EXPERIENCED BY ANOTHER PERSON** Dina Eliezer<sup>1</sup>, Major Brenda<sup>1</sup>; <sup>1</sup>University of California, Santa Barbara

— People who attribute their own poor treatment to discrimination face social costs. The current research examined whether the same social costs occur for people who attribute someone else's poor treatment to discrimination. In addition, the current research explored how people respond to ingroup versus outgroup members who claim discrimination. Across three experiments, male and female participants read a vignette in which a male boss made a sexist remark to a female employee, and in which a co-worker (male or female) overheard and said something to the woman. The co-worker either told the woman that the boss acted in a sexist manner or that he/she was sorry for her outcome. The boss's behavior was ambiguously sexist in study 1 and blatantly sexist in study 2. In Study 3, we compared reactions to ambiguous versus blatant sexism. Overall, participants rated bystanders who claimed discrimination more negatively than bystanders who expressed sympathy. However, female participants were especially punitive towards their own group members as they rated the female bystander who claimed discrimination more negatively than the male bystander who claimed discrimination. Male participants, in contrast, only rated the female bystander more negatively in the blatant sexism condition. Mediation analyses suggest that women rated the female bystander more negatively because they perceived her to be more biased than the male bystander. These results suggest that women who acknowledge discrimination experienced by members of their gender group face especially high social costs; ironically, these social costs may be inflicted upon them by other women.

**TAKING PRIDE IN GROUP MEMBERS' ACCOMPLISHMENTS: THE ROLE OF GROUP MEMBERSHIP SALIENCE** Grace Lau<sup>1</sup>, Steve Spencer<sup>1</sup>;

<sup>1</sup>University of Waterloo — Although many people take pride in their group's accomplishments, they may find such accomplishments threatening to their self-esteem in competitive environments. A woman may feel threatened by another woman's accomplishments if they are competing for the same job promotion. We investigated whether in competitive environments group members would nonetheless take pride in one another's accomplishments when group membership was salient. Female undergraduates completed a difficult math exam and learned that another female participant scored much higher (91st percentile) or lower (38th percentile) than they did (75th percentile). We manipulated group membership salience by telling half of participants that the exam was designed to reveal any gender differences in math ability. We found that when group membership (i.e., gender) was salient, participants took pride in the woman's achievement. They reported higher state self-esteem when the woman did better rather than worse than them. When group membership was not salient, however, participants were threatened by the woman's success. Their self-esteem was lower when the woman did better rather than worse than them. A sense of pride in group members' accomplishments may be important in motivating disadvantaged group members to help one another even when they are in a competitive setting.

**CLIMBING AND KICKING OR CLIMBING AND LIFTING: GROUP IDENTIFICATION MODERATES TREATMENT OF INGROUP SUBORDINATES** Kerry Spalding<sup>1</sup>, Cheryl Kaiser<sup>1</sup>; <sup>1</sup>University of Washington

— It is commonly assumed that as more women and minorities achieve leadership positions, they will help prevent future discrimination against members of the ingroup. However, there is little empirical

evidence demonstrating that women and minorities in positions of power help other ingroup members to advance. We argue that level of group identification influences whether women in positions of power support the advancement of other women. Female participants completed a prescreen measure of gender identification, then served as manager on a lab task in which they selected items for a test to determine whether a male or female subordinate would serve in the desirable role of assistant manager. The difference in the difficulty of the test items given to the subordinates was used as the measure of favoritism. Overall, participants did not favor either the female or the male subordinate. However, participants who were low in gender identification favored the male subordinate over the female subordinate; whereas, those who were high in gender identification favored the female participant. Notably, neither gender activism nor endorsement of system legitimizing ideologies predicted favoritism towards either subordinate. These findings have important implications for the viability of diversity programs that assume women and minorities in leadership positions will necessarily support other members of their ingroup. In fact, they suggest that if weakly identified women or minorities advance, they might actually favor the outgroup.

**Symposia Session J2**

**UNDERSTANDING NARCISSISM: MODERN, EMPIRICAL APPROACHES TO CLASSIC CONTROVERSIES**

Saturday, January 30, 5:00 - 6:15 pm, Royale Pavilion 2

Chairs: Ryan Brown, The University of Oklahoma, and Keith Campbell, The University of Georgia

Speakers: Virgil Zeigler-Hill, Keith Campbell, Robert Horton, Ryan P. Brown

Narcissism is a personality construct that is widely studied and discussed but that still remains full of complexities and questions. In this symposium, we address four classic controversies surrounding narcissism. First, we address the issue of narcissism and implicit cognition. One model of narcissism, which has its roots in early psychoanalytic thought and its branches in a popular conceptualization of narcissism, holds that narcissism is an explicit "mask" covering implicit low self-esteem. Results from the use of modern social-cognitive techniques to map narcissists' implicit cognitions are critically examined and discussed. Second, we examine whether trait narcissism and the clinical disorder, Narcissistic Personality Disorder (NPD), are one and the same. The case is made that trait narcissism and NPD are similar constructs, and that work in social-personality psychology has direct relevance to clinical work on NPD. Third, we examine the decades-old issue of narcissistic culture. Data will be presented showing the dynamic interplay between narcissism and a recent cultural phenomenon, reality television. There appears to be a bi-directional relationship between the two, with narcissists being drawn to reality television, and reality television increasing levels of narcissism. This finding has important implications for how we conceive of the origins of narcissistic tendencies. Finally, we explore the personality structure of narcissism. Data are presented showing that narcissism might be better conceptualized as two related factors, entitlement and grandiosity, rather than a single, monolithic construct. Taken together, these four talks address some of the classic controversies surrounding the nature and dynamics of narcissism.

**ABSTRACTS**

**NARCISSISM AND SELF-ESTEEM: THE ROLE OF DISCREPANCIES BETWEEN IMPLICIT AND EXPLICIT SELF-ESTEEM** Virgil Zeigler-Hill<sup>1</sup>,

Jennifer K. Bosson<sup>2</sup>, Erin M. Myers<sup>1</sup>; <sup>1</sup>University of Southern Mississippi, <sup>2</sup>University of South Florida — Narcissism is a pathological form of self-love characterized by arrogance, self-absorption, a sense of entitlement, and heightened reactivity to criticism. One of the most interesting questions about narcissism concerns how narcissists really feel about themselves "deep down inside." That is, do narcissists like themselves as much as their grandiose self-presentations suggest? Or, in contrast, is their gran-

diosity merely a façade that disguises underlying insecurities and self-doubts (an idea referred to as the psychodynamic mask model)? The purpose of this talk is to summarize empirical evidence both for, and against, the psychodynamic mask model of narcissism and to discuss possible reasons for the inconsistent findings that emerge across studies. For example, consistent with the psychodynamic mask model, two recent studies found that the highest levels of narcissism were reported by individuals with high levels of explicit self-esteem but low levels of implicit self-esteem (Jordan, Spencer, Zanna, Hoshino-Browne, & Correll, 2003; Zeigler-Hill, 2006). However, similar results failed to emerge in subsequent studies (Bosson et al., 2008; Campbell, Bosson, Goheen, Lakey, & Kernis, 2007; Gregg & Sedikides, 2008). Possible explanations for this inconsistency include the limited psychometric properties of implicit self-esteem measures, the failure to account for differences between agentic and communal implicit self-beliefs, and the existence of both grandiose and vulnerable forms of narcissism.

**COMPARING TRAIT NARCISSISM AND NARCISSISTIC PERSONALITY DISORDER (NPD)** Keith Campbell<sup>1</sup>, Joshua Miller<sup>1</sup>; <sup>1</sup>University of Georgia – There are two major traditions in the study of narcissism. On one hand, there is a large and growing body of empirical research on trait or "normal" narcissism; on the other, a theoretically rich but empirically impoverished body of work on Narcissistic Personality Disorder (NPD). Unfortunately, there is not much of a bridge between these two areas because it is uncertain whether trait narcissism and NPD represent the same, or even related, constructs. Past research has examined two important issues related to these questions: the types of narcissism (e.g., vulnerable vs. grandiose) and the continuous nature of narcissism (taxonic vs. normal). A third approach involves comparing the basic personality structure of narcissism versus NPD. In Study 1, the basic personality profile of normal narcissism as assessed by the Narcissistic Personality Inventory (NPI) closely matches the prototypical personality profile of NPD generated by practicing clinicians and clinical researchers. In Study 2, assessments of trait narcissism and NPD were conducted on both normal and clinical samples using two methods: the NPI and a structured clinical interview. Results showed that self-reported NPI scores were closely related to clinically rated NPD symptoms in both normal and clinical samples. Together, these two studies support the conclusion that trait narcissism and NPD share similar personality structures. Discussion focuses on building bridges between social-personality and clinical-psychiatric research and practice.

**A CULTURE OF NARCISSISM: DOES REALITY TV CREATE NARCISSISTS OR VICE VERSA?** Robert Horton<sup>1</sup>, Devin Moss<sup>1</sup>, Jessica Barber<sup>2</sup>, Jeff Green<sup>2</sup>; <sup>1</sup>Wabash College, <sup>2</sup>Virginia Commonwealth University – Three decades of social psychological research have elucidated the emotional, cognitive, and behavioral correlates and consequences of narcissism, yet the factors that contribute to narcissism have received relatively little attention. To date, investigations of such factors have focused upon specific parenting practices or heritability. In this talk, however, we describe research that focuses on the cultural phenomenon of reality TV and its bidirectional relation to narcissism. In our view, reality TV represents a cultural endorsement of narcissism, of exhibitionism, entitlement, and self-absorption that can send powerful messages that create and/or inhibit narcissism. In our first study, participants reported their exposure to reality TV and dispositional narcissism. As expected, narcissism was positively correlated with how much reality TV participants watched, how favorably they evaluated reality TV, and the extent to which the reality shows they watched reflected narcissistic qualities (e.g., self-absorption, exhibitionism, etc.). Our second study expanded upon this work by assessing narcissism after participants viewed either reality or drama TV. Participants who viewed reality TV reported higher narcissism than did those who viewed drama TV. Overall, these data suggest that dispositional narcissism and reality TV programs enjoy a reciprocal causal relation: narcissists are drawn to reality TV, which further perpetuates narcissism. More broadly, this work points to cultural influences on personality and the possibility that the Western world's relatively

new media focus on the "average" person may have unintended consequences.

**WILL THE REAL NARCISSIST PLEASE STAND? A DIMENSIONAL PERSPECTIVE ON THE MEANING OF NARCISSISM** Ryan P. Brown<sup>1</sup>, Michael Tamborski<sup>1</sup>, Karolyn Budzek<sup>1</sup>; <sup>1</sup>University of Oklahoma – For thirty years, social psychologists have used the Narcissistic Personality Inventory (NPI) to define and measure the narcissism construct, with no competing operational definitions gaining widespread acceptance. The dominance of the NPI within this field of research has led to a situation in which the meaning of the construct has become almost synonymous with scores on this measure. Has this virtual hegemony been boon or bane for our understanding of this complex and fascinating individual difference? Perhaps the answer is "both." But perhaps, too, it is time to explore some alternative conceptualizations and measures of narcissism. My colleagues and I have amassed data from thousands of respondents who have completed recently developed measures of narcissistic grandiosity and narcissistic entitlement, and we have examined the similarities and distinctions between these measures as they relate to a host of other variables, from self-report measures of personality and attitudes, to measures of complex decision-making and behavior. Our data support a view of narcissism in which grandiosity and entitlement represent distinct dimensions of the narcissistic self, challenging the reigning perspective of a unified, monolithic construct, and offering directions for a more nuanced approach to one of psychology's favorite dysfunctions.

### Symposia Session J3

#### CONTEXTUALIZING INTERPERSONAL COMMUNICATION: WHEN "POSITIVE" BEHAVIORS ARE NEGATIVE AND "NEGATIVE" BEHAVIORS ARE POSITIVE

Saturday, January 30, 5:00 - 6:15 pm, Royale Pavilion 5

Chairs: James K. McNulty and V. Michelle Russell, University of Tennessee  
Speakers: Laura B. Luchies, Jeffry A. Simpson, James K. McNulty, Ronald D. Rogge

Romantic relationship outcomes are multiply determined. Stable characteristics of each partner (e.g., personality) interact with external factors (e.g., stress) to predict the cognitive and behavioral factors that ultimately determine the health of the relationship. Making the story even more complex, the effects of such cognitive and behavioral factors vary according to the context in which they occur. This symposium illuminates some of the contextualized effects of the communication behaviors that occur during problem-solving interactions. In the first talk, Luchies and Finkel describe three studies demonstrating that forgiveness, typically considered a positive behavior, can adversely affect the self when granted in the absence of amends. In the second talk, Simpson, Overall, and Fletcher describe longitudinal evidence demonstrating that direct negative behaviors can be adaptive for the relationship by motivating partners to make necessary changes to improve the relationship over time. In the third talk, McNulty and Russell describe two longitudinal studies demonstrating that such negative behaviors, although harmful in the context of relationships facing only minor problems, can help sustain marital satisfaction in the context of relationships facing more severe problems. Finally, Rogge and Funk describe longitudinal evidence that expands the scope of this analysis to a more societal level by demonstrating that the broader context in which couples live also moderates the effects of their negative communication behaviors on their relationship outcomes. In sum, these four talks highlight the importance of considering not only the content of couples' problem-solving behaviors, but also the context in which those behaviors occur.

## ABSTRACTS

**THE DOORMAT EFFECT: WHEN FORGIVING ERODES SELF-RESPECT AND SELF-CONCEPT CLARITY**

Laura B. Luchies<sup>1</sup>, Eli J. Finkel<sup>1</sup>; <sup>1</sup>Northwestern University – Are the effects of forgiveness universally positive? Based on McCullough's (2008) assertions that (a) victims' "forgiveness instinct" inclines them to forgive perpetrators who make amends and (b) victims who forgive contrary to their forgiveness instinct "quickly become everybody's doormat" (p. 87), we hypothesized that the effect of forgiveness on self-respect and self-concept clarity depends on the extent to which the perpetrator makes amends: Forgiving (a) bolsters one's self-respect and self-concept clarity if the perpetrator makes amends, but (b) diminishes one's self-respect and self-concept clarity if the perpetrator does not. In two experiments, we manipulated forgiveness of and partner amends made for a hypothetical betrayal (Study 1) and an actual betrayal (Study 2). In both experiments, the effects of forgiveness on self-respect and self-concept clarity depended on whether the perpetrator made weak or strong amends: forgiveness trended toward bolstering self-respect and self-concept clarity when the perpetrator made strong amends, but diminished self-respect and self-concept clarity when the perpetrator made weak amends. In Study 3, participants reported their forgiveness of and partner amends made for naturally occurring partner betrayals over a six-month period. The association of forgiveness with self-respect and self-concept clarity again depended on the extent to which the perpetrator made amends: forgiveness predicted bolstered self-respect and self-concept clarity when the perpetrator made strong amends, but trended toward predicting diminished self-respect and self-concept clarity when the perpetrator made weak amends. These findings highlight the interactive effects of victims' and perpetrators' responses and communication following an interpersonal betrayal.

**REGULATION PROCESSES IN INTIMATE RELATIONSHIPS: THE COSTS AND BENEFITS OF TRYING TO CHANGE INTIMATE PARTNERS**

Jeffrey A. Simpson<sup>1</sup>, Nickola C. Overall<sup>2</sup>, Garth J. O. Fletcher<sup>3</sup>; <sup>1</sup>University of Minnesota, <sup>2</sup>University of Auckland, <sup>3</sup>University of Canterbury – This study tested the success of communication strategies used by relationship partners (N=61 romantic couples) who were videotaped while trying to produce desired changes in each other. Strategies varying in valence (positive versus negative) and directness (direct versus indirect) were differentially associated with post-discussion perceptions of success as well as ratings of demonstrated change in targeted features gathered at 3-month intervals during the following year. Direct strategies (both positive and negative) were initially perceived as relatively unsuccessful, but predicted increased change in the targeted partner over the next 12-months. Positive-indirect strategies, in contrast, were associated with higher concurrent perceived success, but did not predict later change. These findings indicate negative communication that directly engages the partner clearly conveys the severity of the problem and, thus, motivates change by the targeted partner. In contrast, soft and subtle attempts to accomplish change are likely to maintain harmony and satisfaction in the short-term, but may ultimately fail to produce any real change.

**WHEN "NEGATIVE" BEHAVIORS ARE POSITIVE: A CONTEXTUAL ANALYSIS OF THE LONG-TERM EFFECTS OF PROBLEM-SOLVING BEHAVIORS ON CHANGES IN RELATIONSHIP SATISFACTION**

James K. McNulty<sup>1</sup>, V. Michelle Russell<sup>1</sup>; <sup>1</sup>University of Tennessee – How should partners discuss the problems that arise over the course of their intimate relationships? Prior studies have provided inconsistent answers to this question, with some suggesting that partners benefit by avoiding negative behaviors and others suggesting that partners benefit by engaging in negative behaviors. The two longitudinal studies described here attempted to reconcile these inconsistent findings by examining whether direct negative problem-solving behaviors interact with the severity of the problems couples face in their relationships to account for changes in relationship satisfaction over time. Both studies used observations of newlywed couples' behaviors during two problem-solving interactions to predict the

trajectory of their marital satisfaction over time. The first study observed 72 couples and spanned the first 5 years of marriage; the second study observed 135 couples and spanned the first year of marriage. Both studies provided support for predictions. Specifically, whereas spouses' tendencies to blame, command, and reject their partners predicted steeper declines in their own marital satisfaction when exhibited in the context of relationships facing only minor problems, those same behaviors predicted more stable satisfaction in relationships facing more severe problems. Subsequent analyses revealed that changes in the severity of the problems themselves mediated these effects. The current findings join others in highlighting the theoretical importance of accounting for the relational context when examining the implications of various interpersonal processes.

**WHAT DOES THAT MEAN? NEIGHBORHOOD FACTORS MODERATING THE MEANING OF BEHAVIOR IN RELATIONSHIPS**

Ronald D. Rogge<sup>1</sup>, Janette L. Funk<sup>1</sup>; <sup>1</sup>University of Rochester – This study examined the role of neighborhood factors in predicting change in relationship functioning in a sample of 287 newlywed couples followed over the first 2 years of marriage. The study specifically examined how neighborhood factors might moderate the meaning of hostile conflict behavior (e.g., shouting, calling names) in relationships. We examined levels of neighborhood crime (assessed through local police and sheriff's departments), neighborhood SES, demographic risk and youthfulness (assessed with census data), as well as individual perceptions of neighborhood cohesion and decay. Slope-intercept models were created within an HLM framework to test the proposed moderation hypotheses, including the appropriate terms to model both actor and partner effects freely across gender. After controlling for neuroticism, parental divorce and hostile conflict behavior, neighborhood crime was associated with relative decreases in men's satisfaction over time. In addition, the analyses revealed a number of moderation effects. Male hostile conflict was most clearly negatively related to initial levels of marital satisfaction in high-risk neighborhoods (e.g., extreme poverty, high rates of unemployment, high rates of disability), in neighborhoods with fewer children and for males perceiving low levels of neighborhood cohesion. Over time, however, male hostile conflict was unexpectedly associated with better outcomes in neighborhoods with fewer children. Likewise, higher levels of female hostile conflict were also associated with better outcomes over time in high-risk neighborhoods and in neighborhoods with more children. Thus, the results suggest that the impact of behavior on relationships might be dependent on the larger socio-cultural context in which that behavior occurs.

**Symposia Session J4****THE SOCIAL FACE: HOW SOCIAL CATEGORIZATION INFLUENCES FACE PERCEPTION**

Saturday, January 30, 5:00 - 6:15 pm, Royale Pavilion 6

Chairs: Kurt Hugenberg, Miami University, and Olivier Corneille, Catholic University of Louvain

Speakers: Olivier Corneille, Natalie Ebner, Kurt Hugenberg, Tiffany Ito

Recent evidence indicates that the process of social categorization and face perception are linked. We present a series of talks that investigate the interface of social categorization and face perception. Tiffany Ito finds that how a racially ambiguous target is evaluated and categorized depends critically upon contextual influences. While automatic evaluations of racially ambiguous faces falls between those of ingroup and outgroup faces, contextual influences (e.g., racial labels, other faces) can affect categorization, leading an otherwise racially ambiguous face to be judged and evaluated as more prototypic of a racial category. Olivier Corneille and Natalie Ebner provide evidence that social category distinctions (e.g., own-group versus other-group distinctions) affect how faces are processed. Corneille finds that ingroup faces are processed more holistically than are outgroup faces, demonstrating the top down influence of social categorization on how the features of faces are perceptually integrated. Using eye tracking techniques,

Ebner shows that ingroup faces (own-age versus other-age) attract more visual attention than do outgroup faces, for both neutral and expressive faces. Finally, Kurt Hugenberg finds that social categories affect how faces and facial expressions are recognized. Even holding perceiver expertise constant, people are better at encoding the individuating characteristics and facial expressions of ingroup faces, relative to outgroup faces, generating group biases in face and expression recognition. Taken together, the current talks illustrate how faces are categorized, how such categorization affects face perception.

#### ABSTRACTS

#### **HOLISTIC FACE PERCEPTION DEPENDS ON THE SOCIAL CATEGORIZATION OF FACES** Olivier Corneille<sup>1</sup>; <sup>1</sup>Catholic University of Louvain

— Adult's expertise at processing faces relies on how facial features are encoded: as a whole template rather than as a sum of independent features. This holistic processing is reduced for other-race faces, possibly accounting for the difficulty one encounters in recognizing these faces (the 'other-race effect'). In a series of recent experiments, we tested the hypothesis that the racial and social categorization of faces modulate their holistic processing. In Experiment 1 and 2, Caucasian participants performed a face-composite task with racially-ambiguous face-stimuli. Experiment 1 shows that faces are processed more holistically when included in a block comprising predominantly same-race than other-race faces. Experiment 2 relied on a face adaptation paradigm and shows that racially-ambiguous faces are processed more holistically when perceptually adapted with other-race than with same-race faces. Experiment 3 showed that Caucasian faces are perceived more holistically when participants are led to believe that these faces belong to an ingroup (i.e., their university) rather than to an outgroup (i.e., another university). As a set, these findings demonstrate that the social categorization of faces strongly impacts how the features of these face are perceptually integrated.

#### **SOCIAL CATEGORY AFFECTS HOW WE LOOK AT A FACE: VISUAL SCAN PATTERNS DIFFER FOR OWN-AGE VERSUS OTHER-AGE FACES** Natalie Ebner<sup>1</sup>, Yi He<sup>1</sup>, Marcia Johnson<sup>1</sup>; <sup>1</sup>Yale University

— Age is a salient social category. For example, adults of different ages are better at remembering faces of their own compared to other age groups and are more distracted by task-irrelevant faces of their own age. Does the similarity between age of the perceiver and age of the perceived affect how faces are initially inspected? Using eye tracking, in two experiments we examined differences in young and older adults' visual scanning of young and older faces. In Experiment 1, both young and older participants spent more time scanning own-age as compared to other-age faces during passive viewing of neutral young and older faces. Comparing fixation patterns in lower versus upper halves of faces, both age groups fixated longer on upper halves of young faces than upper halves of older faces. In Experiment 2, with emotional face stimuli, both young and older participants showed longer gaze times for own-age than other-age faces during an expression identification task. Differences in pupil diameter, however, suggested a stronger affective response to young than older emotional faces in both age groups. In addition, the age groups differed in their pattern of fixation time on upper halves of angry compared to happy faces for young but not older faces, suggesting that the age of the face also influences how young and older adults inspect positive versus negative faces. Relations of age-related biases in scan patterns to old/new face recognition and accuracy in facial expression identification are discussed.

#### **INGROUPS, OUTGROUPS, AND THE FACE: MERE SOCIAL CATEGORY DISTINCTIONS AFFECT FACE AND FACIAL EXPRESSION RECOGNITION** Kurt Hugenberg<sup>1</sup>; <sup>1</sup>Miami University

— Ingroup/outgroup distinctions have long been known to elicit motivated processing and behavior. Although ingroup/outgroup biases in face and expression recognition have been commonly attributed to superior expertise with decoding ingroup faces, recent evidence suggests that the motivational bases of ingroup/out-

group distinctions can bias face perception, even when holding perceiver expertise constant. In Experiment 1, White participants received bogus feedback about their personality type before encoding and recognizing same-race faces who shared and did not share their personality type. Results indicated that a shared ingroup membership (personality type) was sufficient to improve face recognition, relative to outgroup targets. Experiments 2 and 3 extend these results into the domain of expression recognition. In Experiment 2, a shared ingroup membership improved facial expression recognition in a speeded expression recognition task. Finally, Experiment 3 showed that the improved expression recognition only occurred when participants had sufficient encoding time to bring online additional processing resources to assist the processing of ingroup faces. Taken together, these results demonstrate the importance of social category distinctions (ingroups and outgroups) in face perception, face memory, and facial expression recognition.

#### **FEATURE TYPICALITY AND CONTEXTUAL INFLUENCES ON RACIAL CATEGORIZATION** Tiffany Ito<sup>1</sup>, Eve Willadsen-Jensen<sup>2</sup>; <sup>1</sup>University of Colorado, <sup>2</sup>North Hennepin Community College

— Racial categorization is ubiquitous, and tends to occur quickly and automatically. But what happens when perceivers encounter an individual whose facial features make it difficult to categorize him or her into a single racial group? Our research shows that reactions are influenced by both bottom up and top down processes. Studies will be presented showing that automatic evaluative reactions to racially ambiguous faces are influenced by the particular features of the faces, with evaluations of racially ambiguous faces falling in between those to individuals who are clearly ingroup or outgroup members. Other studies focus on the influence of contextual features on categorization and evaluation. Seeing a racial label (e.g., "Black") leads racially ambiguous faces to be categorized, evaluated, and remembered in accord with the label. Similarly, embedding the face within a context of faces of a particular race (e.g., Black faces) affects categorization and evaluations, but in the direction of a contrast effect. For example, a racially ambiguous face is judged to be more prototypical of Whites and evaluated more favorably when viewed in conjunction with lots of Black faces. These results help to illustrate the interplay of multiple processes that act to influence how faces are categorized, and the subsequent reactions that are influenced by that categorization. They also specifically provide information about the factors that influence categorization of racially ambiguous faces.

#### Symposia Session J5

#### **THE PSYCHOLOGICAL MEANING OF THINGS AND PLACES**

Saturday, January 30, 5:00 - 6:15 pm, Royale Pavilion 3-4

Chair: Alison Ledgerwood, UC Davis

Speakers: Melissa Ferguson, Courtney Bonam, Alison Ledgerwood, Geoffrey Miller

Everyday thinking and behavior plays out in a material context: We live our lives in physical spaces, surrounded by tangible objects. Yet surprisingly little research has examined the psychological meaning we attach to things and places. This symposium brings together an array of perspectives that shed new light on this relatively understudied topic, which has recently begun to attract new interest across different domains. The talks explore how the meaning associated with things and places can influence evaluations, beliefs, and behaviors, as well as why and how people strategically use material objects to communicate meaning to others. Throughout, the presenters highlight the implications of these social-cognitive processes for consequential behaviors and societal outcomes. The symposium begins by exploring the unintentional and powerful effects that objects can exert on cognition and behavior. In the first research to study the effect of national symbols on real-world voting behavior, Ferguson examines the profound impact of a single-shot exposure to the American flag on attitudes and voting in the 2008 elections. Next, Bonam investigates how the perceived Whiteness or Blackness associated with physical spaces changes the way those spaces are valued

and evaluated. Ledgerwood describes research suggesting that part of the reason people value group-owned property is because it communicates aspects of group identity to other people. Finally, Miller discusses how individuals use material objects to signal desirable personality characteristics to others. By bringing these perspectives together, this symposium begins to build an integrative framework for understanding the psychological meaning of things and places.

#### ABSTRACTS

#### **THE ELEPHANT IN THE ROOM: THE EFFECT OF THE AMERICAN FLAG ON POLITICAL BEHAVIOR IN THE 2008 AMERICAN PRESIDENTIAL ELECTION**

Melissa Ferguson<sup>1</sup>, Travis Carter<sup>1</sup>, Ran Hassin<sup>2</sup>; <sup>1</sup>Cornell University, <sup>2</sup>The Hebrew University – Recent research demonstrates that subtle exposure to national symbols leads to a range of effects on beliefs, attitudes, and behavior. In this talk I review findings showing that a single exposure to the American flag during an online study influenced participants' opinions on policies, voting intentions and behavior in the 2008 presidential election, and subsequent support for President Obama following the election. Prior to the election, we recruited a sample of participants from across the United States for a multiple-session online study. We primed some participants with a small American flag while they were reporting their voting intentions. Compared with a control group, they were significantly more likely to intend to vote for McCain over Obama, and marginally more likely to actually do so. These participants were also more likely to express positive attitudes toward the Republican candidates and the Republican Party, and more likely to adopt the conservative position on political issues. These effects lasted well beyond the election. The findings show that a brief, single-shot exposure to the American flag can influence a range of important opinions and behaviors, even well after the exposure.

#### **POLLUTING BLACK SPACE**

Courtney Bonam<sup>1</sup>, Jennifer Eberhardt<sup>1</sup>, Hilary Bergsieker<sup>1</sup>; <sup>1</sup>Stanford University – Do places have races? Why might place-race associations matter? Three studies show that people attach racial meaning to a range of locations, devalue racially-imbued Black space, and experience more comfort polluting it. Study 1 participants rated the extent to which various locations (e.g., inner cities, suburbs) are associated with Whiteness or Blackness. Spaces with high Blackness ratings had low Whiteness ratings, showing that participants made clear distinctions between Black and White places. Places with high Blackness ratings also had high negative, low affluent, and high dangerous ratings. Opposite associations characterized spaces with high Whiteness ratings, showing that participants devalue Black but not White spaces. Study 2 expanded this finding by manipulating the race of one location. Participants viewing a house for sale by a Black or White family devalued the Black versus White house (they thought it would appreciate more slowly and were less eager to move there). In Study 3, not only were participants more likely to devalue Black versus White spaces, they were also more likely to treat them poorly. Specifically, participants reported more comfort with building a chemical plant near a Black, versus White, neighborhood. Devaluing the Black neighborhood mediated this relationship. These results are important because Black communities are disproportionately exposed to industrial pollution (Bullard & Johnson, 2000), yet the role of racial biases in causing this disparity is debated. Our studies are the first to experimentally address this issue, and suggest that racial bias is one factor causing disproportionate amounts of pollution in Black communities.

#### **GROUP IDENTITY GOALS AND THE SYMBOLIC VALUE OF PROPERTY**

Alison Ledgerwood<sup>1</sup>, Ido Liviatan<sup>2</sup>; <sup>1</sup>UC Davis, <sup>2</sup>New York University – Property lies at the heart of conflicts around the globe and throughout history, but what drives the high value that group members often place on land and other forms of property? Drawing on theories of shared reality, symbolic self-completion, and social identity, the present framework conceptualizes group identity as a goal toward which group members strive by seeking out socially-recognized symbols of group identity.

Because group property is often related to a group's history and identity, it can provide a means by which such group identity motivations can be pursued. Accordingly, when group identity goals are highly activated, group members should attach greater value to property and other potential symbols of group identity that help to communicate the defining features of that group identity to others. Importantly, only symbols that are socially recognized as relating to group identity can serve this communicatory function. Across five studies, we show that the value placed on group-owned property depends on the personal and situational importance of identity and on the extent to which the property's symbolic significance is socially recognized. Furthermore, when this desire for social recognition is addressed, group members are more willing to compromise with an outgroup over physical ownership of a group identity symbol. Implications for understanding and ameliorating intergroup conflicts are discussed.

#### **CONSPICUOUS CONSUMPTION AS TRAIT DISPLAY: INTELLIGENCE, THE BIG FIVE PERSONALITY TRAITS, AND PRODUCT BRANDING**

Geoffrey Miller<sup>1</sup>; <sup>1</sup>University of New Mexico – This talk reviews recent theory and evidence on the relationship between sex, evolution, and consumer behavior. In modern life, the psychological meanings of things are heavily influenced by marketing and branding. The new field of evolutionary consumer psychology is clarifying how this works, using theories of sexual selection and costly signaling from evolutionary biology, and theories of conspicuous consumption and positional goods from economics. In particular, consumers seem unconsciously motivated to attract mates and friends by showing off certain mental traits through the products that they buy, use, and display. These traits include general intelligence, the Big Five personality traits, and certain moral virtues. By creating learned associations between universal human mental traits and culture-specific 'brand personalities,' advertising imbues branded products with social and sexual signaling power.

#### Symposia Session J6

#### **THE SOCIAL ECOLOGY OF EMOTIONAL DISCLOSURE**

Saturday, January 30, 5:00 - 6:15 pm, Royale Pavilion 7-8

Chair: Kent Harber, Rutgers University at Newark

Speakers: Matthias Mehl, Anita Kelly, Richard Slatcher, Kent Harber

Few things so define being human as personal disclosure. Social bonds, romantic intimacy, and self-discovery begin and grow through the open exchange of thoughts and feelings. But disclosures can also be risky, leading to embarrassment, rejection, and stigmatization. The social psychology of disclosing – what to say, when, and to whom, with what costs and benefits – has only recently been systematically examined. James Pennebaker's studies on expression and health, which initiated much of the modern research on disclosure, were largely confined to written disclosures monitored in research labs. However, sharing is inherently interpersonal, occurring within fluid, complex social settings. This symposium examines the social ecology of disclosure, tracking new connections between intra-psychic and inter-personal dynamics. Matthias Mehl and Megan Roberts discuss research on how everyday conversations help couples cope with breast cancer. Using Mehl's Electronically Activated Recorder (EAR), which tracks people's acoustical social lives in real time, they find that the degree and quality of conversations predicted symptom management. Anita Kelly examines the interpersonal liabilities of disclosure, and how withholding rather than disclosing personal secrets protects physical health. Achieving closure, she shows, determines whether disclosures promote or hinder health. Richard Slatcher and associates, also using the EAR, shows how everyday disclosures between couples affect cortisol levels. They also show how private self-to-self disclosure affects the quality and longevity of couples' relationships. Kent Harber and associates discuss research on the Emotional Broadcaster Theory of social sharing. EBT research shows that the intra-psychic compulsion to disclose has the inter-personal benefit of spreading news.

## ABSTRACTS

**THE DAILY INTERACTIONS OF COUPLES COPING WITH BREAST CANCER: HOW IS NATURALISTICALLY OBSERVED DISCLOSURE RELATED TO PSYCHOLOGICAL ADJUSTMENT?**

Matthias Mehl<sup>1</sup>, Megan Robbins<sup>1</sup>, Anna Maria Lopez<sup>1</sup>; <sup>1</sup>University of Arizona – This study used the Electronically Activated Recorder (EAR) for studying real-world disclosure processes in couples coping with breast cancer. The EAR is an unobtrusive observation sampling method that operates by periodically recording snippets of ambient sounds from participants' immediate environments. Twenty breast cancer patients and their romantic partners wore the EAR over one weekend during active treatment. The patients' and their partners' psychological adjustment was assessed during the initial study session and at a two-month follow-up. The recorded EAR sound bites were coded for participants' conversation partner (i.e. with romantic partner vs. with a friend or family member) and were also content analyzed for the topics of their interactions (coding of 'about cancer' vs. 'about other topic' and LIWC analysis). Consistent with predictions from disclosure theory and relationship maintenance theory, initial analyses revealed that both cancer-related and non-cancer related conversations predicted couples' psychological adjustment. Whereas participants' total amount of cancer-related talk served as a general "disturbance indicator" and was negatively linked to adjustment, specific healthy forms of disclosure (e.g., working-through cancer talk) were linked to better adjustment. Overall, however, cancer talk represented only a small fraction of couples' daily interactions, leaving plenty of room for non-cancer talk to predict patients' and partners' psychological adjustment. Consistent with theories of couple communication (Duck et al., 1991), we found that general pro-relationship behaviors (e.g., positivity, socializing) were strongly related to better adjustment. We argue that the importance of routine, relationship maintenance interactions (compared to direct, illness-focused interactions) has been underestimated in coping research.

**WHY DISCLOSING TO A CONFIDANT CAN BE SO GOOD (OR BAD) FOR US**

Anita Kelly<sup>1</sup>; <sup>1</sup>Notre Dame University – The purpose of this talk is to explain the theoretical mechanisms behind the health benefits or detriments of disclosing personal information, especially personal secrets, to others. I begin by discussing the complexities behind a decision to reveal a personal secret. I highlight studies that have shown that revealing personal information can go well or backfire, depending on the responsiveness of the confidant. I then critically evaluate leading theoretical explanations that have been offered for why personal disclosures can cause health benefits. I also describe as-yet-unpublished data from my own laboratory that require the modification of these existing theories. I conclude by providing an explanation for why disclosing secrets to another person not only can be healthful, as has been emphasized in the literature, but also can be harmful to the revealer. In doing so, I offer a way to predict when the outcomes will be positive or negative. This prediction hinges on whether the disclosure causes one to gain closure on the revealed information.

**MOMENTARY WORK WORRIES, MARITAL DISCLOSURE AND SALIVARY CORTISOL AMONG PARENTS OF YOUNG CHILDREN**

Richard Slatcher<sup>1</sup>, Theodore Robles<sup>2</sup>, Rena Repetti<sup>2</sup>, Michelle Fellows<sup>3</sup>; <sup>1</sup>Wayne State University, <sup>2</sup>University of California at Los Angeles, <sup>3</sup>University of Texas at Austin – For over a decade researchers have incorporated salivary cortisol sampling into investigations of everyday stress, particularly in the context of families. However, very little is known about how short-term changes in feelings of stress in everyday life (e.g., worries about work) are related to cortisol levels. Further, while research has shown that satisfying marriages may buffer the effects of everyday stress, the specific mechanisms through which marriage influences stress physiology have not yet been identified. This study investigated the effects of momentary work worries on salivary cortisol and the moderating effect of marital disclosure in a sample of 51 married couples with preschool-aged children. Couples completed questionnaires assessing work worries and provided saliva

samples 6 X /day from Saturday through Monday. Actor-Partner Interdependence Model (APIM) analyses showed wives' cortisol levels to be positively associated with their own work worries and with their husbands' work worries. Husbands' cortisol levels were positively associated only with their own work worries. Wives lower in marital disclosure were more physiologically reactive to their own work worries compared to wives reporting high marital disclosure. These results have implications for understanding how daily experiences affect cortisol in everyday life and suggest a pathway through which marital quality may reduce the physiological impact of psychological stress.

**THE EMOTIONAL BROADCASTER THEORY OF SOCIAL SHARING**

Kent Harber<sup>1</sup>, Lisbeth Dyer<sup>1</sup>, Paul Boxer<sup>1</sup>; <sup>1</sup>Rutgers University at Newark – People disclose major events repeatedly, often with little prompting, to both strangers and intimates, and sometimes even when sharing is risky. This drive to disclose has been mostly explained in terms of personal benefits (e.g., mental and physical health). Emotional Broadcaster Theory (EBT) proposes a communal benefit—that the need to disclose transforms people into news-broadcasters, whose stories inform others. EBT predicts that disturbing events create social telegraphs, where the tellers' experiences are absorbed by their hearers, who are themselves compelled to disclose. This was confirmed in a study of 33 students attending a hospital morgue field trip (Harber & Cohen, 2005). The students' morgue-related distress predicted how many friends they told (primary disclosure), how many people their friends told (secondary disclosure), and how many people their friends' friends told (tertiary disclosure). Within 2 weeks nearly 900 people heard about this event. EBT also predicts that story transfer follows the condition that arouses motions—the violation of expectations. Thus, highly negative events will mainly be disclosed by people for whom such events are uncommon. This prediction was confirmed in studies where subjects first reported their own history of violence (HOV), and then days later rated how they would react to witnessing violent events and unusual non-violent events. Violent events disturbed people with low HOV, whose distress predicted their inclination to disclose. However, high HOV people were both less disturbed by violent events and less likely to share them. HOV, as expected, was unrelated to reactions to non violent negative events.

## Symposia Session J7

**DISTINCT AND COMMON EFFECTS OF VARIOUS PSYCHOLOGICAL THREATS**

Saturday, January 30, 5:00 - 6:15 pm, Capri Rooms 101-102

Chairs: Gale M. Lucas and Daniel C. Molden, Northwestern University

Speakers: Dianne M. Tice, Jeff Schimel, Gale M. Lucas, Ian McGregor

People experience different kinds of threats in the social and physical world - from being rejected by others to contemplating our own mortality to being uncertain about what to do. Although much research has examined such threats, each is often considered in isolation. Accordingly, the experiences and outcomes of various threats are not often directly compared, potentially obscuring both their distinct and their common psychological mechanisms and behavioral outcomes. This symposium aims to undertake such a comparison and illuminate the unique and shared effects of a variety of psychological threats. The first two talks will examine some distinct consequences of social rejection and mortality salience. Dianne Tice will first present studies demonstrating that acetaminophen, shown previously to specifically influence pain affect, causes a reduction in hurt feelings from rejection but not other, non-social threats. Jeff Schimel will then present studies demonstrating that, in contrast to other threat experiences that impair subsequent motivation and performance (e.g., social rejection), reminders of death specifically enhance performance and motivation on cognitive tasks compatible with participants' cultural worldview. The last two talks will then describe two contrasting self-regulatory perspectives on the common effects of different threats. Gale Lucas will present studies demonstrating that immediately following various threat experiences people

show general vigilance and distancing responses that are mediated by the activation of prevention-focused self-regulation. Ian McGregor will then present studies demonstrating that after some time passes following various threat experiences, people show reactive shifts toward approach-oriented self-regulation.

#### ABSTRACTS

**TYLENOL REDUCES THE PAIN OF SOCIAL REJECTION: BEHAVIORAL AND NEURAL EVIDENCE** Dianne M. Tice<sup>1</sup>, C. Nathan DeWall<sup>2</sup>, Naomi I. Eisenberger<sup>3</sup>, Carrie Masten<sup>3</sup>, Roy F. Baumeister<sup>1</sup>; <sup>1</sup>Florida State University, <sup>2</sup>University of Kentucky, <sup>3</sup>University of California, Los Angeles – Across cultures, people describe their response to social rejection with metaphors invoking physical pain (e.g., “hurt” feelings). Recent work indicates that social exclusion activates aspects of the body’s pain systems, and reactions to social exclusion appear to be mediated by aspects of physical pain systems. Hurt feelings, a common emotional response to social exclusion, may represent the experience of pain affect following perceived social rejection. If so, analgesics that include pain affect systems among their mechanisms of action may serve to lessen the experience of hurt feelings in daily life. Three studies are presented testing whether acetaminophen, shown previously to influence pain affect mechanisms, reduces hurt feelings and neural pain responses. Participants randomly assigned to consume acetaminophen experienced a decrease in daily hurt feelings over a three-week period (particularly among individuals with a low drive component of the behavioral activation system). Study 2 showed that acetaminophen had no impact on reducing sensitivity to negative, non-social events. Acetaminophen specifically influenced social and physical pain responses instead of having a general analgesic effect to all negative events. Study 3 showed that acetaminophen reduces dorsal anterior cingulate and interior insula activation in response to social rejection. These results suggest acetaminophen may provide a novel, non-addictive, pharmacological route to reducing social pain. This research adds to the growing body of evidence showing that describing social exclusion as causing pain has a neuroscientific basis.

**THE MACGYVER EFFECT: EVIDENCE THAT MORTALITY SALIENCE FACILITATES COGNITIVE PERFORMANCE ON MEANINGFUL TASKS** Jeff Schimel<sup>1</sup>, Todd J. Williams<sup>2</sup>, Joe Hayes<sup>1</sup>, Erik Faucher<sup>1</sup>; <sup>1</sup>University of Alberta, <sup>2</sup>Grand Valley State University – A basic proposition of terror management theory is that people's beliefs about the nature of reality, their cherished cultural values, and feelings of personal significance all function to help them cope with the certainty that they will eventually die. In support of this hypothesis, numerous studies have shown that reminders of death motivate people to uphold and defend their cultural worldview and bases for self-esteem. Consistent with this general theme, reminders of death should also focus people's interest and desire to process information that is compatible with their worldview and personal projects. Five recent studies offer converging support for this idea. The first two studies showed that mortality salience (vs. control) increased participants' reading comprehension of a pro-evolution article for those with a pro-evolution (vs. pro-creation) worldview. Studies 3-4 showed the same effect for participants who read a pro-creation essay: mortality salience increased reading comprehension among pro-creationists but not pro-evolutionists. A final study showed that mortality salience (vs. control) lead to better performance on an anagram task, but only when participants were led to believe that high scores on the task were a good predictor of verbal IQ. Moreover, in Studies 3-5 we obtained a measure of participants' intrinsic motivation, which mirrored the results obtained on the performance measures. Apparently, when activities are perceived as particularly relevant for one's personal sense of meaning and value, existential threats can increase one's intrinsic interest and desire to perform at a high level in those activities.

**ANXIETY AND SECURITY-FOCUSED SELF-REGULATION: AN INTEGRATIVE APPROACH** Gale M. Lucas<sup>1</sup>, Daniel C. Molden<sup>1</sup>, Wendi L. Gardner<sup>1</sup>; <sup>1</sup>Northwestern University – Demonstrations of the differential effects of anxiety from social, physical, and existential threats have illustrated the unique motivations evoked by each of these threats. However, these demonstrations may have somewhat obscured commonalities that exist across different threats. Two primary motivational functions of anxiety are to increase (a) caution and vigilance for the presence of threats and (b) distancing behaviors that allow one to avoid such threats. We thus hypothesized that different sources of anxiety might generally activate similar levels of vigilance and distancing, and furthermore, that these common behaviors would be driven by common motivational mechanisms in the form of broad self-regulatory processes associated with pursuing safety and security (i.e., prevention). Two studies supported these hypotheses. Study 1 induced social rejection, mortality salience, or concerns over contamination through reliving tasks and found that (a) all of these threats increased vigilance in the form of narrowed attention on a digit-span task compared to a control condition, and (b) this effect is mediated by a general index of activated prevention motivations. Study 2 induced attachment anxiety, judgmental uncertainty, or concerns over contamination through reliving tasks and found that (a) all of these threats increased distancing in the form of disparaging the opinions of someone who did not match one's cultural worldview compared to a control condition, and (b) this effect was again mediated by a general index of activated prevention motivations. The results are discussed in terms of their potential to provide an integrated theoretical perspective on the psychological effects of threat.

**THREAT AND REACTIVE APPROACH MOTIVATION** Ian McGregor<sup>1</sup>, Kyle Nash<sup>1</sup>, Nikki Mann<sup>1</sup>, Curtis Phillips<sup>1</sup>, Mickey Inzlicht<sup>2</sup>; <sup>1</sup>York University, <sup>2</sup>University of Toronto – Various experiential threats cause compensatory conviction about personal goals, opinions, identities, groups, ideologies, religions, and worldviews. We interpret such effects as reflecting a basic motivational shift from the anxious uncertainty caused by the threats, to a reactive approach-motivation state that promotes a cherished goal or ideal. Active approach-motivated states may be rewarding because they constrain attention to the compensatory goal or ideal and thereby shield the individual from the anxious uncertainty associated with the eliciting threats. Here we present convergent support for the reactive approach-motivation hypothesis. After a requisite delay, experiential threats related to academic confusion, career uncertainty, relationship insecurities, relationship dilemmas, and mortality salience caused a) more eager and idealistic personal projects in participants' lives; b) behavioral neuroscience evidence of relative left frontal brain activity characteristic of approach-motivation; c) implicit associations of the self with approach on an implicit associations test; and d) electro-encephalographic evidence of relative left frontal brain activity characteristic of approach-motivation. These effects of threat on reactive approach motivation were all most pronounced when dispositional approach motivation was high or when a promotion-focused state had been primed.

#### Symposia Session J8

##### CONSCIOUS AND UNCONSCIOUS THOUGHT IN DECISION-MAKING

Saturday, January 30, 5:00 - 6:15 pm, Capri Rooms 103-106

Chairs: Daniel Wegner, Harvard University, and Carey Morewedge, Carnegie Mellon University

Speakers: Daniel Oppenheimer, Carey Morewedge, John W. Payne, Ap Dijksterhuis

Of the hundreds of decisions each of us make every day, some are made with scant forethought and others are made after much consideration. Scholars have long debated the role that conscious and unconscious processes play in our decision making and the impact of each process on the quality of our decisions, yet much about their relative contribution to decision-making is still unknown. In this symposium, we present new

research examining both decision-making processes, our ability to critically evaluate them, and their benefits and limitations: We explore how multi-attribute decisions might occur in the absence of conscious deliberation (Oppenheimer, Schneider, & Detre). We examine our ability to evaluate the content and influence of conscious processes in our own decision making (Morewedge & Wegner). And divergent evidence is presented in an attempt to assess whether conscious deliberation improves particular kinds of decisions (Payne, Samper, Bettman, & Luce), or if decision making is more generally improved when left to unconscious processes (Dijksterhuis). Dan Wegner will then moderate a constructive discussion in which we will attempt to synthesize these disparate findings and discern what insight they might provide into our understanding of human decision-making.

## ABSTRACTS

**VOTING AGENT MODEL OF PREFERENCES: A COMPUTATIONAL MODEL OF INDIVIDUAL MULTIATTRIBUTE CHOICE** Daniel Oppenheimer<sup>1</sup>, Anouk Schneider<sup>1</sup>, Greg Detre<sup>1</sup>; <sup>1</sup>Princeton University – This paper examines the extent to which decision anomalies can be explained as an emergent property of aggregation of preferences. We assume multiple neurons or neural systems (agents) within an individual, each with different goals and preferences. We show that several puzzling decision anomalies (attraction effects, similarity effects, and compromise effects) arise as a natural consequence of aggregating these preferences. As a result "irrational" behavior at the level of the individual can possibly be explained by the summation of "rational" preferences at the neural level. Importantly, the model does not require that agents be conscious. Agents responding at an associative level can still yield a surprising array of decision phenomena when the preferences of those agents are aggregated.

**RITUALISTIC PREMEDITATION IN DECISION MAKING** Carey Morewedge<sup>1</sup>, Daniel Wegner<sup>2</sup>; <sup>1</sup>Carnegie Mellon University, <sup>2</sup>Harvard University – Premeditation—conscious deliberation about the possible consequences of behavior before acting—is often considered a primary indicator of personal responsibility for decisions. But merely going through the motions of premeditation by considering possible outcomes may be enough to convince people that they determined the outcome they received, even when their premeditation is irrelevant to the outcome. The results of five experiments suggest that people determine their control over an outcome on the basis of their ability to consider its consequences in advance, even when this premeditation ritual had no influence on the outcome. Whether actions corresponded to outcomes or outcomes were randomly determined, for example, premeditation on more outcomes led participants to experience greater feelings of control over outcomes that were both related and unrelated to their premeditation than did premeditation on fewer outcomes. Even when the content of actors' thoughts reflect the outcomes of their decisions, when premeditating they may be ritualistically engaging in an ineffectual behavior.

**IS BENJAMIN FRANKLIN'S ADVICE FOR DECISIONS STILL VALID?** John W. Payne<sup>1</sup>, Adriana Samper<sup>1</sup>, James R. Bettman<sup>1</sup>, Mary Frances Luce<sup>1</sup>; <sup>1</sup>Duke University – When faced with a complex decision, how should one decide? Recently it has been advocated that individuals should delegate thinking about complex choice problems to the unconscious by distracting oneself from the decision for a period of time. Experiments testing some boundary conditions on this suggestion will be presented. It will be argued that it is critical to take into account three factors when considering how to approach complex choice problems. First, one must take into account the interaction of forms of processing with task demands. That is, choice environments must be considered. For example, conscious thought rather than unconscious thought may lead to better choices when the task requires taking payoff or attribute magnitudes into account, not just whether the values are good or bad. Second, one must recognize that failure to execute a strategy properly can lead to poor performance even if the appropriate strategy for a task has been

selected. That is, evidence of the poor performance of a constrained mode of thought in a particular environment may simply reflect a poor implementation of that mode of thought. Third, the decision on how to decide is often made under uncertainty regarding task demands and individual capabilities. Thus, one should consider the robustness of strategies or modes of thought across task demands when giving prescriptive advice. In that regard, it will be argued that Benjamin Franklin's advice to use structured conscious thought is still the best bet for better decision making!

**WHY AND WHEN AND IS UNCONSCIOUS THOUGHT SO GOOD FOR COMPLEX DECISION MAKING?** Ap Dijksterhuis<sup>1</sup>; <sup>1</sup>Radboud University Nijmegen – Many recent experiments showed unconscious thought to lead to better decisions than conscious thought or than quick, immediate decision making. Unconscious thinkers choose alternatives with more positive and fewer negative characteristics, they choose alternatives that lead to more satisfaction, they choose more creative solutions to problems, and they make more accurate future predictions. Our recent meta-analysis (Strick et al., 2009, see www.unconsciouslab.com) across 50 experiments indeed confirmed these and other benefits of unconscious thought. It has been argued that unconscious thought is not an active process, but that people merely benefit from distraction. Decision makers form relatively accurate impressions of the alternatives on-line, and whereas conscious thinkers jeopardize their on-line preference with thought, unconscious thinkers recall their on-line preference at the time of judgment. We present evidence refuting this idea. Unconscious thinkers make better decisions than immediate decision makers who do rely on their on-line impressions. Furthermore, unconscious thinkers making their decisions after a period of unconscious thought make better decisions than unconscious thinkers indicating they already made their decision on-line. However, recent experiments and our meta-analysis show that unconscious thought needs proper on-line information acquisition. It works best when decision makers have processed the information thoroughly. Finally, new experiments show that unconscious thought is useful because it evokes an automatic weighting process. People have long felt intuitively that it was good to "sleep on" a decision rather than to rush. The main benefit seems to be that it leads us to separate the vital from the irrelevant.

## Symposia Session J9

### WHEN AND HOW SOCIAL COMPARATIVE STANDING IMPACTS WELL-BEING AND AFFECT

Saturday, January 30, 5:00 - 6:15 pm, Capri Rooms 107-110

Chairs: Jason P. Rose, University of Toledo, and Zlatan Krizan, Iowa State University

Speakers: William M. P. Klein, Ethan Zell, Jason P. Rose, Richard Lucas

A key axiom in psychology is that social comparative standing in relation to one's peers can have a profound influence on subjective well-being and affect-related experiences. Indeed, numerous studies have illustrated the power of (actual or imagined) comparative standing to make us feel worried about a health risk, pleased with a performance, or satisfied with the way our lives have unfolded. However, there are also numerous empirical and anecdotal examples of situations when social comparative standing has a dulled impact relative to absolute standing. Across 4 unique but conceptually-related domains, the speakers in this symposium provide novel insights regarding the relationship between social comparative standing and various aspects of well-being and affect. Klein and colleagues describe the complex interplay between comparative/absolute risk perceptions and worry, including when comparative risk perceptions might be most predictive of worry and behavior. Zell and Alicke illustrate that performance satisfaction and self-evaluations are more impacted by comparative standing among a small local group than a large (and more diagnostic) reference group. Rose and Krizan show that perceived comparative standing on chronic affective experiences is more predictive of life satisfaction in individualistic than collec-

tivistic cultures. Finally, Lucas provides evidence that the oft-documented finding that relative (and not personal) income accounts for most of the variance in well-being may actually be driven by un-modeled county-level characteristics (e.g., cost of living). Taken together, this symposium highlights the import of gaining a nuanced understanding of how and when social comparative standing impacts well-being and affective experiences.

#### ABSTRACTS

##### **COMPARATIVE RISK PERCEPTIONS AND WORRY ABOUT FUTURE HEALTH OUTCOMES**

William M. P. Klein<sup>1</sup>, Jennifer L. Cerully<sup>2</sup>, Laura E. Zajac<sup>2</sup>; <sup>1</sup>National Cancer Institute, <sup>2</sup>University of Pittsburgh – How people “feel” about their health risks is a key predictor of their health behavior. For example, worry about cancer is a predictor of getting cancer screening tests (McCaul & Mullens, 2003), and worry about the flu (as well as anticipated regret predicated on not getting vaccinated) is predictive of getting a flu shot (Weinstein et al., 2007). In this talk, we consider how perceptions of absolute risk and comparative risk link to health-related worry. Our past work has shown that high comparative risk perceptions increase worry (Klein, 1997), which in turn elevates perceptions of absolute risk (Lipkus et al., 2006), and that there are individual differences in the extent to which each kind of risk perception is related to worry (Zajac et al., 2006). Worry also appears to be a function of comparisons with certain types of comparison targets more than other comparison targets (Klein, 2002). In recent studies we find that worry moderates the relationship between comparative risk perceptions and behavior (such that the risk perception/behavior association is stronger among those low in worry), and that personal experience with health problems can strengthen the relationship between risk perceptions and worry. Building on these and other data, we will discuss the intricate relationship between comparative risk perceptions and worry including important potential moderators and implications for behavior. Finally, we consider how other affective constructs (e.g., incidental affect) may be related to comparative risk perceptions.

##### **THE LOCAL DOMINANCE EFFECT IN SELF-EVALUATION: EVIDENCE AND EXPLANATIONS**

Ethan Zell<sup>1</sup>, Mark D. Alicke<sup>1</sup>; <sup>1</sup>Ohio University – Social comparisons with a few immediate peers in the local environment ironically have a greater impact on self-assessments and performance satisfaction than more diagnostic comparisons with larger samples. This tendency is referred to as the local dominance effect. Two relevant studies provide direct support for the local dominance hypothesis. In the first study, participants completed a verbal task and were told that they were the best or worst person in a local group of five people, and that they ranked better than 84% or 32% of nearly 1500 previous participants. As expected, being the best or worst person in the local group had a greater impact on self-evaluations and affect than ranking better or worse than over one thousand peers. In a subsequent study, each session contained ten participants who were subdivided into two minimal groups of five. Participants then completed a lie detection test and were told that their performance ranked best or worst in their five-person group, and fifth or sixth among all ten students involved in the study. Consistent with the local dominance hypothesis, participants evaluated themselves more favorably when they ranked best in their group of five but sixth overall than worst in their group of five but fifth overall. This finding suggests that mere social categorization may be sufficient to produce the local dominance effect. The implications of these findings for social comparison theory are discussed.

##### **SOCIAL COMPARISONS OF AFFECTIVITY AND THEIR ROLE IN WELL-BEING: A CROSS-CULTURAL ANALYSIS**

Jason P. Rose<sup>1</sup>, Zlatan Krizan<sup>2</sup>; <sup>1</sup>University of Toledo, <sup>2</sup>Iowa State University – Chronic experiences of positive and negative affect (PA and NA) are important predictors of life satisfaction and subjective well-being. The current research examined people's perceived comparative standing on PA and NA, and whether such affect comparisons were uniquely associated with life satisfaction.

In an initial study, a majority of participants in a U.S. student sample indicated being above-average in the intensity of their PA experiences (e.g., pride), but below-average in their NA experiences (e.g., anxiety). Critically, such affect comparisons were uniquely predictive of life satisfaction, above and beyond traditional affect judgments (i.e., the PANAS; Watson, Clark, & Tellegen, 1988). In a second study, participants from both China and the U.S. indicated being above-average in the intensity of their PA experiences and below-average in their NA experiences. However, only in the U.S. did these affect comparisons uniquely predict life satisfaction. In the Chinese sample, only self judgments of affect (particularly positive affect) predicted life satisfaction. We argue and provide data that this cultural difference may be due to the fact that both self-reported emotional expressiveness and normative appropriateness of emotional expression are lower in collectivistic cultures (e.g., China) than in individualistic cultures (e.g., the U.S.) Therefore, because affective experiences are, generally speaking, less observable and appropriate in collectivistic cultures, the affective experiences of others might be less noticeable, relevant, and informative when making self-evaluations and satisfaction judgments. Results are discussed in the broader framework of both social comparison theory and cultural differences in well-being.

##### **DO RICH NEIGHBORS REALLY MAKE PEOPLE LESS SATISFIED? A COUNTY-LEVEL EXAMINATION OF THE ASSOCIATION BETWEEN INCOME AND LIFE SATISFACTION**

Richard Lucas<sup>1</sup>; <sup>1</sup>Michigan State University – A critical area of research on subjective well-being concerns the links between income and well-being. Intuition suggests that income should correlate with well-being because income is associated with many factors that are presumed to contribute to well-being. Indeed, income is one of the most robust correlates of well-being. Some have suggested that income effects are mostly or even entirely relative—one's absolute level of income may not matter; instead his or her standing relative to others may be the primary determinant of life satisfaction. Initial evidence for this idea came from the Easterlin Paradox: within-nation correlations between income and life satisfaction are moderate, but as national income goes up, life satisfaction scores remain stable. More direct evidence can be found by showing that the income of proximal others negatively affects well-being. Recently, economists have begun to investigate these “neighborhood” effects, and these studies show that after controlling for personal income, neighbors' income is negatively associated with life satisfaction. However, one alternative to the social comparison/relative-income explanation is that additional un-modeled neighborhood effects are responsible for this context effect. The current study uses a nationally representative sample of almost 1.2 million Americans to examine the links between personal income, county-level income, and life satisfaction. Initial analyses replicated the negative “neighborhood” effect: people living in wealthier areas reported lower levels of life satisfaction after controlling for personal income. However, this context effect was almost completely eliminated once county characteristics (including cost of living and population density) were taken into account.

#### Symposia Session J10

##### **FOR THE LOVE OF THE FRAME: MOTIVATIONAL SOURCES OF VARIATION IN EFFECTIVENESS OF HEALTH MESSAGES**

Saturday, January 30, 5:00 - 6:15 pm, Capri Rooms 114-116

Chairs: Tamara Sims and Nanna Notthoff, Stanford University

Speakers: John A. Updegraff, Nanna Notthoff, Tamara L. Sims, Andrew Ward

The prevalence of chronic health conditions, such as type II diabetes and cardiovascular disease continues to rise across the globe resulting in rapidly increasing healthcare costs and major economic strains for many countries. Despite advice from national health campaigns and health care professionals to engage in preventative health behaviors to offset these conditions, many people do not. High noncompliance rates suggest that standardized health messages are not effective in changing health behavior. In part, this may be because individuals vary along a

number of dimensions that are typically ignored by standardized health messages. In this symposium, four speakers present different theoretical approaches and empirical evidence suggesting that differences in attention, disposition, age, and cultural orientation influence the effectiveness of specific health message frames. Taking these factors into account when developing health messages may play an important role in optimizing health communication and ultimately, in improving health outcomes across diverse populations.

#### ABSTRACTS

##### **A TEST OF TWO APPROACHES TO USING MESSAGE FRAMING TO PROMOTE MAMMOGRAPHY USAGE**

John A. Updegraff<sup>1</sup>, Alexander J. Rothman<sup>2</sup>, Kristel M. Gallagher<sup>1</sup>; <sup>1</sup>Kent State University, <sup>2</sup>University of Minnesota – Research on message framing has provided practitioners with a theoretically-grounded strategy for designing and disseminating health messages. Historically, health message framing research has rested on the thesis that one's construal of a health behavior as risky v. certain determines whether a gain- or loss-framed message is more effective (Rothman & Salovey, 1997). More recently, another perspective has identified dispositional differences in approach/avoidance motivational orientation as a moderator of responses to framed health messages (Mann, Sherman & Updegraff, 2004). At present, it remains unclear how these two approaches are related and how they can be integrated. The present study is the first to simultaneously assess the effect these two classes of moderators have on the impact of framed messages to promote a health behavior: mammography. 319 women were recruited from a clinic and viewed either a loss- or gain-framed video about mammography. Screening was assessed at a 3 months follow-up. Overall, an advantage for loss-framed messages emerged on subsequent screening. However, among women with a family history of BC, those with an illness-detecting (risky) construal were screened at a significantly higher rate after viewing the loss-framed message, whereas those with a health-affirming (certain) construal were screened at a somewhat higher rate after viewing the gain-framed message. Motivational orientation shaped these construals, but did not moderate the influence of framing on screening. Findings support the importance of behavioral construals as a pivotal health belief that shapes people's responses to framed messages.

##### **TO WALK OR NOT TO WALK: USING MESSAGE FRAMING TO PROMOTE PHYSICAL ACTIVITY AMONG OLDER ADULTS**

Nanna Notthoff<sup>1</sup>, Laura L. Carstensen<sup>1</sup>; <sup>1</sup>Stanford University – People tend to be risk-averse, not just in financial transactions (originally described by Prospect Theory), but also in the health domain. Younger adults engage more in health promotion and disease prevention behaviors when information is framed in terms of gains rather than losses. Given the increasing number of older adults in the US population and world-wide, it is important to examine whether these findings generalize to older age groups. Based on prior research and on older adults' increased attention to positive information as predicted by Socioemotional Selectivity Theory, we expected that older adults would also be more responsive to gain framing (vs. loss or neutral framing). Participants (age range=60-89; n=61) either received information about walking that was framed: (1) in terms of potential gains (e.g., "Walking can have important cardiovascular health benefits."), (2) in terms of potential losses (e.g., "Not walking enough can lead to an increased risk for cardiovascular disease."), or (3) in neutral terms (e.g., "Walking is an aerobic activity."). Participants were then given pedometers for one week to measure how much they walked. Older adults walked the most steps when information was gain-framed rather than loss- or neutrally-framed. Older adults who received gain-framed information walked almost as many steps as a control group of younger adults (age range=18-32; n=65) who received the same types of messages regarding walking. Thus, as predicted, framing information in terms of potential gains (vs. losses) was more effective for promoting walking among older adults.

##### **CULTURAL DIFFERENCES IN IDEAL AFFECT INFLUENCE HEALTH CARE DECISIONS ACROSS THE LIFE SPAN**

Tamara L. Sims<sup>1</sup>, Jeanne L. Tsai<sup>1</sup>, Mary K. Goldstein<sup>1,2</sup>; <sup>1</sup>Stanford University, <sup>2</sup>VA Palo Alto Health Care System – As predicted by Affect Valuation Theory (AVT), previous findings reveal that cultural differences in the types of emotions people ideally want to feel (their "ideal affect") have implications for their behavioral choices. For example, European Americans value high arousal positive states such as excitement and enthusiasm (i.e., HAP states) more than Hong Kong Chinese, and these differences account for European Americans' greater preferences for exciting (vs. calm) vacations compared to Hong Kong Chinese. Here, we examine whether AVT applies to the decisions people make about health care. We hypothesized that cultural differences in preferences for excitement (and other HAP states) would account for cultural differences in their preferences for several health care choices (e.g., physicians, medications) framed in terms of excitement (vs. calm) states. Participants from the San Francisco Bay Area (50% Chinese American; 50% European American) between ages 20 and 80 completed measures of their ideal affect and rated the desirability of various "exciting" vs. "calm" healthcare choices. Analyses revealed that Chinese American older adults preferred "exciting" options less than European American older adults. As predicted, cultural differences in ideal affect mediated cultural differences in health care preferences across the life span. These findings suggest that health care professionals should consider participants' ideal affect when recommending and prescribing treatments.

##### **HEALTH CHOICES IN THE PRESENCE OF CONFLICTING INFORMATIONAL CUES: IS IT BETTER TO BE "HOT" OR "COOL"?**

Andrew Ward<sup>1</sup>, Traci Mann<sup>2</sup>, Sara Parent<sup>3</sup>; <sup>1</sup>Swarthmore College, <sup>2</sup>University of Minnesota, <sup>3</sup>University of California, San Diego – The attentional myopia model (Mann & Ward, 2004, 2007) posits that under conditions of limited attention, individuals will be disproportionately influenced by highly salient cues. In two studies investigating the health implications of this model, participants heard information regarding the use of a zinc supplement and reported their intentions to try it. In Study 1, "cool" message cues promoting the use of zinc were more salient than "hot" cues discouraging its use. In Study 2, hot cues discouraging the use of zinc were more salient than cool cues promoting its use. In both studies, the imposition of cognitive load increased the influence of salient cues, regardless of their motivational "temperature." Consistent with the attentional myopia model, either hot or cool message cues can exert strong influence over individuals' health choices, depending on the relative salience of those cues.

# Poster Session A

Thursday, January 28, 7:00 – 8:30 pm, Grande Ballroom

## Close Relationships/Belonging/Rejection

### A1

#### **RECOVERING FROM SOCIAL OSTRACISM: "SOCIAL SNACKING" AS A MEANS OF REPLENISHING THREATENED PSYCHOLOGICAL NEEDS**

Kristen Oates<sup>1</sup>, Kristine Kelly<sup>2</sup>; <sup>1</sup>New Mexico State University, <sup>2</sup>Western Illinois University – Social ostracism is thought to affect four fundamental psychological needs; belongingness, self-esteem, control and meaningful existence. The purpose of the present study was to examine if social snacking, or the reminder of positive social bonds, could act as a means of recovering threatened psychological needs following social ostracism. It was hypothesized that rejected participants who were allowed to engage in social snacking would experience less threat to their psychological needs. It was also hypothesized that rejected participants who were not allowed to socially snack would indicate a desire to do so by endorsing socially symbolic behaviors. Participants were first included or excluded during Cyberball, a computer ball-tossing game. They were then instructed to write about a loved one (social snacking), their favorite meal, or were given no instructions. Next, they filled out the Needs Threat Scale and the Social Snacking Scale. It was found that ostracized participants who wrote about a loved one reported significantly less threat to all four needs. Ostracized participants who wrote about their favorite meal reported less threat to their belonging and control needs. The results suggest that social snacking is a means of recovering from an ostracism experience.

### A2

#### **ARE LOVERS BELIEVERS? THE ASSOCIATION BETWEEN RELATIONSHIP STATUS AND IMPLICIT THEORIES OF RELATIONSHIPS**

Natalie Deitz-Bales West<sup>1</sup>, Alicia Limke<sup>1</sup>; <sup>1</sup>University of Central Oklahoma – This study examines implicit theories of relationships (i.e., destiny and growth), relationship status, and relationship closeness and satisfaction in a sample of undergraduate college students. Although Knee and others (e.g., Knee, 1998; Knee, Lonsbary, Canevello, & Patrick, 2005; West & Limke, 2009) have investigated the association between these thoughts about romantic relationships and long-term outcomes within specific relationships as well as other individual differences, no research to date has examined whether these implicit theories of relationships are associated with current relationship status. In the current study, there were differences in both destiny beliefs and growth beliefs by relationship status, such that those in serious relationships reported higher levels of destiny beliefs and lower levels of growth beliefs than those not in serious relationships. Discussion focuses on these somewhat surprising results, as well as implications for relationship closeness and relationship satisfaction. Ideas for future investigation are also presented.

### A3

#### **THE POSITIVE AND NEGATIVE MARITAL QUALITIES SCALES AND RELATIONSHIP SATISFACTION IN NEWLYWED COUPLES**

Matthew Shaffer<sup>1</sup>, Jean-Philippe Laurenceau<sup>1</sup>; <sup>1</sup>University of Delaware – Identifying and understanding the determinants of marital quality has been a major topic of interest in psychology for decades (Gottman, 1998). Nevertheless, there is still some debate on the best ways to measure marital quality (Spanier 1976, 1979; Norton, 1983; Fincham & Linfield 1997). The current research sought to evaluate the utility of Fincham & Linfield's (1997) Positive and Negative Quality in Marriage Scale, specifically by showing the positive and negative constructs as predictive of marital outcomes. One-hundred twenty newlywed couples from Miami-Dade County in Florida volunteered to complete a series of self-report measures once within 4 months of their marriage and again fifteen months later. Results suggest that negative quality early in marriage was more

predictive of future marital satisfaction and divorce proneness, above and beyond positive quality or global measures of satisfaction early in marriage. Findings are discussed in terms of the field's tendency to focus on negativity in marital research and the challenge to assess positivity in marriage.

### A4

#### **IN PURSUIT OF ESTEEM: RELATIONSHIP CONTINGENCIES AND COMMUNICATION WITH FORMER PARTNERS**

Amber L. Bush<sup>1</sup>, Lindsey M. Rodriguez<sup>1</sup>, C. Raymond Knee<sup>1</sup>; <sup>1</sup>University of Houston – Relationship-contingent self-esteem (RCSE) is the extent to which one's self-worth is hooked on daily relationship events and outcomes (Knee, Canevello, Bush, & Cook, 2008). RCSE involves heavily investing one's self-worth in the outcomes of one's relationship. Therefore, those higher in RCSE are more greatly impacted by relationship events. A study was designed to examine whether those higher (relative to lower) in RCSE rely more on former romantic partners. Predictors of and reasons for communicating with former partners will be examined. It was hypothesized that when less satisfied with their current relationship, those higher in RCSE will be more likely to communicate with a former partner whom they believe still desires them. Individuals (N = 260) currently in a relationship completed an online survey. Factor analyses suggested that individuals communicate with their former partners for several reasons, including investment in the former relationship and for a back-up in case one's current relationship fails. Multiple regression revealed that being less satisfied with one's current relationship and perceiving that one's former partner desires a relationship were associated with communicating more with one's former partner for back-up and investment reasons. Importantly, three way interactions showed that those higher in RCSE were more likely to communicate with their former partners, especially when they were unsatisfied with their current relationship and felt their former partner desired a relationship with them. Thus, when the self is highly contingent on one's relationship and one's relationship is not doing well, one is more likely to communicate with former partners.

### A5

#### **INVESTIGATING THE ROLE OF TWO TYPES OF UNDERSTANDING IN RELATIONSHIP WELL-BEING: UNDERSTANDING IS MORE IMPORTANT THAN KNOWLEDGE**

Monique Pollmann<sup>1</sup>, Catrin Finkenauer<sup>2</sup>; <sup>1</sup>Tilburg University, Netherlands, <sup>2</sup>VU University Amsterdam, Netherlands – Understanding is at the heart of intimate relationships. It is unclear, however, whether understanding – partners' subjective feeling that they understand each other – or knowledge – partners' accurate knowledge of each other – is more important for relationship well-being. The present paper pits these two types of understanding against each other and investigates their effects on relationship well-being. In a prospective study among 199 newlywed couples, we assessed partners' self-reported and perceived understanding and their knowledge about each others personality, behavior, and food preferences. Understanding was independent of knowledge. Self-reported and perceived understanding predicted relationship well-being but neither type of knowledge did. Thus, subjectively feeling that one understands and is understood by one's partner appears to be more important to relationship well-being than actually knowing and being known by one's partner.

### A6

#### **THE EFFECT OF RELATIONSHIP DURATION ON MAINTENANCE EXPECTATIONS**

Chenika Fowler<sup>1</sup>, Steve Seidel<sup>1</sup>; <sup>1</sup>Texas A&M University - Corpus Christi – A rather depressing statistic in the realm of relationship science is the finding that marital satisfaction decreases over the duration of a marriage (Kurdek, 1999). Caughlin & Huston (2006) have sug-

gested that disillusionment may be a major factor of such decreased satisfaction. The goal of the present study was to explore peoples' expectations for how much effort was required to maintain a successful relationship. Participants were asked to evaluate a set of relational maintenance strategies as they applied to a successful premarital relationship, a 1 year marriage, and a 10 year marriage. It was predicted that people would expect to work less at a relationship that had lasted a long time and that men would have lower expectations than women. Consistent with our predictions, the results of this study suggest that people expect to work less hard at maintaining marriages the longer they last. In addition, men were found to have lower expectations than women and that this difference increases with the duration of a marriage. Interestingly, men indicated a marriage needed to last 16 years in order to be labeled "successful" whereas women implied a 10 year requirement. In explaining decreases in marital satisfaction over time, future research might further explore the link between such decreased expectations as an element of disillusionment.

#### A7

**TESTING A DUAL-PROCESS MODEL OF AVOIDANT DEFENSES** David Chun<sup>1</sup>, Phillip Shaver<sup>1</sup>, Omri Gillath<sup>2</sup>, Andrew Mathews<sup>1</sup>, <sup>1</sup>University of California, Davis, <sup>2</sup>University of Kansas – Recent research raises questions about the defensive attentional processes of people with an avoidant attachment style. It suggests that avoidant individuals' deactivating strategies involve two processes: (a) automatic vigilance concerning interpersonal threats (e.g., negative emotional expressions on another person's face) followed by (b) a shift of attention away from threatening stimuli. We investigated two hypotheses based on this dual-process model. In Study 1, we used an emotional cueing task and two different stimulus exposure times to explore the influence of avoidant attachment on tendencies to focus on or away from pictures of contempt facial expressions. Avoidant individuals were vigilant toward contempt faces when the faces were presented for only 100 ms, but they were able to disengage from these same faces when the faces were presented for 750 ms. In Study 2, we tested the automaticity versus effortfulness of avoidant defenses by measuring participants' performance on the cueing task while under a cognitive load. More avoidant people were quicker than less avoidant people to disengage from contempt faces presented for 750 ms while also rehearsing a 1-digit number, but they could no longer do this while rehearsing a 7-digit number, and in fact took longer to disengage than less avoidant people. Taken together, the results of the two studies suggest that avoidant defenses include two stages and, at least when they involve attention, are not fully automatic. The results will be discussed in relation to the broader literature on avoidant defenses.

#### A8

**SEX AND NEUROTICISM: FREQUENT SEX PROTECTS INTIMATES' RELATIONSHIP SATISFACTION AGAINST THE NEGATIVE EFFECTS OF THEIR NEUROTICISM** V. Michelle Russell<sup>1</sup>, James K McNulty<sup>1</sup>, <sup>1</sup>University of Tennessee – A robust literature documents the negative association between neuroticism and romantic relationships. Neurotic intimates elicit more negative behaviors from their partners, perceive their partners' behaviors more negatively than they actually are, and are less satisfied with their relationships overall. Nevertheless, these associations tend to be imperfect, suggesting that some neurotic intimates are able to achieve positive relationship outcomes despite the negative implications of their neuroticism. How can neurotic intimates achieve high levels of satisfaction with their relationships? Given that the relationship difficulties of neurotic intimates appear to be driven by their tendencies to react negatively to stress (Bolger & Schilling, 1991), factors that buffer neurotic intimates against stress may buffer them against the negative effects of neuroticism. Because sex releases oxytocin, which helps the body cope with stress (see Sbarra & Hazan, 2008), sex may be one such factor. We used a longitudinal study of 72 newlywed couples to test the hypothesis that frequent sexual intercourse buffers spouses against the negative effects of neuroticism. Specifically, we assessed spouses' neuroticism, relationship satisfaction, and the frequency with which they engaged in

sexual intercourse over the previous 6 months every 6-8 months for approximately 5 years. Analyses revealed that the effects of neuroticism on changes in satisfaction depended on the frequency of sex, such that, although neuroticism was negatively associated with changes in marital satisfaction among spouses engaging in less frequent sex over the past 6 months, neuroticism was unrelated to changes in satisfaction among spouses reporting more frequent sex.

#### A9

**HOW ANXIOUSLY ATTACHED WOMEN INTERPRET SOCIAL REJECTION: THE TRANSFER OF REJECTION EXPECTATIONS FROM PEER GROUPS TO ROMANTIC PARTNERS** Leigh Turner<sup>1</sup>, Tara MacDonald<sup>1</sup>, <sup>1</sup>Queen's University – Attachment anxiety has been described as the degree to which one fears rejection and abandonment from others (Fraley & Waller, 1998) and previous research has shown that highly anxious individuals have a heightened sensitivity to rejection (Baldwin & Kay, 2003). However, little research has experimentally manipulated rejection and then assessed its interaction with attachment anxiety on rejection fears and expectations across different life domains. We experimentally assessed whether social rejection by peers interacted with attachment anxiety to influence fears and expectations of later rejection by a romantic partner. Female participants (n = 78) completed the Attachment in Close Relationships Questionnaire (Brennan et al., 1998) and in a method borrowed from Twenge et al. (2001), were led to believe that other participants in a laboratory session either rejected or accepted them. All participants then read a vignette depicting a romantic encounter, imagining themselves in that scenario. They then reported on their fears and expectations of partner rejection. Controlling for attachment avoidance, peer rejection condition interacted with attachment anxiety to influence fears and expectations of later partner rejection. Simple slopes analyses indicated that at low levels of anxiety, fears and expectations of romantic rejection did not differ by peer rejection condition. As expected, however, at high levels of anxiety, those that experienced peer rejection had greater fears and expectations of later romantic rejection than those who were not rejected by peers. The transfer of rejection expectations and fears across different life domains among highly anxious women and their implications are discussed.

#### A10

**A PROTOTYPE ANALYSIS OF HOOKING UP** Sal Meyers<sup>1</sup>, <sup>1</sup>Simpson College – College students no longer go on dates, they "hook up" (Bogle, 2008). The few studies of hooking up conducted by social scientists provide rule-based definitions of hooking up indicating that hooking up 1) is a sexual encounter involving physical interaction though not necessarily sexual intercourse, and 2) occurs with a stranger or brief acquaintance (Paul, McManus, & Hayes, 2000; Eshbaugh & Gute, 2008). No evidence exists to indicate whether this definition actually matches the way students themselves use the term. The purpose of the present research is to determine college students' prototype of hooking up. Participants (N=148) were asked to list all the features they associate with "hooking up." Participants listed a total of 957 terms. Using Fehr's (1988) criteria, the 957 words listed were reduced to 92 features by combining terms with similar meanings and dropping words that appeared only once. A new group of participants rated the centrality of these 92 features. Based on the average centrality ratings, participants viewed hooking up as impulsive and unplanned and as involving sexual activity -- everything from kissing to sexual intercourse. However, whereas previous researchers have focused on hook-up partners being strangers or casual acquaintances, college students' prototype appeared to focus more on the lack of future commitment between the two people.

#### A11

**EXPLORING THE EMOTIONAL SIDE OF COMMITMENT IN ROMANTIC RELATIONSHIPS** Kristy Cahoon<sup>1</sup>, Daniel Weigel<sup>1</sup>, Deborah Ballard-Reisch<sup>2</sup>, <sup>1</sup>University of Nevada, Reno, <sup>2</sup>Wichita State University – Despite the central role of emotion in perceptions of commitment, research has yet to fully explore the type and breadth of emotions that people experience in con-

nection with their commitment in romantic relationships. The following four studies were conducted in order to advance the breadth of understanding about the positive and negative emotions involved. All four presented studies involved either internet-based or paper and pencil surveys administered to university students. The purpose of Study 1 was to identify the types of emotions people associate with commitment. Participants were asked to list positive and negative feelings that came to mind when thinking of their current commitment. The results demonstrated 17 positive and 20 negative categories, with some differences between males and females. The purpose of Study 2 was to establish how often individuals feel the emotions elucidated in Study 1. Results demonstrated that specific feelings fell into eight emotion factors: attachment, restriction, irritation, rejection, sensuality, expansion, faithfulness, and jealousy. Study 3 was to investigate whether perceptions of commitment varied based on the type/length of the relationship, or gender of the participant. Results demonstrated that participants reported different levels of all eight factors based on relationship type, five factors based on relationship length, and only one factor based on participant gender. The purpose of Study 4 was to examine how three aspects of commitment: positivity, negativity, and constraint, align with overall perceptions of relationship commitment. The results demonstrated differences based on commitment type, and correlations between positivity, negativity, and constraint.

#### A12

**INTERNET SOCIAL NETWORKING AND VULNERABLE POPULATIONS: IMPLICATIONS CONCERNING USAGE PATTERNS** Kara Turcotte<sup>1</sup>, Aubrey Litvack<sup>1</sup>, Doug McCann<sup>1</sup>; <sup>1</sup>York University – The development and proliferation of social networking sites on the internet has had a significant impact on interpersonal communication. Despite this, little research to date has examined links between usage of such sites, and vulnerable populations that are known to have specific mental health problems surrounding interpersonal communication. An exploratory study examining several personality factors that have been previously tied to interpersonal dependence or withdrawal was conducted to determine possible relations between such individual characteristics and a multitude of social network usage statistics. Two hundred and twenty-eight undergraduate students participated for course credit by responding to a series of online questionnaires examining dimensions such as specific forms of depressive vulnerability (Sociotropy/Automony), and depressive symptoms (BDI-II). A significant predictive relation was revealed between sociotropic depressive vulnerability (a tendency to define oneself and depend on relationships with others for self-meaning), general depressive symptoms, and social network usage such as average time spent on networking sites, number of friends/contacts, and frequency of usage. Implications for interpersonal communication and vulnerable populations are discussed.

#### A13

**THE EFFECT OF THE QUALITY OF PARENTAL MARITAL RELATIONSHIPS ON THE QUALITY OF CHILD-PARENT RELATIONSHIPS: THE MODERATING EFFECT OF DYADIC PERSPECTIVE TAKING** Mizuka Ohtaka<sup>1</sup>, Kaori Karasawa<sup>1</sup>; <sup>1</sup>The University of Tokyo – The previous studies showed that the quality of child-father relationships is more vulnerable to the quality of parental marital relationships than the quality of child-mother relationships (see Cummings & O'Reilly, 1997; Cummings, Goeke-Morey, & Raymond, 2004, for reviews). However, psychological reasons for such asymmetrical effect have not offered yet. We explored this issue by focusing on dyadic perspective taking (Long, 1990). More specifically, we hypothesized that the quality of parental marital relationships influences more on the quality of child-father relationships than on the quality of child-mother relationships because children understand the point of view of their mothers more than those of their fathers. To test our hypothesis, we conducted a panel survey of 397 undergraduate students. They answered the questions twice with about two months of duration. This study measured the quality of relationships by positive affect. The results revealed that children understand the point of view of their

mothers more than those of their fathers. Moreover, fathers' positive affect toward mothers significantly influences on children's positive affect toward mothers only when children understand the point of view of their fathers. Mothers' positive affect toward fathers significantly influences on children's positive affect toward fathers only when children understand the point of view of their mothers. That is, dyadic perspective taking explains why the quality of the child-father relationship is more vulnerable to the parental marital relationship quality than the quality of the child-mother relationship.

#### A14

**SELF-FOCUSED STRATEGIES FOR MINIMIZING THE NEGATIVE EFFECTS OF RELATIONSHIP DISSOLUTION** Gary Lewandowski, Jr.<sup>1</sup>; <sup>1</sup>Monmouth University – The break-up of a romantic relationship commonly results in negative experiences. Thus, it is beneficial to identify strategies for minimizing these negative experiences. Previous research suggests that rediscovery of the self and self-expansion correlate with better post-dissolution outcomes (Lewandowski & Bizzoco, 2007). The purpose of the present study is to test two theoretically-based strategies for coping with romantic relationship dissolution. To accomplish this, I randomly assigned 87 (22 males, 65 females) currently single participants who experienced relationship dissolution within the past 6 months to one of three types of activities. Those in the rediscovery of self condition engaged in activities that the dissolved relationship prevented them from doing. Those in the self-expansion condition engaged in activities that were new and challenging. Finally, those in the control condition engaged in activities they had done on a regular basis over the past month. In each case, participants completed activities at their discretion outside of the laboratory over a two week period. As predicted, those in the self-expansion and rediscovery condition both experienced less loss of self and more positive emotions compared to the control condition. Further, compared to the control condition, those in the rediscovery of self condition experienced less loss of self, fewer negative emotions, less loneliness, and greater happiness, self-acceptance, and purpose in life compared to the control condition. There were no significant differences between the self-expansion and rediscovery of the self conditions.

#### A15

**WHEN "I'M SORRY" ISN'T GOOD ENOUGH: IMMEDIATE REACTIONS TO APOLOGIES DEPEND ON THE AMBIGUITY OF THE TRANSGRESSION** Leonard Newman<sup>1</sup>, Lindsay Kraynak<sup>1</sup>; <sup>1</sup>Syracuse University – Apologies that include explicit acknowledgements of wrongdoing have been found to elicit forgiveness and make others feel better. Trope's (1986) dual process model of social information processing suggests this may not be so when interpersonal transgressions are ambiguous. In those cases, full apologies might primarily serve to disambiguate behaviors and allow people to identify them as affronts. Participants read one of four vignettes (about revealing a confidence, stealing, insulting someone, or being caught flirting) in which the transgression was either clear or ambiguous. Vignettes ended with either no apology, a full apology (e.g., "David admitted that he had flirted and said he was sorry"), or an expression of concern for the other's feelings (e.g., "David told Heather he was sorry she was feeling bad about what happened"). Participants (n = 502) were asked to guess what the wronged individual's immediate reaction would be (whether he or she would be more or less upset). Transgression type (clear, ambiguous) significantly (p < .001) interacted with apology type (full, none, expression of concern). For clear transgressions, participants expected full apologies to elicit more positive reactions than expressions of concern, which in turn were expected to elicit more positive reactions than no apologies at all. But when transgressions were ambiguous, participants expected full apologies and no apologies at all to elicit equally negative reactions (with expressions of concern eliciting more positive reactions). Thus, reactions to apologies were an interactive effect of the nature of the apology and the nature of the transgression.

**A16****MODELING CONTROL IN RELATIONSHIPS** Ivelina Naydenova<sup>1</sup>;

<sup>1</sup>University of Tennessee – Although considerable research attention has been devoted to issues of control in general (e.g. locus of control, desire for control), the more contextualized, relationship-specific control construct has remained relatively unexplored. The main purpose of the present study was to examine the associations between control in relationships and related constructs (e.g. conflict) in a sexual minority population. 166 sexual minority persons (61 men and 105 women) completed measures of control in relationships (e.g. CIR), conflict, mastery, partner trust and perspective taking. Based on extant research, we expected CIR to be positively related to relationship conflict and inversely related to all the other measures. As predicted, CIR was significantly positively correlated with conflict in relationships and inversely associated with perspective taking, mastery over the environment and partner trust. Next, we sought to create a more comprehensive theoretical model of the association between control and the other constructs hypothesizing that relationship conflict, partner trust, mastery and perspective taking each directly influence self-perceived control in the relationship. AMOS 6 structural equation modeling was used to test the fit of our model. The data adequately fit the model (CMIN/DF = 2.23; CFI = .97,  $\chi^2(5, 166 = 11.15, p = .05)$  and all standardized path coefficients were significant. While the cross-sectional nature of the data limits assumptions of causal direction, the observed pattern provides important insight into the operating characteristics of control. Further research is needed to clarify the association between control and related constructs by use of experimental and longitudinal methods.

**A17****VALIDATION OF THE NEED FOR SEXUAL INTIMACY SCALE** Erin D.

Shelton<sup>1</sup>, William D. Marelich<sup>2</sup>, Elizabeth Grandfield<sup>2</sup>, Farina Chinoy<sup>2</sup>, Brianne Levine<sup>2</sup>; <sup>1</sup>University of Southern California, <sup>2</sup>California State University, Fullerton – The objective of this study was to validate the Need for Sexual Intimacy Scale (NSIS; Marelich & Lundquist, 2008) by confirming the factor structure and assessing reliability and validity. The NSIS was originally developed to assess motivations for sexual intimacy, focusing on three oblique needs (need for sex, need for affiliation, and need for dominance). It was designed to complement the current available measures addressing sexual desires and motivations, and to be used in research addressing close/intimate relationships and sexuality. Participants were 298 college students enrolled in psychology courses at California State University, Fullerton. Confirmatory factor analysis (CFA) was used to evaluate the factor structure. First order and second order factor models were produced, and results confirmed the NSIS subscales (need for sex, need for dominance, and need for affiliation) and the existence of a broader Need for Sexual Intimacy construct. The subscales showed good internal consistency reliability. Validity was assessed through associations between the NSIS and several attitudinal and behavioral measures assessing sexuality, dominance, and affiliation. Individuals with a higher need for sex were found to have higher levels of sexual desire, more unrestricted sexual attitudes, and higher sexual awareness. Those reporting higher needs for dominance engaged in more dominant behaviors. Those reporting higher needs for affiliation had more positive attitudes about emotional support and closeness in relationships, and reported less comfort in social situations. Both theoretical and practical implications for the NSIS are discussed.

**A18****EVERYBODY HATES ME: CONSEQUENCES OF ONE-PERSON SOCIAL EXCLUSION** Nadia Chernyak<sup>1</sup>, Vivian Zayas<sup>1</sup>; <sup>1</sup>Cornell University – A

growing body of research shows that social exclusion negatively impacts well-being. This work, however, has focused primarily on how people respond to situations involving complete exclusion, in which everyone present in the situation engages in exclusionary behaviors towards one individual. It is therefore unclear whether the widely documented negative consequences of social exclusion are elicited only as a result of com-

plete exclusion or whether they would have been produced if only one person in the situation engaged in exclusionary behaviors. To investigate this issue, in the present research, participants played a virtual ball-throwing game (Cyberball; Williams et al., 2000) with two confederates who were programmed to either include or exclude the participant. Participants were randomly assigned to experience inclusion by both players, exclusion by both players (two-person exclusion), or exclusion by one player and inclusion by the other (one-person exclusion). The results showed that compared to inclusion, one-person exclusion negatively impacted feelings of belongingness and decreased liking of the excluder to the same extent as two-person exclusion. Moreover, in the one-person exclusion condition, participants inaccurately recalled that the includer had excluded them, albeit to a lesser extent than the excluder. These results suggest that the previously documented deleterious effects of complete social exclusion may be caused not necessarily by being excluded by one's entire group, but by being rejected by a single person within the group. Moreover, these findings indicate that even in the presence of an inclusive person, being excluded by another person has negative consequences on well-being.

**A19****PERSONALITY COUNTS: REQUESTING SPACE AS SUPPORT IN STRESSFUL SITUATIONS** Kenzie Snyder<sup>1</sup>, Gertraud Stadler<sup>1</sup>, Niall Bolger<sup>1</sup>, Sarah Bums<sup>1</sup>, Patrick Shrout<sup>2</sup>; <sup>1</sup>Columbia University, <sup>2</sup>New York University –

Balancing closeness and distance in relationships is challenging. The preferred amount of each may be affected by an individual's personality. The present study investigated dyadic support processes, and coded if individuals wanted space from their partner when under stress. Personality was hypothesized to explain, on an individual level, why some individuals may want space from their partner when under stress. Participants were 95 heterosexual couples who lived together for at least six months. Partners individually filled out questionnaires that included the Big Five and one free response question regarding support: "When you are feeling stress at work or school are there things that your partner can do to help you?" The category "wanting space" was coded if participants reported wanting space or wanting to cope with the stressor on their own, rather than indicating what their partner could do. Out of 193 participants, 34 reported wanting space. Data analysis was performed using logistic regression. Results showed that individuals who wanted space from their partner when under stress were higher on openness to experience (odds ratio = 2.44,  $z = 5.56, p < .01$ ), more emotionally stable (odds ratio = 2.08,  $z = 7.42, p < .01$ ), and less agreeable (odds ratio = .41,  $z = 6.27, p < .01$ ), than those that did not seek space. Personality might help explain why some people want space when feeling stressed. For those individuals more open to experience, more emotionally stable, and less agreeable space was a preferred means of support.

**A20****RELATIONSHIP THEORIES AND RELATIONSHIP VIOLENCE: SHOULD YOU STAY TO WORK IT OUT?** Renae Franiuk<sup>1</sup>; <sup>1</sup>Aurora University –

Implicit theories of relationships (ITRs) are beliefs that people hold about the nature of relationships (Franiuk, Pomerantz, & Cohen, 2002; Knee, 1998). Loosely based on Dweck and Leggett's (1988) entity and incremental theories, the soulmate theory is based on the belief that relationship partners are "meant to be" and the work-it-out theory is based on the belief that relationships take effort to be successful. Past research, focusing primarily on healthy romantic relationships, has shown that ITRs play a role in relationship satisfaction and longevity. Further, Franiuk and colleagues (2004) speculated that the cognitive strategies soulmate theorists' use to maintain their relationship satisfaction may also serve to keep them in dysfunctional relationships. The current research investigated the association between ITRs and relationship violence. In Study 1 ( $N = 46$ ), we found that, in a female undergraduate sample, women who were high in soulmate theory but low in work-it-out theory reported fewer acts of violence in their current relationship than women high in work-it-out theory and low in soulmate theory. Further, for strong soulmate theorists, perceptions of good partner fit were associated with low rates of

violence. In Study 2 (N = 43), we replicated the main findings from Study 1 in a clinical sample (women at a domestic violence shelter). Contrary to speculation by past researchers, results from both studies suggest that strong work-it-out beliefs are associated with being in a violent relationship while strong soulmate beliefs may be protective against violence in relationships.

#### A21

**WHEN CONFLICT MAKES THE HEART GROW FONDER: THE RELATIONSHIP-PROMOTIVE EFFECTS OF HIGH SELF-ESTEEM DURING PARTNER DISAGREEMENTS** Joanna E. Anderson<sup>1</sup>, John G. Holmes<sup>1</sup>, Sandra L. Murray<sup>2</sup>; <sup>1</sup>University of Waterloo, <sup>2</sup>University at Buffalo, State University of New York – The purpose of the present study was to examine how self-esteem affects romantic partners' perceptions of their relationship when their goals conflict. Specifically, the Risk Regulation Model (Murray, Holmes, & Collins, 2006) predicts that for people with low self-esteem, conflict is associated with negative feelings and behaviour toward the partner, but that this relationship is reduced or reversed in those with high self-esteem. To test these predictions, eighty-four female participants were randomly assigned to imagine either a major or a minor conflict with their partner, then completed questions about their feelings toward their partner, their perceptions of their partner's feelings toward them, and their motivations in the conflict situation. As predicted, women with lower self-esteem (LSEs) tended to feel less positively toward their partners in a major conflict situation than in a minor one, and to be less altruistically motivated toward them, whereas women with higher self-esteem (HSEs) tended to feel more positively toward their partners in a major than a minor conflict situation, to believe their partners thought well of them, and to be altruistically motivated toward them. These findings suggest that the potential negative effects of conflict, seen in LSE participants, are reversed in people with high self-esteem. We believe conflict makes people consider how much their partners value them; LSEs may doubt their partners' caring and distance themselves in order to self-protect; HSEs, however, may assume their partners share their positive feelings about themselves, thus causing them to draw closer to their partners in conflict situations.

#### A22

**LOOKING THROUGH THE MAGIC MIRROR: SOCIAL REJECTION AND SELF-VERSUS OTHER-AWARENESS** Yanine Hess<sup>1</sup>, Cynthia Pickett<sup>1</sup>; <sup>1</sup>University of California, Davis – Recent research indicates that socially rejected individuals show decreased self-awareness (Twenge, Catanese, & Baumeister, 2003) as a defensive strategy designed to buffer the self from the distress of rejection. Although this response may provide psychological refuge to the socially excluded, an adaptive response to social-inclusion threat may be two-pronged - defending the self from the immediate pain of rejection, while at the same time engaging the cognitive, emotional, and behavioral mechanisms that can aid in the formation and maintenance of social relationships. However, research to date has provided little evidence for this two-pronged response. To fill this gap, we employed a social memory paradigm. After being included or excluded from a game of Cyberball, participants read a series of journal entries consisting of social and non-social events. Participants were instructed to imagine the author of the journal as either themselves (self-target), their best friend, or a stranger (other-targets). Finally, participants attempted to recall the journal entries. Our primary hypothesis was that rejection would lead to both decreased awareness of the self and increased awareness of the behavior of others. Furthermore, we predicted these effects would be manifested most clearly in socially-relevant domains. In line with predictions, the results showed that rejected participants exhibited decreased social memory and increased non-social memory for the self, but increased social memory and decreased non-social memory for the other targets. These data provide evidence for a two-pronged response to social rejection characterized by both self-protective strategies and strategies aimed at regaining and maintaining social relationships.

#### A23

**SOCIAL EXCLUSION AND SOCIAL ACCEPTANCE: A MULTIMODAL EMOTIONAL ANALYSIS** Mark Davis<sup>1</sup>, Stephanie Murray<sup>1</sup>; <sup>1</sup>The University of West Alabama – The following studies investigated the effects of social exclusion and social acceptance on emotional reactions (self-report, EMG, and FACS), and the emotional reactions' relationship to depression. Previous research has supported the claim that individuals become emotionally numb after social exclusion, although emotions were assessed with self-report (Twenge, Baumeister, DeWall, Ciarocco, & Bartels, 2007). Using a multimodal analysis of emotional reactions, it was hypothesized that individuals do experience negative emotions when socially rejected. Participants were socially rejected, socially accepted, or simply observed (control) while in a chat-room virtual environment. In study I, participants were attached to a facial EMG machine, with an electrode placement on the corrugator supercilii to assess positive and negative affect (Larsen, Norris, & Cacioppo, 2003). In study II, participants were videotaped to assess facial reactions, using the Facial Action Coding System (Ekman & Friesen, 1978). In addition, participants in both studies completed self-report questionnaires on emotion, empathy, and depression. Contrary to previous research, the results indicated negative affect from social rejection. For study I, there was a significant increase in EMG activity within the rejection condition (negative affect), compared to a decrease in activity within the acceptance condition (positive affect), and flat EMG activity in the control condition. For study II, there was evidence of the upper and lower facial action units associated with positive and negative affect, corresponding to the rejection and acceptance conditions. Finally, there was a moderate relationship between the emotional reactions, ratings of empathy, and self-reported symptoms of depression.

#### A24

**FURTHER VALIDATION OF THE CASUAL PHYSICAL ACQUAINTANCE ATTITUDINAL SCALE** William Marelich<sup>1</sup>, Erin Shelton<sup>2</sup>, Danielle George<sup>1</sup>, Elizabeth Grandfield<sup>1</sup>, Theresa Fraser<sup>1</sup>, Kathleen Preston<sup>3</sup>; <sup>1</sup>California State University, Fullerton, <sup>2</sup>University of Southern California, <sup>3</sup>University of California, Los Angeles – The goal of the current study was to further assess the validity of the Casual Physical Acquaintance attitude scale (the CPA, Johnson, 2007; Preston & Marelich, 2008). Casual physical acquaintances, sometimes known as "friends with benefits" or uncommitted sexual relationships, are a small but possibly growing part of our current U.S. culture. To predict an individual's openness to such behavior, the CPA was developed using Ajzen's Theory of Planned Behavior. Prior research derived an overall attitudinal scale and three subscales (addressing social norms, personal attitudes, and perceived control). For the current study, a sample of 298 individuals was retained to confirm the previous factor structure of the CPA and assess validity. Confirmatory factor analysis showed the original CPA factor structure was viable (CFI and IFI = .90; GFI = .95; RMSEA = .08). Correlations of the three subscales and total score with various behavioral and dispositional measures showed that those with more favorable attitudes toward "friends with benefits" situations reported a higher likelihood of experiencing such relationships in their past. In addition, those with more favorable attitudes were more likely to use intoxicants during sex, report more lifetime sexual partners and one-night stands, be more dominant sexually, have a higher need for sex, and have an unrestricted sociosexual orientation. The study results are discussed in terms of the Theory of Planned Behavior, and in applications of the CPA for researchers who wish to further explore "friends with benefits" attitudes and behaviors.

#### A25

**IMAGINARY FRIENDS AREN'T JUST FOR KIDS: THE NATURE OF RELATIONSHIPS WITH FICTIONAL CHARACTERS** Randi Shedlosky-Shoemaker<sup>1</sup>, Kristi A. Costabile<sup>1</sup>, Robert M. Arkin<sup>1</sup>; <sup>1</sup>Ohio State University – When we turn on the television or open a book, we open ourselves to a narrative world, populated with a variety of intriguing characters that might provide an opportunity for social relationships. Relationships

with fictional characters may be better understood by using concepts applied to relationships with close others. The current studies employed the self-expansion model (a model originally proposed to explain our motivation to form and maintain relationships) to understand relationships formed with narrative characters. Study 1 ( $N = 88$ ) measured self-reported inclusion of other in self (IOS: Aron, Aron, & Smollan, 1992) and self-expansion (Lewandowski & Aron, 2002) with favorite and non-favorite TV characters, as well as a close friend and classmate. Results revealed greater self-other overlap and greater self-expansion with the favorite character compared to both a non-favorite character on the same show and a classmate ( $t_s > 2.75$ ,  $p_s < .01$ ). Study 2 ( $N = 89$ ) found that becoming immersed, or psychologically transported (Green & Brock, 2000), into a short story predicted greater self-other overlap and self-expansion with the narrative protagonist ( $r_s > 0.45$ ,  $p_s < .001$ ). Together, the results of these studies suggest that ersatz relationships with fictional characters may function to provide similar self-expansion experiences as relationships with real people. Considering the prevalence of entertainment media, further research may explore different qualities of relationships with fictional versus real people, such as the distinct motivational basis for one type of relationship over the other and the likely consequences of fiction-based versus actual relationships.

#### A26

**DATING A BAD BOY OR A BAD GIRL: THE DARK TRIAD WITHIN COUPLES** C. Veronica Smith<sup>1</sup>, Peter K. Jonason<sup>2</sup>, Benjamin W. Hadden<sup>1</sup>; <sup>1</sup>University of Delaware, <sup>2</sup>New Mexico State University – The Dark Triad (Paulhus & Williams, 2002) has strong and consistent associations with short-term mating and relatively weak associations with long-term mating (Jonason, Li, Webster, & Schmitt, 2009). However, people scoring high in Dark Triad do participate in on-going romantic relationships but little is known about how this individual difference functions in these relationships. In a study of 45 heterosexual couples (mean length of relationship: 55.18 weeks), relationship satisfaction and commitment were measured at two time points (3 weeks apart) in addition to measuring Dark Triad at Time 1. Multilevel random coefficient modeling analyses were used (with people nested within couples). Individual's Time 2 satisfaction with their relationship was negatively affected by having a partner who scored high in Dark Triad (controlling for Time 1 satisfaction). Individual's Time 2 commitment was not significantly predicted by either individual or partner's Dark Triad score, however, inclusion of the facets of the Dark Triad revealed that people higher in Machiavellianism, lower in psychopathy, and having a partner high in Narcissism was associated with greater commitment (controlling for Time 1 commitment). Being or dating a person high in the Dark Triad may be associated with relationship costs, such as decreased satisfaction. Although mate choice is not particularly rational or pre-meditated, the results of the present study suggest that individuals should be weary about engaging in long-term pairbonds with those high on the Dark Triad.

#### A27

**SOCIAL REJECTION AND SOCIAL ANXIETY: A TEST OF THE BELONGINGNESS ORIENTATION MODEL** Genevieve L. Lavigne<sup>1</sup>, Robert J. Vallerand<sup>1</sup>; <sup>1</sup>Universite du Quebec a Montreal – The need for belongingness (need to form and maintain positive, stable interpersonal relationships, Baumeister & Leary, 1995; Deci & Ryan, 1985) has led to much research over the past decade. While it is typically assumed that such a need is basically invariant in people, we have proposed (Lavigne, Vallerand, & Braud, under revision) that some individual differences may exist. Specifically, two forms of belongingness orientations were proposed: a growth-oriented need (intrinsic orientation toward interpersonal actualisation) and a deficit-oriented need (extrinsic orientation toward interpersonal deficit reduction or repair). Lavigne and colleagues (under revision) showed that a deficit orientation predicts lower levels of intrapersonal and interpersonal psychological adjustment compared with a growth orientation because relational insufficiencies and personal contingencies are activated by social contexts for deficit-oriented individuals. In the present research, we investigated the different impact of

social rejection for deficit-oriented and growth-oriented individuals on their experience of social anxiety. Three studies were conducted in which social rejection was self-reported (Study 1), primed by a scrambled sentences task (Study 2), and primed by having participants write about a time when they experienced rejection (Study 3). A social acceptance (control) condition was also created in all three studies. Results showed that the highest means of social anxiety are found for individuals having a deficit-oriented need to belong in the social rejection conditions. The three other groups do not differ in their levels of social anxiety. Implications of the present research for future research on the need to belong are discussed.

#### A28

**THE INFLUENCE OF ATTACHMENT AVOIDANCE AND IMAGINED PARTNER REJECTION ON FEMALE BODY IMAGE** Erica J. Reffling<sup>1</sup>, Tara K. MacDonald<sup>1</sup>; <sup>1</sup>Queen's University, Ontario, Canada – We examined whether attachment styles and imagined partner rejection interact to influence women's body-esteem. During prescreening, participants completed the Attachment in Close Relationships Questionnaire (Brennan, Clark, & Shaver, 1998). In the lab, 58 female participants read a vignette either describing their current romantic partner distancing himself from the relationship (rejection condition) or behaving in a manner consistent with their normal interaction (non-rejection condition). Participants were also given various strings of words and instructed to make meaningful phrases by crossing out the words that did not belong (Sommer & Baumeister, 2000). In the rejection condition, half of the phrases involved rejection whereas in the non-rejection condition, half of the phrases were negative but not related to rejection. After completing these two activities, participants filled out the State Self-Esteem Scale (Heatherton & Polivy, 1991), the Body-Esteem Scale (Franzoi & Shields, 1984), and the Rosenberg Self-Esteem Scale (Rosenberg, 1965). Analyses revealed significant avoidance x rejection interactions when predicting appearance state self-esteem, body-esteem and self-esteem. Simple slopes analyses revealed that at low levels of avoidance, women in the rejection condition had significantly higher scores on all three measures than women in the non-rejection condition. However, at high levels of avoidance, women in the rejection condition reported lower scores on the three measures than women in the non-rejection condition, although this finding was significant only for appearance state self-esteem. The implications of these results for promoting and fostering a more positive body-image are discussed.

#### A29

**EQUITY IN BLACK AND WHITE MARRIED COUPLES** Susan Sprecher<sup>1</sup>, Terri Orbuch, Diane Felmlee; <sup>1</sup>Illinois State University, <sup>2</sup>University of Michigan and Oakland University, <sup>3</sup>University of CA-Davis – In the past few decades, marriage has evolved to be more egalitarian. However, exchange in marriage is not always perceived to be equitable or fair. Equity refers to the perceived balance in the partners' contributions and outcome. Equity theorists predict that both underbenefiting inequity (contributing more and/or receiving less, relative to the partner) and overbenefiting inequity (being advantaged in the exchange) are associated with distress. Perceived inequity has been found to lead to dissatisfaction and sometimes relationship termination. However, much of the research testing equity theory in intimate relationships has been conducted with dating couples or young married couples at one point in time. Very few longitudinal studies of marriages include measures of equity or fairness. One exception is the Early Years of Marriage (EYM) project, which includes data collected multiple times from a representative sample of urban white couples and black couples. The purpose of this study is to examine, with the EYM data, the combined moderating roles of gender and race in perceptions and outcomes of equity in marriage. The participants completed measures asking who gets more out of marriage; and happiness, anger, and guilt in response to exchange in the relationship. Preliminary results indicate that: a majority of respondents perceive equity in their marriages, there is a tendency for perceived equity to decrease over time especially among black wives; perceptions of equity are associated

with emotions in ways predicted by equity theory, and those who divorced later experienced equity-generated distress in the early years of their marriage.

### A30

**AN EXISTENTIAL FUNCTION OF ENEMYSHIP: EVIDENCE THAT PEOPLE ATTRIBUTE INFLUENCE TO PERSONAL AND POLITICAL ENEMIES TO COMPENSATE FOR THREATS TO CONTROL** Daniel Sullivan<sup>1</sup>, Mark J. Landau<sup>1</sup>, Zachary K. Rothschild<sup>1</sup>; <sup>1</sup>University of Kansas – Past research suggests that the majority of Americans claim to have at least one personal enemy. Yet no prior research has examined the possibility that perceptions of personal and political enemyship, although superficially disagreeable, may serve an important psychological function. Based on psychodynamic and anthropological theorizing, we argue that people attribute exaggerated influence to enemies as a means of compensating for perceptions of reduced control over their environment. If negative events are perceived as random and impersonal, they seem difficult to control, predict, and understand; however, if negative events stem primarily from a clearly identifiable enemy figure, they seem relatively more preventable and interpretable. In two studies, we examined the possibility that, after receiving a threat to one's ability to control chaotic hazards in the environment, people would be motivated to attribute greater influence to an enemy, and having an enemy would actually boost people's sense of personal control after such a threat. In Study 1, people were especially likely to attribute influence over life events to a hypothetical personal enemy in response to a control threat when the broader social system appeared disordered (i.e., incapable of providing protection from negative events). Study 2 showed that perceiving an ambiguously powerful political enemy under conditions of control threat decreased perceptions of external risk and bolstered feelings of personal control. These findings point to a novel explanation of the importance of enemyship, a form of close relationship relatively understudied in social psychology.

### A31

**ATTACHMENT, BELONGINGNESS NEEDS, AND RELATIONSHIP STATUS PREDICT IMAGINED INTIMACIES WITH MEDIA FIGURES** Christopher Long<sup>1</sup>, Dara Greenwood<sup>2</sup>; <sup>1</sup>Ouachita Baptist University, <sup>2</sup>University of Michigan – The present study utilizes an interpersonal relationships measure (RRF, Fraley & Davis, 1997) to assess real intimacies with same gender friends and romantic partners and imagined intimacies with favorite media figures among 173 undergraduates. We also examine how relational style (attachment, need to belong) as well as relationship status (single or in a romantic relationship) predict imagined intimacies. Results indicate that passion, care, and intimacy for a same gender best friend were each significantly correlated with imagined intimacies for same gender media figures. A compensatory pattern emerged with romantic relationships. Single individuals reported greater imagined care and intimacy for opposite gender media figures than those in a relationship. Moreover, we found evidence that relationship status moderated between existing relational needs and imagined intimacies with opposite gender media figures: Attachment anxiety and need to belong (NTB) positively predicted imagined intimacies with opposite gender media figures for single individuals only. NTB was more strongly linked to imagined intimacies than attachment anxiety. Social psychological motivations and functions of media attachments are discussed.

### A32

**VARIABLES ASSOCIATED WITH ATTRACTION TO INDIVIDUALS WITH PSYCHOPATHIC TRAITS** Amber Dukes<sup>1</sup>, Charles Negy<sup>1</sup>, Randy Fisher<sup>1</sup>; <sup>1</sup>University of Central Florida – Psychopaths are charming, manipulative, remorseless individuals who compose two to five percent of the population; the majority of these individuals are not incarcerated. Hare (1993) stated that psychopaths leave behind them a trail of "broken hearts, empty wallets, and shattered promises" (p. iv). This study, entitled "Variables associated with attraction to individuals with psychopathic traits," sought to explore potential vulnerabilities that may lead an individual to

the involvement with this potentially dangerous population. Participants were presented with a dating profile/vignette if an other-sexed individual with psychopathic characteristics. Undergraduate participants (n=587) were pooled from a large southeastern university. Participants rated their desire to associate with an individual with psychopathic traits on six different scaled items; this was combined as the attraction score. Participants then completed a series of valid and reliable personality instruments. Using multiple regression analyses, results suggested that scores on psychopathy, empathy, need for affiliation, age, and impulsiveness were significant predictors of attraction score. Whereas the majority of research regarding psychopathy focuses on clinical populations of psychopaths themselves, this study sought to explore variables that would correlate with a desire to become involved with a sub-clinical psychopath. Results also suggest that there are personality variables that correlate with attraction to a potentially psychopathic mate, with younger participants being more apt to indicate higher attraction scores. Future directions of this research are to create programs to make at-risk individuals aware of ways to recognize and inhibit psychopaths.

### A33

**RELATIONSHIP BREAKUP AND POSTTRAUMATIC GROWTH** Erin Buck<sup>1</sup>, Susan S. Hendrick<sup>1</sup>, Clyde Hendrick<sup>1</sup>, Stephen W. Cook<sup>1</sup>; <sup>1</sup>Texas Tech University – Theory and research indicate that growth can result from trauma. This research focused on the associations among several variables: people's attributions about their relationship breakups, coping strategies used post-breakup, posttraumatic growth following the breakup, relationship satisfaction, respect for romantic partner, and satisfaction with life. The final sample included 310 women and 153 men. Measures included a background inventory and scales assessing relationship breakup attributions, posttraumatic (i.e., breakup) growth, relationship satisfaction, respect for one's romantic partner, and general life satisfaction. (Descriptions of and references for all of the measures are included in the poster.) Correlations, regression analyses, and analyses of variance were employed. Significant correlations among variables were found for the total sample, for women and men separately, and for current relationship status (in a relationship, not in a relationship). For both men and women, life satisfaction was related to growth from a prior relationship breakup, relationship satisfaction, and respect. Life satisfaction was also related to coping by emotional processing, for women only. For both genders, coping by emotional processing was related to growth from a prior breakup. Respect and relationship satisfaction were correlated positively for both genders. Attributions and selected coping strategies were predictive of posttraumatic growth for both genders. Persons in a current romantic relationship reported greater life satisfaction than those not in a romantic relationship, but this effect held only for men. Women reported greater life satisfaction than did men. Applications of this research to couple counseling, as well as possibilities for future research, are discussed.

### A34

**THE COMMONALITY AMONG MOTHER-CHILD DYADS IN EARLY ADULTS, ROMANTIC COUPLES IN EARLY ADULTS, AND MIDDLE-AGE COUPLES IN JAPAN** Yuji Kanemasa<sup>1</sup>; <sup>1</sup>Faculty of Human Sciences, Osaka University Of Human Sciences – This study was conducted to reveal the commonality among mother-child dyads in early adults, romantic couples in early adults, and middle-age couples in Japan, based on the relationships between early adult attachment dimensions, emotional experiences in the relationships, and evaluation toward the relationships. Participants were 209 pairs of early adults and their mothers, 103 romantic couples in early adults, and 156 pairs of middle-age couples. The main results were as follows: in those three relationships, attachment anxiety was positively correlated to one's own and partner's negative emotion in the relationships and negatively related to one's own and partner's evaluation toward relationships. But with regard to attachment avoidance, the commonality among those relationships was that attachment avoidance was only related to one's own negative emotion. In addition, the relations

between attachment anxiety and one's own and partner's evaluation toward relationships were mediated by one's own and partner's negative emotion respectively in those three relationships. Only in middle-age couples, the relations between attachment avoidance and one's own evaluation toward relationships were mediated by one's own negative emotion. The results were discussed in terms of the similarities and differences among mother-child dyads in early adults, romantic couples in early adults, and middle-age couples, and the self-fulfilling prophecy of attachment styles.

### A35

**THE BENEFITS OF GRATITUDE IN CLOSE RELATIONSHIP MAINTENANCE** Kaska Kubacka<sup>1</sup>, Catrin Finkenauer<sup>1</sup>, Caryl E. Rusbult<sup>1</sup>; <sup>1</sup>VU University Amsterdam – Although the benefits of gratitude have been much investigated in the field of social psychology, we know surprisingly little about the causes and consequences of gratitude in close relationships (cf. McCullough, Kimeldorf, & Cohen, 2008). The present research contributes to the literature by examining gratitude as experienced by, and toward, spouses. Our model focuses on the role of gratitude in connection with perceived partner responsiveness and maintenance behaviours between partners. In a cross-sectional study of married couples, we examined both within-, and across-partner factors, investigating the determinants and effects of gratitude. We found that feelings of gratitude toward a partner stem from the partner's relationship maintenance behaviours, partly because such behaviours create the perception of responsiveness to one's needs. In turn, gratitude motivates individuals to act for the maintenance of their relationships. Hence, the present model emphasizes that gratitude between close partners (a) originates from partners' relationship maintenance behaviours, as well as the perception of a partner's responsiveness to one's needs; and (b) promotes a partner's reciprocal relationship maintenance behaviours. As a result, our model shows that gratitude plays a role in mutual cyclical growth processes (cf. Wieselquist, Rusbult, Foster, & Agnew, 1999), whereby each person's maintenance behaviours, perceptions of responsiveness, and feelings of gratitude feed back on and influence the other partner's behaviours, perceptions, and feelings.

### A36

**WHAT PREDICTS GROWTH BELIEFS ABOUT RELATIONSHIPS? INTRAPERSONAL AND INTERPERSONAL CONSEQUENCES OF THE GOAL TO SUPPORT OTHERS** Amy Canevello<sup>1</sup>, Jennifer Crocker<sup>1</sup>; <sup>1</sup>University of Michigan – Relationship growth theorists believe that relationships can improve and problems can be overcome. Relationship growth beliefs have consequences for relationship functioning, and are particularly beneficial when relationship problems occur (e.g., Knee, 1998). But what predicts changes in relationship growth beliefs? Two longitudinal studies explored associations between compassionate goals to support others and self-image goals to construct and maintain desired images of the self (Crocker & Canevello, 2008) and change in growth belief. In Study 1, 199 first-semester college freshmen completed pretest and posttest assessments of growth and destiny beliefs about friendships, and 10 weekly reports of their friendship goals. In Study 2, 65 roommate pairs completed 21 daily reports of their goals for their roommate relationships and responsiveness to roommates and pretest and posttest measures of relationship growth belief and responsiveness. Across both studies, students' chronic compassionate goals predicted their increased relationship growth belief. In Study 2, partners' compassionate goals predicted actors' increased growth belief. Mediation and path analyses suggest that compassionate goals change relationship growth belief via responsiveness to roommates. When people have compassionate goals, they are more responsive to roommates, which leads to change in their own relationship growth belief. This research suggests that compassionate goals foster growth relationship belief, underscoring the extent to which people create their own relationship destinies. By having compassionate goals and responding to others' needs, people can be catalysts for changing their own and others' assumptions about the nature of relationships, which may ultimately improve the quality of their relationships.

### A37

**DO HARMONIOUS AND OBSESSIVE PASSIONS TOWARDS ONE'S ROMANTIC PARTNER MAKE INDIVIDUALS CHANGE FOR THE BETTER? THE MEDIATING ROLE OF SELF-EXPANSION AND SELF-CONSTRICTION** Noemie Carboneau<sup>1</sup>, Robert J. Vallerand<sup>1</sup>; <sup>1</sup>Research Laboratory on Social Behavior, University of Quebec in Montreal – The Dualistic Model of Passion (Vallerand et al., 2003) posits the existence of two distinct types of passion toward activities. Harmonious passion (HP) is at play when one freely accepts an activity as important for him/her such that activity engagement is personally endorsed. Conversely, when one feels an uncontrollable urge to engage in a beloved activity, one is said to have an obsessive passion (OP). Previous research has shown that the Dualistic Model of Passion applies to the study of romantic relationships (Ratelle et al., 2009). The purpose of the present study was to test whether harmonious and obsessive romantic passion lead individuals to change for the better as a result of their involvement in their romantic relationship. Participants were 207 young adults currently involved in a romantic relationship. Results of Structural Equation Modeling revealed that HP was positively associated with self-expansion and negatively associated with self-constriction. Conversely, OP was positively associated with both self-expansion and self-constriction. In turn, self-expansion and self-constriction were respectively positively and negatively associated with individuals' perceptions that they had changed for the better since they have been involved in their current romantic relationship. Results are discussed in light of the Dualistic Model of Passion (Vallerand et al., 2003) and the Self-Expansion Model (e.g., Aron, Norman, & Aron, 1998).

### A38

**TIMING IS EVERYTHING: THE POINT AT WHICH AN APOLOGY IS GIVEN AFFECTS WILLINGNESS TO FORGIVE** Erinn C. Squires<sup>1</sup>, Michael J. A. Wohl<sup>1</sup>; <sup>1</sup>Carleton University – In two experiments we investigated when an apology is most likely to lead to forgiveness following an interpersonal transgression. In Experiment 1 (N = 77), participants read a hypothetical scenario in which a friend failed to show up for a pre-arranged date. An apology was given that same night, the next day, or two weeks later. Results showed that as time distanced the apology from the transgression, the victim's willingness to forgive decreased. Although both empathy and perceived responsibility of the transgressor mediated this effect, when submitted to a multiple mediation analysis, only perceived responsibility was found to be a unique mediator. In Experiment 2 (N = 165), participants were asked to recall and describe a real life minor or severe interpersonal transgression. Thereafter, participants indicated whether an apology was given and if so, whether that apology was offered immediately, shortly after, or well after the transgression. Results showed that severe transgressions were less forgiven than minor transgressions. No differences were found among the no, immediate and well after apologies on any of the measured variables, but all were significantly different from the apology that occurred shortly after the transgression. Multiple mediation showed when the apology was shortly after the transgression (compared to a collapsed comparison) forgiveness increased to the extent that participants felt empathy for the transgressor, perceived the transgressor not to be responsible, and perceived the post-transgression relationship to be close. No interaction between apology timing and severity emerged. Implications for pro-relationship behaviour following interpersonal transgressions are discussed.

### A39

**MOTIVATING CHANGE IN RELATIONSHIPS: CAN PRAYER INCREASE FORGIVENESS?** Nathaniel Lambert<sup>1</sup>, Frank Fincham<sup>1</sup>, Tyler Stillman<sup>1</sup>, Steven Graham<sup>2</sup>, Steven Beach<sup>3</sup>; <sup>1</sup>Florida State University, <sup>2</sup>New College of Florida, <sup>3</sup>University of Georgia – The objective of the current studies was to test whether praying for a relationship partner would increase forgiveness of that partner. In Study 1 (N=52), we found that participants assigned to pray reported greater willingness to forgive a romantic partner than those who described their partner to an imagined parent. In Study 2 (N=67) participants were assigned to either pray for a friend,

pray about any topic, or think positive thoughts about a friend every day for four weeks. Those who prayed for their friend reported higher forgiveness scores for their friend than did those in the other two conditions, even when controlling for baseline forgiveness scores. They also increased in selfless concern during that period and this mediated the relationship between experimental condition and increased forgiveness. Together, these studies provide an enhanced understanding of the relationship benefits of praying for a relationship partner and begin to map potential mediators of the effect.

**A40**

**EMPATHIC ACCURACY AND THE MANAGEMENT OF SUPPORT VISIBILITY** Maryhope Howland<sup>1</sup>, Jeffrey A. Simpson<sup>1</sup>; <sup>1</sup>University of Minnesota – Recent work in the area of social support has demonstrated that the most beneficial support is often "invisible" – that is it goes unnoticed by the recipient (Bolger, Zuckerman, & Kessler, 2000; Bolger & Amarel, 2007). Little is known, however, about how this type of support occurs – it may hinge on the perceptual discrepancies between the partners or it may signal a specific supportive behavior on the part of the provider. Similarly, little is known about when invisible support is likely to occur and who is likely to provide it. The present study attempts to understand this process in light of another interpersonal phenomenon – empathic accuracy, or the ability to accurately infer the thoughts and feelings of another. Specifically we hypothesized that individuals high in empathic accuracy would be better equipped and more likely to provide invisible support to their partners. Eighty-five couples, who had been dating for at least one year, engaged in a social interaction study involving the discussion of a personal goal and an empathic accuracy task. The videotaped interactions were then coded by independent raters for the presence of a variety of visible and invisible support behaviors. Results suggest that providers' ability to be empathically accurate is associated with a tendency to manage the visibility of their support behaviors differentially depending on type of support provided. These findings begin to explain how empathic accuracy is beneficial in the non-threatening everyday interactions of couples and goes a step towards understanding the nature of invisible support.

**A41**

**ADULT ATTACHMENT AND EXPLORATION: PRIMING ROMANTIC PARTNERS INCREASES CURIOSITY** Emre Selcuk<sup>1</sup>, Cindy Hazan<sup>1</sup>; <sup>1</sup>Cornell University – Despite its centrality for attachment theory, normative effects of adult attachment on exploration have been understudied. The aim of the present project was to investigate whether romantic partners, as potential attachment figures, facilitate individuals' exploration. We hypothesized that for participants who were attached to their romantic partner, priming the mental representation of the partner would increase self-reported curiosity and exploration. We expected this effect to be absent for participants who were not attached to their partner. In two experiments (Ns = 69 and 94, respectively), participants who were involved in a romantic relationship completed measures of attachment status (WHOTO; assessing whether the participant is attached to the romantic partner or not) and attachment style (ECR; assessing attachment-related anxiety and avoidance). Next, we primed participants with either the mental representation of their romantic partner or various neutral, nonsocial control topics. Finally, participants completed measures of curiosity and exploration. In both studies, priming the mental representation of the romantic partner, as compared to priming control topics, resulted in higher self-reported curiosity and exploration only for participants who were attached to their romantic partner but not for those who were not attached to their romantic partner. Attachment-related anxiety and avoidance did not moderate the effects in either study. These findings imply that as a romantic attachment is established, partners become "secure bases" facilitating each other's exploratory activities. The presence of this "secure base" component may be a marker of attachment in adulthood.

**A42**

**MODERATING EFFECT OF ROMANTIC PARTNERS' OVERLAPPING NETWORKS ON THE RELATIONSHIP BETWEEN THE PERCEIVED DISTINCTIVENESS OF THEIR RELATIONSHIP AND AN UNCOOPERATIVE ORIENTATION.** Toshihiko Souma<sup>1</sup>; <sup>1</sup>Kawaguchi Junior College – Romantic partners often believe their relationship is distinct from their other relationships. This perceived distinctiveness can promote a cooperative orientation and suppress an uncooperative orientation (Souma et al., 2008). Uncooperative behavior is important if couples are to cope constructively with conflict. Perceived distinctiveness inhibits an uncooperative orientation because it reduces motivation to seek support outside the relationship, resulting in partners being less likely to insist that their position in a conflict is legitimate. Nevertheless, if perceived distinctiveness reduces motivation to seek support, the perceived availability of social support may increase it (e.g., Vroom, 1974). It has been suggested that an uncooperative orientation does not diminish when romantic partners perceive the availability of support only for their position in a conflict, even if their perception of distinctiveness is strong. Moreover, it has been shown that the less the networks of the couple overlap, the more they can perceive the availability of support for only their position in the conflict (Klein et al., 2000). I conducted a survey of married couples to examine the following hypothesis: The less a couple's networks outside their relationship overlap, the weaker the relationship between an uncooperative orientation and the distinctiveness of their relationship. Seventy-two Japanese married people participated in the mail-in survey. The results of path analysis supported this hypothesis. Overlaps of the partners' networks moderated the relationship between the perceived distinctiveness of their relationship and an uncooperative orientation. However, with the relationship between perceived distinctiveness and a cooperative orientation, no moderating effect was observed.

**A43**

**TACTILE WARMTH MITIGATES NEGATIVE EFFECTS OF SOCIAL EXCLUSION TO INCREASE PRO-SOCIAL BEHAVIOR** Tze Suen Tai<sup>1</sup>, Xue Zheng<sup>1</sup>, Jayanth Narayanan<sup>1</sup>; <sup>1</sup>National University of Singapore – Recent research suggests that social exclusion is associated with physical coldness (Zhong & Leonardelli, 2008). However, there is no research that explores whether the same relationship holds for tactile warmth and social exclusion. We define tactile warmth as warmth derived from a sense of touch. In our research, we examine the impact of tactile warmth on social exclusion in a pro-social context. We conjecture that tactile warmth mitigates the negative effects of social exclusion and subsequently increases pro-social behavior. Social exclusion was manipulated experimentally with bogus personality feedback indicating that participants may end up alone later in life (e.g. Baumeister, Twenge, & Nuss, 2002). A teddy bear was used to elicit sensations of tactile warmth due to its anthropomorphized nature (Horowitz & Bekoff, 2007) and physical texture. We find that socially excluded individuals who hugged a teddy bear volunteered for more lab experiments as compared to socially excluded individuals who did not hug a teddy bear. However, hugging a teddy bear did not significantly increase volunteering behavior across socially accepted and control participants. Preliminary results also show that positive affect induced by hugging of the teddy bear may potentially mediate the relationship between tactile warmth and pro-social behavior. We conclude that socially excluded individuals derive a sense of tactile warmth from hugging a teddy bear that may be sufficient to attenuate the negative effects of social rejection, which in turn translates to increased helping behavior. Results contribute to the existing literature linking physical warmth, tactile warmth and social exclusion.

**A44**

**THE INTERPERSONAL LEGACY OF POSITIVE ENGAGEMENT IN THE FAMILY-OF-ORIGIN: SEPARATING THE FAMILY CLIMATE FROM DISPOSITIONAL BEHAVIOR IN THE PREDICTION OF MARITAL OUTCOMES** Robert Ackerman<sup>1</sup>, Deborah A. Kashy<sup>1</sup>, M. Brent Donnellan<sup>1</sup>, Rand D. Conger<sup>2</sup>, Tricia Neppel<sup>3</sup>, <sup>1</sup>Michigan State University, <sup>2</sup>University of California, Davis, <sup>3</sup>Iowa State University – This research evaluates the connection between individuals' experiences in their families of origin and their later marital experiences. We use insights from the Social Relations Model (Kenny, Kashy, & Cook, 2006) to partition variation in observed positive engagement behaviors (e.g., effective communication, warmth) into family climate effects (i.e., the tendency for all family members to be positively engaged with one another) and dispositional effects (i.e., the person's tendency to be especially engaged with other family members). We use these factors, assessed in 1989 to 1991, to predict marital interaction outcomes 15 years later. The data used for these analyses consist of 218 target children from the Iowa Youth and Families Project (Conger & Conger, 2002) that became married by 2005. Results show that individuals coming from families with higher average positive engagement expressed more positive engagement ( $\beta = .32$ ) and less hostility ( $\beta = -.16$ ) towards their spouses, and reported greater relationship satisfaction ( $\beta = .16$ ). Likewise, spouses of individuals who came from families with more positive engagement displayed more positive ( $\beta = .29$ ) and less hostile ( $\beta = -.17$ ) behaviors towards the focal individuals. These partners also reported greater relationship satisfaction ( $\beta = .30$ ). Individuals' dispositional expressions of positive engagement in their families of origin were also associated with positive engagement towards their spouses ( $\beta = .14$ ) and their spouses' reports of relationship satisfaction ( $\beta = .15$ ). Taken together, these findings suggest that observed characteristics of the family of origin are associated with later adult romantic relationships.

**A45**

**FRIENDS AND LOVERS: THE INTRAPERSONAL AND RELATIONAL FACTORS AFFECTING SOCIAL NETWORK DYNAMICS** Molly Metz<sup>1</sup>; <sup>1</sup>University of California - Santa Barbara – The literature on the association between romantic relationships and social support networks has focused in the past on how the friendships of one partner affect a romantic relationship and how social interactions change when one is engaged in a romantic relationship. Attempts to explain what factors cause these changes, and why these changes are not universal, have been scarce. The purpose of the present study is to explore how sex, gender, and relationship status and qualities may impact the ways in which the existence of one relationship, specifically a romantic one, affects the existing social relationships in an individual's life. One hundred and twenty-eight undergraduates completed surveys concerning their sex, gender role identification, and social support networks; participants in a romantic relationship went on to measures about intimacy, commitment, relationship satisfaction, investment size, and quality of alternatives. Using network size, emotional support, and tangible support as dependent variables, analyses revealed that while there was little overall difference between single participants and those in a relationship, individuals in relationships differed by intimacy and commitment level, particularly on measures of network size. Results are discussed in light of the role of social support in our lives. This study adds to the literature in both close relationships and social networks by exploring the factors that predict the type and extent of network change that occurs in the context of a romantic relationship, and begs further investigation into the variation in social support amongst those individuals in a romantic relationship.

**A46**

**EXPERIENCES IN ROMANTIC RELATIONSHIPS ARE ASSOCIATED WITH THE DEVELOPMENT OF NEGATIVE EMOTIONALITY IN YOUNG ADULTHOOD** Kimberly K. McAdams<sup>1</sup>, M. Brent Donnellan<sup>1</sup>, Rand D. Conger<sup>2</sup>; <sup>1</sup>Michigan State University, <sup>2</sup>University of California, Davis – Anxious and distressed individuals tend to be involved in less satisfying romantic relationships; however, it is also possible that romantic rela-

tionships affect the development of personality (Robins et al., 2002). Indeed, Huston (2000) argued that relationships influence individual psychological attributes, a proposition that is consistent with recent theorizing in personality development (e.g., Lang et al., 2006). Accordingly, we investigated the association between the development of Negative Emotionality (the tendency to readily experience anxiety, distress, and hostility) and experiences in romantic relationships using longitudinal data from the Family Transitions Project (FTP; see Conger & Conger, 2002; N = 323 for these analyses). Negative Emotionality was assessed during Years 1 and 10 of the FTP when participants were an average of 18 and 27 years old, respectively. Participants and their romantic partners provided reports of Relationship Quality during Years 8. Negative Emotionality in Year 1 predicted a latent Relationship Quality variable at Year 8 ( $\beta = -.21$ ). Relationship Quality at Year 8 predicted Negative Emotionality in Year 10 controlling for Negative Emotionality in Year 1 ( $\beta = -.25$ ). This effect held when restricting the measurement to just partner reports of Relationship Quality. In short, experiences in romantic relationships are associated with personality development given that involvement in a distressed relationship predicted relative increases in Negative Emotionality. Furthermore, results followed the corresponsive principle of personality development (e.g., Roberts et al., 2003) because relationship experiences appeared to accentuate a trait that was associated with the characteristics of the relationship in the first place.

**A47**

**PREDICTING ADULTS' GENERAL ATTACHMENT AND CAREGIVING REPRESENTATIONS FROM RELATIONSHIP-SPECIFIC MODELS.** Katherine M. Hitchcock<sup>1</sup>, Kelley Chappell<sup>2</sup>; <sup>1</sup>University of Maryland University College, Asia, <sup>2</sup>Capella University – This research extended previous investigations of the links between general and relationship-specific attachment models using a new instrument for measuring attachment: the Relationship Structures Questionnaire (Fraley, Niedenthal, Marks, Brumbaugh, & Vicary, 2006). Given the theoretically complementary nature of attachment and caregiving, this study also initiated a preliminary exploration of the predictive power of relationship-specific caregiving models on general caregiving models. A survey method assessed two dimensions of attachment (avoidance, anxiety) and four dimensions of caregiving (proximity, sensitivity, cooperation, compulsive caregiving) in adults from the following relationship perspectives: general representations and representations in relationships with mother, father, best friend, and romantic partner. Multiple regression analysis revealed that all models predicting general attachment or caregiving representations from those in specific relationships were significant, accounting for a substantial amount of the variation in the general models. With respect to attachment, representations from relationships with best friends made the strongest contributions to the general models, but the relative contributions of other specific close relationships varied along dimensional lines. Similarly, relationships with best friends emerged as the strongest predictors of general models of caregiving proximity and sensitivity, and played a significant role in predicting general models of caregiving cooperation and compulsive caregiving. These results highlight a primary connection between best friend relationships and general models of attachment and provide new evidence for the contributions of best friend relationships to general caregiving models. These findings suggest that the quality of best friend relationships influences how adults view relationships in a broader, more general sense.

**A48**

**ATTENTION TO RELATIONSHIP ALTERNATIVES HAS (AT LEAST) THREE FACETS** Rowland S. Miller<sup>1</sup>, Lopa Paul<sup>1</sup>, Kelsey Quitugua<sup>1</sup>, Karen Husband<sup>1</sup>, Jenivie Isgitt<sup>1</sup>, Emily Kennedy<sup>1</sup>, Tatyana Menaker<sup>1</sup>, Sarah Murray<sup>1</sup>, Katrina Rufino<sup>1</sup>, Jennifer Sanders<sup>1</sup>, Holly Tabernik<sup>1</sup>, Di Wang<sup>1</sup>; <sup>1</sup>Sam Houston State University – Motivated inattention to alluring alternatives may be one way in which devoted partners protect and maintain their relationships and fulfill their interpersonal goals. However, attention to one's alternatives may be multifaceted. Being distractible when alluring alternatives

present themselves may be less intentional than is active, effortful, intentional prowling for novel partners; both instill an awareness that alternatives may be available, but the former is more passive and (perhaps) innocuous, whereas the latter is deliberate and (probably) more destructive. To address these issues, we refined a new measure of self-reported attention to alternatives. We wrote 117 items addressing various aspects of attentiveness (e.g., "There's no harm in looking"; "I'm always on the prowl for an exciting new relationship") and invited 307 respondents to describe themselves and their current romantic relationships on an online survey. Three correlated factors emerged from the items, delineating three distinct facets of attention to alternatives. The first involved active prowling for desirable alternatives (e.g., "I visit singles websites without my partner's knowledge"), the second entailed more passive awareness (e.g., "Good-looking people always catch my attention") and the third was willful disinterest (e.g., "There's no point in looking around because I will never find someone better than my current partner"). Prowling was deleterious – being substantially and positively related to avoidance of intimacy and negatively related to self-control and relationship satisfaction and commitment – but passive alertness and blissful ignorance were not; they were both associated with relationship well-being. Attention to alternatives clearly has discrete components.

#### A49

**THE CONSEQUENCES OF IDEALIZATION IN ROMANTIC RELATIONSHIPS** Krista Hill<sup>1</sup>, C. Randall Colvin<sup>1</sup>; <sup>1</sup>Northeastern University – All dating couples encounter relationship obstacles yet some thrive while others wither. Idealization of one's partner is one characteristic that has been identified as influencing a relationship's success. The present study investigates the relationship between idealization and how romantic partners interact with one another. Heterosexual dating couples rated the personality of (a) the self, (b) their partner, and (c) their ideal partner on a 46-item Adjective Q-sort (ADJ). Men's real and ideal partner profile correlations were calculated to assess their perceptions of partner (POP). Each woman's aggregated self and friend ADJ rating profile was correlated with the ideal partner profile to establish how close each woman was to the man's ideal. We used this correlation for our accuracy criterion (AC). The difference between POP and AC indicated the degree in which men idealized their partners. Identical procedures were used to create female idealization scores. Trained coders used items from the Riverside Behavioral Q-sort (RBQ; Funder, et al., 2000) and an emotional expression coding system (Waldinger, et al., 2004) to evaluate the digitally-recorded behavior between couples who described an issue affecting their relationship. Each person's idealization score was related to the coded behavior of self and partner to evaluate the role idealization has on romantic relationships. Preliminary results reveal large individual differences in partner idealization and significant correlations between idealization and behavior between couples. Partner idealization was associated with interaction behaviors characterized as aloof, hostile, and anxious. Results suggest that idealization may negatively impact romantic relationships.

#### A50

**SOCIAL REWARD, SOCIAL THREAT, AND REGULATION OF ROMANTIC INVESTMENT** Stephanie S. Spielmann<sup>1</sup>, Geoff MacDonald<sup>1</sup>, Jennifer L. Tackett<sup>1</sup>; <sup>1</sup>University of Toronto – The regulation of emotional investment is often discussed in terms of concerns over self-protection from socially threatening experiences of hurt feelings and rejection. However, such a focus has overlooked the extent to which people seek out socially rewarding intimate connection. We argue that perceptions of social reward from romantic partners are stronger predictors of continued emotional investment in past romantic partners than perceptions of social threat. In four correlational studies, participants reported their level of anxious/avoidant attachment, and how much social reward and threat they perceived from ex-partners, future partners (among single participants) and current partners (among participants in relationships). Participants then reported emotional investment to ex-partners, such as feelings of continued emotional attachment and intentions to pursue the

ex. Anxious attachment predicted perceptions of higher social threat, while avoidant attachment predicted perceptions of lower social reward. Across attachment styles, continued emotional attachment to an ex-partner was more strongly predicted by perceptions of the ex as socially rewarding than as non-threatening. Similarly, continued longing for an ex was stronger when future or current partners were perceived as non-rewarding rather than highly threatening. An interaction between perceptions of social reward revealed that continued emotional attachment to an ex-partner was greatest when the ex-partner was perceived as socially rewarding and future/current partners were not perceived to be socially rewarding. Among single individuals, this interaction also predicted behavioral intentions to pursue ex-partners. These findings suggest that a focus on social reward is a primary driving force behind the regulation of emotional investment.

#### A51

**THE INFLUENCE OF MORAL COMMITMENT ON NEWLYWED WOMEN'S INFIDELITY EXPECTATIONS** Carlos Flores<sup>1</sup>, Kelly Campbell<sup>1</sup>; <sup>1</sup>California State University, San Bernardino – The Commitment Framework, developed by Johnson (1999), describes commitment in terms of personal, moral, and structural factors. Flores and Campbell (2009) used this framework to ascertain newlywed women's expectations of infidelity and divorce. Findings indicated that moral commitment was significantly related to women's expectations of engaging in infidelity, but not divorce. In the current study, we extend these findings by investigating which sub-components of moral commitment (i.e., values about relationship dissolution, moral obligations to a partner, personal consistency values) are related to women's expectations of infidelity. One hundred and ninety seven women who had been married two years or less completed an online survey. Two of Johnson's moral commitment subscales were significantly related to women's infidelity expectations. Women were less likely to expect to engage in extramarital sex if they felt morally obligated to a partner and if they held personal values of consistency. The third subscale, values about relationship dissolution, did not predict infidelity expectations. This finding is noteworthy because the subscale contains items to assess the influence of religious values on commitment and 40% of the sample reported being "very" or "fairly" religious. Taken together, these findings suggest that obligations toward oneself (i.e., consistency values) and a partner are more important determinants of infidelity expectations than obligations felt toward God or religion. Additionally, the common occurrence of divorce in the U.S. may contribute to an overall view of relationships as replaceable or disposable, and thereby reduce the effect of relationship dissolution values on infidelity expectations.

#### A52

**ATTACHMENT STYLE AS A PREDICTOR OF NEWLYWEDS' REACTIONS TO CONFLICT** Ariel Baruch<sup>1</sup>, Paula R. Pietromonaco<sup>1</sup>, Sally I. Powers<sup>1</sup>; <sup>1</sup>University of Massachusetts Amherst – Previous research has shown that more anxiously attached dating partners evidence less positive views of their partner and their relationship after discussing a conflict (Simpson, Rholes, & Phillips, 1996). The present study extended this work on dating couples by examining the extent to which newlywed partners' attachment styles predict their post-conflict feelings and those of their partner. It was expected that more anxiously attached spouses would show more negative feelings coming out of the conflict, and that the partners of anxiously attached spouses also would evidence more negative feelings. Furthermore, because attachment style is not always related to outcome variables in the same way for men and women, we examined whether the predicted patterns would differ for husbands and wives. Forty-eight heterosexual newlywed couples completed a 36-item attachment style measure and discussed a major, unresolved conflict for 15 min. After the discussion, participants indicated how they were currently feeling on a mood measure (PANAS). Consistent with the hypothesis, more anxiously attached husbands experienced more negative feelings after the discussion ( $r = .54, p < .01$ ), but wives did not show this association. Furthermore, the wives of more anxiously attached hus-

bands also expressed more negative feelings post-conflict, ( $r = .28, p = .05$ ). These findings highlight the importance of examining attachment style together with gender and suggest that men's attachment anxiety may be particularly important to both spouses' reactions to a conflict discussion. Examining both spouses' behavior during the interactions will help to clarify the mechanism underlying this effect.

#### A53

##### **WHAT LEADS TO BREAK-UP? PREDICTIVE EFFECT OF ADULT ATTACHMENT AND RELATIONSHIP QUALITY ON RELATIONSHIP STABILITY AMONG BLACK AND WHITE COMMUNITY RESIDING COUPLES**

Ruixue Zhaoyang<sup>1</sup>, M. Lynne Cooper<sup>1</sup>; <sup>1</sup>University of Missouri-Columbia – Using a prospective research design, this study explored the predictive effects of adult attachment style and relationship quality on the stability of romantic relationships in early adulthood. Black and White community residents and their romantic partners completed self-report measures of attachment style and relationship functioning ( $N=280$  couples) at baseline. Approximately 4 1/2 years later, one member of each couple provided information on the status of their romantic relationship. Results revealed that race, gender, attachment style, and relationship quality interacted to predict relationship stability over time such that individuals with low models of self were equally likely to stay in their relationship regardless of relationship quality, whereas those with high self models were more likely to stay in a good quality relationship but to leave a poor quality one. This pattern was observed among Whites of both genders and among Black men. Black women, however, showed the different pattern in which relationship quality did not predict relationship stability regardless of their attachment security. Results are interpreted in light of demographic differences in the sex ratio among Black and white men and women, and suggest that what is adaptive varies according to environmental context.

#### A54

##### **SPONTANEOUS PARTNER FEELINGS, RELATIONSHIP SATISFACTION, AND THE PREDICTION OF ROMANTIC BREAKUP**

Etienne P. LeBel<sup>1</sup>, Lorne Campbell<sup>1</sup>; <sup>1</sup>The University of Western Ontario – The current research investigated the role of spontaneous partner feelings (implicit partner affect) in the dynamics of relationship satisfaction, commitment, and romantic dissolution. Participants completed a variant of the name-letter task as a measure of implicit partner affect, and self-report measures of relationship satisfaction and commitment. Approximately four months later, participants were contacted to assess their current relationship status. Overall, participants showed a biased preference for their partner's initials (after adjusting for proper baselines), indicating the presence of positive implicit partner affect. Participants with more positive implicit partner affect were more satisfied with, but not more committed to, their relationship. Additionally, implicit partner affect exerted a significant indirect effect on relationship termination. These effects were independent of relationship length, age, and gender. Implications for the role of automatic affective processes in relationship processes and the utility of indirect measures for shedding light on relationship dynamics are discussed.

#### A55

##### **THE COSTS OF RELATIONSHIP LOSS AND RESPONSIVENESS TO INTERPERSONAL REJECTION: THE MODERATING ROLE OF SOCIAL ENVIRONMENT.**

Genta Miyazaki<sup>1,2</sup>, Tomoko Ikegami<sup>1</sup>; <sup>1</sup>Osaka City University, <sup>2</sup>Japan Society for the Promotion of Science Fellows – In our previous research, a greater amount of shared activities with one's friends (i.e., greater cost of relationship loss) was found to be related to heightened sensitivity to interpersonal rejection cues and increased motivation to behave in more relationship-constructive ways. The present study extends this work by examining the moderating role of social environment on the effects of cost of relationship loss on responsiveness to interpersonal rejection. In high-density interpersonal networks, rejection by one member can potentially lead to the loss of an entire network of relationships because all members are closely connected to each other.

Therefore, we hypothesize that the cost of one relationship loss will be more significant among those who are embedded in high-density rather than low-density interpersonal networks. A questionnaire study was conducted with 355 Japanese undergraduates whose university settings were characterized by high-density or low-density interpersonal networks. Participants rated the degree of intimacy and the number of shared activities with their closest same-sex friend, and indicated how they would feel and behave if they were rejected by the friend. As predicted, multiple regression analyses revealed that a greater number of shared activities led to lowered self-regard and reduced relationship-destructive behaviors following the imaginary rejection in high-density but not in low-density interpersonal networks. This moderating effect of social environment, however, disappeared when intimacy with one's friend was relatively high. The adaptive nature of response systems to interpersonal rejection was discussed.

#### A56

##### **HAPPILY EVER AFTER? AN ACTOR-PARTNER INTERDEPENDENCE MODEL ANALYSIS OF SELF-ESTEEM AND INTIMATE RELATIONSHIP OUTCOMES**

Kelley J. Robinson<sup>1</sup>, Jessica J. Cameron<sup>1</sup>; <sup>1</sup>University of Manitoba – That personality is related to individuals' relationship experiences is widely accepted in psychological research. With few exceptions (e.g., Davila & Kashy, 2009; Robins et al., 2000), however, the influence of partners' personalities on individuals' relationship assessments are often neglected. The current study investigated the contributions of both partners' self-esteem levels to individuals' evaluations of their relationships. Self-esteem is of particular importance in close relationships: It is responsive to social feedback (e.g., Leary et al., 1995), predictive of social perceptions, and a precursor to relationship behaviours (e.g., Murray et al., 2008). Despite this abundance of self-esteem research on individuals' own outcomes, the implied contributions of partners' self-esteem levels have not been investigated, nor has the interactive quality of couples' self-esteem levels been addressed. Over 300 heterosexual dating couples completed assessments of self-esteem and relationship outcomes. Using Actor-Partner Interdependence Model analyses we estimated actor, partner, and interactive effects of self-esteem on three relationship outcome variables: perceived regard, satisfaction, and commitment. As predicted, lower self-esteem individuals reported lower perceived regard and lower satisfaction (actor effects). Also, the partners of lower self-esteem individuals were less satisfied in their relationships than the partners of higher self-esteem individuals (partner effect). Finally, the interaction between partners' self-esteem levels predicted commitment to the relationship. The current study reflects the dyadic nature of relationship processes and highlights the importance of considering both partners in theories and research on close relationships. Implications for choosing partners, intervening in troubled relationships, and maintaining intimate bonds will be discussed.

#### A57

##### **THE JEKYL AND HYDE EFFECT IN RELATIONSHIPS REVISITED: THE ROLE OF FRIENDSHIP CONTINGENT SELF-ESTEEM IN EVALUATING ROOMMATES**

Sara Nicole Wrenn<sup>1</sup>, M. Janelle Cambron<sup>1</sup>; <sup>1</sup>Texas A&M University – Previous research indicates that individuals with low self-esteem segregate positive and negative information about close others. Simply put, low self-esteem individuals see close others as either "all good" or "all bad" at any given time. To explain this finding, researchers have argued that low self-esteem individuals are motivated by two goals: to form satisfying relationships with others and to avoid rejection. However, a more important variable may be the extent to which individuals base their self-esteem on their interpersonal relationships. Individuals who base their self-esteem on their relationships are strongly affected by interactions with close others and may be especially motivated to have satisfying relationships and avoid rejection. The purpose of this study was to examine the relation between basing one's self-esteem on one's friendship quality (friendship contingent self-esteem; FCSE) and the tendency to segregate positive and negative information about close

others. 237 participants (145 females, 92 males) completed diary records for 5 consecutive days about their roommates. Results showed that high FCSE individuals were more likely to segregate positive and negative information in general, and were more likely to be unstable in their evaluations of their roommates over 5 days. In addition, the segregation of positive and negative information about others mediated the relation between FCSE and the stability of their evaluations over the 5 days. Therefore, this research supports the idea that individuals who base their self-worth on the quality of their friendships tend to segregate positive and negative information about other close others at any given time.

**A58****"YOU TURN ME ON": AN ATTACHMENT PERSPECTIVE ON PERCEIVED PARTNER RESPONSIVENESS AND SEXUAL DESIRES** Gurit Birnbaum<sup>1</sup>, Harry Reis<sup>2</sup>, Maayan Dvir<sup>1</sup>; <sup>1</sup>Interdisciplinary Center (IDC) Herzliya, <sup>2</sup>University of Rochester

The belief that a relationship partner is responsive and understands, values, and supports important aspects of the self is inherent to the development of intimate and satisfying long-term relationships (Reis, Clark, & Holmes, 2004). Although sex is considered a prominent context in which people seek a sense of felt understanding, validation, and caring, little attention has been given to the role of perceived partner responsiveness in the sexual realm. It is therefore not clear whether and how personal and interpersonal goals served by positive responsiveness are reflected in specific motives for engaging in sex and whether perceiving a partner as responsive increases the desire to have sex with him or her. The present research adopted an attachment-theoretical perspective to examine the contribution of partner responsiveness to sexual desires. In Study 1, 1,617 participants completed self-report scales of attachment orientations, perceived partner responsiveness, and sexual desires and fantasies. In Study 2, 150 participants imagined scenes in which their partner was responsive or unresponsive and then rated their desire to have sex. Results indicated that perceived partner responsiveness was associated with more frequent sexual fantasizing about one's partner and heightened interest in sex with him or her. Not all people reacted to positive responsiveness in the same way, however. Avoidantly attached individuals were less likely than their less avoidant counterparts to desire their partner, possibly reflecting intimacy concerns. These findings suggest that perceiving one's partner as responsive may facilitate sexual desire, primarily among those people who engage in sex for attachment-related reasons.

**A59****TOWARD A PSYCHOLOGICAL CONSTRUCT OF ENMITY** Christopher

Jones<sup>1</sup>, Russell Fazio<sup>1</sup>; <sup>1</sup>The Ohio State University – Though the term "enemy" is common and describes a distinct form of social relationship, scant research has addressed the concept. A questionnaire was administered to 265 undergraduate students with the goal of validating a construct definition of enmity as consisting of three elements: negative feelings toward an individual, beliefs that the individual is malevolent or threatening, and a desire that the individual experience psychological, physical, or social harm. The study also explored how the person came to be an enemy and the correlates of the presence and intensity of such relationships in participants' lives. Participants first provided spontaneous definitions of "enemy" and described someone fitting this category, if one existed. Then, participants were given the definition above, assessed its viability, and described the individual best fitting this definition. A series of questions about this person followed, as did a Big-5 personality inventory. Results indicated that the proposed construct definition is highly consistent with participants' lay usage. Of the 201 participants who had an enemy according to their own lay definitions, 85% later assessed the proposed construct definition as completely applicable. Regarding enemies fitting the provided definition, the modal enemy was a competitor at school, work, or sport. Various correlates of extent of negativity towards the enemy and/or desire for harm were observed, including the Big-5 factor agreeableness, such that less agreeable individuals reported more intense enmity. We conclude that the

proposed definition is viable and the construct meaningful, reflecting a prevalent phenomenon that can be fruitfully studied in normal populations.

**A60****RELATIONAL EFFICACY, SHARED EMOTIONS, AND RELATIONSHIP STABILITY IN ROMANTIC RELATIONSHIPS** Ryosuke Asano<sup>1</sup>; <sup>1</sup>Nagoya

University – It is beneficial for close relationship partners to share their emotions with one another to form and maintain good relationships (Gable et al., 2006; Gonzaga et al., 2007). This study investigated how relational efficacy affects shared positive and negative emotions between romantic partners. Relational efficacy, which is a pair-level efficacy, refers to a couple's belief that they can mutually coordinate and integrate their resources to prevent and resolve any problems; this concept is based on the social cognitive theory (Bandura, 2001). In addition, the current study examined how these shared emotions predict relationship stability for six months. One hundred and seven dating heterosexual couples completed a questionnaire survey, and 25 of them participated in a follow-up study. In this study, multi-level structural equation modeling (MSEM) was conducted to distinguish between the actual phenomenon of dyadic relationships (between model) and the subjective processes of individuals within relationships (within model). The results of a MSEM revealed that the relational efficacy significantly predicted positive emotions ( $B = 0.42, p < .001$ ), but not negative emotions ( $B = 0.03, ns.$ ) in the between model. Moreover, a logistic regression analysis showed that positive emotions marginally promote relationship stability ( $B = 5.94, p < .10$ ), whereas negative emotions inhibit it ( $B = -12.11, p < .05$ ). Therefore, it is suggested that relational efficacy facilitates relationship stability through the mediation of shared positive emotions between romantic partners. Implications for mechanisms of relational efficacy and shared emotions between partners in building relational well-being are discussed.

**A61****DON'T STAND SO CLOSE TO ME** Katherine Carnelley<sup>1</sup>, Erica G. Hepper<sup>1</sup>, Angela C. Rowe<sup>2</sup>, Richard Gramzow<sup>1</sup>; <sup>1</sup>University of Southampton, <sup>2</sup>University of Bristol

Research shows that when forced to focus on attachment-related concerns those high in attachment avoidance show physiological stress, such as increased Skin Conductance Level (SCL) (e.g., Diamond et al., 2006; Dozier & Kobak, 1992). However, Fraley and Shaver (1997) show that dismissing-avoidant individuals when asked to suppress thoughts of partner separation can also suppress physiological reactions (SCL). They suggest that if given an opportunity to focus attention away from attachment-related concerns those high in avoidance can successfully avoid stress. We used the Hierarchical Mapping Technique (Kahn & Antonucci, 1980) to symbolically impose closeness (IC) of attachment network members to participants' core-self. Given that the IC task might allow avoidant participants to focus attention away from the task (e.g., by doing it quickly) we expected that global avoidance would be associated with lower SCL during IC. Participants ( $n = 58, 93\%$  female;  $MAGE = 21$ ) completed Time 1 measures of adult attachment dimensions and various self-report measures. We assessed SCL during imposed closeness and measured self-report items post-IC. Consistent with hypotheses, those high in attachment avoidance showed suppressed SCL (controlling for baseline SCL) during IC. After IC those high in avoidance felt smothered, less autonomous, and desired self-reliance. Participants reported feeling less close to, and placed further from the core-self, network members with whom they have an avoidant relationship. Work on IC has implications for individuals who require care (e.g., frail; ill). In future we will manipulate attachment-threat to examine whether avoidants are still able to suppress physiological activity during IC.

**A62**

**EMOTIONAL REACTIONS TO MILD ACCEPTANCE AND REJECTION BY POTENTIAL RELATIONSHIP PARTNERS** Lindsey A. Beck<sup>1</sup>, Margaret S. Clark<sup>1</sup>, <sup>1</sup>Yale University – We currently know little about how people move from initial attraction to another person as a possible close relationship partner to the establishment of an ongoing relationship with that person. Relationship formation should be facilitated if cues of a potential partner's interest--or lack thereof--are handled with equanimity. However, we expect that not everyone responds to such cues with equanimity, and that insecurely attached individuals may be especially emotionally reactive to mild social acceptance and rejection. Two studies examine people's affective reactions to mild acceptance and rejection from potential relationship partners. In Study 1, participants and a confederate both completed an initial individual task before they were given the opportunity to work on a second individual task or a joint task. The confederate indicated that she wished to work with the participant (acceptance cue) or independently (rejection cue). In a second study, community volunteers reported their anticipated emotional reactions to social situations involving mild acceptance or rejection. In both studies, high participant attachment avoidance predicted reacting to rejection with hostility, whereas high participant attachment anxiety predicted reacting to acceptance with fear. Additional evidence of the association between attachment anxiety and negative emotional reactions emerged in Study 2, including greater hostility and shame in response to acceptance and greater hostility, shame, and fear in response to rejection. Implications of insecure individuals' lack of emotional equanimity in response to early signs of social interest or disinterest for the initiation of close relationships are discussed.

**A63**

**FIRST TIME SEXUAL EXPERIENCE AND CURRENT SEXUAL WELL-BEING: A DIARY STUDY** Lauren Pulinka<sup>1</sup>, C. Veronica Smith<sup>1</sup>, <sup>1</sup>University of Delaware – The loss of one's virginity remains a highly salient experience throughout a person's lifetime (Elyse-Quest, Hyde, & DeLamater, 2005) and characteristics of the first sexual encounter have been shown to have an influence on general adult sexual functioning (e.g., sexual satisfaction, frequency). However, previous research has tended to ask participants about their first time and their current sexual functioning concurrently, which may lead to spillover effects. What the literature has seemingly ignored is the role it may play in day-to-day sexual behavior. In this study, 331 undergraduate participants answered questions about their first time sexual encounter as well as their present sexual functioning (e.g., global sexual satisfaction, sexual depression). In addition, participants described and rated their sexual interactions for two weeks using a variant of the Rochester Interaction Record (Wheeler & Nezlek, 1977). Results suggest that participants who had more positive first time sexual experiences (e.g., intimacy, respect) report having greater feelings of general sexual satisfaction and esteem and less sexual depression. In addition, a series of multilevel random coefficient modeling analyses of the 156 participants who recorded multiple sexual interactions over the two weeks also revealed that positive first time experiences were predictive of both physical and emotional satisfaction in their current sexual interactions. These results remained significant even when controlling for global sexual satisfaction. These results suggest that one's first time sexual experience is more than just an important step or milestone in their development. Rather, it appears to have important implications for their sexual well-being years later.

**A64**

**AGGRESSION AFTER SOCIAL REJECTION: IS IT MEDIATED BY DOMINANCE?** Jennifer Crowhurst<sup>1</sup>, Jean Twenge<sup>1</sup>, <sup>1</sup>San Diego State University – This study was designed to investigate dominance as a possible mediator for the effect of social rejection on aggression. Previous research shows that people generally become more aggressive toward others, even strangers, after they have been rejected. Evolutionarily, humans have adapted to survive in groups, and many behaviors are

affected by the group dynamic. Feelings of dominance or one's ranking in the social pecking order may become threatened after social rejection, and people may then resort to aggression as a strategy to re-establish rank. Social rejection was manipulated by informing the participant that none of the other participants in the study chose to work with him. Participants then completed an Implicit Associations Test (IAT) measuring how quickly he associated himself with dominant or non-dominant words. It was assumed that participants' reaction times were affected by implicit feelings of dominance. Aggression was measured by using the noise blast game in which participants believed they were blasting an unknown partner with white noise. The hypothesis was that social rejection will lead to lower feelings of dominance, and will therefore lead people to act more aggressively. The results showed that feelings of dominance after a rejection depended upon preexisting personality traits. Those who were low on narcissism and/or trait dominance felt significantly less dominant when rejected. This could mean that those who are narcissistic or high in trait dominance may be unaffected by a rejection whereas those who are low on these traits react in a way that makes them feel less dominant.

**A65**

**ADJUSTMENT FOLLOWING RELATIONAL DISSOLUTION: THE IMPACT OF POST-DISSOLUTION COMMUNICATION** Kenneth Sheppard<sup>1</sup>, Susan Boon<sup>1</sup>, <sup>1</sup>University of Calgary – Lay people and researchers alike often assume that contact between former partners ceases once their romantic relationship is terminated (Lannutti & Cameron, 2002). However, Koenig Kellas, Bean, Cunningham and Cheng (2008) found that 78% of participants maintained some form of communication with their ex-partner, suggesting that the ending of a relationship does not necessarily signify the end of communication between ex-partners. The present study explored the extent to which people's feelings toward their ex-partner (i.e., affective reaction) following a breakup were related to the nature of the post-dissolution communication engaged in with their ex-partners and, in turn, whether the perceived quality of such communication was related to their concurrent adjustment. Participants were 180 undergraduate students (84 men, 96 women) who had experienced the dissolution of a romantic relationship of at least three months duration within the past three months. Participants completed adjective checklists assessing affective reactions and communication, the SCL-90 (Derogatis, Lipman & Covi, 1973), and the Profile of Mood States (Shacham, 1983). Tests of mediation revealed that, as predicted, post-dissolution communication significantly mediated the relationship between (a) affective reaction and psychological/physical adjustment (Sobel = 4.43,  $p < .001$ ); and (b) affective reaction and emotional adjustment (Sobel = 4.86,  $p < .001$ ). These results suggest that, depending on how an individual experiences post-dissolution communication, such communication may be beneficial to the post-dissolution adjustment process. This is a noteworthy finding given that adjustment is an important indicator of an individual's acceptance of a major shift in his/her life following relational dissolution.

**A66**

**SOCIAL EXCLUSION AND PERSONAL SECURITY: EXPLORING THE PROTECTIVE BENEFITS OF PERSONAL SECURITY ON RESPONSES TO OSTRACISM** Courtney Shade<sup>1</sup>, Robert Arkin<sup>1</sup>, <sup>1</sup>The Ohio State University – This study investigated the role of personal security in moderating reactions to ostracism. It was hypothesized that participants would engage in conformity of opinion toward the majority following exclusion, but that participants in a secure state would experience the pain of exclusion less intensely, therefore exhibiting less conformity than their more insecure peers. Participants first provided their opinions concerning various attitude issues. Next, participants were primed with either a feeling of security or insecurity (through a short story followed by guided questions). Participants were then led to feel either included or excluded by a group through Cyberball. Next, participants were provided with their fellow players' supposed responses on the previous opinion questionnaire, formed an impression based on that information, and responded to the opinion questionnaire a second time. Not surprisingly, partici-

pants who had just been excluded exhibited more conformity (as measured by attitude change in the direction of the majority) on the second questionnaire than did included participants ( $F(1,173)=4.072, p<.05$ ). On another item, participants who had been primed to experience personal security exhibited less conformity than participants who were primed to feel insecure ( $F(1,26)=4.008, p=.05$ ). In sum, exclusion prompts participants to use conformity as a vehicle to regain a sense of belongingness. A sense of security appears to act as a moderator of this tendency, is a psychological state that provides some level of protection against the negative impact of ostracism, and results in a diminished tendency to strive to regain a sense of belongingness when it has been threatened.

#### A67

**WHAT WOMEN WANT: HOW SELF-PERCEIVED APPEARANCE AFFECTS RELATIONSHIP STANDARDS** Vanessa Buote<sup>1</sup>, Erin Strahan, Anne Wilson; <sup>1</sup>Wilfrid Laurier University – The need to belong is a basic human need (Baumeister & Leary, 1995). Relational value is the extent to which an individual feels valued, important and loved within their relationships, with most people striving for high levels of relational value (Baumeister & Leary, 2000). In our past research, we have demonstrated that socio-cultural norms for ideal appearance may contribute to a positive association between physical appearance and relational value among women, such that favorable appearance self-appraisals are linked to feeling more valued and accepted by others. Moreover, we find that an appearance threat leads to lower relational value. Given that belonging is a fundamental need, it is likely that when women evaluate their appearance unfavorably, and hence feel less valued in their relationships, they will be motivated to restore their relational value. In this study, we investigated relationship standards as an outcome of the connection between appearance and relational value. We hypothesized that when women are motivated to increase their relational value, they may temporarily lower their relationship standards to ensure that their relational value needs will be met. We examined the relationship standards women reported for staying committed to a romantic relationship, and their standards for ending a relationship. Results indicated that after an appearance threat, women reported lower relational value, indicated willingness to remain committed to a less positive relationship, and willingness to accept more negative behaviors from their partner before dissolving the relationship. Relational value mediated the effect of appearance threat on commitment, but not on dissolution.

#### A68

**CAN BEING BULLIED LEAD TO SUBSTANCE USE IN ADOLESCENCE?** Linda L. Batto<sup>1</sup>, Jennifer M. Knack<sup>1</sup>, Lauri A. Jensen-Campbell<sup>1</sup>; <sup>1</sup>The University of Texas at Arlington – Although research has examined the link between bullying and mental health, little work has examined its influence on the development of substance use (SU). To the extent that being bullied is a stressor, it should influence the likelihood of SU via depression and biological pathways associated with stress. Stress-related cortisol levels increase SU vulnerability and partially account for the association between SU and depression (Choa et al., 2009). Social defeat is also associated with alterations in the mesolimbic dopamine system, which is associated with both depression and addiction (Berton et al., 2006). This poster examined whether (1) being bullied was associated with depression, the cortisol awakening response (CAR), and SU; (2) SU was associated with depression and CAR; and (3) depression and/or CAR mediated the link between being bullied and SU. Study 1 ( $N=14041$ ) used the 2007 YRBS, which is a national survey given every 2 years that assesses health/risk in adolescents. Being bullied was associated with increased use of cigarettes, alcohol, and drugs ( $r$ -range: 0.24-0.41,  $p<.001$ ). Being bullied was also associated with depression/suicidal attempts ( $r = 0.36$ ). Depression/suicide attempts mediated the link between being bullied and addiction (e.g., alcohol: indirect  $z=11.22, p<.001$ ). Study 2 ( $N=107$ ) examined the links between victimization, CAR, depression, and SU in young adolescents. Victimization was related to depression ( $r=0.53$ ), tobacco use ( $r=0.23$ ), CAR ( $r = -0.20$ ). For

boys, CAR was also related to tobacco use ( $-0.37$ ). These findings suggest an association between bullying and SU that may be mediated by depression and HPA activity.

**REMINDERS OF UNCONDITIONALLY ACCEPTING SIGNIFICANT OTHERS INCREASE SELF-COMPASSION** Juliana Breines<sup>1</sup>, Serena Chen<sup>1</sup>; <sup>1</sup>University of California, Berkeley – In this experiment we examined the hypothesis that self-compassion, which involves treating one's own suffering with kindness and understanding, can be elicited through the activation of mental representations of unconditionally accepting significant others (SOs). After recalling a failure experience, participants were randomly assigned to write about an SO who was unconditionally accepting, conditionally accepting, or neutral, and then filled out a measure of state self-compassion. As predicted, thinking about an unconditionally accepting SO led to greater state self-compassion, compared to the other two conditions. This effect held when controlling for self-esteem and positive affect. These results provide support for the idea that the capacity for self-care originates in supportive interactions with caregivers and long-term relationship partners.

## Emotion

#### A70

**ADOLESCENTS' RESPONSES TO EMOTIONAL EVENTS PREDICT WELL-BEING: EFFECTS ON DEPRESSION, SELF-ESTEEM, AND GRADES** Carissa Romero<sup>1</sup>, Allison Master<sup>1</sup>, Carol Dweck<sup>1</sup>, James Gross<sup>1</sup>; <sup>1</sup>Stanford University – Emotion regulation strategies and lay theories about emotion control have been found to be related to self-esteem and depression in college students (Gross & John, 2003; Tamir, John, Srivastava, & Gross, 2007). We extended this work by exploring the role of emotion regulation strategies and beliefs about the controllability of emotion in middle school students. We further examined how beliefs about emotion control are not only related to emotional outcomes, but also to achievement. We surveyed 116 6th grade students about their beliefs about the controllability of emotion (agreement with statements such as "No matter how hard you try, you can't really change the emotions you have"), emotion regulation strategies (agreement with statements such as "I control my emotions by changing the way I think about the situation I'm in"), frequency of rumination, depression, self-esteem, and grades. Beliefs about emotion control were related to depression, self-esteem, use of reappraisal, and grades. Use of reappraisal (changing the way one thinks about a situation to feel better) and rumination were related to self-esteem and depression.

#### A71

**GLAD TO BE SAD: EXPLORING PREFERENCES FOR NEGATIVE AESTHETIC EXPERIENCES** Lily Guillot<sup>1</sup>, Paul Rozin<sup>2</sup>, Katrina Fincher<sup>2</sup>, Danielle Blake<sup>2</sup>, Alexander Rozin<sup>3</sup>; <sup>1</sup>Yale University, <sup>2</sup>University of Pennsylvania, <sup>3</sup>West Chester University – Sadness in art is an interesting puzzle, as the emotion offers neither positive affect nor high arousal. Two studies were carried out to explore the preference for sad aesthetic experiences. In a survey of undergraduate students, participants rated their general liking of a variety of artistic exemplars that would be perceived as negative by most children and many adults. Among these, a strong correlation was found between enjoyment of sad movies, music, novels, and paintings. Furthermore, people who enjoyed sad things tended to say they enjoyed crying in response to them, and females were more likely to enjoy sad things than males. A factor analysis of these data showed that liking for sad aesthetics separated out from liking for experiences that produce fear, disgust, physical pain, and bitter or irritant tastes. A second study examined the possibility that preference for sad entertainment is due to some difference in sensitivity to the emotionality of the stimulus. Undergraduates were asked to listen to a variety of songs representing different genres and affects, and rate each song on a variety of items (e.g. speed, liking, happiness, sadness, etc). When comparing those partici-

pants who reported disliking the sad songs to those who enjoyed them, there were no significant differences in either how sad each group found those songs, or in how they rated other musical features that correlate with sadness. The current data point to a role for sadness in aesthetic enjoyment which extends beyond sensation seeking, toward a domain-specific theory of aesthetic pleasure.

**A72**

**EMOTION AND THREAT DETECTION: EXPECTING GUNS WHERE THERE ARE NONE** Jolie Baumann<sup>1</sup>, David DeSteno<sup>1</sup>; <sup>1</sup>Northeastern University – Preliminary research has demonstrated the influential role of emotion in assessments of threat, including even very rapid assessments that occur at the automatic level. It appears that applicable emotions, emotions that provide information about the relative costs or opportunities of acting in a given environment, introduce a bias that is characterized by increased vigilance for relevant threats. The current research explores potential mechanisms underlying an anger-based bias in gun detection, exploring whether it occurs at the perceptual level or reflects interactions with higher order expectancies. Anger may be affecting how an individual perceives or interprets ambiguous stimuli in the environment. That is, participants may believe neutral objects actually "look" more like threatening weapons when experiencing anger. Alternatively, anger could be increasing an individual's perceived likelihood of encountering certain classes of threat in the immediate environment, in essence setting the priors for threats the mind "expects" to encounter. Results suggest that the emotion-based bias in rapid assessments of threat occurs as a result of executive failure, or an inability to control for biased expectancies, as opposed to a direct influence on cognition at the subjective, perceptual level.

**A73**

**THE ANGRY SPOTLIGHT: THE EFFECTS OF ANGER ON SELECTIVE ATTENTION TO THREAT AND REWARD** Brett Q. Ford<sup>1</sup>, Maya Tamir<sup>1</sup>, Tad T. Brunye<sup>2,3</sup>, William R. Shirer<sup>2,3</sup>, Caroline R. Mahoney<sup>2,3</sup>, Holly A. Taylor<sup>2</sup>; <sup>1</sup>Boston College, <sup>2</sup>Tufts University, <sup>3</sup>US Army NSRDEC – Emotional states can bias selective attention toward emotion-relevant information. Prior research has shown that fear and anxiety tend to bias attention towards threatening information, whereas happiness and excitement tend to bias attention towards rewarding information. According to a valence-based account, such findings suggest that emotions bias attention towards valence-congruent information. For instance, because fear is a negative emotion, it biases attention towards negative information (i.e., threats). According to a motivational account, however, emotions bias attention towards motivationally-congruent information. For instance, because fear is associated with avoidance motivation, it biases attention towards threats. The current investigation tested these two alternatives by examining the effect of anger, an unpleasant emotion associated with approach motivation, on attention to threats and rewards. Following an emotion induction, participants completed a visual attention task and their attention to threatening and rewarding pictures was assessed using an eye tracker. We found that, following an anger induction, participants attended more to rewarding than threatening images. Such findings are inconsistent with a valence-based account and suggest that the effect of emotion on visual attention may be motivationally driven.

**A74**

**INTRAINDIVIDUAL RELATIONS BETWEEN EMOTIONAL INTENSITY AND DISCLOSURE: THE MODERATING ROLE OF DEPRESSION** Angela M. Garrison<sup>1</sup>, Jeffrey H. Kahn<sup>1</sup>; <sup>1</sup>Illinois State University – Self-disclosure theory and research suggest that individuals are more likely to disclose to others intense emotions than mild emotions. Yet recent theories of emotion dysregulation (Campbell-Sills & Barlow, 2007) and emotion-context insensitivity (Rottenberg, 2005) suggest this intensity-disclosure relationship might not hold for depressed individuals. Thus, we examined whether depression moderates the intraindividual relation between event intensity and event disclosure. To attain intraindividual data, college students (N = 239) participated in a daily diary study. Participants

came to the lab to complete measures of depression and disclosure tendencies (used as a covariate). They then logged onto a secure website each night for the next week where they described the day's most unpleasant emotional event and completed items assessing the intensity of the event and their disclosure of that event. Compliance was strengthened via daily contact with participants and adequate incentives (as demonstrated by an earlier pilot study). Data comprised 1,271 daily reports of intensity and disclosure. Hierarchical linear modeling (HLM; Raudenbush & Bryk, 2002) analyses were used to analyze the nested data (i.e., daily reports nested within participants). A random coefficients regression indicated that daily event intensity explained 43% of the intraindividual variability in disclosure. Hierarchical intercepts- and slopes-as-outcomes models revealed that disclosure tendencies predicted both the intraindividual disclosure intercept and intensity-disclosure slope. More importantly, depression moderated the intensity-disclosure relation while controlling for disclosure tendencies, such that the intensity-disclosure relation was weaker for individuals with greater depression symptoms. Results will be discussed in the context of self-disclosure and emotion regulation theories.

**A75**

**WHO'S THE MOST CREATIVE OF THEM ALL? HOW TRAIT AUTHENTIC VS. HUBRISTIC PRIDE RELATE TO CREATIVE VS. NON-CREATIVE TASK PERFORMANCE** Rodica Damian<sup>1</sup>, Yanine Hess<sup>1</sup>, Richard Robins<sup>1</sup>; <sup>1</sup>University of California, Davis – Because research on emotions and creativity has commonly explored the effects of emotion valence and activation level, self-conscious emotions have been overlooked. To address this oversight, we examined the relationship between trait pride and creative versus non-creative task performance. Within achievement domains, pride is an especially germane self-conscious emotion due to the motivational style it engenders (Williams & DeSteno, 2008) and is likely to affect creativity. Pride is double-faceted: Authentic pride is characterized by internal unstable attributions for success, and task-oriented focus, whereas hubristic pride is characterized by internal stable attributions for success, and self-oriented focus (Tracy & Robins, 2007). Based on research which shows that a lack of task-oriented focus harms creativity more than it harms performance on non-creative tasks (Csikszentmihalyi, 1978), we hypothesized that (a) authentic pride would correlate positively with both creative and non-creative tasks whereas (b) hubristic pride would correlate negatively with creative tasks, but not correlate with non-creative tasks. Participants completed Tracy and Robins's (2007) Authentic and Hubristic Trait Pride Scale during a pre-screen battery; participants later completed a common creativity measure, the Unusual Uses Test (UUT; Guilford, 1967) and a five-part GRE analytical problem. Consistent with the hypotheses, authentic pride positively predicted UUT and analytical task performance. Hubristic pride, however, negatively predicted UUT performance, but not analytical task performance. The results suggest that authentic and hubristic pride may differentially impact performance in achievement domains, and that hubristic pride may be especially harmful in creative settings. Future research should manipulate state pride to determine causality.

**A76**

**ELEVATION PREDICTS DOMAIN SPECIFIC VOLUNTEERISM THREE MONTHS LATER** Keith Cox<sup>1</sup>; <sup>1</sup>Northwestern University – Elevation, the feeling of moral uplift when viewing the virtuous action of another, has been shown to be a distinct moral emotion (Haidt & Algoe, 2009). Prosocial behaviors have been theorized to be one of the behavioral effects of elevation, but this behavioral connection has not been strongly established empirically. The current study followed college students in a naturalistic setting known to induce elevation, a spring break service trip to Central America. Participant self-reports of elevation during the service trip were collected at the conclusion of the trip. At one week and three months later, participants reported on trip related volunteerism (e.g. raising funds for the organization that led the trip) and general volunteerism (e.g. volunteering at a soup kitchen in their hometown). Self reports of elevation during the trip predicted trip specific volunteerism

at one week and three months but did not relate to general volunteerism at either time. This predictive connection was maintained even when pre-trip volunteerism, trait empathy, and the Big Five were controlled for. These results suggest that the experience of elevation motivated participants to volunteer in the domain in which they were elevated. This finding supports the hypothesis that prosocial responses are a behavioral effect of elevation, but further refines this hypothesis by suggesting that the prosocial response occurs in a domain linked to the context in which elevation was experienced.

#### A77

**MIXED EMOTIONAL APPEALS IN EMOTIONAL AND DANGER CONTROL PROCESSES** Pilar Carrera<sup>1</sup>, Dolores Muñoz<sup>1</sup>, Amparo Caballero<sup>1</sup>, Luis Oceja<sup>1</sup>; <sup>1</sup>Universidad Autonoma de Madrid – Negative emotional appeals do not always help to reduce risk behaviors. We report two studies about a new strategy based on the presentation of appeals with mixed emotions (e.g., sadness-joy/relief). Study 1 shows that a mixed message generates lower post-message discomfort than an exclusively negative message; moreover, in this first study, reported probability of performing the risk behavior (binge drinking) in the future is also lower in the mixed condition. Study 2 replicates these results and relates them to the EPPM model (Witte, 1992). Here, the mixed message again generates lower post-message discomfort than the negative one, and participants are motivated to control the danger (response efficacy is evaluated more positively in the mixed condition).

#### A78

**AN EXAMINATION OF THE RELATIONSHIP BETWEEN ACCURACY OF MENTAL STATE DECODING AND DYSPHORIA IN UNIVERSITY STUDENTS** Meghan M. McPhie<sup>1</sup>, Jill A. Jacobson<sup>1</sup>; <sup>1</sup>Queen's University – Dysphoria is associated with significant social impairments. Consequently, understanding the possible cognitive mechanisms that may underlie these difficulties is important, especially because these individuals are at an elevated risk for developing major depression (Fergusson et al., 2005). Dysphoria researchers have examined emotion recognition ability as a possible explanation with mixed results. Specifically, dysphoria has been positively associated with greater emotion identification accuracy when the stimuli are confined to the eyes region (Harkness et al., 2005), but in studies using the entire face as stimuli, dysphoria either was not related to (Frewen & Dozois, 2005) or was negatively associated with (Persad & Polivy, 1993) accuracy. Furthermore, researchers recently have begun to examine the link between focusing on another person's mouth and greater social competence in autistic individuals (Klin et al., 2002). However, no similar studies have been conducted to determine if dysphoric individuals also benefit socially from focusing on mouth stimuli. In the current study, we attempted to help reconcile and extend the previous research by comparing dysphoric and nondysphoric participants' emotion recognition performance using the same targets to construct the eyes versus mouth versus full face stimuli and examining the same participants' performance on each set. Consistent with previous research using eyes stimuli, higher levels of dysphoria were associated with greater emotion identification accuracy regardless of which type of facial information was presented. Still dysphoric individuals' enhanced ability to detect other people's emotions does not confer positive social benefits for them, and possible reasons for this disconnect will be discussed.

#### A79

**SELF DISCLOSURE INCREASES AND DECREASES ALTRUISTIC PUNISHMENT IN NEGOTIATIONS** Emma C. Fabiansson<sup>1</sup>, Thomas F. Denson<sup>1</sup>; <sup>1</sup>University of New South Wales – Anger is a common response to interpersonal conflict. Within the negotiation context, anger increases competitive and self-interested behavior and often leads to stalemates. Furthermore, angry participants often display economically irrational decision-making by rejecting offers to their own financial detriment. Specifically, angry participants are typically willing to suffer financial losses in exchange for the opportunity to punish their negotiation partner out

of spite. The Ultimatum Game is a paradigm within the context of game theory used to examine the effects of anger on negotiation-relevant variables. Two experiments explored the effects of self-disclosure on negotiation performance using the Ultimatum Game. Prior self-disclosure typically increases interpersonal rapport, satisfaction and liking and improves negotiation performance. In the first research to do so, our goal was to examine the conditions under which mutual self-disclosure would buffer and augment punitive behavior. Experiment 1 found that self-disclosure reduced punishment in response to ruthless bargaining. Experiment 2 illustrated that self-disclosure increased punishment when combined with ruthless bargaining and rude behavior (i.e., an insult) and increased rewarding behavior when combined with ruthless bargaining and neutral behavior (i.e., no insult). Moreover, anger resulted in person-specific irrational decision making rather than generally impairing rational behavior. Specifically, participants who received anger inducing feedback chose to solely punish the participant they self-disclosed with than anonymous participants despite receiving identical offers. These findings illustrate that self-disclosure can have positive and negative negotiation outcomes that should be considered in negotiation contexts.

**A PROTOTYPE ANALYSIS OF NOSTALGIA** Erica Hepper<sup>1</sup>, Timothy Ritchie<sup>2</sup>, Constantine Sedikides<sup>1</sup>, Tim Wildschut<sup>1</sup>; <sup>1</sup>University of Southampton, <sup>2</sup>University of Limerick – The construct of nostalgia has received increased empirical attention (Batcho, 2007; Wildschut, Sedikides, Arndt, & Routledge, 2006; Zauberman & Ratner, 2009). Nostalgia serves important functions, boosting positive affect, self-regard, meaning in life, self-continuity, and social connectedness. However, an empirically grounded definition of nostalgia is lacking. Four studies sought to develop such a definition using a prototype approach. In Study 1 (N=232), participants generated characteristics descriptive of nostalgia, resulting in 1752 exemplars. Two independent coders sorted exemplars into thematic categories, and a third coder used the resulting 35-category coding scheme to categorise every exemplar. Study 2 examined self-reported prototypicality of the 35 categories. Participants (N=102) rated the relevance of each category to their view of nostalgia; ratings were used to define central (e.g., reminiscence, happiness) and peripheral (e.g., daydreaming, regret) features of nostalgia. Study 3 showed that having seen prototypical features of nostalgia one-by-one on computer, participants (N=99) were more likely to remember central (vs. peripheral) features in a surprise recall test, and to falsely recognise central (vs. peripheral) non-presented features. Study 4 showed that when presented with prototypical and non-prototypical words on computer screen, participants (N=53) were quicker to verify that central (vs. peripheral) prototypical features were related to nostalgia. Understanding these features may help in future nostalgia research and interventions.

#### A81

**SELF AND AFFECTIVE FORECASTING: INDIVIDUAL DIFFERENCES IN PREDICTING IN-GROUP MEMBERS' AFFECTIVE EXPERIENCE** Kimin Eom<sup>1</sup>, Kwanghee Han<sup>1</sup>; <sup>1</sup>Yonsei University – This study investigated how individualists and collectivists forecast their in-group members' affective experience differently; especially their parents'. We hypothesized that collectivists would predict in-group members' negative emotion more strongly than individualists when they imagine a situation in which they cannot meet in-group's expectation. It can be advantageous for collectivists to predict negative emotional feedback more strongly from their in-group members so that they can avoid such a situation; because failing to meet in-group's expectation is more stressful for collectivists than individualists. Participants were asked to rate how strongly their parents would feel each of twelve emotions (5 pleasant emotions, 7 unpleasant emotions) on a 11-point scale if they received a grade one level below their expectation and the grade one level above their expectation. The score of the pleasant emotions were averaged to yield a pleasant affect score and unpleasant emotions were averaged to produce an unpleasant affect score. We measured dispositional differences in self-construal and

divided participants into two sub-groups: individualists and collectivists. The data were analyzed on the basis of a 2(outcome: positive, negative) X 2(self-construal: independent, interdependent) mixed-model ANOVA. The dependent measures were positive affect and negative affect. As predicted, collectivists ( $M = 2.10$ ) predicted negative emotional responses more strongly from their parents than individualists ( $M = 1.41$ ) in a negative outcome situation,  $F(1, 32) = 3.650, p < .065$ . Interestingly, in a positive situation where they received a higher grade than they expected, collectivists predicted their parents would feel positive emotion less strongly and negative emotion more strongly than individualists.

#### A82

**NEGATIVE FEEDBACK AND PERFORMANCE: THE MODERATING EFFECT OF EMOTION REGULATION** Jacquelyn Rafferty<sup>1</sup>, George Bizer<sup>2</sup>; <sup>1</sup>Clark University, <sup>2</sup>Union College – We explored how individual differences in emotion regulation predict people's responses to negative feedback. Undergraduate students completed an ostensibly important test on which they would be unable to gauge their performance. Some participants were told that they performed poorly relative to other students, while others were told that they performed slightly above average. Participants then completed a second test that ostensibly measured a similar construct. The number of correct answers and time required to complete the second exam were assessed as outcome variables. Finally, after taking part in an unrelated task, participants completed the Emotion Regulation Questionnaire (Gross & John, 2003) to assess reappraisal (thinking about a situation to change its emotional impact) and suppression (inhibiting emotion-expressive behavior). Standard analyses assessing outcome variables as a function of reappraisal and suppression scores separately yielded nonsignificant results. However, a global regulation score computed as the difference between reappraisal and suppression scores yielded effects consistent with our hypotheses: Among relative reappraisers (individuals with more frequent use of reappraisal relative to suppression), those who received negative feedback completed the second test more quickly and performed better than did such people who received moderate feedback. No such effects were found among relative suppressors (individuals with more frequent use of suppression relative to reappraisal). These findings suggest that individual differences in reappraisal and suppression are meaningful in terms of how negative feedback affects subsequent cognitive performance and that, in some circumstances, a global measure of emotion regulation may be useful in predicting important cognitive processes.

#### A83

**HOW MOOD INFLUENCE EMOTION RECOGNITION** Petra Schmid<sup>1</sup>, Marianne Schmid Mast<sup>1</sup>; <sup>1</sup>University of Neuchatel – Previous research has shown that mood affects social judgments, such as the ability to recognize other people's emotions. However, findings are not consistent with regard to how mood affects facial emotion recognition: For sad mood, general performance decrements in emotion recognition have been reported as well as a more emotion specific bias, such as a better recognition of sad facial expression compared to happy expressions (negative bias). Much less research has been done on the influence of happy mood on emotion recognition. There is some evidence for emotion specific bias in terms of reduced recognition of sad facial expressions compared to happy ones (positive bias). Most studies have been conducted with clinical samples (depression or mania) and not with healthy individuals and especially data for happy mood effects is missing. We induced 93 participants with happy, sad, or neutral mood and had them perform an emotion recognition task. Results showed a negative bias for participants in sad mood and a positive bias for participants in happy mood. Also, the overall performance was decreased in happy and sad mood compared to the control group in neutral mood. This was due to a specific decrement in the recognition of mood-incongruent facial expressions; the recognition of mood-congruent facial expressions was not impaired. Because

reading other people's emotions accurately is important for social functioning, people should be aware of the fact that their own affective states may bias how they perceive others' emotions.

#### A84

**THE EFFECT OF PRIMED CULTURAL CONTEXT ON THE EXPERIENCE AND COMMUNICATION OF PRIDE** Yvette M. J. van Osch<sup>1</sup>, Marcel Zeelenberg<sup>1</sup>, Seger M. Breugelmans<sup>1</sup>; <sup>1</sup>Tilburg University, the Netherlands – It has been suggested that, based on the distinction of independence-interdependence, the experience of pride differs across cultures (Markus & Kitayama, 1991). However, the phenomenological experience of emotions has shown to be culturally universal to a large extent (e.g., Matsumoto, Nezlek, & Koopmann, 2007). We propose that culture does affect pride, but only its verbal expression, and not its phenomenological experience (i.e., thoughts, feelings, action tendencies), due to differences in cultural norms on the expression of emotions (Eid & Diener, 2001). We tested this hypothesis with both culture as a quasi-experimental and a situationally primed factor among Dutch and bicultural Chinese-Dutch subjects. In a between-subjects design we primed (1) Chinese-Dutch biculturals with a Chinese cultural frame ( $n = 29$ ), (2) Chinese-Dutch biculturals with a Dutch cultural frame ( $n = 30$ ), and (3) Dutch with a Dutch cultural frame ( $n = 30$ ). We induced pride through a scenario and subsequently measured the intensity and phenomenological content of pride. The results showed that participants primed with a Dutch cultural frame felt pride more intensely, and communicated their pride more to others, than did participants primed with a Chinese cultural frame. However, no differences were found in the phenomenological content of the pride experience across conditions. The data clearly revealed that although culture affected the expression of pride, it did not affect its phenomenological experience.

#### A85

**FASTER IN GETTING CLOSER THAN IN GETTING AWAY** Jana Nikitin<sup>1</sup>, Alexandra M. Freund<sup>1</sup>; <sup>1</sup>University of Zurich – Previous research on the speed of reacting to positive and negative emotional stimuli provides an unclear picture: Research using visual search paradigms provides evidence for faster processing of negative than to positive stimuli, whereas categorization paradigms show the opposite pattern. This research leaves open the role of motivation. The present four experiments investigated the role of approach and avoidance motivation in the reaction to emotional (happy vs. angry) faces. Experiment 1 ( $N = 40$ ) and 2 ( $N = 40$ ) show consistently that approach behavior in response to happy faces was significantly faster than avoidance behavior in response to angry faces. Experiment 3 ( $N = 94$ ) rules out that this result simply reflects the Simon effect. Even when including an incongruent condition (i.e., moving away from happy and toward angry faces), participants approached happy faces more readily than they avoided angry faces. Experiment 4 ( $N = 40$ ) supported the hypothesis that the advantage of happy faces is motivational in nature: A simple categorization task revealed no differences between the reaction times to happy as compared to angry faces.

#### A86

**EFFECTS OF DISASTER PRIMING ON THE PERCEPTION OF RISK AND EXPECTATION OF POSITIVE EVENTS.** Hideya Kitamura<sup>1</sup>, Shigetaka Sato<sup>1</sup>; <sup>1</sup>Toyo University – Johnson & Tversky (1983) found that reading stories of risky events caused negative affect and increased the frequency estimates of risk. We categorized the risky events and focused the risk on disaster and the risk on disease. Our object is to investigate the priming effects of disaster-related and disease-related articles on the perception of risks. In Experiment 1, thirty-six participants read the article about disaster, disease, or a positive event, and then estimated the subjective probabilities of positive and negative events. Negative events included the events related to disaster and disease. We found in the result, disease priming increased the estimates of both disease and disaster. And positive priming increased the probability of positive events. In Experiment 2, we presented thirty-six participants with articles of positive or negative events. The results showed more pronounced effects of disaster prim-

ing on the estimates of future probabilities of experiencing disasters. We found domain-limited effects of reading articles and effects of positive priming on the probabilities of expecting negative and positive events. Contextual factors of risk perception and the role of emotion would be discussed.

**A87****HOW MUCH DO I CARE? INTEREST EXACERBATES AFFECTIVE FORECASTING ERRORS**

Jennifer Pattershall<sup>1</sup>, Scott Eidelman<sup>1</sup>; <sup>1</sup>University of Arkansas – Errors in affective forecasts are persistent and robust, but are more typical for negative events than positive events (Wilson & Gilbert, 2003). In the present research we explored a moderator of affective forecasting errors that may explain why negative errors are stronger, and when positive errors are more likely to occur. Asymmetry between positive and negative forecasts is consistent with a differential focus on negative events (Baumeister, Bratslavsky, Finkenauer, & Vohs, 2001; Kahneman & Tversky, 1979; Taylor, 1991). Considering this, we reasoned that level of interest in an event—that is, how much the person cares about the outcome—would magnify affective forecasting errors. If interest is high, forecasting errors should be enhanced for negative events and should emerge for positive events. We tested this hypothesis in two studies. In Study 1, participants forecasted their feelings about possible outcomes of the 2008 US presidential election, and indicated their actual feelings after the event. For both Obama and McCain supporters, affective forecasting errors increased as interest increased. In Study 2 we manipulated interest in an outcome by telling participants that an upcoming test was important or not. After receiving a performance goal, participants predicted how they would feel about successful or unsuccessful performance. After taking the test and receiving positive feedback, participants indicated their actual feelings. Participants in the important condition made larger affective forecasting errors than participants in the unimportant condition. These data suggest that, ironically, people will be less accurate when they care the most.

**A88****THE PSYCHOLOGICAL CONSTRUCTION OF BASIC EMOTIONS FROM HEDONIC TRAJECTORIES**

Tabitha Kirkland<sup>1</sup>, William A. Cunningham<sup>1</sup>; <sup>1</sup>The Ohio State University – Every day, we experience qualitatively distinct emotional states such as joy, sadness, and fear. The basis of these experiences has been a source of debate. In contemporary social psychology, two dominant themes have emerged. One idea is that discrete emotions result from basic "natural kind" categories. According to this view, each specific emotion originates from a biological module resulting in a stereotyped cognitive and behavioral response. An alternate view is that emotions are the consequence of cognitive constructions based on situational appraisals. Thus, all emotions are experienced by categorizing and labeling relatively undifferentiated affective arousal. In one model, each emotion uses independent processes; in the other, all emotions have an identical affective core and are differentiated by the cognitive categories that are used to quantify experience. We suggest a hybrid of these models. It is proposed that basic emotions are not socially constructed from semantic categories (i.e., relational themes), but rather emerge from separable affective representations that consider the hedonic trajectory of the individual. In four studies participants were presented with information about their own or another's past, current, and/or future hedonic states and were asked to indicate or rate the expected emotions the situation would elicit. The basic emotion categories were predicted by specific interactions in hedonic space, indicating that emotions can be modeled successfully by understanding affect through time. Thus, fully separable emotions can be constructed in a lawful manner from dimensional states without the need for semantic categories.

**A89****THE ROLE OF DIALECTICAL THINKING IN MIXED EMOTIONS: AN EXPERIMENTAL APPROACH**

Bradley J. Stastny<sup>1</sup>, Jeff T. Larsen<sup>1</sup>; <sup>1</sup>Texas Tech University – Dialectical thinkers are more willing to accept contradiction in everyday life (Peng & Nisbett, 1999); as such, dialectical thinking may foster the experience of mixed emotions. Evidence suggests that Easterners, who think more dialectically than Westerners, experience more mixed emotions than Westerners (Bagozzi, Wong, & Yi, 1999; Schimmack, Oishi, & Diener, 2002), which suggests that dialectical thinkers experience more mixed emotions than non-dialectical thinkers (Goetz, Spencer-Rodgers, & Peng, 2008). We developed a manipulation of dialectical thinking to more directly investigate whether dialectical thinking influences mixed emotions. We asked 14 participants to read pairs of contradictory findings (e.g., "Research indicates that watching violent TV or movies makes a person more violent while other research indicates that watching violent TV or movies makes a person less violent") and indicate how much they felt each finding was right or wrong (see Peng & Nisbett, 1999). We then asked participants to think about how both findings could be true. Finally, participants re-read each finding and again indicated whether they thought each finding was right or wrong. Following the induction, participants listened to 16 music clips known to elicit mixed emotions (Hunter, Schellenberg, and Shimmack, 2008). During the clips, participants reported whether they felt neutral, happy, sad, or both happy and sad. Results revealed that those induced to think dialectically experienced more mixed emotions during the clips than a control group (n = 14). This finding provided experimental evidence that dialectical thinking fosters the experience of mixed emotions.

**A90****HOW RELATIONSHIP MOOD FLUCTUATIONS RELATE TO GENERAL MOOD CHANGES**

Sean P. Lane Jr.<sup>1</sup>, Ammara Khalid<sup>2</sup>, Patrick E. Shrout<sup>1</sup>, Niall Bolger<sup>3</sup>; <sup>1</sup>New York University, <sup>2</sup>Argosy University, Chicago, <sup>3</sup>Columbia University – In close relationships, both relationship-specific and general moods are often used as indicators of relationship processes (e.g. Thompson & Bolger, 1999). However, there is scant literature on the conceptual distinctiveness or overlap of these constructs. Furthermore, little work has described the way these processes relate to each other over time. Using two samples, we show that relationship-specific and general moods are clearly dissociable and differentially predictive of one another. In Study 1, 76 romantic couples completed daily diaries for 35 days. Over time, relationship moods and general moods were only moderately correlated for the average couple. Relationship-specific moods (anger, anxiety, depression, vigor) predicted same-type general moods significantly more strongly than general moods predicted relationship-specific ones. In addition, relationship moods had significantly stronger lagged effects onto themselves than did general moods. Study 2 used the same daily diary design with 308 romantic couples, except that one partner was preparing for a stressful examination. The effects for examinees' partners largely replicated the effects found in Study 1. Among examinees however, both same-mood lagged effects and same-day cross-mood effects were symmetrical: relationship mood was as predicted by general mood as the converse. These results are consistent with theories of mood regulation (Schwarz & Clore, 1996), which suggest that moods with a defined object (e.g. relationship-specific) may be represented and handled differently than more diffuse moods that may lack a clearly defined object (e.g. general). However, context (e.g. stress) may disrupt the ability to compartmentalize different mood types, resulting in more symmetrical joint regulation.

**A91****PREDICTING SELF-CONTROL SUCCESS AND FAILURE FROM THE EMOTION GOALS TO EXPERIENCE PRIDE AND PLEASURE**

Lillia Cherkasskiy<sup>1</sup>, Peter Salovey<sup>1</sup>; <sup>1</sup>Yale University – We propose that individuals may have goals to experience certain emotions such as hedonic pleasure and pride, which we term "emotion goals." We further hypothesize that these emotion goals have the same properties as behavioral goals

(i.e. prompting behaviors instrumental to reaching the goals). In a series of two studies, we tested the specific hypothesis that the endorsement of certain emotion goals has important consequences for behavior requiring self-control. In a preliminary study, a new measure called the Pleasure and Pride Emotion Goal questionnaire (PPEG) was validated to assess the emotion goal to experience hedonic pleasure as well as the emotion goal to experience the positive self-evaluative emotion of pride. In a second study, endorsement of the emotion goal to experience pleasure (but not endorsement of the emotion goal to experience pride) predicted self-control failure in snack choice between an indulgent versus a healthy snack alternative, only under conditions of low cognitive load. These results suggest that specific emotion goals vary among individuals and may have important consequences for behaviors requiring self-control, which afford the opportunity to satisfy or frustrate these goals.

#### A92

**DOES TRACY AND ROBINS' (2007) AUTHENTIC AND HUBRISTIC PRIDE SCALE REALLY MEASURE TWO DISTINCT ATTRIBUTION STYLES?** Jared Piazza<sup>1</sup>, Colin Holbrook<sup>1</sup>, Paulo Sousa<sup>1</sup>; <sup>1</sup>Institute of Cognition & Culture, Queen's University Belfast, UK – Recently, Tracy and Robins (2004, 2007) proposed a two-facet structure of pride, with "authentic" and "hubristic" pride arising from distinct antecedent appraisals. In their model, attributing a positive event to internal, controllable, and unstable causes is thought to promote authentic pride, whereas attributing a positive event to internal, uncontrollable, and stable causes is thought to promote hubristic pride. Tracy and Robins' (2007) Authentic and Hubristic Pride Scale (AHPS), which is comprised of seven positive adjectives relating to authentic pride (e.g., accomplished) and seven negative adjectives relating to hubristic pride (e.g., arrogant), is thought to distinguish between these two facets of pride. However, an alternative account is that the AHPS simply measures differences in trait or state self-esteem, which Tracy and Robins (2007) have shown to correlate negatively with Authentic Pride and positively with Hubristic Pride. We administered the AHPS to one hundred participants, who were asked to describe and answer questions about a personal success and failure. The questions measured tendencies to attribute success and failure to internal-external, controllable-uncontrollable, and stable-unstable causes. The results support the view that AHPS is a measure of self-esteem differences and not a measure of the distinct appraisal tendencies postulated by Tracy and Robins (2007). Authentic Pride was associated with a self-enhancing response pattern, whereas Hubristic Pride was associated with a self-defeated response pattern. We argue that the AHPS is more accurately construed as a measure of positive and negative self-construals than of authentic and hubristic pride.

#### A93

**AFFECTIVE FORECASTING FOR COOPERATIVE AND COMPETITIVE BEHAVIOR: IT FEELS BETTER THAN YOU THINK TO COOPERATE** Jeffrey D. Green<sup>1</sup>, Jody L. Davis<sup>1</sup>, Eli J. Finkel<sup>2</sup>, Anthony E. Coy<sup>1</sup>, Daryl R. Van Tongeren<sup>1</sup>, Julie A. Kittel<sup>1</sup>, Michelle Irby<sup>1</sup>; <sup>1</sup>Virginia Commonwealth University, <sup>2</sup>Northwestern University – Research on affective forecasting suggests that individuals overestimate the intensity and duration of both positive and negative experiences. The present work extends affective forecasting research from events that simply happen to people to behaviors people may enact – cooperation and competition. Forecasts for moral behaviors that have affective implications for both the self and others may play a large part in determining whether or not the behavior occurs. Participants in the experimenter condition were trained in game-theory matrix interactions like the PDG, and were told that they were going to play the game via computer with another participant. They made choices quickly on 10 different matrices and then received false feedback regarding their matrix choices: the computer program notified them that their choices reflected either very competitive or very cooperative behavior. They reported how they felt at that moment. Participants in the forecaster condition were similarly trained in the matrix interactions, viewed the same 10 matrices, and reported how they thought they would feel after going

through the same procedure and receiving feedback that they had made either very cooperative or very competitive choices. The two-way interaction (experimenter vs. forecaster x cooperative vs. competitive) was significant. Individuals forecasted that they would feel significantly worse after cooperation than they actually did, whereas they forecasted that they would feel somewhat better after competition than they actually did. It's possible that individuals may cooperate less and compete more, due to faulty forecasts. Put another way, individuals underestimate how good it feels to cooperate.

#### A94

**THE SELF IN SHAME AND VICARIOUS SHAME** Stephanie C. M. Welten<sup>1</sup>, Seger M. Breugelmans<sup>1</sup>, Marcel Zeelenberg<sup>1</sup>; <sup>1</sup>Tilburg University – People can experience shame vicariously for others. Central in shame is a threat to the self. In shame the self is both personally and socially threatened. The question is whether this experienced self-threat in shame also exists in vicarious shame. We argue that people in vicarious shame experience a threat only to the social self. In three studies, using different emotion inductions (between-subject designs) and different dependent measures, we revealed that shame affects both the personal and social self, whereas vicarious shame affects only the social self. This explains why vicarious shame can trigger markedly different behaviors than shame. In Study 1, 85 participants autobiographically recalled a shame, vicarious shame, or a regular day experience. Performance self-esteem (as proxy for personal self-esteem) and social self-esteem (Heatherton & Polivy, 1991) were measured. Analyses revealed that in shame both performance and social self-esteem decreased, whereas in vicarious shame only social self-esteem decreased. In Study 2, 117 participants read a shame, vicarious shame, or control scenario. Personal and social self-esteem were measured. Analyses revealed that in shame both personal and social self-esteem decreased, whereas in vicarious shame only social self-esteem decreased. In Study 3, 62 participants autobiographically recalled a shame or vicarious shame experience. Personal and social shame components were measured. Analyses showed that in shame both personal and social shame components increased, whereas in vicarious shame only social shame components increased. Our studies revealed that vicarious shame differs from shame not only in consequences for self-esteem but also in the emotion itself.

#### A95

**THE INFLUENCE OF PRIMED, STATE, AND TRAIT AFFECT ON TEMPORAL DISCOUNTING RATES.** Adam Augustine<sup>1</sup>, Aaron Weidman<sup>1</sup>, Alexandra Fine<sup>1</sup>; <sup>1</sup>Washington University in St. Louis – Previous research has largely focused on the influence of experienced affect on decision making; however, other sources of affective information may also shape decisions. In two studies, we examine the interacting influences of affective information, state affect, and personality on temporal discounting rates (i.e. the tendency to choose small rewards today rather than larger rewards in the future). In Study 1, participants were primed with either positive or negative affect adjectives prior to making each reward choice. In Study 2, participants underwent either a positive or negative affect induction prior to making reward choices. Results in both studies indicate that extraversion interacts with state pleasant affect and condition (i.e. positive or negative primes or induction) to predict discounting rates. Additionally, neuroticism interacts with state unpleasant affect and condition to predict discounting rates. However, the nature of these interactions depends on the source of the information, with neurotics and extraverts showing lower discounting when primed with affect and higher discounting when experiencing affect. These results suggest that irrelevant (i.e. primes) and stable (i.e. personality traits) sources of affective information also shape judgments and decision making. Thus, current affect levels are not the only sources of affective information that guide individuals when they make quick decisions.

**A96**

**THE PRICE OF AWESOMENESS: EVIDENCE FOR AN EXPERIENCE-STRETCHING PROCESS** Jordi Quoidbach<sup>1</sup>, Elizabeth W. Dunn<sup>2</sup>; <sup>1</sup>University of Liège, Belgium, <sup>2</sup>University of British Columbia, Canada – The present research investigates the paradoxical notion that having awesome experiences may undercut enjoyment for simpler pleasures. In a first study, 269 working adults were presented with pictures of equally enjoyable vacation destinations that differed in terms of extraordinariness. Participants were asked to imagine winning a trip to each of the destinations and to report how excited about the trip they would be the week before leaving, providing a measure of anticipatory savoring. To provide a measure of past amazing experiences, participants were asked to complete a brief record of their travel history. Results show that participants who had traveled the world reported less anticipatory savoring for an ordinary but enjoyable vacation destination. This effect was moderated by the time elapsed since the last travels, such that the detrimental impact of past travel was reduced when a long time had elapsed since participants had last traveled. As expected, this pattern was not significant for the extraordinary location, indicating that world travel does not induce broad anhedonia, but merely impairs savoring of more ordinary experiences. Converging evidence supporting the experience-stretching process will be discussed. Our findings provide the first evidence for the notion that great experiences may actually undermine the ability to reap enjoyment from life's smaller pleasures.

**A97**

**DISGUST SENSITIVITY MODERATES THE INFLUENCE OF CONDITIONED DISGUST ON MORAL JUDGMENT** Bieke David<sup>1</sup>, Bunmi Olatunji<sup>1</sup>; <sup>1</sup>Vanderbilt University, Nashville, TN – A growing body of research suggests that the experience of disgust results in more severe moral judgments. However, the parameters of this effect have not been fully explored, and some research suggests that certain individual difference variables (e.g., private body consciousness) are important moderators of this phenomenon. In the current study, we examined the influence of Disgust Sensitivity (DS, the propensity towards experiencing disgust) as potential moderator of the increase in severity of moral judgment upon the experience of disgust. An evaluative conditioning (EC) paradigm was used to experimentally induce disgust. Participants (n = 61) were exposed to a differential EC experiment where a neutral word was paired with disgusting images (CS+). They then evaluated descriptions of moral transgressions that either contained the conditioned word ('part') or a neutral word that was not conditioned with disgust ('some'). Transgressions containing 'part' were evaluated as more disgusting, but not more morally wrong, than transgressions containing 'some'. However, those high in DS found transgressions containing 'part', but not 'some', more disgusting and more morally wrong than those low in DS. These findings highlight the importance of individual differences in one's tendency to feel disgusted, and their influence on moral judgment. The implications of these findings for better understanding the role of disgust and disgust sensitivity in moral decision-making will be discussed.

**A98**

**FURTHER EVIDENCE THAT PEOPLE CAN FEEL HAPPY AND SAD AT THE SAME TIME** Jennifer D. Green<sup>1</sup>, Jeff T. Larsen<sup>1</sup>; <sup>1</sup>Texas Tech University – Cacioppo and Berntson's (1994) evaluative space model contends that positivity and negativity are separable, thereby raising the possibility that people can experience mixed emotions of happiness and sadness. To test this hypothesis, Larsen and McGraw (2009) asked participants to watch a bittersweet clip from the Italian film *Life Is Beautiful* while continuously reporting their emotions by pressing one computer mouse button whenever they felt happy and another button whenever they felt sad. These participants spent more time pressing both buttons simultaneously than those who watched a control clip, which provided evidence for mixed emotions. One limitation of their study is that participants continuously reported their emotions throughout the film. This may have led to inflated reports of mixed emotions if participants

forgot to release buttons when their emotions changed. We addressed this limitation by cuing participants to report their emotions only occasionally during two film clips. Pilot testing (n=17) revealed 5 times each when people generally reported happiness, sadness, and mixed emotions during a clip from *Life is Beautiful*, and 5 times when participants generally reported no emotions during a neutral clip from another Italian film. Auditory cues were then embedded into the films at these times. Whenever they heard a cue, participants' (n=40) task was to use the mouse buttons to report their current emotions. Results showed that participants spent more time pressing both buttons during the mixed cues than during any other type of cue. These data provide further evidence that people can feel happy and sad simultaneously.

**A99**

**"I'M SO ANGRY I'M SEEING RED!": REACTION TIME EVIDENCE FOR AN IMPLICIT ASSOCIATION.** Adam Fetterman<sup>1</sup>, Michael D. Robinson<sup>2</sup>, Brian P. Meier<sup>3</sup>; <sup>1</sup>North Dakota State University, <sup>2</sup>North Dakota State University, <sup>3</sup>Gettysburg College – The language of emotion reveals extensive use of physical metaphors (e.g., down referring to feeling bad and also to a low vertical position). Most such language concerns affective valence in general rather than any discrete emotion in particular. On the other hand, there are a few such metaphors that do appear to be emotion-specific. One such link relates the emotion of anger to the color red (e.g., "red with anger", "seeing red"). In two studies, we sought to investigate whether anger and red are implicitly linked and, importantly, whether such a link would be observed with an actual color manipulation. In Study 1, anger and sadness words were presented in a red font color or a blue font color, at random. In Study 2, the colors were red or gray and the categories were anger, fear, or neutral words. In both studies, colors were completely irrelevant as participants were to categorize each word (e.g., as an anger or sadness word) as quickly as possible. Despite the irrelevance of the colors, participants in both studies categorized anger words faster when assigned a red font color versus the control color. The association was discrete in nature because font color did not influence how quickly sadness words (Study 1) or fear words (Study 2) could be categorized. Aside from using metaphors to communicate, these results suggest, people also use them in real time as they attempt to conceptualize emotion. Anger and red, in particular, are implicitly linked.

**A100**

**MOOD AS INFORMATION? PARTICULARLY WHEN TIME IS SHORT.** Jason Trent<sup>1</sup>, Laura King<sup>1</sup>; <sup>1</sup>University of Missouri - Columbia – Socioemotional selectivity theory (Carstensen, 1993) posits that when time is perceived as limited people shift their priorities from knowledge-based goals to more emotion-based goals. Based on this idea, we hypothesized that positive emotions would be a much stronger predictor of meaning in life when one perceives his or her life as being closer to the end. To test this idea, participants (n=137) were shown a "life-line" and told that the line represented the human lifespan from beginning to end. Participants were instructed to mark an 'X' on the line where they thought they were in their own lives. They then completed measures of mood and meaning in life. Results showed that positive affect was a much stronger predictor of meaning in life the more participants' perceived their lives as limited (i.e., for those who marked the 'X' closer to the end of their life). Thus, as predicted, the more limited that time is perceived by a person, the more the person's emotional state takes priority in their life. Implications and future directions are discussed.

**A101**

**ASSESSING CENTRAL AND RESPONSE-RELATED ERP COMPONENTS IN AN AFFECTIVE PRIMING PARADIGM** Nicholas W. Jackson<sup>1</sup>, Stephen L. Crites, Jr.<sup>1</sup>, David R. Herring<sup>1</sup>, Jennifer H. Taylor<sup>1</sup>, Katherine R. White<sup>1</sup>, Guadalupe Corral<sup>1</sup>, Jennifer Gonzalez<sup>1</sup>; <sup>1</sup>University of Texas at El Paso – Affective priming refers to facilitated responding to a target stimulus due to affective congruence with a previously presented prime stimulus. The process (es) underlying this effect has been interpreted primarily as being either central or response-related. Event-related potentials (ERPs)

may shed light on the processes underlying affective priming. Recent work using affective verbal stimuli has demonstrated a response-related component of the ERP (a lateralized readiness potential, LRP), while work from our lab using affective pictures has found a late positive potential (LPP), a more central component sensitive to motivational significance. Thus, the major goal of the current study was to add to the affective priming literature by examining both ERP components. Fourteen participants so far have taken part in a sequential affective priming paradigm in which they were presented pictures pairs from the International Affective Picture System (IAPS) that were either affectively congruent (e.g., pleasant-pleasant) or affectively incongruent (e.g., unpleasant-pleasant). Behavioral responses and electroencephalographic data were recorded. Our findings are approaching significance and show a trend for affective priming, such that affectively congruent picture pairs were responded to quicker ( $M = 759$ ) than affectively incongruent picture pairs ( $M = 770$ ). The ERP data, once analyzed, should support our previous study in showing a LPP larger to incongruent than congruent affective stimuli, independent of response activity. The current study may be useful in illustrating that different types of stimuli, though producing similar behavioral findings, have different neural manifestations in the affective priming paradigm.

### A102

#### FEELINGS FROM A NEAR AND DISTANT FUTURE TIME PERSPECTIVE

Daniel Heller<sup>1</sup>, Elena Stephan<sup>1</sup>, Liberman Nira<sup>1</sup>; <sup>1</sup>Tel Aviv University – Based on Construal Level Theory (Liberman, Trope, & Stephan, 2007), we argue that individuals' predictions of their affect in near and distant future are systematically different. Whereas the near future involves a lower level construal that is focused on many details and specific events, the distant future representation involves a higher level representation that is more schematic, coherent, simple, and theory-based. Thus, we expect that imagining ourselves in the near future (i.e., next month) would be associated with a consideration of both positive and negative events and, consequently, with a mixture of Positive and Negative Affect (PA and NA, respectively). In contrast, the representation of the distant future is less restricted by events and, instead, is likely based on implicit theories or optimistic, self-enhancing biases. Consequently, we hypothesized greater levels of PA, and lower levels of both NA and emotional ambivalence in the distant, relative to near, future.

### A103

#### ARE PREDICTED AND REMEMBERED EMOTIONS OVER- OR UNDERESTIMATED? ADDRESSING THE PARADOX BETWEEN IMPACT BIAS AND EMPATHY GAP

Robin Kaplan<sup>1</sup>, Linda Levine<sup>1</sup>, Martin Safer<sup>2</sup>, Heather Lench<sup>3</sup>; <sup>1</sup>University of California, Irvine, <sup>2</sup>The Catholic University of America, <sup>3</sup>Texas A & M University – This research examined conditions leading people to over- or underestimate future and past emotional intensity. Affective forecasting research indicates that people typically overestimate emotional intensity when predicting and recalling emotion—termed impact bias (Wilson et al., 2003). Paradoxically, other research shows that people making judgments in a "cold" (rational) state typically underestimate the influence emotion will have in a "hot" (emotional) state, displaying an empathy gap (Loewenstein & Schkade, 1999). To date, research has not accounted for these contradictory findings. We hypothesized that the direction of bias may depend on the manner in which emotional experience is assessed. To investigate this, we assessed participants' reactions to the 2008 Presidential election. Participants were randomly assigned to predict, report, and recall either (a) their general emotional state following Obama's victory, or (b) their specific emotional reaction to Obama's victory. Results showed that those in the general condition anticipated and recalled more intense emotion than they actually experienced, consistent with an impact bias. In contrast, those in the specific condition, though more accurate overall, predicted and recalled less intense emotion than they experienced—consistent with an empathy gap. Thus, whether people exhibit an impact bias or empathy gap may depend on the manner in which they are asked about their emotional experience. General versus specific questions promote different strate-

gies in how people report current, and reconstruct past, emotional experience. Additionally, factors such as intensity of anticipated emotion, levels of rumination, and current appraisals of candidates contributed to how people recalled their emotional reactions.

### A104

#### ON THE RELATIONSHIP BETWEEN TRAIT EMOTION REGULATION AND ANXIETY: DOES DESIRABILITY PLAY A ROLE? Jody Amdt<sup>1</sup>, Esther Fujiwara<sup>1</sup>; <sup>1</sup>University of Alberta, Edmonton, AB

Emotion regulation (ER) refers to attempts by an individual to alter their experience and expression of emotions. Prominent ER strategies reappraisal (i.e., the cognitive reinterpretation of emotional experiences) and suppression (the inhibition of outward emotional expressions) have been shown to have opposing effects on the experience of negative emotions. In line with findings from studies with the instructed use of these ER strategies, individual-differences studies have suggested that trait-reappraisal is associated with healthier emotional, individual, and social well-being than trait-suppression. Paradoxically, we recently found that trait-reappraisal was related to threat vigilance, much like high trait-anxiety. One possible interpretation of this finding is that anxiety levels may be underestimated in individuals high in trait-reappraisal. Therefore, we tested relationships between self-reported anxiety, trait ER, and variables of desirable responding in a sample of 2169 psychology undergraduate students. Correlation analyses of the data revealed that trait-suppression was related to high self-reported trait-anxiety, while trait-reappraisal was related to low trait-anxiety. A simple mediation model was used to examine whether desirable responding exerted a mediating effect on the relationship between ER strategy and anxiety. We found that while desirable responding does in fact play a mediating role in the relationship between reappraisal and anxiety, the direct negative relationship between reappraisal and anxiety was still substantial. Desirable responding did not mediate a positive relationship between suppression and anxiety. Thus, trait-suppression is associated with high anxiety, and trait-reappraisal is associated with low anxiety, despite the fact that self-reported anxiety levels in high reappraisal individuals might be underestimated.

### A105

#### EVIDENCE FOR THE DELIBERATE DUCHENNE SMILE Sarah Gunnery<sup>1</sup>, Judith Hall<sup>1</sup>, Susan Andrzejewski<sup>1</sup>; <sup>1</sup>Northeastern University

Previous research distinguished Duchenne smiles (smiles with both the zygomatic and orbicularis oculi muscles) as those that show true happiness and thus cannot be produced at will (Ekman, Davidson, & Friesen, 1999). While studies show that females do more Duchenne smiling than males (Hecht & LaFrance, 1998), it has not been determined whether this is due to females being genuinely happier or if they have greater ability to pose the Duchenne smile. The goal of this research is to test the hypothesis that people are able to produce a Duchenne smile on purpose and to examine gender differences in this skill. Participants posed scripted scenarios where they were instructed to smile while posing real happiness and to smile to mask negative emotions. Participants then copied two expressions of a photographed person doing a Duchenne and non-Duchenne smile. There was no difference in the proportion of participants doing Duchenne smiles between the posed real happiness ( $M=.11$ ) and posed fake happiness scenarios ( $M=.15$ ), but there was a difference in the proportion of Duchenne smiles when copying the Duchenne photograph ( $M=.51$ ) and non-Duchenne one ( $M=.12$ ),  $t(56)=5.93$ ,  $p<.01$ . Females ( $M=.64$ ) produced a higher proportion of Duchenne smiles than males ( $M=.33$ ) when asked to copy a Duchenne smile,  $t(55)=2.33$ ,  $p<.05$ . These data provide evidence that the Duchenne smile is not commonly used when posing happy or masked feelings, but that people, especially females, can pose a Duchenne smile when asked to do so even when not feeling happy.

**A106**

**INTERESTING MUSIC: INTEREST'S APPRAISAL STRUCTURE AND EMOTION DECODING IN MUSIC** Scott Motyka<sup>1</sup>, Emily Schmidt<sup>1</sup>, Derek Isaacowitz<sup>1</sup>, Joseph Cunningham<sup>1</sup>, <sup>1</sup>Brandeis University – When considering theories of emotion, interest has long been regarded as a questionable category. Partly due to the advent of appraisal theory, interest and its motivational properties are becoming a major topic in the field of affective science (Izard, 2007; Silvia, 2008). The present study seeks for the first time to examine the appraisal structure of interest when elicited through an auditory channel (specifically instrumental music), and to test competing models of how interest and enjoyment are related in aesthetic expression (Smith & Ellsworth, 1985; Turner and Silvia, 2006). 44 participants completed measures of personality (MIDI; Lachman & Weaver, 1997) and current mood (PANAS; Watson, Clark, & Tellegen, 1988), and listened to 12 brief classical and jazz segments (6 negatively valenced in primary emotion, 6 positively valenced in primary emotion), rating them on interest, enjoyment, novelty, complexity, coping potential, and dimensional and categorical aspects of emotion. Using Hierarchical Linear Modeling (HLM), researchers were able to successfully model 70% of the variance related to the elicitation of interest, and found support for Smith and Ellsworth's (1985) appraisal model of interest, as well as evidence for a strong association between enjoyment and interest as related to music.

**A107**

**THANK GOODNESS FOR THAT: CHILDREN'S EARLY EXPERIENCE OF REGRET AND RELIEF** Daniel Weisberg<sup>1</sup>, Sarah R Beck<sup>1</sup>, <sup>1</sup>University of Birmingham, United Kingdom – Counterfactual thinking (what might have been) is a powerful learning mechanism that can trigger regret or relief, comparisons of a current state of affairs to a better or worse imagined possibility respectively. The minimal literature suggests that children are able to experience regret from 7 years (Guttentag & Ferrell, 2004). We aimed to identify the specific conditions under which children demonstrate regret and relief based on previous work that suggests that negative outcomes and a substantial potential loss trigger these emotions. 162 participants (4;8–7;8) won or lost stars based on a 50:50 card choice. Participants rated their happiness on a 5-point scale, were shown what could have been (the unchosen card) and consequently stated if they now felt happier, sadder or the same. Participants had four trials: regret-win (win 2/3 stars, could have won 8), regret-lose (lose 2/3, could have won 3), relief-win (win 2/3, could have lost 3) and relief-lose (lose 2/3, could have lost 8). Children aged 4-5 demonstrated no understanding of regret or relief. The 5- to 7-year-olds demonstrated regret on the regret-win and regret-lose trials. These children also demonstrated relief on relief-win trials, providing the first positive evidence of this ability. Both groups failed to experience relief on relief-lose trials. Five-year-olds experience counterfactual emotions substantially earlier than previous research suggests they can explain these emotions. Parents and teachers alike may attempt to induce comparisons to what could have been, but children younger than 7 do not understand that a negative outcome could have been worse.

**A108**

**DO THE CHIMPANZEE BLUFF DISPLAY AND HUMAN PRIDE EXPRESSION SHARE EVOLUTIONARY ORIGINS?** Jason P. Martens<sup>1</sup>, Jessica L. Tracy<sup>1</sup>, Joey Cheng<sup>1</sup>, Lisa A. Parr<sup>2</sup>, Sarah Price<sup>3</sup>, <sup>1</sup>University of British Columbia, Vancouver, B.C., <sup>2</sup>Yerkes National Primate Research Center, Emory University, Atlanta, GA, <sup>3</sup>Emory University, Atlanta, GA – Primatologists have noted that dominant chimpanzees tend to show a set of behaviors collectively referred to as the "bluff display" (De Waal, 1982). This display typically includes piloerection and upper-body swaying, which may make the individual appear larger. The bluff display is, in this way, similar to the human pride expression, which also includes a set of behaviors that make the individual appear larger (e.g., expanded posture, arms extended). Given evidence that the pride expression functions to signal high-status (Shariff & Tracy, in press), and observations of the bluff display

in predominantly high-status group members, it is possible that the two displays serve similar functions, and may share evolutionary origins. However, previous studies have not examined whether (a) the bluff display is characterized by a coherent set of behaviors that co-occur in predicted contexts, and (b) whether these behaviors are similar to those in the human pride expression. We developed a chimpanzee behavioral coding scheme, based on the human pride coding scheme (Tracy & Robins, 2007), and used it to analyze behaviors shown by two social groups of chimpanzees (N=27) interacting in different contexts at the Yerkes field station. Factor analyses of coded behaviors indicated a distinct "bluff display" factor, with high-loading items including raised arms and standing erect, two key components of the human pride expression. Chimpanzees highest on this factor tended to be engaging, or preparing to engage, in an agonistic encounter, consistent with the expectation that the display functions, like the pride expression, to signal dominance.

**A109**

**THE INTERDEPENDENCE BETWEEN THE EMOTIONS OF TEAM MEMBERS: RELATIONSHIPS WITH JOB OUTCOMES** Ellen Delvaux<sup>1</sup>, Batja Mesquita<sup>1</sup>, Jan Van Raes<sup>1</sup>, Norbert Vanbeselaere<sup>1</sup>, <sup>1</sup>Katholieke Universiteit Leuven – Many studies on group emotions either define emotions at the aggregate level, as when they average the emotions of all group members, or at the level of the individual, as when they ask an individual how he/she feels as a group member. In the current study, we examined the relationship between group emotions at the individual and aggregate levels. In a professional mental health organization, 88 employees distributed over 15 different teams filled out a questionnaire regarding the emotions they had as an individual as well as as a team member, and regarding job outcomes. In addition to individual patterns of emotions, a team profile was calculated for each employee separately by averaging the other team members' team emotions. This team profile (calculated by omitting the individual's own score) predicted the emotions that an individual reported as a team member, thereby providing support for a relationship between an individual's emotions as a team member and the emotions of the team members around him/her. Moreover, emotional fit was calculated by correlating the individual's team emotions with the team profile. Emotional fit can be seen as a measure of the congruence of an individual's team emotions with those of their colleagues. Fit turned out negatively associated with negative personal emotions. Finally, we explored the association between, on the one hand, team emotion profile and an individual's emotional fit with the team and, on the other hand, job outcomes. Both fit and team emotion profile predicted job outcomes as reported.

**A110**

**COMPARING PALESTINIAN AND AMERICAN CHILDREN'S UNDERSTANDING OF EMOTION—ITS ASSOCIATED FACIAL EXPRESSIONS, SITUATIONAL CAUSES, AND BEHAVIORAL CONSEQUENCES** Mary Kayyal<sup>1</sup>, James Russell<sup>1</sup>, Sherri Widen<sup>1</sup>, <sup>1</sup>Boston College – In two studies (Study 1: N=40; Study 2: N=120; in each study, both samples were equally divided between Palestinians and Americans matched in age and in sex) we compared Palestinian and American children's (aged of 3 to 7 years) understanding of the facial expressions, situational causes, and behavioral consequences of 5 basic emotions. Children were asked to categorize the emotion expressed in facial expressions (Study 1: happiness, fear, and surprise; Study 2: happiness, fear, surprise, sadness, and anger). Compared to Americans, Palestinians included significantly more nontarget facial expressions in their emotion categories. The nontarget facial expressions children included, however, were nonrandom and systematic as they were similar to the target in terms of valence. With age, children's categories narrowed as they included fewer nontarget facial expressions. Children categorized facial expressions of emotion systematically, but Palestinians were more inclusive than Americans. In a story-telling task (Study 2), children generated a possible cause and, separately, a consequence for different emotions: Children generated highly plausible stories; Palestinians' overall performance was slightly, but significantly, lower than Americans; performance. The results sug-

gest that Palestinian and American children have a similarly discrete understanding emotion's causes and consequences. Taken together, our results suggest that the difference between Palestinian and American children in their understanding of the most basic emotions are developmental rather than conceptual in nature. Both groups are traveling the same developmental path, but Americans are slightly ahead. Children's emotion categories narrow with age, but at a given age, Palestinians categories are broader than Americans' categories.

#### A111

**DIFFERENTIAL DISTRACTING EFFECTS BETWEEN SOCIAL VS. NON-SOCIAL TASKS ON EMOTION RECOGNITION** Sun-Mee Kang<sup>1</sup>, Josh Lapin<sup>1</sup>, Erin McMichael<sup>1</sup>, <sup>1</sup>California State University at Northridge – A new social intelligence test named the "Multiple Social Tasks" was developed to assess the ability to handle multiple social demands in social situations. In this test, both the main (an emotion recognition test) and distracting tasks (questions commonly used in a job interview) consist of social tasks in order to simulate interpersonal interactions that occur in social situations. One interesting question is what would happen if individuals deal with social (e.g., emotion recognition) and non-social tasks (e.g., solving math questions) simultaneously. Would there be any noticeable differences in the distracting effects between social vs. non-social tasks on emotion recognition? Based on the empirical studies showing that working memory is partly domain specific (Davidson & Irwin, 1999; Mikels et al., 2008), it was hypothesized that social distracting tasks should have more detrimental effects on emotion recognition than non-social distracting tasks. To test this hypothesis, one-hundred participants were randomly assigned to either social or non-social distracting condition. Two equivalent versions of the emotion recognition test were administered - first, without distracting tasks, and then, with distracting tasks. The results showed that when the emotion recognition test was given without distracting tasks, there was no significant mean difference in recognition accuracy between the two conditions (90% vs. 92%). With the distracting tasks, however, a significant mean difference between the social (72%) and non-social (82%) conditions emerged,  $t(98) = -2.36, p = .02$ , showing that the participants performed worse on the emotion recognition test with social distracting tasks than non-social tasks.

#### A112

**SELECTIVE ATTENTION TO ANGER OCCURS FOR INGROUP BUT NOT OUTGROUP FACES** John Paul Wilson<sup>1</sup>, Kurt Hugenberg<sup>1</sup>, Andrew McClintock<sup>1</sup>, <sup>1</sup>Miami University – This research examined whether the attentional bias for angry faces is unique to ingroup faces. Past research indicates that angry faces hold attention relative to neutral faces (Mogg, Garner, & Bradley, 2007). The current study investigates whether anger holds attention equally across ingroup and outgroup faces, as indexed by a dot-probe measure of attention. Twenty-six White undergraduates completed a face attention task wherein they were shown a series of pairs of ingroup (White) and outgroup (Black) faces. Each pair of faces always consisted of 2 targets of the same race (2 White; 2 Black), and one face always displayed a neutral expression whereas the other face displayed some amount (25%, 50%, 75%, 100%) of a negative facial expression (anger or fear). Thus, target race (Black, White), expression (angry, fearful), and level of expression were manipulated within-subjects. Each face pair was presented for 500 milliseconds, after which a dot probe appeared at the location of one of the two faces, and participants indicated the location of the probe by keystroke as quickly as possible. Of interest was whether the tendency for anger to hold attention occurred equally for ingroup and outgroup targets. Results indicate that the attention holding advantage of angry faces was moderated by target race: participants' attention was held by angry faces relative to neutral, but only for ingroup (White) target faces. Fearful faces did not elicit an attentional bias. The results are discussed in terms of the functional significance of ingroups.

#### A113

**CONTROLLING NEGATIVE AROUSAL IN CHOKING UNDER PRESSURE: INFLUENCE OF PERFORMANCE ENVIRONMENT AND TRAIT EMPATHY** Saya Yamanaka<sup>1</sup>, Toshikazu Yoshida<sup>1</sup>, <sup>1</sup>Nagoya University – This study investigated whether the performance environment created by the audience affects the intensity of subjective response of choking under pressure. Trait empathy, including perspective-taking and sensitiveness to environmental stimuli, was considered. Choking under pressure was defined as a performance decrement when the pressure to perform (e.g., competition, audience-induced pressure) is salient (Baumeister, 1984). Choking is related not only to performance, but also to negative arousal (i.e., subjective choking). Perceived subjective choking would be affected by the atmosphere of the performance environment, as created by the audience. It was hypothesized that individuals with high trait empathy would feel more subjective choking than those with low, and those who perceive the environment as supportive, would feel less. A 2 (feedback: Positive/Negative) by 2 (trait empathy: High/Low) design experiment was conducted on Japanese undergraduates. Participants were asked to read aloud an essay without making mistakes (e.g., choke, miscue, filler etc.) in front of two confederates in the audience. Participants were informed each time they made a mistake by a clicking sound made by the experimenter, and they received non-verbal feedback (e.g., nodding, shaking head) from the confederates. The ANOVA revealed that negative feedback from the confederates, and high trait empathy resulted in greater subjective choking. Also, subjective choking was found to be related to task performance. Possible explanations of the results, along with future research directions were discussed.

#### A114

**ELICITING HELP: INSTRUMENTAL MOTIVES IN SADNESS REGULATION** Joy Hackenbracht<sup>1</sup>, Maya Tamir<sup>2</sup>, <sup>1</sup>Pennsylvania State University, <sup>2</sup>Boston College – Sadness signals a loss (Lazarus, 1991). By signaling that a loss has occurred or is about to occur, sadness may facilitate the elicitation of help from others (Frijda, 1986). Based on these arguments, we hypothesized that people may be relatively more willing to express as well as experience sadness when asking for help to prevent future losses (vs. obtain future benefits). We tested this hypothesis by examining preferences for expressing and experiencing sadness and by assessing the expected usefulness of sadness when eliciting help from another person to prevent a potential loss (i.e., GPA dropping dramatically and losing a chance to earn a high paying summer internship) and to obtain future benefits (i.e., GPA rising dramatically and earning a high paying summer internship). As predicted, participants reported stronger preferences for expressing as well as experiencing sadness when eliciting help to prevent a future loss than when eliciting help to obtain a future benefit. Furthermore, participants were more likely to expect sadness to be useful when eliciting help to prevent a loss (vs. attain a benefit), and such expected usefulness was positively linked to preferences for sadness. The current research suggests that the degree to which people want to be sad and how useful they expect sadness to be depend on the type of help they attempt to elicit.

## Motivation/Goals

#### A115

**MERE BELONGING INCREASES ACHIEVEMENT MOTIVATION IN PRESCHOOLERS** Allison Master<sup>1</sup>, Gregory Walton<sup>1</sup>, <sup>1</sup>Stanford University – Much recent social psychological research explores the importance of social belonging for human functioning and well-being (e.g., Baumeister & Leary, 1995; Cacioppo & Patrick, 2008). For instance, research on "mere belonging" suggests that even minimal cues that create a sense of social connectedness with others in an achievement domain—like a shared birthday with a role model in a field—can increase adults' achievement motivation (Walton & Cohen, 2009). These findings complement past research with both adults and children, which instead locates motivation in perceptions of self-attributes (e.g., self-efficacy, autonomy). They con-

verge with recent developmental research suggesting that even very young children may share goals with caregivers (Tomasello et al., 2005). But do young children develop shared goals with peers as a function of minimal social connections? If so, it would suggest a readiness early in development to engage in cooperative joint action with relationship partners. We examined this question among four- and five-year-olds. Children were randomly assigned to a social identity condition where they were told they were part of a minimal "puzzles group," to a personal identity condition where they were told they were the "puzzles child," or to a no-treatment control condition. As predicted, children in the "puzzles group" condition worked significantly longer on a challenging puzzle than children in either control condition. Together with other recent evidence, the finding suggests that social relationships and group memberships serve as a basic foundation for human motivation from early in life.

#### A116

**THE IMPACT OF MORTALITY SALIENCE AND COMPASSIONATE VALUES ON SUPPORT FOR JOHN MCCAIN AND BARACK OBAMA IN THE 2008 PRESIDENTIAL ELECTION.** Kenneth E Vail III<sup>1</sup>, Jamie Arndt<sup>1</sup>, Matt Motyl<sup>2</sup>, Tom Pyszczynski<sup>2</sup>, <sup>1</sup>University of Missouri-Columbia, <sup>2</sup>University of Colorado at Colorado Springs – Building on terror management theory, this research examined influences on support for candidates of the 2008 Presidential election. Just prior to the November election, ninety-one participants were (a) reminded of either mortality or personal uncertainty, (b) reminded of compassionate cultural values or a neutral control topic, and (c) asked to indicate their support for either John McCain or Barack Obama. It was hypothesized that death reminders would motivate increased support for John McCain, in line with previous research demonstrating that existential fear can be eased through increased reliance on leaders emphasizing American supremacy. However, other research has demonstrated that death reminders motivate increased adherence to and defense of cultural values. Thus, because public opinion polls conducted prior to data collection had indicated that Barack Obama was generally perceived as the more compassionate of the two candidates, we hypothesized that when compassionate values are made salient death reminders would motivate participants to uphold these values by significantly increasing their support for the more compassionate Barack Obama instead. Indeed, results indicated that when not reminded of compassionate values, mortality salience motivated increased support for John McCain; but when reminded of compassionate values, death reminders motivated participants to uphold this value by boosting support for Barack Obama. The implications of these findings for terror management theory and the 2008 Presidential election are discussed.

#### A117

**USING THE VOLUNTEER FUNCTIONS INVENTORY TO MEASURE MOTIVES FOR POLITICAL PARTICIPATION** Geoffrey Sheagley<sup>1</sup>, Joanne M. Miller<sup>1</sup>, Mark Snyder<sup>1</sup>, <sup>1</sup>University of Minnesota – The question of why people choose to participate in politics is of fundamental importance in a democracy. Most prominent models attempt to answer this question with cost/benefit analyses that tend to overemphasize the ability dimension of participation at the expense of the motivation dimension. To provide a fuller understanding of the motivational bases of political participation, the current study employs theory and research on volunteerism as a model for understanding political participation, uses measures of motivations for volunteerism as a template for measuring motives for political participation, compares the structure of motives for political participation with the structure of motives for volunteering, and explores the impact of motives on willingness to engage in political behaviors. To do so, we conducted an online survey of 2,228 employees of the University of Minnesota in the week prior to the November 2008 election. We find that: 1) the structure of motives for political involvement is similar to the structure of motives for volunteerism (reducible to the same factors – protective, values, career, social, understanding, and enhancement); and 2) motives are differentially correlated with participation acts (controlling for traditionally examined antecedents) in theo-

retically sensible ways (e.g., the enhancement, understanding, and values motives are positively correlated with willingness to contact an elected official; and the career motive is negatively correlated with willingness to participate in a rally). These findings contribute to our understanding of the applicability of psychological theories of motivation to the study of political participation and provide insights into the psychological theories themselves.

#### A118

**ENGAGEMENT IN A MASTERY-ORIENTED ENVIRONMENT AND RELATED CHANGES IN ACHIEVEMENT GOAL ORIENTATIONS, CONTINGENCIES OF SELF-WORTH, AND INTEREST** Paul A. O'Keefe<sup>1</sup>, Adar Ben-Eliyahu<sup>1</sup>, Lisa Linnenbrink-Garcia<sup>1</sup>, <sup>1</sup>Duke University – Employing an achievement goal theoretical framework, achievement goal orientations, achievement-related contingencies of self-worth, and interest for adolescent students (n = 117) were examined before, during, and after participating in a mastery-oriented academic summer program. As expected, endorsement of a mastery goal orientation and course-specific interest increased during the mastery-focused program and remained high 6 months after students returned to their home educational environments. Growth curve analyses revealed significantly correlated slopes, suggesting that changes in mastery goal orientations positively covaried with changes in interest. In contrast, performance-approach and performance-avoidance orientations decreased during the mastery-oriented program, but later returned to previous levels. Growth curve analyses revealed a significant correlation between slopes for the contingency of self-worth based on outperforming others and both performance goal orientations, suggesting that they positively covaried over time. Temporal changes in self-worth contingent on others' approval, however, did not covary with either performance goal orientation. Implications for theory and the design of learning environments are discussed.

#### A119

**FIT FROM SHARED STRATEGIC PREFERENCES BETWEEN NEGOTIATOR ROLE AND GOAL FOCUS** Kirstin Appelt<sup>1</sup>, E. Tory Higgins<sup>1</sup>, <sup>1</sup>Columbia University – Regulatory fit is a feeling of rightness that intensifies responses. Classic models suggest that fit occurs when the manner of goal pursuit (i.e., strategy) sustains the orientation to the goal (Higgins, 2000). We posit a new source of regulatory fit—shared strategic preferences between negotiator role and goal focus. In negotiations emphasizing price, negotiators approach the goal with an assigned role (buyer or seller) and a chronic regulatory focus (prevention or promotion). Because of their concern with non-losses/losses, buyers and a prevention focus prefer a vigilant strategy. Because of their concern with gains/non-gains, sellers and a promotion focus prefer an eager strategy. Prevention buyers (shared vigilant strategy preference) and promotion sellers (shared eager strategy preference) are in focus-role fit whereas promotion buyers and prevention sellers (mismatched strategy preferences) are in non-fit (Appelt, Zou, Arora, & Higgins, 2009). To test whether the strategic commonalities between regulatory focus and role are the source of focus-role fit, we randomly assigned participants to a vigilant or eager strategy in a real negotiation over a notebook. When strategy is manipulated, focus-role fit is replaced by its components—focus-strategy fit and role-strategy fit. Fit negotiators (prevention-vigilant and promotion-eager; buyer-vigilant and seller-eager) report greater fit with their roles and greater planned demand than non-fit negotiators (prevention-eager and promotion-vigilant; buyer-eager and seller-vigilant). These results confirm that roles and focus with shared strategic preferences can create regulatory fit. This new role-related source of regulatory fit has implications for behavior in a variety of domains.

**A120****LET'S GET READY TO RUBBLE! THE EFFECTS OF DESTRUCTION AND CONSTRUCTION ON DEATH-THOUGHT ACCESSIBILITY AND WORLDVIEW DEFENSE.**

Jamie Arndt<sup>1</sup>, Kenneth E. Vail III<sup>1</sup>, Matt Motyl<sup>2</sup>, Tom Pyszczynski<sup>2</sup>; <sup>1</sup>University of Missouri-Columbia, <sup>2</sup>University of Colorado at Colorado Springs – Building on TMT, two studies tested whether viewing images of destroyed infrastructure would increase death-thought accessibility (DTA) and motivate hostile worldview defense, even without direct reminders of death. In Study 1, the destruction condition presented images of destroyed buildings; the terrorism condition viewed images of buildings being blown up by bombs and airplanes. The third and fourth conditions were control conditions. The third condition presented images of intact buildings; and a fourth condition presented images of construction sites to allow for the possibility that DTA is simply affected by any incomplete infrastructure. A word-stem completion measure of DTA followed. Results indicated that images of destruction increased DTA to a level also produced by viewing graphic images of terrorism, and that both of these conditions each produced greater DTA than the construction and control conditions, which did not differ. Study 2 presented participants with either the destruction, construction, or control condition images, and then assessed participants' support for war against Iran. Results demonstrated that the destruction condition increased anti-Iranian militarism compared to the construction and control conditions, which did not differ. This research demonstrates that viewing damaged and destroyed infrastructure produces increased accessibility of death-related cognition to a level similar to that produced by overt reminders of death, and similarly increases hostile worldview defense. Notably, the effects of viewing deficient infrastructure on DTA and worldview defense were attenuated by evidence that this circumstance entailed constructive instead of destructive efforts. Implications for TMT and intergroup relations are discussed.

**A121****RESOURCE DEPENDENT INHIBITION OF UNCERTAINTY-INDUCED WORLDVIEW DEFENSE**

Aaron Wichman<sup>1</sup>, Ryan Brunner<sup>2</sup>, Gifford Weary<sup>2</sup>; <sup>1</sup>Western Kentucky University, <sup>2</sup>The Ohio State University – Uncertainty-induced worldview defense has many social implications, but previous work suggests that an inhibition process may sometimes block post-uncertainty worldview defense (Wichman, Brunner, & Weary, 2008). We experimentally test this idea. One study demonstrates that an inhibition process appears to influence post-uncertainty worldview defense. Another study tests the resource-dependency of this inhibition process. We find that cognitive load causes worldview defense immediately after an uncertainty prime and eliminates the need for a post-uncertainty distraction task. Although previous research indicates that uncertainty inhibition can occur in the absence of awareness, it appears to be a cognitively effortful process.

**A122****PATIENCE IN THE PURSUIT OF PERSONAL PROJECTS ACROSS THE QUARTER PREDICTS GOAL ACHIEVEMENT AND WELL-BEING**

Sarah Schnitker<sup>1</sup>, Robert Emmons<sup>1</sup>; <sup>1</sup>University of California, Davis – Patience, conceptualized as the propensity to wait calmly in the face of frustration, adversity, or suffering, is integral to the process of goal achievement, but psychological investigation of the role of patience in goal achievement and subsequent changes in well-being (or even of the trait more generally) is minimal. Initial research evidences the distinctiveness of patience from similar psychological constructs and details significant relationships between patience and well-being outcomes (Schnitker & Emmons, 2007). To further examine the roles of both trait patience and goal-specific patience in subsequent goal achievement and well-being, undergraduate participants (N=251) were assessed five times across the course of a 10-week quarter. At the initial measurement occasion, participants were asked to list 10 personal projects (Little, 1983) they would be working on during the upcoming quarter. They rated each of these projects on 15 dimensions (e.g., project difficulty, patience enacted, achievement sat-

isfaction/progress, competence, etc.) and then completed a variety of personality and well-being scales, measuring constructs such as trait patience, life satisfaction, depression, the Big Five, self-efficacy, etc. At times 2, 3, 4, and 5, participants again rated the projects they originally provided on the 15 project dimensions, and in the final survey, participants retook the well-being and personality measures. Using a multi-level modeling framework of projects nested within persons, both trait patience and project-specific patience predicted subsequent goal achievement and satisfaction for a project. Moreover, higher levels of patience enacted on personal projects during the quarter positively predicted well-being at the last measurement occasion.

**A123****DO PEOPLE DIFFERENTIATE BETWEEN INTRINSIC AND EXTRINSIC GOALS IN PHYSICAL ACTIVITY BEHAVIOUR?**

Sarah McLachlan<sup>1</sup>, Martin S. Hagger<sup>1</sup>; <sup>1</sup>University of Nottingham, UK. – Self-determination theory draws a broad distinction between intrinsic and extrinsic motivation and proposes that goal pursuit grounded in intrinsic motivation will lead to more adaptive outcomes than the pursuit of goals rooted in extrinsic motivation (Deci & Ryan, 1985, 2000). Despite a wealth of empirical evidence to support this prediction (e.g., Vansteenkiste, Simons, Soenens, & Lens, 2004), research has not yet explored whether individuals can and do differentiate between intrinsic and extrinsic goals. Three studies aimed to determine whether this differentiation occurs in people's memory for goals in leisure-time physical activity. Using memory recall methods from social cognition, participants in the first study were asked to freely generate physical activity goals that they or others may wish to attain, while participants in the second study were also asked to code their freely-generated goals as intrinsic or extrinsic. In the third study, participants were asked to recall a list of intrinsic and extrinsic goals after making a behavioural decision regarding their future physical activity behaviour. The results of the first and third studies revealed that individuals' goal generation and recall exhibited significant clustering by goal type. However, participants seemed to encounter difficulties when explicitly coding goals in the second study. Implicit recall methods are recommended for future research to determine whether individuals discriminate between goal types within self-determination theory.

**A124****REGULATORY FIT FROM STEREOTYPES ADVANTAGEOUS FOR GOLF PUTTING NOVICES**

Lisa Grimm<sup>1</sup>, W. Todd Maddox<sup>2</sup>, Arthur B. Markman<sup>2</sup>; <sup>1</sup>The College of New Jersey, <sup>2</sup>The University of Texas at Austin – Research on stereotype threat demonstrates that negative stereotypes are disadvantageous in many task contexts. For example, Stone, Lynch, Sjomeling, & Darley (1999) framed a golf putting task as diagnostic of natural athletic ability or sports intelligence. Relative to control groups, they found that White participants underperformed in the natural athletic ability frame while Black participants underperformed in the sports intelligence frame. We expand on this finding using recent work connecting stereotype threat with the regulatory fit framework (Grimm, Markman, Maddox, & Baldwin, 2009). Grimm et al. (2009) demonstrates that participants learned a new task more effectively when their stereotype matched the reward structure of the task. That is, participants with a positive task-relevant stereotype performed better when the task goal was to maximize points, while participants with a negative task-relevant stereotype performed better when the task goal was to minimize points. In the current study, White participants, who were relative novices at golf putting, were told our golf putting task was diagnostic of natural athletic ability (i.e., negative stereotype) or sports intelligence (i.e., positive stereotype). Participants either tried to maximize earned points or minimize lost points. Points were assigned after every putt and were calculated using the distance to a target. We find an interaction of Stereotype and Task Reward Structure for golf putting. We demonstrate better performance for participants experiencing a fit between their global task stereotype and the task goal. Negative stereotypes can produce good performance when paired with a task goal to minimize losses.

**A125**

**GOAL APPRAISALS AND PERSONALITY TRAITS PREDICT PERSONAL GOAL ATTAINMENT** Tierra S. Stimson<sup>1</sup>, Daniel J. Ozer<sup>1</sup>; <sup>1</sup>University of California Riverside – Goal attainment is important in virtually all life contexts. Getting good grades, advancing one's career, maintaining social relationships and adherence to exercise and diet regimens are all consequential. Various goal appraisal processes may be associated with successful goal attainment; and personality attributes are certainly associated with outcomes often associated with goal attainment (e.g., conscientiousness predicts academic achievement). The current study examines how personality traits and goal appraisal processes contribute to success in attaining specific goals such as “getting good grades” and “exercising more.” Students (N = 89) completed questionnaires at the beginning and end of their freshman year. At the first assessment, students listed ten of their goals and rated them, on a four point scale, on seven dimensions (e.g., how important is this goal compared to other goals?). Traits were measured using the Big Five Inventory. At the second assessment, students reported their success at attaining their original 10 goals. Multi-level models estimated goal attainment from goal appraisals and traits. Results indicated that goal appraisals predict goal attainment. Goals that reflected personal desires rather than obligations were more likely to be successfully attained and students who successfully prioritized goals reported greater success in attaining their more important goals. Personality traits were not associated with general success in goal attainment, but moderated the relation between goal appraisal and successful attainment.

**A126**

**SELF-EXPANSION IN COLLEGE: A NOVEL APPLICATION OF THE SELF-EXPANSION MODEL** David B. Strohmetz<sup>1</sup>, Gary W. Lewandowski Jr.<sup>1</sup>, Aubrey N. Clark<sup>1</sup>; <sup>1</sup>Monmouth University – The self-expansion model has been used to explore individuals' motivation for entering into and maintaining close relationships (Aron & Aron, 1997). However, to this point, the model's potential for elucidating motivation in non-romantic relationships has been largely overlooked. The purpose of this paper is to use the principles of the self-expansion model to provide a theoretical explanation for why student engagement is predictive of college satisfaction. 283 undergraduates completed the College Self-Expansion Questionnaire (C-SEQ), an adaptation of Lewandowski and Aron's (2002) Self-Expansion Scale for interpersonal relationships (alpha = .96). Participants also answered questions concerning the extent to which they had engaged in specific educational activities associated with enhanced learning and personal development during the past year. To measure college satisfaction, students rated their overall educational experience and whether they would choose the same institution again if given a chance. Consistent with past research, activities such as discussing ideas in and out of the classroom with other students, and collaborating with professors and/or other students on projects was predictive of college satisfaction. In each case, these relations were completely mediated by college self-expansion. That is, participation in these activities appears to have increased one's self-expansion in college, which in turn, increased college satisfaction. These results suggest that the self-expansion model has utility beyond interpersonal relationships and can serve as framework for understanding why educational engagement relates to student learning and personal development.

**A127**

**THE EFFECTS OF NEGATIVE EMOTIONS GUIDED BY REGULATORY FOCUS ON RESOURCE ALLOCATION AMONG MULTIPLE GOALS** Hiroki Takehashi<sup>1</sup>, Kaori Karasawa<sup>2</sup>; <sup>1</sup>Nagoya University, <sup>2</sup>The University of Tokyo – Although previous studies have found that regulatory focus determined the quality of emotions, there are few studies to reveal their effect on the goal pursuit. This study examined the effects of negative emotions evoked by regulatory concerns, that is, dejection and agitation, on resource allocation among multiple goals. One hundred and fourteen participants were asked to imagine the scenario in which they failed to

attain an important goal. In the scenario, the goal was framed with either the promotion concern or the prevention concern. Then, they were asked to indicate the degree of disappointment and agitation they felt at the situation and the intention to allocate their effort for the current and the new goals. The results indicated that the participants in the prevention condition estimated agitation higher than dejection whereas the participants in the promotion condition estimated dejection as much as agitation. Moreover, the participants in the promotion condition allocated more regulatory resource for the new goal than the current goal, while the participants in the prevention condition allocated resource for the current goal as much as the new goal. Importantly, this effect disappeared when dejection and agitation were entered as covariance in the analysis. Furthermore, dejection predicted resource allocation for the new goal, whereas agitation predicted the allocation for the current goal. These results suggest that the effect of regulatory focus on resource allocation was mediated by negative emotions. The discussion considered the relationship between negative emotions and self-regulation.

**A128**

**PROGRESSIVE HOPE: THE PROMISE OF FUTURE CONTROL** Bastiaan Rutjens<sup>1</sup>, Frenk van Harreveld<sup>1</sup>, Joop van der Pligt<sup>1</sup>; <sup>1</sup>University of Amsterdam, The Netherlands – The present research shows that progressive hope helps to alleviate the aversive experience of low levels of control. When personal control is low, progressive hope provides people with the promise of future control restoration in a broader sense. In four experiments, we found evidence for enhanced beliefs in progress when personal control is low. In Experiments 1 and 2, low control (experienced or anticipated) participants disagreed more with an essay on the illusory nature of human progress. Experiment 3 corroborated these findings in a field study with airplane passengers. Participants in an airplane reported enhanced beliefs in progress and this effect was mediated by feelings of control. Experiment 4 assessed belief in progress more directly and showed an increased willingness to invest in specific fields of progress-oriented research when personal control was low. Moreover, low control participants preferred high tech policy solutions to combat environmental problems and indicated, in a drawing task, an increased belief in both scientific and moral progress. The link between progressive hope and religion is discussed.

**A129**

**PERCEPTIONS OF OTHER'S GOAL COMMITMENT: A MODEL OF GOAL MANAGEMENT ACCOUNT** Edward Burkley<sup>1</sup>, Darshon Anderson<sup>1</sup>; <sup>1</sup>Oklahoma State University – The present study investigated perceptions of how committed others are to their goals. Based on the model of goal management (MGM), participants were presented with information about another's satisfaction with, investments in, and alternatives to a focal goal. These factors were manipulated between groups, resulting in a 2 X 2 X 2 factorial design. Results showed that perceptions of goal commitment were higher when satisfaction and investment were high and alternatives were low. These findings support the MGM and offer insight into the social cognitive factors that influence perceptions of goal commitment.

**A130**

**PRIMING ATTRACTIVENESS INTERFERES WITH COMPETENCE FOR WOMEN WHO PREFER DATING SMARTER PARTNERS** Jordan D. Troisi<sup>1</sup>, Lora E. Park<sup>1</sup>; <sup>1</sup>University at Buffalo, SUNY – Previous research has shown that women who prefer dating smarter partners show decrements in intelligence when primed with the goal to appear attractive (Park, Troisi, & Young, in prep). In the present study, we examined whether women who prefer smarter partners show greater self-handicapping and automatic cognitive interference between the concepts of attractiveness and competence. To examine this, 87 college men and women completed items assessing their Dating Preference (DP), then completed a lexical decision task and a self-handicapping measure. Specifically, participants were subliminally primed with a competence, attractiveness, or neutral word, followed by a string of letters that they were to categorize, as

quickly as possible, as a word or nonword. Of primary interest was the difference in reaction times to respond to competence target words following attractiveness versus neutral word primes. Regression analyses revealed the expected Gender x DP interaction ( $\beta = .35, p < .05$ ). Specifically, among women, wanting to date smarter partners predicted slower reaction times to respond to competence words when primed with attractiveness versus neutral words ( $\beta = .32, p < .05$ ); this effect was not found among men as a function of their DP ( $\beta = -.18, p = .27$ ). There was no significant Gender X DP interaction ( $p = .85$ ) when examining differences in mean reaction times to attractiveness target words following competence versus neutral word primes. In addition, the more women wanted to date smarter partners, the greater self-handicapping they reported. Implications for women's motivation and academic performance are discussed.

### A131

**INTEGRATED MOTIVES OF AGENCY AND COMMUNION EVIDENCED IN MORAL HEROES** Jeremy A. Frimer<sup>1</sup>, Lawrence J. Walker<sup>1</sup>, William L. Dunlop<sup>1</sup>; <sup>1</sup>University of British Columbia – Motives of agency and communion generally compete with one another in personality functioning; but for moral heroes, this tension may not be at play. This study advances the Reconciliation Model, which posits that the relationship between agentic and communal motives ideally develops from one of mutual competition to one of synergy. The goal of this study was to demonstrate and validate a new empirical methodology for tapping the adaptive integration of agency and communion. Participants were 25 individuals who had received national awards for extraordinary caring action and 25 individually matched comparison persons. Among other assessments of personality, participants provided a list of personal strivings (tapping their goal motivation), which were later coded blindly and reliably for themes of agency (power and achievement) and communion (benevolence and universalism). To isolate constructs, three metrics were calculated: unmitigated agency (strivings coded for agency but not for communion), unmitigated communion (communion without agency), and integration (agency and communion). Exemplar and comparison groups did not differ on unmitigated agency or unmitigated communion. But exemplars evidenced significantly more (three times as many) integration strivings than comparisons. Follow-up analyses indicated that this integration could not be attributed to chance co-occurrence of the motives, implying that an active aspect of personality was responsible for the synergistic interaction. These results imply that the interaction of agency and communion is a specific and important personality achievement associated with moral exemplarity. The reconciliation of agency and communion holds considerable promise in explaining moral motivation and its development.

### A132

**THE "SOUR-GRAPES-EFFECT" REVISITED: HOW LIKING- AND WANTING-RELATED ASSOCIATIONS TOWARD FOOD CUES VARY AS A FUNCTION OF DIFFERENT LEVELS OF FOOD DEPRIVATION.** Philippe Türk Pereira<sup>1</sup>, Roland Deutsch<sup>1</sup>, Beate Seibt<sup>2</sup>, Michael Häfner<sup>3</sup>; <sup>1</sup>University of Wuerzburg, <sup>2</sup>ISCTE Lisbon, <sup>3</sup>Utrecht University – Usually, hungry subjects are found to respond with more favorable liking responses as well as pronounced approach orientations (wanting) toward food cues than satiated subjects. However, there is also contradicting evidence showing dissociations between liking- and wanting-related reactions toward food cues due to food deprivation in such a way that food-deprived participants surprisingly show more negative liking-related despite more positive wanting-related reactions toward need-relevant objects. Therefore, two studies were conducted in order to shed more light on this controversy. Specifically, the present research was mainly interested in participants' spontaneous evaluations measured more systematically via single-target IATs. First of all, the level of food deprivation could be identified as crucial variable by showing that implicit liking-related responses varied as a function of different levels of food deprivation. In particular, in contrast to satiated subjects, those with low levels of food deprivation showed more positive, whereas those with high levels of food deprivation

showed more negative food-related associations. Moreover, we could replicate the dissociation of liking- and wanting-related associations toward food cues under high levels of food deprivation and conditions of nonreward, showing that implicit liking- and wanting-related processes can be differently influenced by food deprivation. As depicted in the famous Aesop fable "the fox and the grapes", it seems to be easy to despise something one is wanting but that cannot be reached when it is needed. The results will be discussed under the perspective of cognitive dissonance and the theory of frustrative nonreward.

### A133

**THE MEDIATING ROLE OF PERCEIVED USEFULNESS OF SCHOOL ACTIVITIES IN THE RELATIONSHIP BETWEEN NEED SATISFACTION AND ACADEMIC MOTIVATION** Celine Blanchard<sup>1</sup>, Danielle Patry<sup>1</sup>; <sup>1</sup>University of Ottawa – In the school setting, social-contextual factors that promote perceived academic autonomy, competence, and relatedness are generally experienced as informational. Autonomy supportive practices have been shown to enhance perceived usefulness. For example, the work of Deci et al. (1994) showed that providing a meaningful rationale to engage in an activity predicted changes in perceived usefulness and enjoyment of a boring task. Results of this study also found that environments where two autonomy supportive practices were employed (i.e., conveying choice and low controllingness) enhanced perceived usefulness. Consistent with this finding, Reeve et al. (2002) showed that providing a rationale in an autonomy supportive way enhanced participants' personal endorsement and valuing of an uninteresting activity. The purpose of the present study was to examine the mediating role of perceived usefulness of school activities in the relationship between academic need satisfaction and academic self-determined motivation. Thus, we hypothesized that academic need satisfaction would be positively associated with perceived usefulness of school activities and academic self-determined motivation. In addition, we anticipated that perceived usefulness of school activities would mediate the relationship between academic need satisfaction and academic self-determined motivation. Grade 7 students ( $n=647$ ) attending one of 17 French schools in the region were asked to complete a short electronic questionnaire during class time. Results suggest that academic need satisfaction promotes academic self-determined motivation, in part by helping students perceive greater usefulness of their school activities.

### A134

**WHEN DOES POWER CREATE CREATIVITY? THE ROLE OF STABILITY OF THE POWER HIERARCHY AND FUNCTIONALITY OF CREATIVE EFFORTS** Daniel Sligte<sup>1</sup>, Carsten De Dreu<sup>1</sup>, Bernard Nijstad<sup>2</sup>; <sup>1</sup>University of Amsterdam, <sup>2</sup>University of Groningen – Previous work has shown that having power benefits creativity because it associates with approach-related tendencies and broad attentional focus. In an unstable power hierarchy, however, the powerful face the risk of losing their position. Across two experiments, we show that stability of the power hierarchy and functionality of the creativity task qualify the relationship between power and creativity. Furthermore, effects depend on the type of creativity task and the degree to which this task benefits from effort versus a broad attentional focus. In an unstable power hierarchy, the powerful rather than the powerless had superior performance on a verbal creativity task -the remote associates test (RAT)- but only when doing so was functional to saving their power position. This suggests performance was raised by increased efforts. For creative insight measured by the snow pictures test (SPT), however, this pattern reversed. The powerful performed worse than the powerless on the SPT when doing so was functional to saving their position, but not when performance on this task was irrelevant to their power position. In addition, this effect was fully mediated by processing style -measured by the Navon task. Powerful individuals performed worse on creative insight when this was functional to their position because they suffered from a local processing style and thus narrow attentional focus. Moreover, the prospect of losing power associated

with avoidance tendencies. Having disputed power thus seems to facilitate creative thinking because of increased effort, but to kill creative insight because of a narrow attentional focus.

### A135

**BELONGING AND COLLABORATIVE ACTIVITY: HOW MINIMAL SOCIAL CONNECTIONS CAN CREATE SHARED GOALS** David Cwir<sup>1</sup>, Gregory M. Walton<sup>2</sup>, Steven J. Spencer<sup>1</sup>; <sup>1</sup>University of Waterloo, <sup>2</sup>Stanford University – Cooperation is a fundamental to successfully human communities. We examined the underlying motivational dynamics that make cooperation possible. Specifically, we tested the prediction that a minimal sense of social connectedness (i.e., "mere belonging," Walton & Cohen, in press) would lead people to internalize and share the goals of an otherwise unknown target person. We manipulated whether a confederate shared task-irrelevant personal preferences with participants ("social link" condition) or not (control condition). We then examined participants' activation and inhibition of goal-relevant words as assessed by reaction time measures as the confederate pursued and completed a series of goals. As predicted, participants in the social link condition showed enhanced accessibility (i.e., faster response times) to goal-relevant words as the confederate pursued the goals and reduced accessibility (i.e., slower response times) to goal-relevant words after the confederate had completed those goals. This pattern suggests that participants in the social link condition internalized the confederate's goals (see Förster, Liberman, & Higgins 2005). Additionally, participants in the social link condition were more likely to enact these goals by helping the confederate with the tasks. Implications for goal pursuit and shared intentionality are discussed.

### A136

**NONCONSCIOUS REWARDS BOOST PERFORMANCE, BUT DO NOT CHANGE SPEED-ACCURACY TRADEOFFS** Erik Bijleveld<sup>1</sup>, Ruud Custers<sup>1</sup>, Henk Aarts<sup>1</sup>; <sup>1</sup>Utrecht University – People's performance is known to be boosted when valuable rewards are at stake, regardless of whether reward information is presented above (supraliminal) or below (subliminal) the threshold of conscious awareness. This prior finding seems to suggest that the pursuit of rewards works the same for conscious and nonconscious rewards. Here we show that this is not the case. Specifically, we investigate whether supraliminal vs. subliminal reward information has different effects on tradeoffs that people make in performance tasks. In a speed-accuracy paradigm, a high or low value coin was presented supraliminally or subliminally. Participants could earn a proportion of this coin's value, dependent on their speed and accuracy on that trial. In Experiment 1, subliminal high (vs. low) rewards made participants perform better (i.e., faster, but equally accurate). Instead, supraliminal high (vs. low) rewards caused participants to become cautious (i.e., they made a tradeoff by becoming slower but more accurate). In Experiment 2, room for making such tradeoffs was taken away by emphasizing the importance of overall high accuracy. Results showed that participants performed better (i.e., faster, but equally accurate) for both supraliminal and subliminal high (vs. low) rewards. It is concluded that information about rewards indeed boosts performance, regardless of whether people are aware of what is at stake. Importantly, these experiments also demonstrate that when people become aware of a reward, this causes them to make different tradeoffs for rewards of different value. Social implications of this research are discussed.

### A137

**CONCEPTUALIZING ENVIRONMENTALISM: A QUALITATIVE APPROACH** Benjamin J. Marcus<sup>1</sup>, Allen M. Omoto<sup>1</sup>, Patricia L. Winter<sup>2</sup>; <sup>1</sup>Claremont Graduate University, <sup>2</sup>US Forest Service – Environmental quality and sustainability are increasingly important social issues that can be related to individual attitudes, beliefs, and behaviors. Environmentalism has been explored from many perspectives in the social sciences. For example, environmental concern and action has been linked to environmental awareness, identification, values, and numerous demographic factors

like race and socioeconomic status (e.g., Clayton & Opatow, 2003; Dunlap et al., 2000; Johnson et al., 2004; Kaiser et al., 1999; Schultz et al., 2005; Stern et al., 1993; Van Liere & Dunlap, 1980). Most of this research has relied on large-scale survey methods. Qualitative research is a complementary approach that can add depth to information about how environmentalism is conceptualized by individuals. In this study, 9 ethnically diverse individuals who had visited parks or recreation areas within the last year participated in semi-structured interviews that asked them to define and describe environmentalism. This presentation explores the range of responses in participant descriptions and uses verbatim quotes to illustrate the categories of responses. In summary, participants seemed to respond from different perspectives, including connecting environmentalism to conservation, aesthetics, stewardship, and/or activism. Further, responses were often contextualized in issues like education, politics, and religion. Thus, it appears that individuals think about environmentalism in distinct and complex ways, with beliefs often related to other attitudes and experiences. This type of research provides descriptive information about how people conceptualize pressing social issues (e.g., environmentalism) and provides a foundation for future research on the antecedents of environmentally friendly beliefs and behaviors.

### A138

**A PROCESS HEALTH MOTIVATION THEORETICAL MODEL AND ITS VALIDATION** Xiaoyan Xu<sup>1</sup>, Murray Millar<sup>2</sup>; <sup>1</sup>University of Nevada, Las Vegas, <sup>2</sup>Sichuan Normal University – Previous studies have shown that health motivation can enhance health behaviors. Although researchers have used this term for a long time, there is no widely accepted definition or theoretical model of health motivation. To bridge this gap, the present research proposed a definition and a theoretical model of health motivation. This model suggests that health motivation consists of four stages: to develop health motivation tendency, to form health intention, to initiate health related action, and to persist in those actions to achieve goals developed at the first stage. Based upon this model, Health Motivation Scale in Healthy Eating (HMS-HE) was developed, with 12 items in total. The present study examined the construct validity and predictive validity of the scores obtained using the HMS-HE among 287 undergraduate participants in a southern university of the United States. The higher order confirmatory factor analysis suggested that the model fit the data well. The predictor power of health motivation, health self-efficacy, health value, and BMI were examined using multiple regression analysis. The finding indicated that health motivation was generally the most powerful predictor of health behaviors. Health motivation was most predictive of health behaviors among females, but health self-efficacy was a stronger predictor of health behaviors than health motivation for males. In conclusion, the proposed theoretical model of health motivation and the scale were effective to capture individuals' health motivation. This model and the scale can be applied to related theoretical and empirical studies.

### A139

**MOTIVATION BY ROLE MODELS: INFLUENCE OF ROLE MODEL TYPE AND STRATEGY IMPLEMENTED ON ACADEMIC MOTIVATION** Tzu-Yeng Kuo<sup>1</sup>, Kuang-Hui Yeh<sup>1,2</sup>; <sup>1</sup>National Taiwan University, Taipei, Taiwan, <sup>2</sup>Academia Sinica, Taipei, Taiwan – In the present study, the impact of role models on academic motivation was examined. The authors demonstrated that negative role models make a larger motivational impact on our participants. In this study, the participants were presented with description on one of two types of role model (positive and negative) and others accordingly. The role models were described to be reaching success or failure through either eagerness or vigilant strategy. Participants' academic motivation was measured. Participants were 201 students from National Taiwan University. Results showed influence on motivation were more prominent on those presented with negative role models than those presented with positive role models. This suggested that negative role models have a greater impact on academic motivation for our sample of Asian participants. According to Higgins's regulatory fit principle, negative role

models and vigilant strategy, both demonstrating prevention focus would be most motivational. Our results, in contrast, show that negative role model with eagerness strategy results in the highest motivational rating. The authors suggest that while role model type may operate under Higgins' regulatory fit principle, strategy implemented by role models may influence motivation through another mechanism, possibly the issue at hand. In conclusion, our study found that when motivating an individual academically, a negative role model with eagerness strategy would produce the most prominent results.

#### A140

**MEASURING IMPLICIT MOTIVES IN ROMANTIC RELATIONSHIPS** Birk Hagemeyer<sup>1</sup>, Franz Josef Neyer<sup>2</sup>; <sup>1</sup>University of Potsdam, Germany, <sup>2</sup>Friedrich-Schiller-University, Jena, Germany – There are two basic motivational tendencies which guide people's behavior in social relationships: one that aims to preserve and enhance the individual self, often called agency, and another one that aims to establish and maintain interpersonal contact and close relationships, often called communion (Bakan, 1967). In our research, we focus on individual differences in agentic and communal needs to understand distinct patterns of distance regulation in romantic couple relationships (e.g., living together in one household vs. keeping separate households). In order to measure the needs for agency and communion in the life-domain of romantic relationships on the implicit level, we developed a new TAT-like picture-story-task, using stimulus materials from the Operant Multi-Motive-Test (Kuhl & Scheffer, 1999; Baumann et al., 2005). In an internet experiment (N=252), we employed a three-group-design to develop an empirically based thematic coding system for the evaluation of test answers. The two experimental groups were primed with autobiographical memories related to experiences of either agency or communion in the participants' ongoing relationships. Results show that the new coding system captures experimentally induced motivational differences between the experimental groups and a control group. Furthermore, results from a study of 550 German couples affirm the discriminant and incremental validity of the new motive test compared to explicit measures of agency and communion as well as attachment styles.

#### A141

**THE BENEFITS OF INTERPERSONAL REGULATORY FIT FOR INDIVIDUAL GOAL PURSUIT** Francesca Righetti<sup>1</sup>, Catrin Finkenauer<sup>1</sup>, Caryll Rusbult<sup>1</sup>; <sup>1</sup>Vrije Universiteit Amsterdam – People do not pursue goals in isolation but they are often surrounded and influenced by others. Regulatory focus theory and the concept of regulatory fit may illuminate when an interpersonal influence can be motivating and instrumental for the individual's goal pursuit. Specifically, the present work examines how the individual's goal pursuit is affected by advice and support received from a close other whose orientation fits (or does not fit) the individual's orientation. We sought to investigate whether this type of interpersonal regulatory fit causes consequences for goal pursuit that parallel those of intrapersonal regulatory fit. Furthermore, we investigated whether these effects occur in a symmetrical fashion for both promotion and prevention oriented individuals. We conducted five studies. We investigated the possible consequences of interpersonal regulatory fit, such as instrumentality of the close other (Study 1 and 2), feeling right, motivation and enjoyment of goal pursuit (Study 2). We replicated the previous results manipulating the individual's regulatory orientation (Study 3) and using a laboratory task (Study 4). Finally, we gathered data from both partners involved in a romantic relationship (Study 5). Results consistently revealed that only promotion oriented individuals profited from interpersonal regulatory fit and experienced motivational benefits when receiving goal related suggestions from promotion oriented others. Prevention oriented individuals did not profit from interpersonal regulatory fit. This work supports the proposal that regulatory fit can fruitfully be examined as an interpersonal phenomenon, highlighting the important role interpersonal relationships play in the pursuit of personal goals.

#### A142

**WHAT IS HATE? A PROTOTYPE ANALYSIS** Darius Fathi<sup>2</sup>, John K. Rempel, Christopher Burris; <sup>1</sup>University of Waterloo, <sup>2</sup>St. Jerome's University – There is currently little empirical research on the topic of hate and little agreement on how it should be defined. We used a prototype approach to examine how laypeople conceptualize hate. In an initial study 200+ participants provided open-ended definitions of hate. These definitions were subsequently analyzed for common patterns and elements resulting in a list of 52 hate-related statements. A second group of 100 participants rated the centrality of each statement to the concept of hate. Results showed that, at the top of the list, the most highly rated features of hate involved two main components. First, central features of hate involved goals of harm, suffering, and destruction for the hated target, with more extreme negative outcomes such as violence, abuse, and death being seen as more central. Second, the most central features involved wishes or desires for the hated target incur these negative outcomes. Contrary to the view of hate as an emotion, even intense emotions such as detesting, loathing, and despising were in the center rather than at the top of the list. Less intense emotions such as anger, disgust, and fear were seen as even less prototypical and appeared near the bottom of the list. Thus, laypersons' conceptualization of hate is most consistent with Rempel and Burris (2005) definition of hate as a motive associated with the goal of diminishing or destroying the other's wellbeing.

#### A143

**OBSESSIVE VS HARMONIOUS PASSION: SELF-ESTEEM CONTINGENCIES AS THE PSYCHOLOGICAL PROCESS UNDERLYING THE DISTINCTION BETWEEN THE TWO TYPES OF PASSION** Joelle Carpentier<sup>1</sup>, Geneviève A. Mageau<sup>1</sup>, Robert J. Vallerand<sup>2</sup>; <sup>1</sup>Université de Montréal, <sup>2</sup>Université du Québec à Montréal – The Dualistic Model of Passion proposes two distinct types of passion: obsessive and harmonious passion (Vallerand et al., 2003). Given the negative consequences linked to obsessive passion (Vallerand et al., 2006), Mageau et al. (2009) looked at the determinants of passion and showed that identification with the activity, preference for activity specialization, parents' activity valuation and controlling social environments influence the development of obsessive passion. These variables were hypothesized to influence the type of passion that will be experienced because they lead people to form contingencies between their activity and their sense of self-worth. The goal of the present study was to test this hypothesis by investigating self-esteem contingencies as one of the psychological processes underlying the distinction between obsessive and harmonious passion. The study was conducted during MagicThe Gathering tournaments, where a total of 40 players participated. Self-esteem contingencies and passion were measured at the beginning of the tournament, while performance and state self-esteem were assessed after each round. Results of correlations first showed that people with a more obsessive passion perceive their self-esteem to be more strongly tied to their passionate activity than people with a more harmonious passion. Analyses using hierarchical linear modeling also showed that obsessive passion moderates the impact of perceived and actual performance on self-esteem. Thus, the more people reported an obsessive passion toward their activity, the greater was the positive impact of a good performance on state self-esteem. Findings are discussed in terms of their theoretical implications for the self-esteem and passion literatures.

#### A144

**UNDER COMPETITIVE SCRUTINY: RECONCILING EVALUATION APPREHENSION AND SOCIAL COMPARISON EFFECTS IN COACTION** Patricia Chen<sup>1</sup>, Leslie Stuber<sup>1</sup>, Christian Sprang<sup>1</sup>, Stephen M. Garcia<sup>1</sup>; <sup>1</sup>University of Michigan, Ann Arbor – We explore how social comparison and evaluation apprehension processes drive competitive performance in coaction scenarios. Subjects' accuracy performances were recorded on a simple typing task under three conditions, namely, coaction with both social comparison and evaluation apprehension at work condition (control), coaction and social comparison without evaluation apprehension,

and coercion and evaluation apprehension without social comparison. Our results show that subjects' accuracy significantly drop from one condition to the next, respectively. We conclude that social comparison processes are a stronger driving force behind competitive motivation under circumstances of coercion, as compared to evaluation apprehension. These results hold promise for the design of organizational and athletic motivational strategies.

**A145****POSITIVE FEEDBACK AND MENTAL CONTRASTING CREATES STRONG GOAL COMMITMENT AND BETTER PERFORMANCE** Michael K.

Marquardt<sup>1</sup>, Gabriele Oettingen<sup>2,3</sup>, Peter M. Gollwitzer<sup>1,2</sup>; <sup>1</sup>University of Konstanz, Konstanz, Germany, <sup>2</sup>New York University, New York, <sup>3</sup>University of Hamburg, Hamburg, Germany – In contrast to common belief, positive feedback has often been found to have no or sometimes even negative effects on performance (Kluger & Denisi, 1996). We hypothesized that mental contrasting (MC), a motivational self-regulation strategy originating from fantasy realization theory (FRT - Oettingen, 1999, 2001), enables individuals to transform high expectations of success resulting from positive feedback into better performance. Mentally contrasting fantasies about the positive future with reflections on the negative reality helps to form goal commitment based on previous expectations of success. In contrast, solely indulging the positive future or dwelling on the negative present leads to goal setting independent of expectations. In two studies, participants either received positive or moderate bogus feedback regarding their capability to solve nonroutine problems (Mayer, 1995, 1999). Afterwards the three self-regulation strategies as proposed in FRT (MC, dwelling, and indulging) were induced. Study 2 included an additional control group. Participants then worked on non-routine problems as an indicator of performance. In both studies, participants who received positive feedback and mentally contrasted correctly solved more problems than those with moderate feedback or other strategies. Hence, MC represents an effective self-regulation strategy to transform positive feedback into better performance. Besides their practical importance, these studies corroborate previous findings on FRT by manipulating expectations of success instead of merely measuring them, which represents a new approach in FRT research.

**A146****THE INTERPLAY OF MASTERY AND PERFORMANCE GOALS IN SOCIAL COMPARISON. A MULTIPLE GOAL PERSPECTIVE** Fabrizio Butera<sup>1</sup>,

Céline Darnon<sup>2</sup>, Benoît Dompnier<sup>1</sup>, Ophélie Gilliéron<sup>1</sup>; <sup>1</sup>University of Lausanne, <sup>2</sup>Clermont University – Recent research have demonstrated that not only performance-approach and performance avoidance goals (respectively, the desire to outperform others, or not be outperformed by others) but also mastery goals (the desire to acquire knowledge) were related to social comparison orientation (the tendency to search for social comparison information, see Régner, Escribe, & Dupeyrat, 2007). However, educational settings are rarely free from performance-approach goals, notably prompted by normative assessment and selection, even when mastery goals are explicitly promoted. In the present set of studies, the possibility of a link between mastery goals and social comparison that depends on the level of performance-approach goals—a possibility supported by a multiple goal perspective, was tested by examining the interaction effect between mastery and performance-approach goals. Study 1 tested self-set achievement goals (mastery, performance-approach, and performance-avoidance) as predictors of social comparison orientation (SCO). The interaction between mastery goals and performance-approach goals indicated that the higher the performance-approach goal endorsement, the stronger the link between mastery goals and SCO. Study 2 manipulated goal conditions. Results indicated that mastery goals predicted interest in social comparison in the performance-approach goal condition only. Results are discussed in terms of the importance of multiple goal pursuit in academic settings.

**A147****A CASE OF MOTIVATED REASONING: THE INTERACTIVE ROLE OF COGNITIVE RESOURCES AND MOTIVATION ON PERCEPTION OF SOCIAL ACCEPTANCE.**

Jocelyn Belanger<sup>1</sup>, Ashley Fielbig<sup>1</sup>, Rachel Stein<sup>1</sup>, Kara Barron<sup>1</sup>, Arie Kruglanski<sup>1</sup>; <sup>1</sup>University of Maryland – Previous research (Chen, Orehek, and Kruglanski, 2008) has underpinned the importance of cognitive resources in predicting motivated reasoning. Specifically, mounting evidence supports the notion that resources-depletion diminished individuals' ability to motivationally bias judgments. The present research sought to extend such findings by demonstrating that availability of cognitive resources can also alter the experience of social rejection. In line with theories proposing that the need to belong is a fundamental human motivation (Baumeister and Leary, 1995, Maslow, 1954) and that socially deprived individuals seek to retrieve social approval (Eisenberger, 1970), it was predicted that cognitive resources would enable socially rejected participants to perceive greater social acceptance in their environment. The absence of such resources was expected to impede such motivated reasoning process, and thus, lead to lesser biased perception. Researchers randomly assigned participants to a 2 (Rejection vs. Control) X 2 (Resources vs. No-Resources) between subjects research design. Participants were either presented with subliminal rejection or control primes and were either assigned to cognitive or no-cognitive load condition. Participants were then presented with a picture and were asked to evaluate the facial expression of the character and the extent to which that character was welcoming and warm. Results provided support for the hypothesis. Participants in the Resources/rejection condition perceived greater smiling, warmth and perceived the character as more welcoming than any other conditions. Theoretical and applied implications, as well as directions for future research are proposed.

**A148****EMBODIED APPROACH AND AVOIDANCE MOTIVATIONS AFFECT SELF-PERCEPTIONS FOLLOWING SOCIAL COMPARISON** Kevin P. McIntyre<sup>1,2</sup>,

Nicholas Jessop<sup>2</sup>, Jessica Hartman<sup>2</sup>, Michael J. Walsh<sup>2</sup>, Christopher Graham<sup>2</sup>, Claire Specht<sup>2</sup>, Gerard Randolph<sup>2</sup>, Shannon M. Rauch<sup>3</sup>, <sup>1</sup>Trinity University, <sup>2</sup>Boston College, <sup>3</sup>Providence College – Embodied approach and avoidance motivations affect a variety of perceptual and attitudinal processes. Arm flexion (a pulling motion associated with approach) has been shown to increase positive evaluations of novel objects and positively valenced words, and arm extension (a pushing motion associated with avoidance) has been shown to increase negative evaluations of novel objects and negatively valenced words. No previous work, however, has examined whether these embodied motivations affect self-perceptions. In the current study, we suggest that embodied motivations affect the self via their effects on comparative thinking. When people make motor actions associated with approach, we predict that social comparison will result in assimilation, whereas when they make motor actions associated with avoidance, we predict that social comparison will result in contrast. To test these predictions, participants (N = 41) completed a social comparison task in which they saw photos of attractive targets while making arm flexion or extension contractions and then completed several self-evaluation measures. The results supported our predictions, revealing that participants primed with approach, relative to those primed with avoidance, reported higher self-esteem, more self-esteem certainty, and less negative affect after exposure to the positive comparison target. These findings suggest that motor feedback can affect comparative thinking, with approach-primed individuals more likely to assimilate with comparison targets and avoidance-primed individuals more likely to contrast themselves against comparison targets. In general, the results suggest that self-perceptions are shaped in part by feedback obtained from bodily cues.

**A149****THE ROLE OF GOAL SALIENCY AND GOAL VALUE IN RISK TAKING BEHAVIOR**

Nicholas Calvin<sup>1</sup>, Angela Lee<sup>1</sup>, Catalina Kopetz<sup>1</sup>, Carl Lejuez<sup>1</sup>; <sup>1</sup>University of Maryland – Risk taking behaviors involve the simultaneous pursuit of two goals: maximization of reward and minimization of loss (approach-avoid conflict). We propose that the likelihood of engaging in highly risky behaviors may be a joint function of the saliency and value (commitment) corresponding to each of these two goals (motivations). The present research aimed to test empirically the above notions in two studies using a computerized laboratory measure (The Balloon Analogue Risk Task or BART). The task involves actually risky behavior for which, similar to real-world situations, riskiness is rewarded up until a point at which further riskiness results in poorer outcomes (earnings being lost). In study 1, we manipulated the saliency of the potential for loss in two experimental conditions. Specifically in the low saliency condition participants completed a version of the BART where the monetary earnings (potential for gain) were visible on the screen. In the high saliency condition the possibility of losing money was visible on the screen during the task. Participants' risk taking behavior was significantly reduced when the possibility for loss was salient. Study 2 manipulated goal value through an evaluative priming procedure in four experimental conditions: decreased value of risk, increased value of avoiding risk and two corresponding control conditions. The results showed that risk taking behavior decreased significantly, even when the potential for earnings was subsequently highly visible when the value of avoiding risk was subtly enhanced compared to when the value of risk taking was decreased and to the control conditions.

**A150****WANTING LESS IS MORE – DYADIC SELECTIVITY HELPS COUPLES START A FAMILY**

Antje Rauer<sup>1</sup>, Anja Böhnke<sup>1</sup>, Michaela Riediger<sup>1</sup>; <sup>1</sup>Max Planck Institute for Human Development – Motivational selectivity – focusing on a few goals instead of "wanting it all" – has been proposed to help people realize what they have resolved to achieve. We tested this proposition by following up on 24 heterosexual, initially childless couples in which both partners had reported the goal of starting a family in the near future. At baseline, we assessed the partners' perceptions of their dyadic selectivity, that is, their self-reported tendency to focus on the most important goals in their partnership, and reject secondary goals if necessary. Three and a half years later, we obtained information on whether the goal to have a child had been realized, which was the case in 50% of the couples. As hypothesized, the higher the couples' initial dyadic-selectivity score had been, the more likely they were to indeed have started a family. Intra-dyadic discrepancies in dyadic selectivity were not related to couples' success in realizing their goal of having a child. Results were robust to controlling for socio-demographic and relationship variables, and were obtained while considering both cases of unplanned parenthood and involuntary childlessness. These findings suggest that the motivational strategy of dyadic selectivity helps couples to attain their goals. Our results thus support the notion that motivational factors may not only characterize individuals, but also social entities such as couples.

**A151****ENGINEERING SUCCESSFUL ACADEMIC MINDSETS WITH RELATIVE ACCESSIBILITY: THE ROLE OF EASY SUCCESS AND DIFFICULT FAILURE RECALLS.**

Eric Fuller<sup>1</sup>, Rusty B. McIntyre<sup>1</sup>, David Oberleitner<sup>1</sup>; <sup>1</sup>Wayne State University – The current research brings together unique lines of research suggesting that priming specific mindsets can affect performance on subsequent tasks, and that the relative ease that these mindsets are recalled moderates this relationship. Study 1 was conducted to show that participants, primed to think of relatively few or many incidents of academic success or failure, would differ in performance on a knowledge test, and hold different ability beliefs (internality attributions). Study 1 manipulated mindsets by have students recall academic experiences (success, failure) under varying recall demands (recall 5 vs. 10 experiences). Consistent with predictions, participants induced to easily

recall thoughts of success (5 experiences) received higher knowledge test scores and made greater internal success attributions than those in the difficult success condition (10 experiences). Conversely, those who recalled failure relevant thoughts under difficult constraints had higher test scores and greater ability attributions than those asked to recall failure under easy constraints. Study 2 replicated these mindset findings using different levels of accessibility constraints (3 vs. 9 experiences) and examined the speed of success vs. failure recognition (using an LD task). Participants asked to recall three successes scored higher on the knowledge test and were faster at identifying success related words than those recalling nine successes; those recalling nine failures scored higher and identified success words faster than those recalling three failures. These findings indicate that behavioral differences emerge as a result of applicability to promote success related mindsets. Implications for accessibility, automaticity, and mindset engineering are discussed.

**A152****DIRECTION OR DISTRACTION: HOW CONSCIOUS AND UNCONSCIOUS REWARD PRIMING AFFECTS THE ACTIVE MAINTENANCE OF GOAL-RELEVANT INFORMATION**

Claire M. Zedelius<sup>1</sup>, Harm Veling<sup>1</sup>, Henk Aarts<sup>1</sup>; <sup>1</sup>Utrecht University – People can be motivated by unconsciously perceived cues in the environment that signal reward. This research examines similarities and differences in effects of conscious and unconscious rewards on keeping goal-relevant information active. The idea is that more resources are dedicated to attain high rewards, which facilitates the maintenance of relevant information. However, at times, becoming conscious of a high reward can counteract this process due to distracting thoughts. In two studies, we compared the effects of consciously and unconsciously processed monetary rewards at different moments during the progress of goal-pursuit. Participants could earn 1 cent or 50 cents by maintaining words over a short delay. The rewards were indicated by 1 and 50 cents coins, which were presented either subliminally (i.e. too quickly to be consciously perceived) or supraliminally (i.e. exceeding the threshold for conscious perception). In Study 1, rewards were presented before participants read the target words. Enhanced performance was found in response to higher rewards, regardless whether they were presented supraliminally or subliminally. In a second study, rewards were presented after showing the target words. Performance increased in response to high rewards when they were presented subliminally, but decreased when they were presented supraliminally. We conclude that both conscious and unconscious rewards cause increased resource recruitment, supporting the maintenance of goal-relevant information. However, conscious rewards additionally provoke reflective thoughts. When engaged in a goal-directed maintenance process, these thoughts distract attention and interfere with the ongoing maintenance process. Implications for research on conscious and unconscious goal pursuit are discussed.

**Person Perception/Impression Formation****A153****EXPRESSIVE SUPPRESSION AND SOCIAL PERCEPTION: THE ROLE OF SPECIFIC EMOTIONS AND PERCEIVER EXPECTATIONS**

Allison Tackman<sup>1</sup>, Sanjay Srivastava<sup>1</sup>; <sup>1</sup>University of Oregon – How does emotion regulation relate to social functioning? Previous research has shown that the use of expressive suppression disrupts interpersonal closeness and support (Srivastava, Tamir, McGonigal, John, Gross, 2009), but the reasons for that are not yet clear. In the present experiment, we examined how suppression relates to others' perceptions of a person who suppresses. We were especially interested in whether the effects of suppression depend on the emotion being suppressed (amusement vs. sadness) and whether the perceiver expects the target to display an emotion. The participants (N = 149) watched short videos of target persons who were either suppressing or not suppressing to an amusing or sad movie clip. In addition, we manipulated participants' expectations about the targets by showing some participants the movie clip that the targets watched.

Afterward, participants reported their impressions of the targets' attributes (including personality and supportiveness) and their interest in affiliating with the targets. Overall, targets who suppressed were viewed less favorably and participants were less interested in affiliating with them. However this main effect was qualified by interactions with perceivers' expectations and with the emotion being suppressed. Suppression effects were larger in the expectation condition, indicating that suppression affects others' perceptions by creating a mismatch between expected and actual expressive behavior. Further, we found that many effects were more pronounced when the targets suppressed in response to an amusing stimulus. The findings suggest that suppressors may have difficulty in relationships because they do not display positive emotions when others expect them to.

**A154****NATURAL AMBIGUITIES? PERCEPTIONS OF MULTIRACIAL INDIVIDUALS BY MONORACIAL PERCEIVERS** Jacqueline Chen<sup>1</sup>, David Hamilton<sup>1</sup>,

<sup>1</sup>University of California at Santa Barbara – Understanding Multiracial person perception is becoming increasingly important in today's diverse society. The present research investigates the nature of the racial categorization of Multiracials. We hypothesize that, due to the legacy of the Black-White dichotomy and the automaticity of monoracial categorization, perceivers will make more errors in categorizing Multiracials and that categorization as "Multiracial" will take longer than monoracial categorizations such as "Black" or "White." Using a novel categorization task, we find support for these hypotheses in two studies. In addition, in Study 2, we demonstrate that cognitive load detrimentally affects Multiracial, but not monoracial, categorizations. Importantly, in both studies, perceivers are able to categorize Multiracials at a rate significantly above chance, suggesting that monoracial perceivers can perceive multiracialism relatively quickly and accurately. Implications and future directions are discussed.

**A155****WHERE THE DIVISION LIES: COMMON INGROUP IDENTITY MODERATES THE CROSS-RACE RECOGNITION EFFECT** Eric Hehman<sup>1</sup>, Eric W. Mania<sup>1</sup>,

Samuel L. Gaertner<sup>1</sup>; <sup>1</sup>University of Delaware – This research investigated the hypothesis that better recognition for same-race faces than other-race faces is a result of social categorization rather than perceptual expertise. Specifically, we were interested in how the salience of race or university categorization would affect the recognition of individuals within each group. Whereas previous research found that facial recall for same-race individuals is reduced by inducing an additional non-racial categorization (e.g. university, Shriver et al., 2008), the goal of the current study was to increase recognition accuracy for other-race individuals without decreasing memory for racial ingroup members by inducing a common ingroup identity. A modified facial recognition paradigm presented 61 White participants with 40 faces organized by race or university affiliation. On each trial 8 faces were simultaneously displayed and included 4 Blacks, 2 from each university, and 4 Whites, 2 from each university. In the university condition, faces were physically organized above or below a diagonal by same or different university affiliation. In the race condition, faces were similarly organized by race. In the test phase, 40 novel faces were interspersed with the originals and were displayed individually with university affiliation clearly indicated. Participants indicated whether each face was "Old" or "New." When grouped by race, participants had superior recall for same-race faces, and university affiliation had no effect. When grouped by university, participants had superior recall for same-university faces, and race had no effect. No interaction between race and university occurred in either condition. Results support social-cognitive models of the cross-race effect.

**A156****MIND ATTRIBUTION AS A FUNCTION OF PERCEIVED THREAT** Megan

Kozak<sup>1</sup>; <sup>1</sup>Pace University – Research has shown that people often overlook the mental states of those they dislike (Kozak, Marsh, & Wegner, 2006). However, there may be instances when it is beneficial to recognize cer-

tain mental states of a disliked other, specifically in cases where a person poses a threat to one's well-being. The current research explored the relationship between threat and mind attribution, the degree to which a perceiver imbues an individual with intention, cognition, and emotion. In Study 1, participants read a vignette describing a fictitious person who had engaged in anti-US activities. Perceived threat, mind attribution, and liking were measured. Correlational analyses revealed a positive relationship between threat and intention such that intention increased as threat increased. No relationship was found between threat and cognition or emotion. There was a negative relationship between threat and liking. Therefore, these results depart from our earlier work in that attributions of intention increased as threat increased, despite a decrease in liking. In Study 2, threat was manipulated. Participants were assigned to a low-threat, medium-threat, or high-threat condition. Attributions of intention differed significantly across conditions, with the highest being in the high-threat condition and the lowest in the low-threat condition. Mediation analyses revealed that differences in perceived threat fully accounted for the differences in intention. No differences in cognition or emotion were found. Taken together these findings suggest that the mental states of those we dislike are not always overlooked. If a person is perceived as threatening, certain mental states such as intention are recognized.

**A157****I THINK, THEREFORE I (FREE) WILL: THE SELF-OTHER DIFFERENCE IN FREE WILL PERCEPTION** Juan Manuel Contreras<sup>1</sup>, Emily Pronin<sup>2</sup>, <sup>1</sup>Harvard

University, <sup>2</sup>Princeton University – When seeking self-understanding, people tend to place a good deal of weight on information derived from introspection such as information about thoughts and feelings. When seeking to understand others, people place less weight on those others' introspections. The present research aimed to explore whether this difference might lead people to think that they have more free will than do others. In two experiments, actors were asked to make a choice after being given sufficient or insufficient time to think about that choice. Observers were informed of actors' choices and of the amount of time they were given. In Experiment 1, actors chose an offer to make in a Dictator Game; in Experiment 2, actors chose a charity to donate their subject payment to. Both experiments revealed an interaction between participant role and the time manipulation. Actors who were rushed into making their choices perceived those choices as less freely willed than did actors who had sufficient time to think before making a choice, whereas observers' assessments of free will were unaffected by the time manipulation (even when observers were led to experience that manipulation directly, by being induced to take that much time themselves to read about the relevant choice). Moreover, as expected, observers showed a general tendency to perceive actors' choices as less freely willed than did actors. This asymmetry in the perception of free will speaks to the question of why the debate over whether people have free will is so persistent.

**A158****ABOUT FACE: CROSS-CULTURAL DIFFERENCES IN THE PERCEPTIONS OF RACIAL PROTOTYPICALITY** Michael Strom<sup>1</sup>, Leslie Zebrowitz<sup>1</sup>, Shunan

Zhang<sup>1</sup>, Hoon Koo Lee<sup>2</sup>; <sup>1</sup>Brandeis University, <sup>2</sup>Yonsei University – Provocative research on 'Afrocentric bias' in judging Black and White faces reveals that Afrocentricity can affect impression formation, trait judgments, and even criminal sentencing (Blair, Judd, Sadler, & Jenkins, 2002; Blair, Judd, & Chapleau, 2004; Eberhart, Davies, Purdie-Vaughns, & Johnson, 2006). However, this research has not assessed what qualities make faces more racially prototypical, whether those qualities are the same for different race targets, or whether the qualities that lead to prototypicality assessments vary with race of judge. The present study answered these questions utilizing facial metrics of White, Black, and Korean target faces and ratings of racial prototypicality by Koreans and White, Black, and Asian Americans. White and Black faces differed in nose and mouth regions, as one might predict, and in lower face length and jaw and eye regions; White and Korean faces differed in eye and

mouth regions; Black and Korean faces differed in jaw, nose, mouth, and eye regions. Facial metrics that were positively related to rated African appearance were negatively related to rated White appearance, whereas there was no such inverse relation for the metrics predicting ratings of Asian vs. White or Asian vs. African appearance. Rater differences in the metrics that predicted racial prototypicality ratings further revealed an influence of culture. Facial metrics predicting ratings of White appearance, African appearance, and Asian appearance were similar for American judges regardless of race, and they differed from the metrics that predicted these ratings by Koreans.

#### A159

##### **CAN A REPARATION OFFER FUNCTION AS AN APOLOGY?** Heather

Coon<sup>1</sup>, Fukumi Matsubara<sup>1</sup>,<sup>1</sup> North Central College – One reason people apologize is to admit responsibility for their actions. Is it possible to be perceived positively following a misdeed if you only take responsibility for the consequence, without actually apologizing? In two studies undergraduates read a vignette in which another student ran into them on a bicycle. In Study 1, students read that the cyclist had muddied their clothing. Using a 2x2 design, we varied whether the cyclist apologized and whether the cyclist took responsibility by offering a reparation -- to pay a cleaning bill for dirty clothing. Two main effects emerged. Apologizing resulted in a more positive (and less negative) impression of the cyclist, as did offering a reparation. Does this mean apologies are not always necessary to form a good impression following a transgression? In Study 2 we further examined the role of appropriate reparations. In this study, the cyclist ruined a jean jacket. In this 2x2x2 design we again varied whether or not the cyclist apologized, and whether he offered reparations -- by offering to buy a new jacket. We also varied whether the jacket was new or had belonged to a good friend who moved away. Presumably, the jacket from the friend could not simply be replaced. Results again showed positive effects of apologizing and especially of offering reparations on impression formation. However, this was especially true only when the jacket was new and could be replaced. Overall, results suggest that reparations may substitute for apologies, but only when appropriate for the situation.

#### A160

##### **DON'T PUSH MY BUTTONS! THE VALUE OF SITUATIONAL KNOWLEDGE IN FRIENDSHIPS** Charity Friesen<sup>1</sup>, Lara Kammrath<sup>1</sup>;

<sup>1</sup>Wilfrid Laurier University, Ontario, Canada – Past research has debated whether having accurate knowledge about a close other is beneficial to the relationship. However, this research has only looked at accuracy related to traits and states. We argue that having accurate situational knowledge, knowing a person's characteristic profile of responses to different situations, should be particularly useful in maintaining a positive relationship. We approach the issue of profile accuracy by looking at interpersonal triggers, which are interpersonal situations where a person experiences a negative emotional reaction (such as irritation, anger, or anxiety) in response to another person's behavior. In order to measure trigger profiles we developed the Trigger Profile Questionnaire (TPQ), which consists of 72 descriptions of potentially bothersome interpersonal behaviors. Participants were asked to rate how much each type of behavior triggers them personally, and how much they thought it would trigger a friend. Defining accuracy as self-other agreement, we found that friend-pairs who had known each other longer tended to be more accurate about each other's trigger profiles. In addition, knowledge about the specific situations in which a friend characteristically becomes angry or irritated was associated with reduced feelings of conflict in the relationship, and increased feelings of depth. These results suggest that it is valuable to have accurate situational knowledge about a relationship partner.

#### A161

##### **THE COLOR OF POLITICS: COLOR AND RACE IN THE 2008 ELECTION** Midge Wilson<sup>1</sup>, Or'Shaundra Benson<sup>1</sup>, Monika Black<sup>1</sup>;

<sup>1</sup>DePaul University – During the waning months of the 2008 election, accusations began to fly that the conservative Fox News network was altering its photos of then presidential candidate Barack Obama to make him appear darker than he really is. Based on prior research on colorism, intra-racial discrimination based on varying shades of skin color, an online study was developed to assess the influence of Skin Color and Participant Race on Obama's bid for the Presidency. A campaign poster of Obama was manipulated to make him appear in one version lighter than he actually is, and in another version darker. Non-White and White Participants were asked to assume the role of an undecided voter, and to respond, based on the poster alone, to questions about Obama's attractiveness, toughness, patriotism, and electability. They were also asked to judge, independent of the poster, to what extent Obama's race and/or skin color were playing a negative role in the current presidential campaign. Results indicated the manipulation check for the light versus dark versions of Obama was successful, but Skin Color yielded no significant difference in perceptions of his overall favorability, an effect possibly due to "the Obama factor." Based on studies documenting a race gap in perceptions about racial progress, we did predict and find, however, significant differences for Participant Race. Non-white participants overall gave higher favorability ratings of Obama, but also generally believed both race and color were playing more negative roles in the campaign than did White participants.

#### A162

##### **CHILDREN'S ANTICIPATED RESPONSES TO HYPOTHETICAL PEERS WITH UNDESIRABLE CHARACTERISTICS: ROLE OF PEERS' DESIRE TO CHANGE, EFFORT TO CHANGE, AND OUTCOME** Tammy L. Sonnentag<sup>1</sup>,

Jennifer L. Livengood<sup>1</sup>, Mark A. Barnett<sup>1</sup>, Rachel Y. Witham<sup>1</sup>;

<sup>1</sup>Kansas State University – In a prior investigation, the more children perceived hypothetical peers as wanting to change an undesirable personal characteristic (e.g., being extremely overweight), the more favorable the children's anticipated responses to those peers. In this extension of our prior study, we examined the extent to which children's anticipated responses to hypothetical peers are influenced by the peers' desire to change, effort to change, and success in changing an undesirable characteristic. Fifth- and sixth-grade students read summaries of a pair of interviews with several hypothetical peers who discussed something about themselves that they or someone else considered a problem. During the first interview, the peers described the specific characteristic and indicated whether they wanted to change that characteristic. During the second interview, which presumably occurred six months later, the peers described whether they (a) had tried to change that characteristic and (b) had been successful in changing that characteristic. After reading the interview summaries, the students rated the extent to which they agreed with several statements concerning their anticipated reactions toward each peer. A series of ANOVAs revealed that the children anticipated responding more favorably to peers who were successful in changing an undesirable characteristic than peers who were unsuccessful. Furthermore, for both outcome conditions, peers who wanted to change and exerted effort to change were rated most favorably. In contrast, peers who reported no effort to change an undesirable characteristic were rated relatively unfavorably, regardless of whether or not they had expressed a desire to change that characteristic.

#### A163

##### **BRAND DILUTION: THE IMPACT OF THE USER OF COUNTERFEITS ON ORIGINAL BRAND PERCEPTION** Nelson Amaral<sup>1</sup>, Barbara Loken<sup>1</sup>;

<sup>1</sup>University of Minnesota – Our findings provide the first empirical evidence to suggest that, for prestige products, the use of counterfeit products can dilute people's perceptions of the original brand. We find evidence of dilution effects on beliefs about the original brand's prestige, beliefs about whether the original brand is high-class, and overall atti-

tudes toward the original brand. More interestingly, we find a significant two-way interaction that provides evidence for the process that causes this dilution. Specifically, because of the symbolic value of some brands as tools for self-affirmation and self-verification goals, for example, the social class of the users of these counterfeits plays an important role in understanding the effects of these counterfeit products on the original products. An analysis of variance with covariates provided evidence for a significant two way interaction between the two factors in the study such that the social class of the user had a significant impact on the participants' evaluations of the original brand. Specifically, the social class of the user had a significant effect on both the belief (prestige and high-class) and attitude ratings when the user in the photo was seen using a counterfeit prestige product, but the same effect did not occur when the user was seen using a real product. When a lower-class individual was seen using a counterfeit product it resulted in significantly lower evaluations than when the same counterfeit product was seen being used by a high-class individual.

#### A164

**A META-ANALYTIC REVIEW OF INTERPERSONAL DECODING ACCURACY AND INTELLIGENCE** Nora A. Murphy<sup>1</sup>, Judith A. Hall<sup>2</sup>; <sup>1</sup>Loyola Marymount University, <sup>2</sup>Northeastern University – There is a long history investigating the relationship between intelligence and interpersonal sensitivity, particularly regarding decoding accuracy. Yet, findings from such research are mixed. Some research reported little or no relationship between measured intelligence and the ability to judge social interactions and another set of research showed significant correlations between intelligence and decoding accuracy. A meta-analysis was conducted to clarify the relationship between intelligence and decoding accuracy. A total of 27 articles or book chapters containing 38 independent samples fit the inclusion criteria. A total of 72 effect sizes from these samples were recorded from these samples; 2,988 participants were involved in analysis. Results found a mean weighted effect size across the 38 samples of  $r = .19$ , 95% CI = .16 - .23;  $Z = 10.66$ ,  $p < .01$ . There was a highly significant small-to-medium effect for intelligence measures to be correlated with decoding accuracy. A non-significant Q-value ( $Q = 41.30$ ,  $p = .29$ ) suggested that studies included in the analysis were obtained from a common population, indicating generalizability from the sampled studies. Significant moderators included larger effects for emotion judgments (vs. intended-meaning judgments), judgments based on audio-only decoding channel (vs. audio-plus-video channel), and mixed-gender targets (vs. female-only targets). Interpersonal decoding accuracy requires some level of social sophistication in being able to accurately assess a person or situation. Results of this meta-analysis suggest that part of that social sophistication involves the cognitive abilities comprising general intelligence.

#### A165

**SUSIE'S SIREN SONG SEDUCES SAILORS: SHARED INITIALS INCREASE MARRIAGES, BUT NOT STABLE ONES** Jesse Chandler<sup>1</sup>, Norbert Schwarz<sup>1</sup>, Jonathan Gole<sup>1</sup>; <sup>1</sup>University of Michigan – People prefer their own initials over other letters. This preference influences important decisions, including the selection of occupations, places of residence, and spouses. We address whether these preferences withstand the test of time. Texas marriage and divorce records from 1968-2007 were examined and aggregated using meta-analysis. Replicating earlier findings, archival marriage data show a preference for same first-initial spouses,  $OR = 1.06$  (95% CI = 1.057, 1.066),  $z = 27.06$ ,  $p < .0001$  and same last-initial spouses,  $OR = 1.16$ , (95% CI = 1.154, 1.164)  $z = 67.33$ ,  $p < .0001$ . Moreover, divorce records show that people may be less likely to divorce same-initial spouses within the first year, ( $L, N = 314\ 762$ ) = 5.94,  $p < .02$ . Over the long term, however, marriages between same-initial spouses are more likely to end in divorce than marriages between different-initial spouses,  $OR 1.01$  (95% CI = 1.005, 1.017),  $z = 3.44$ ,  $p < .001$ . Furthermore, marriages between same-initial spouses do not last as long ( $M = 3110$  days) as marriages between different-initial spouses ( $M = 3168$  days),  $g+ = .92$

(95% CI = .917, .926)  $z = 393.46$ ,  $p < .0001$ . This suggests that the positive feelings engendered by a shared initial are insufficient to overcome other factors that influence relationship longevity.

#### A166

**ARE DOMINANCE AND PRESTIGE DISTINCT STRATEGIES FOR ATTAINING SOCIAL STATUS?** Joey T. Cheng<sup>1</sup>, Jessica L. Tracy<sup>1</sup>, Joseph Henrich<sup>1</sup>; <sup>1</sup>University of British Columbia – Based on evolutionary theories of group dynamics, Henrich and Gil-White (2001) distinguished between two routes to attaining social status in human societies: dominance (i.e., the use of force and intimidation) and prestige (i.e., sharing of wisdom, skills, or expertise). The present research examines several questions emerging from this model: (a) Do dominant and prestigious leaders engage in divergent patterns of behavior when seeking status (e.g., intimidation/aggression vs. persuasion/competence)? (b) Can group members reliably distinguish between dominant and prestigious leaders? And, (c) do both dominance and prestige promote social influence? Small zero-acquaintance groups (4-6 members;  $N=192$ ) engaged in a 20-minute interactive task. Each member rated all others on dominance, prestige, social influence, and related traits, in a round-robin design. Peer ratings were subsequently parsed into actor, perceiver, and dyadic components, using Kenny's (1994) Social Relations Model. Outside observers also coded each individual's behavior from videotapes. Results demonstrated that: (a) dominance predicted displays of coercion, humiliation, and other low-communal behaviors, whereas prestige predicted self-deprecation, deferential humor, coalition-building, and other high-communal behaviors; (b) group members and outside observers showed consensus in their ratings of dominance and prestige, and rated prestigious leaders as confident and likeable, and dominant leaders as arrogant; and (c) individuals high in both dominance and prestige were rated as influential and agentic by group members and outside observers, and demonstrated greater social influence in an objective behavioral measure. In sum, this research provides the first evidence that dominance and prestige are distinct strategies to attaining status.

#### A167

**SOCIAL INTELLIGENCE AND NONVERBAL DECODING ABILITY** Robin M. Akert<sup>1</sup>, Jonathan M. Cheek<sup>1</sup>, Julia Rutenber<sup>1</sup>, Joa Ahern-Seronde<sup>1</sup>, Rebecca Dautoff<sup>1</sup>; <sup>1</sup>Wellesley College – The idea that social intelligence correlates with nonverbal communication decoding ability has been both appealing and compelling to researchers for the past four decades; however, research has presented a conflicting and contradictory picture of such a relationship. For example, a meta-analysis of social intelligence and interpersonal accuracy obtained a mean effect size of only .08 (Davis & Kraus, 1997). One possible explanation for these disappointing findings is the need for better measures of both social intelligence and nonverbal decoding ability. In the present investigation, we administered a videotape performance test of nonverbal decoding ability—the Visual Nonverbal Decoding Task (VNDT; adapted from Akert & Panter, 1988) along with the Tromsø Social Intelligence Scale (Silvera, Martinussen & Dahl, 2001) and other personality scales to 168 Wellesley College students. The Tromsø Scale was developed in Norway to overcome perceived shortcomings in previous measures of social intelligence by specifying three factors: Social Information Processing; Social Skills; and Social Awareness. The VNDT was developed to provide an ecologically valid accuracy measure with multiple encoders; unposed, natural conversations; simultaneous, multi-channel communication; and a clear criterion for accuracy. The total Tromsø Scale correlated significantly ( $r = .19$ ,  $p < .05$ ) with performance on the VNDT, as did its three subscales: Social Information Processing (.15); Social Skills (.16); and Social Awareness (.15). While these effects are not large, they do suggest that continuing to improve measures on both sides of the equation is a worthwhile approach for future research on social intelligence and nonverbal decoding ability.

**A168****THE EFFECT OF GENDER STEREOTYPES ON IMPRESSIONS OF SMILING**

**FACES** Tay Hack<sup>1</sup>, <sup>1</sup>Angelo State University – Studies of facial expression indicate that men and women create rather different impressions when they are smiling than when they are not. The present research investigated whether such impressions are influenced by gender stereotypes. To explore this possibility, participants completed several questionnaires, which included a gender stereotype endorsement scale. Participants were then presented with facial photographs of forty different men and women and asked to form impressions by rating the faces on traits reflecting the basic dimensions of warmth and competence. Some participants rated the faces with a smiling expression, and other participants rated the same faces with a neutral expression. Results revealed that although smiling faces were perceived as warmer and more competent than non-smiling faces, this effect was especially enhanced for female targets. Compared to men, smiling women were evaluated more favorably; however, when not smiling, women were judged more harshly, especially on traits reflecting warmth. Further analyses revealed that gender stereotype endorsement predicted impressions; however, this was true only for impressions of female targets. Taken together, the findings suggest that, for women, failing to smile may be perceived as behavior inconsistent with prescriptive female stereotypes reflecting communal qualities. As such, women who do not smile may suffer the consequences in terms of perceived warmth.

**A169****A CROSS-CULTURAL LENS ANALYSIS OF HEALTH CARE PRACTITIONERS' PERCEPTIONS OF PEOPLE WITH PARKINSON'S DISEASE**

Kathleen Bogart<sup>1</sup>, Linda Tickle-Degnen<sup>1</sup>, Hui-ing Ma<sup>2</sup>, <sup>1</sup>Tufts University, <sup>2</sup>National Cheng Kung University – Parkinson's disease (PD) results in a poverty of expression known as facial masking. Decades of research have shown health care practitioners to be biased by facial masking when making personality judgments, regardless of whether or not it is a valid cue. Most notably, they perceive people with facial masking to be less extraverted. The masking bias has been studied only in Western cultures, in which extraversion is a highly important trait. This study utilized a lens model (Brunswick, 1955) to examine two possible cultural influences, variation in trait importance (Williams, Satterwhite, & Saiz, 1998) and ingroup recognition bias (Meissner & Brigham, 2001), on the accuracy of practitioners' impressions of patients' personality relative to patients' self-reported personality. Practitioners (N = 285) from the United States (US) and Taiwan (TW) judged personality from 80 s. video clips of 24 patients with PD from the US and TW. Patients' expressive behavior was coded by trained research assistants. We found that practitioners across cultures made personality judgments based on facial masking, particularly for extraversion, regardless of whether or not it was a valid cue. Cross-cultural differences in accuracy were found most notably in two traits which are highly important in TW culture: agreeableness and conscientiousness. The pattern of cross-cultural differences in the patients' expressive cues to personality and in the practitioners' decision making patterns suggests that cross-cultural differences in trait importance, not ingroup bias, affected trait perception accuracy.

**A170****TOUCH THE TRUTH: HAND OVER HEART AS AN EMBODIMENT OF**

**SINCERITY** Michal Parzuchowski<sup>1</sup>, Maria Parzuchowska<sup>1</sup>, Aleksandra Szymkow-Sudzarska<sup>1</sup>, Wieslaw Baryla<sup>2</sup>, Bogdan Wojciszke<sup>3</sup>, <sup>1</sup>Warsaw School of Social Sciences and Humanities, <sup>2</sup>University of Gdansk, <sup>3</sup>Polish Academy of Sciences – Body movements can prime related abstract concepts since motor movements increase the accessibility of the thought content and processes they typically co-occur with. Embodied perspectives have been supported by many studies demonstrating that gestures, arm movements and hand configurations can influence individuals' thoughts and feelings. Specifically, putting a hand on one's heart is correlated with appearing to be truthful (giving a word of honour, appearing to have genuine intentions and not lying, pledging allegiance). Based on

models of embodied concept representation (Barsalou, 1999) we suggest that the conceptualization of sincerity can be grounded in bodily experience of gesture that involves placing one's hand over the heart. Three studies show that the level of frankness can be manipulated through unobtrusive use of this gesture. Participants assessed their level of self-knowledge on important domain (Study 1) and provided judgment of physical attractiveness (Study 2) while putting their hand over the heart or the hip. Placing one's hand over heart decreased level of self-enhancement when judging amount of knowledge on bogus names of psychological theories. It also caused more unconstrained judgments indicated by lower ratings of unattractive faces. Study 3 extends these findings, showing that a person photographed while putting a hand over heart is believed to be more honest than with a hand over hip. Taken together, the three experiments suggest that bodily experience of abstract metaphors can not only influence the actors' judgment but also contribute to the actors' perception of their social environment.

**A171****INTERPERSONAL SENSITIVITY AS A PREDICTOR OF MEDICAL STUDENT**

**PERFORMANCE IN CLINICAL INTERACTIONS** Danielle Blanch<sup>1</sup>, Judith Hall<sup>1</sup>, Debra Roter<sup>2</sup>, Richard Franke<sup>3</sup>, <sup>1</sup>Northeastern University, <sup>2</sup>Johns Hopkins Bloomberg School of Public Health, <sup>3</sup>Indiana University School of Medicine – Interpersonal sensitivity, or accurately judging the meanings of others' appearance and behavioral cues, is a skill with great clinical relevance that has received insufficient study in health settings. The interpersonal sensitivity of 275 third-year medical students was measured using two validated tests, the Profile of Nonverbal Sensitivity (PONS) and the Diagnostic Analysis of Nonverbal Accuracy (DANVA). Students also self-reported their perceived emotional intelligence, empathy, and patient-centered attitudes and were later videotaped interacting with a standardized patient. Reliable trained coders evaluated the quality of the students' communication skills and coded medical student and standardized patient behaviors. The encounters were then shown to analogue patients (undergraduates watching the video imagining they were the patient), who rated their impressions of the student. Female medical students scored higher on interpersonal sensitivity than male students. Overall, interpersonal sensitivity was significantly positively correlated with self-reported patient-centered attitudes and the ability to name one's own emotions; with less distressed, more dominant, and more engaged behavior by the standardized patient; and with more liking of the student and higher ratings of compassion by the analogue patients. Correlations between interpersonal sensitivity and other variables were generally stronger and different for males than females, but interpersonal sensitivity predicted analogue patients' impressions similarly for both genders. In regression analyses, objectively measured interpersonal sensitivity emerged as a better predictor of subsequent analogue patient perceptions than self-reported empathy, attitudes, and emotional intelligence. Interpersonal sensitivity is associated with favorable impressions of medical students and is a skill that deserves increased attention in clinical contexts.

**A172****BEAUTY IN THE BEAST: INFERRED LIKING AS AN ANTECEDENT OF PHYSICAL ATTRACTIVENESS JUDGMENTS**

Christopher J. Wilbur<sup>1</sup>, Lorne Campbell<sup>1</sup>, <sup>1</sup>University of Western Ontario – A wealth of research has catalogued features characterizing objective beauty. Yet, several intriguing investigations have uncovered a variety of nonphysical antecedents of attractiveness judgments, indicating that, to some degree, beauty is in the eye of the beholder. The present research examined whether learning of another's interest facilitates enhanced judgments of that other's physical attractiveness – the "beauty-in-the-beast" hypothesis. In two studies, participants answered personal questions, with these answers ostensibly reviewed by another participant. The ostensible other subsequently expressed an interest in meeting the real participant, expressed indifference to meeting, or preferred not to meet. Participants later viewed a photograph of this ostensible other and rated his or her physical attractiveness. Participants in both studies rated the interested targets as more

physically attractive than the targets who expressed a lack of interest, supporting the "beauty-in-the-beast" hypothesis. Learning of another's interest level did not influence attractiveness judgments of unrelated control faces, suggesting that distorted perceptions of attractiveness result from inferred liking specifically, and do not generalize to targets who do not carry belongingness implications. The present findings comport neatly with recent observations that romantic "chemistry" better predicts mate choice than do explicitly articulated mate preferences. Biased perceptions of others' attractiveness resulting from inferred liking might constitute one mechanism underlying so-called romantic "chemistry."

**A173**

**MEAT, MORALS, AND MASCULINITY** Matthew B. Ruby<sup>1</sup>, Joseph Henrich<sup>1</sup>, Steven J. Heine<sup>1</sup>; <sup>1</sup>University of British Columbia – Much research has demonstrated that people perceive consumers of "good," low-fat foods as more moral, intelligent, and feminine, and perceive consumers of "bad," high-fat foods as less intelligent, less moral, and more masculine (for a review, see Vartanian, Herman, & Polivy, 2007). Little research has contrasted perceptions of omnivores and vegetarians, focusing chiefly on personality and political leanings, rather than morality or gender characteristics (e.g. Sadallah & Burroughs, 1981). We examined how people perceive vegetarians and omnivores, in terms of virtue and gender characteristics, above and beyond the demonstrated impact of diet healthiness. In Study 1, in a 2X2 between-subjects design, online participants read the profile of a male or female student, whose favorite foods either did or did not include meat. All other profile information was the same for omnivorous and vegetarian targets. Participants rated the target's personality, morality, gender characteristics, and diet healthiness on a series of 8-point scales. Controlling for perceived diet healthiness, both omnivorous and vegetarian participants rated vegetarians as significantly more virtuous than omnivores, and male vegetarians as significantly less masculine than male omnivores. Ratings of females' gender characteristics did not significantly differ. Study 2 replicated these findings with omnivorous students from Vancouver, who read and rated the profiles of fictional targets that followed either an omnivorous or vegetarian diet, without mention of specific foods. Thus, we have found support for the concept that people make inferences about others' morality and gender characteristics as a function of meat consumption.

**A174**

**INTERJUDGE AGREEMENT BETWEEN CHILDREN AND ADULTS** Dave Kolar<sup>1</sup>; <sup>1</sup>University of Mary Washington – Research on the accuracy of personality judgment often uses interjudge agreement as one criterion for accuracy (Hall, Andrzejewski, Murphy, Mast, & Feinstein, 2008; Letzring, Wells, & Funder, 2006). Much of this research evaluates interjudge agreement for college-aged and older individuals. The current study expands research on interjudge agreement by evaluating agreement between elementary school aged children and adults. Children (age 7 - 12; N = 205), parents, and guidance counselors all provided judgments about the child on several different characteristics. The results indicated there were good levels of self-other agreement between children and their parents. For example, on ratings of how well the child liked school, there was a correlation of .37 between children and parents. Also, there was a correlation of .32 between children and parents on ratings of how well the child got along with other children. Self-other agreement was mixed between children and counselors. For example, there was a .33 correlation between children and counselors on ratings of how well the child behaved in class. However, there was only a .13 (ns) correlation between children and counselors on ratings of how well the child got along with adults. Consensus results were also mixed. Parents and counselors had a .36 correlation on ratings of how well the child behaved in class but a correlation of .00 (ns) on ratings of how well the child got along with adults. Results are discussed in terms of their implications for research on interjudge agreement and the accuracy of personality judgment.

**A175**

**BEYOND INFRA-HUMANIZATION: THE PERCEPTION OF HUMAN GROUPS, THE SELF, AND SUPERNATURAL ENTITIES AS MORE OR LESS THAN HUMAN** Mark Brandt<sup>1</sup>, Christine Reyna<sup>1</sup>; <sup>1</sup>DePaul University – The philosophical idea of the great chain of being suggests that people, supernatural entities, and the self can be perceived as both greater than and less than human (Haidt, 2003; Lovejoy 1936/1964). Infra-humanization research has aptly demonstrated the propensity to perceive some human groups as less than human (Haslam, 2006). The current research tests the idea of a chain of being in social cognition by using a repeated measures survey design assessing the perception of several human groups, God, the devil, and the self along measures of humanness (Haslam & Bain, 2007) and sacredness (Mahoney et al., 2003) in a university sample. Results suggest that people perceive both supernatural entities and human groups along a dimension of being that extends above and below a conceptual midpoint of "human." Christians were especially likely to use the full range of this dimension including perceiving God, the self, and other Christians as more sacred and the Devil as less sacred than their non-Christian counterparts. Consistent with past research participants attributed more humanness to the self than to any of the other human groups. The devil was attributed the least amount of humanness. Results suggest that the perception of humanness can be expanded to include the perception of humans as more than human. Furthermore, some people (e.g. Christians) may be more likely to utilize the expanded dimension of being both above and below humanness.

**A176**

**THE STRANGER EFFECT: NEGATIVE CONSEQUENCES OF VIOLATING EMOTIONAL NORMS** Lauren Szczurek<sup>1</sup>, Benoit Monin<sup>1</sup>; <sup>1</sup>Stanford University – Two studies explore the social consequences of displaying unexpected emotional responses. We find that violators of emotional norms are perceived more negatively than their appropriately reacting counterparts, and that violating some emotional norms has more severe consequences than violating others. In study 1, 95 participants rated a target who violated emotional norms by going skiing and displaying excitement the day after his mother died significantly lower than appropriate targets on morality, warmth, and kindness. Perceptions of the target were most negative when the incongruent emotion was made highly salient with a photograph. In study 2, 56 participants watched a video of a peer reacting to an emotional slideshow, compiled using IAPS images that were either funny, neutral, or sad/disgusting. We rotated which slideshow participants thought the target was watching, to create matched and mismatched conditions. Mismatched targets were rated more negatively on personality traits, were predicted to experience more negative and fewer positive life events, and were rated as less suitable for professions associated with interpersonal warmth (e.g. nursing, elementary school teaching). Participants also placed mismatched targets further away on a scale of social distance. Violating sadness and disgust norms had significantly more negative consequences than violating happiness norms. This research explores the boundary conditions of emotional norm violations to document when and how they influence person perception.

**A177**

**THE POT CALLS THE KETTLE BLACK... BUT WHY? DISENTANGLING SOCIAL PROJECTION AND SELF-STEREOTYPING** Jeff Cho<sup>1</sup>; <sup>1</sup>University of California, Irvine – People tend to see others as being similar to themselves. Although the empirical evidence for the correlation between self- and other-judgments is robust, the precise causes and mechanisms are neither clear nor agreed upon among theorists. Social projection is the hypothesis assuming that correlations in self- and other-judgments reflect that people anchor their other-judgments on their self-knowledge. We expect that "most people are like me" and use our self-views as an egocentric template for judging others. Self-stereotyping is the opposing theory positing that the same correlations instead represent that people identify themselves based on their knowledge about prototypical others.

We expect "I am like most people" and most of our self-knowledge is in fact grounded on knowledge about generic persons. In a series of 2 studies, the present research tackled this ambiguity between egocentrism and protocentrism and empirically distinguished the two alternatives. By experimentally manipulating self-knowledge about personality traits via an Ease of Retrieval (Schwarz et al., 1991) manipulation, other-judgments were found to be de-coupled from self-judgments, which is more consistent with self-stereotyping than social projection.

**A178****ON THE VIRTUES OF BEING MEAN OR LAZY: NEW EVIDENCE OF A NEGATIVE RELATION BETWEEN WARMTH AND COMPETENCE**

Nicolas Kervyn<sup>1,2</sup>, Fiona Grignard<sup>1</sup>, Vincent Yzerbyt<sup>1</sup>; <sup>1</sup>Université catholique de Louvain, <sup>2</sup>Fonds de la Recherche Scientifique, Belgium – In three experiments, we examine some unsuspected consequences of perceivers' tendency to compensate warmth for competence and vice versa in person perception. The compensation effect corresponds to the fact that a person seen as high (low) on one dimension also tends to be perceived as low (high) on the other dimension. In Experiment 1, using lists of traits we found that a competent and cold target is perceived as more competent than a competent and warm target. In Experiment 2 we extended that result by manipulating either warmth or competence and by using a more ecological presentation of the targets. Results showed that, as in Experiment 1, the competent and cold target is perceived as being more competent than a competent and warm target. We also show that the warm and incompetent target is perceived as warmer than the warm and competent target. In Experiment 3, we replicate this compensation effect on the negative side of compensated stereotypes. These results are discussed in terms of how they relate to traditional person perception models. In addition to offering new evidence of a negative relation between the two fundamental dimensions of social perception, our findings also call for more elaborated models than those traditionally used to study person perception.

**A179****APPLYING THE PROCESS-DISSOCIATION PROCEDURE TO BEHAVIOR PREDICTIONS**

John Skowronski<sup>1</sup>, Randy McCarthy<sup>1</sup>; <sup>1</sup>Northern Illinois University – Memory for an other's past behavior may influence our predictions of that other's future behavior. Our memory for an other's past behavior is a combination of automatic, implicit memories as well as controllable, explicit memories. The current study used the logic of the process-dissociation procedure to estimate the contribution of automatic and controlled processes to a behavior prediction task. Specifically, some participants read actors describing trait-implicative behaviors; a task that elicits spontaneous inferences about the actors. Some participants read the trait-implicative behaviors while trying to decide whether the actor was telling the truth or was lying; this task has interfered with spontaneous inference making in past studies. Later, participants tried to recall the trait-implicative behaviors before making predictions of the actors' future behaviors. Participants either tried to use their memories of the actors' past behavior to help them predict future behaviors or tried to inhibit their memory for past behaviors so as not to let the past behaviors influence their behavior predictions. Process-dissociation procedure estimates showed that all participants had similar levels of controlled estimates regardless of the instructions they received while reading the trait-implicative behaviors. However, participants in the lie detection condition had low levels of automatic estimates compared to those in the spontaneous inference condition. Presumably, in the absence of alternative processing goals (e.g., lie detection), people can make trait inferences without awareness (as evidenced by their inability to inhibit the influence) and these inferences influence subsequent behavior predictions.

**A180****SPEED OF MOVEMENT: A CUE FOR THE PERCEPTION OF DOMINANCE AND WARMTH IN OTHERS**

Mary Giffen<sup>1</sup>, Michael Conway<sup>1,2</sup>; <sup>1</sup>Concordia University, <sup>2</sup>Centre for Research in Human Development – Two studies examined speed of movement as a cue for the perception of dominance and warmth in others. Hypothesis 1 was that there is an association between faster speed of movement and dominance in social perception, as well as between slower speed and warmth. Hypothesis 2 was that these associations are due to the causal impact of speed on perceptions of dominance and warmth. The methodology of the current studies, which focused on perceptions of animals and moving shapes, was in line with Morewedge and Wegner (2007), whose findings indicate a timescale bias in the attribution of "mind" (i.e., intentionality). The current studies examined how the attribution of interpersonal intentionality may be of either dominance or warmth. Results of study 1 (N=553) supported the hypothesis: the more participants perceived various animals as moving fast, the more they perceived them as dominant toward conspecifics. In study 2 (N=48), speed was manipulated experimentally using an animacy paradigm (i.e., one that fosters anthropomorphism). As expected, participants rated faster, relative to slower moving shapes, as more dominant and less warm. These findings provide support for a general link between perceived speed of movement and dominance, which has been demonstrated more specifically in past research: that people who smile and speak faster are perceived as more dominant (Hall et al., 2005; Krumhuber et al., 2007). The present findings suggest that when people move more slowly, be it because of age, culture, or other factors, they may be seen as more warm and less dominant.

**A181****ACCURACY MOTIVATION OR WORKING MEMORY CAPACITY? THE INHIBITION OF INTERPERSONAL EXPECTANCY EFFECT**

Ayano Yoshida<sup>1</sup>; <sup>1</sup>Tohoku Fukushi University – Working Memory (WM) is a temporary type of memory that processes and stores information. Previous research suggests that WM is used in a wide range of cognitive processes, including reading comprehension, analogical inference, and learning. Barret, Tugade, and Engle (2004) have shown that differences in working memory capacity (WMC) are the result of individual differences in the ability to control attention. They have also proposed the notion that individuals who have a lower WMC can be characterized as "cognitive misers" (Taylor, 1981) and, in contrast, individuals who have a higher WMC can be characterized as "motivated tacticians" (Fiske & Taylor, 1991). This study examines the influence of individual differences in WMC and accuracy motivation on the inhibition of interpersonal expectancy effect. Forty-seven undergraduates (41 women and 6 men) participated in a study on "attention and performance," in return for a course credit. The experiment consisted of a 2 (WMC: high vs. low) × 2 (accuracy motivation: high vs. low) between-subjects design. The participants' impressions of the negative target were assessed for expectation-consistency. Results indicated that (1) low-WMC individuals formed expectation-consistent impressions, whether they were high or low in accuracy motivation; (2) in contrast, participants with high-WMC, who were accuracy-motivated perceivers, did not form expectation-consistent impressions. Without sufficient working memory capacity, even accuracy-motivated perceivers can fail to inhibit interpersonal expectancy effect.

**Self/Identity****A182****AFRICAN AMERICAN RACIAL IDEOLOGY AND POLITICAL PARTICIPATION**

Elizabeth Shockley<sup>1</sup>, Penny S. Visser<sup>1</sup>, Leslie Ashburn-Nardo<sup>2</sup>; <sup>1</sup>University of Chicago, <sup>2</sup>Indiana University-Purdue University Indianapolis – African American racial ideology has been shown to predict academic outcomes. For example, endorsing a "minority" ideology (emphasizing the shared experience of minority groups) has been associated with positive outcomes, whereas endorsing an "assimilationist" ide-

ology (emphasizing the value of integrating into the dominant culture) has been associated with negative outcomes (e.g., Sellers et al., 1998). If these associations reflect a generalized effect of racial ideology on engagement with mainstream institutions, we should similarly observe associations between racial ideology and political participation. In the current research we tested the hypothesis that racial ideology predicts the types of political behavior that African Americans perform, shedding new light on the long-observed gap between Whites and Blacks in traditional forms of political participation. African American college students completed measures of racial identity, academic outcomes, and political engagement. Previous academic findings were partially replicated (e.g., nationalism predicted negative outcomes). And as expected, we found some interesting parallels in the political domain. For example, as with academic engagement, nationalism predicted less political participation. Other interesting effects emerged as well. Humanism and assimilation revealed contradictory results – serving both as positive and negative predictors of political engagement – depending on the level of racial centrality reported. We also explored the potential mediating role of system justification beliefs in explaining the relation between racial ideology and political engagement. Taken together, this research suggests that racial ideology is related in complex ways to political participation, with important practical as well as theoretical implications for democracy.

### A183

**THE NATURE OF IMPLICIT AND EXPLICIT ATTITUDES ABOUT SOCIAL STATUS** Neha John-Henderson<sup>1</sup>, Emily Jacobs<sup>2</sup>, Darlene Francis<sup>1,3</sup>, Rodolfo Mendoza-Denton<sup>1</sup>, <sup>1</sup>Department of Psychology, UC Berkeley, <sup>2</sup>Helen Wills Neuroscience Institute, <sup>3</sup>Department of Public Health, UC Berkeley – At every increment of our social hierarchy, higher socioeconomic status (SES) is associated with better health. Objective measures such as income, occupation, and education are typically used to probe the health disparities between social classes. Recent research shows that subjective perceptions of status may be more closely connected to health outcomes than objective indicators. Subjective status is probed by having subjects indicate, on picture of a 10-rung ladder, where they see themselves in relation to others. Here, we used a series of implicit association tasks (IATs) to probe implicit subjective status (me/not me – upper class/lower class) as well as the strength of the association between “good” and “bad” words with the concepts “upper class” and “lower class”. Subjects then completed a questionnaire with explicit attitudes measures and demographic data. The data, collected from 100 participants (age 18-58) demonstrate that a person’s implicit sense of their own status and implicit class biases diverge from explicitly reported attitudes. Overwhelmingly, participants harbored an implicit bias against “lower class”, a finding that was strongest in Caucasians and weakest in Latinos. Furthermore, the strength of the bias against “lower class” correlated positively with maternal education- a variable that is a classic indicator of a person’s SES. Future research should explore whether a person's implicit status relates as or more strongly to health outcomes than explicit status or objective SES indicators.

### A184

**THE EFFECTS OF PERSPECTIVE-TAKING ON VISUAL PERCEPTION: A SELF-OTHER MERGING** Sylvia Morelli<sup>1</sup>, Austin Grinberg<sup>1</sup>, Robert Wickersham<sup>1</sup>, Naomi I. Eisenberger<sup>1</sup>, <sup>1</sup>University of California, Los Angeles – Although the act of perspective-taking has been described as the ability to ‘put oneself into another’s shoes,’ to what extent does perspective-taking actually lead one to psychologically merge with another? The current study explored whether perspective-taking (vs. a control condition) increased the degree to which subjects visualized themselves as being merged with an individual they took the perspective of. In the perspective-taking condition, participants viewed a photo of an individual and were asked to write about a day in the life of that individual as if they were the individual, seeing the world through his/her eyes. In the control condition, participants were simply asked to look at the photo of the individual and copy unrelated paragraphs. All participants were then asked to pick out the actual photo of themselves from a display of 11 different faces. Five

of the faces were the participant’s face morphed with the face of the pictured individual in various increments (10-50% of the other). Five additional faces were the participant’s face morphed with the face of a random person. The original picture of the participant was also included. Results (n = 84) suggest that perspective-taking (vs. control) caused participants to judge that a blend of their own face and the pictured individual was more likely to be their own face than a blend of their own face and a random other. These findings support the notion that perspective-taking involves putting oneself into another’s shoes by demonstrating that perspective-taking can increase visual perception of self-other overlap.

### A185

**SCARILY COMING TO THE CENTER: POLITICAL CENTRISM AS AN EFFECT OF MORTALITY SALIENCE AND A NEED FOR CLOSURE** Carlos Alberto Rivera-García<sup>1</sup>, Philip J. Cozzolino<sup>1</sup>, <sup>1</sup>University of Essex – Two studies assessed the relationship between need for closure (NFC; Kruglanski, Webster, & Klem, 1993) and evaluations of political ideology changes, as a function of mortality salience (MS). Based on terror management theory (Greenberg, Pyszczynski, & Solomon, 1986) and previous research (e.g., Cozzolino, 2006; Jost et al., 2003), we hypothesized that abstract reminders of death would activate the facet of NFC that seeks group consensus and stability (as opposed to deviation and persuasion). Following an MS or control induction, 161 participants evaluated politicians who switched political ideologies (moved from the left to the right). In line with recent research (Fu et al., 2007), results indicate that MS induced people high in NFC to express greater support for politicians seeking consensus in the political center, compared to politicians endorsing liberal or conservative ideologies, an effect consistent with research linking NFC to desires for group centrism and collective closure. A second study (N= 122) clarified this issue further with participants evaluating political parties (rather than individual politicians) that were depicted as moving from their traditional left/right positions toward the political center in one condition, or parties that remained true to their traditional ideologies in a second condition. Results revealed that participants high in NFC exposed to MS expressed significantly higher levels of support for parties moving from the extreme right to the center, than for parties moving from the extreme left to the center. Full results from both studies will be presented, along with a discussion of theoretical and practical implications.

### A186

**IDENTITY THEFT: MORAL ANTECEDENTS, MORAL ANGER, AND IMPRESSION MANAGEMENT** Stephen Reysen<sup>1</sup>, Nyla R. Branscombe<sup>1</sup>, Mark J. Landau<sup>1</sup>, <sup>1</sup>University of Kansas – In two experiments (N = 162; N = 192) participants’ reactions to identity theft are examined. Identity theft is defined as a situation in which a person intentionally appropriates distinctive characteristics of another person’s public identity. Identity theft represents a moral violation against an individual's claim to display a unique public identity. Participants reported greater negative reactions when imagining another person appropriating many, but not one, self-characteristics. Moral appraisals of the theft (i.e., illegitimacy, intention to harm) mediated the relationship between the increase in number of self-characteristics copied and anger expressed by participants (Experiment 1). When the thief acknowledged the theft, anger was attenuated. The perception that the harm was not intentional and the perceived honesty of the copier mediated the relationship between the thief acknowledging the theft and participants’ anger (Experiment 2). The implications of the present findings for past identity theft research and impression management is discussed.

**A187****THE THREATS OF IDENTITY MISCLASSIFICATION AND ACCURATE CLASSIFICATION IN STIGMATIZED INDIVIDUALS** Jennifer Prewitt-Freilino<sup>1</sup>, Jennifer Bosson<sup>2</sup>, Jonathan Weaver<sup>2</sup>; <sup>1</sup>Rhode Island School of Design, <sup>2</sup>University of South Florida – Previous research on identity misclassification (Bosson, Prewitt-Freilino, & Taylor, 2005; Prewitt-Freilino & Bosson, 2008) examined how non-stigmatized individuals' expectations of being mistaken as a member of a stigmatized out-group can threaten both their need for belonging (positive social connections) and their need for coherence (feedback that confirms their stable self-views). In the current study, we investigated the reaction of stigmatized individuals when enacting behaviors diagnostic of either their social group or a non-stigmatized out-group. Specifically, we had gay men and lesbian women imagine engaging in behaviors that would likely lead others to assume they were either gay or straight. We found that enacting behaviors diagnostic of gay men/lesbian women (i.e., revealing homosexual status) lead stigmatized individuals to expect accurate classification as gay/lesbian, which produced little threat to coherence but heightened belonging concerns. Conversely, enacting behaviors diagnostic of heterosexuals (i.e., concealing homosexual status), lead to expectations of misclassification as straight, which threatened individuals' need for coherence, but preserved their need for belonging. Discussion focuses on how belonging and coherence threats may influence the strategic self-presentation of individuals with concealable stigmas.

showed great variability in their selection of Rockquemore's biracial identity categories, but the pattern of responses differed across the two groups. Specifically, Asian/White individuals were most likely to have a protean identity (i.e., sometimes Asian, sometimes White, and sometimes biracial), whereas Black/White individuals were most likely to have an exclusively biracial identity that they perceived as either validated or unvalidated by other people. In addition, variations in racial identity were in line with cognitive measures of self-concept clarity (SCC) and bicultural identity integration (BII), such that individuals with a validated biracial identity scored higher on SCC and BII than those with a protean or an unvalidated biracial identity. These findings suggest that having a clearly-defined, stable, and integrated bicultural self-concept is associated with the extent to which individuals' biracial identity is validated by others in their social network. Theoretical implications for extending Rockquemore's model to other biracial groups are discussed.

**A188****EFFECTS OF SOCIAL COMPARISON WITH INDIVIDUATED VERSUS NON-INDIVIDUATED TARGETS** Justin Buckingham<sup>1</sup>, Chet Meinzer<sup>1</sup>, Andrea Weber<sup>1</sup>, Marianne Riley<sup>1</sup>, William Klein<sup>2</sup>; <sup>1</sup>Towson University, <sup>2</sup>National Cancer Institute – Social comparisons are particularly potent when people compare with individuals who are physically present (Buckingham & Alicke, 2002). This may be because such comparison targets are proximal as well as individuated. The purpose of the present study was to disentangle physical proximity and individuation by holding proximity constant while manipulating individuation. We hypothesized that individuated targets would have stronger effects on self-evaluations than non-individuated targets. 201 students were randomly assigned to conditions in a 2 (Individuation) X 2 (Social Comparison Direction) factorial design. Participants received bogus feedback that they had scored 14 out of 20 on a social perception ability test. Participants were also led to believe that their score was better or worse than another student in the room. In the individuated condition, the other participant was identified (e.g., the person sitting across from you); in the non-individuated condition, the other participant was said to be a randomly selected person from the room and was not identified. Participants then rated their social perception ability. We analyzed the data with one-tailed planned comparisons using the Bonferroni correction. In the individuated condition, downward comparison ( $M = 6.47$ ) led to higher self-evaluations than upward comparison ( $M = 5.86$ ),  $t(118) = 2.52, p < .05$ . This effect was not significant in the non-individuated condition,  $t(81) = 1.34, p > .05$ . The results suggest that the effect of proximal individual social comparisons on self-evaluation depends on the individuation of the target. Proximity was not sufficient to produce significant social comparison effects.

showed great variability in their selection of Rockquemore's biracial identity categories, but the pattern of responses differed across the two groups. Specifically, Asian/White individuals were most likely to have a protean identity (i.e., sometimes Asian, sometimes White, and sometimes biracial), whereas Black/White individuals were most likely to have an exclusively biracial identity that they perceived as either validated or unvalidated by other people. In addition, variations in racial identity were in line with cognitive measures of self-concept clarity (SCC) and bicultural identity integration (BII), such that individuals with a validated biracial identity scored higher on SCC and BII than those with a protean or an unvalidated biracial identity. These findings suggest that having a clearly-defined, stable, and integrated bicultural self-concept is associated with the extent to which individuals' biracial identity is validated by others in their social network. Theoretical implications for extending Rockquemore's model to other biracial groups are discussed.

**A189****A MULTIDIMENSIONAL FRAMEWORK FOR EXAMINING RACIAL IDENTITY ACROSS DIFFERENT BIRACIAL GROUPS** Evelina Lou<sup>1</sup>, Richard N. Lalonde<sup>1</sup>, Carlos Wilson<sup>1</sup>; <sup>1</sup>York University – Recent research has adopted a multidimensional view initially proposed by Rockquemore and colleagues (2002, 2009) for examining racial identity among Black/White biracials. This approach has acknowledged the social construction of and has widened the range of racial identity options beyond the two "traditional" options of "Black" or "biracial." This study was designed to further assess this framework by examining a more diverse multiracial sample from Canada and the U.S. ( $N = 122$ ). Results indicated that similar to Black/White biracials ( $n = 38$ ), Asian/White biracials ( $n = 40$ )

showed great variability in their selection of Rockquemore's biracial identity categories, but the pattern of responses differed across the two groups. Specifically, Asian/White individuals were most likely to have a protean identity (i.e., sometimes Asian, sometimes White, and sometimes biracial), whereas Black/White individuals were most likely to have an exclusively biracial identity that they perceived as either validated or unvalidated by other people. In addition, variations in racial identity were in line with cognitive measures of self-concept clarity (SCC) and bicultural identity integration (BII), such that individuals with a validated biracial identity scored higher on SCC and BII than those with a protean or an unvalidated biracial identity. These findings suggest that having a clearly-defined, stable, and integrated bicultural self-concept is associated with the extent to which individuals' biracial identity is validated by others in their social network. Theoretical implications for extending Rockquemore's model to other biracial groups are discussed.

Theoretical implications for extending Rockquemore's model to other biracial groups are discussed.

**A190****THE MULTIDIMENSIONAL NATURE OF IDENTIFICATION WITH SPORTS TEAMS: IMPLICATIONS FOR TEAM LOYALTY** Jhon Wlaschin<sup>1</sup>, Mark Snyder<sup>1</sup>; <sup>1</sup>University of Minnesota – Theories of group identity propose separate cognitive, affective and evaluative components of identity (e.g., Ellemers, et al. 1999). To examine these components of identity in the context of identification with sports teams, we compiled 60 items from existing measures of identity and administered them to a sample of 270 participants (173 F, 97 M) in an online survey of beliefs, attitudes, and behavior toward a favorite team. Factor analysis revealed that items tapping cognitive and affective aspects converged to form a single identity factor. An evaluative component also emerged as two factors: private evaluation of one's favorite team, and perceptions of how others value the team. We then examined the ability of these identity measures to predict loyalty to one's team. Regression analysis revealed that the identity and personal valuation factors predicted loyalty to one's favorite team, even after controlling for length of time being a fan, number of friends and family who are also fans, and gender. Moreover, a composite measure of fan behaviors did not significantly predict team loyalty when the identity factors were included in the model. However, the public evaluative component of team identity did moderate loyalty such that those with low levels of behavioral involvement with their team were more loyal when others valued their team, but those with high involvement were less loyal when others valued their team. Implications for theory and research on group identity and group loyalty will be discussed.

showed great variability in their selection of Rockquemore's biracial identity categories, but the pattern of responses differed across the two groups. Specifically, Asian/White individuals were most likely to have a protean identity (i.e., sometimes Asian, sometimes White, and sometimes biracial), whereas Black/White individuals were most likely to have an exclusively biracial identity that they perceived as either validated or unvalidated by other people. These findings suggest that having a clearly-defined, stable, and integrated bicultural self-concept is associated with the extent to which individuals' biracial identity is validated by others in their social network. Theoretical implications for extending Rockquemore's model to other biracial groups are discussed.

**A191****SELF-PERCEIVED MINORITY PROTOTYPICALITY AND IDENTIFICATION IN MIXED RACE INDIVIDUALS: IMPLICATIONS FOR SELF-ESTEEM AND AFFIRMATIVE ACTION** Jessica Good<sup>1</sup>, George Chavez<sup>1</sup>, Diana Sanchez<sup>1</sup>; <sup>1</sup>Rutgers University – In 2008, Barack Obama became the first multiracial individual to be elected President of the United States. Multiracial individuals are in the unique position of having multiple racial backgrounds with which to identify, ranging from monoracial (i.e. identifying with only one racial group) to extraracial (i.e. identifying with the human race; Renn, 2004). However, little research has examined the psychological processes linked to racial identification in mixed-race individuals. We proposed that the extent to which multiracial individuals identify as minority depends on their perceptions of their own prototypicality (similarity to the prototype of the minority group), which may be linked with feelings of connectedness to the minority group and perceived similarity in physical appearance to other members of the minority group. Data were collected from 107 mixed race minority-White participants using online sampling methods. Results from structural equation analysis supported our hypotheses; connectedness to the minority community and perceived similarity in physical appearance to members of the minority group predicted self-identification as minority due to perceived prototypicality. Additionally, minority identification was positively predictive of both psychological (self-esteem) and practical/real world (comfort applying for affirmative action) benefits. Implications for perceived affir-

showed great variability in their selection of Rockquemore's biracial identity categories, but the pattern of responses differed across the two groups. These findings suggest that having a clearly-defined, stable, and integrated bicultural self-concept is associated with the extent to which individuals' biracial identity is validated by others in their social network. Theoretical implications for extending Rockquemore's model to other biracial groups are discussed.

mative action eligibility are discussed. These results add to a growing literature on the affective and behavioral consequences of multiracial individuals' identity choices.

#### A192

**THE POSITIVE AND NEGATIVE COMPARTMENTALIZATION INVENTORY (PNCI): A SURVEY ALTERNATIVE TO THE CARD SORTING TASK** Alicia Limke<sup>1</sup>, Virgil Zeigler-Hill<sup>2</sup>, Patrick B. Mayfield<sup>1</sup>; <sup>1</sup>University of Central Oklahoma, <sup>2</sup>University of Southern Mississippi – The evaluative organization of self-knowledge refers to the manner in which individuals organize self-relevant knowledge (Showers, 1992). This model refers to a continuum that ranges from perfect compartmentalization (i.e., organizing positively and negatively valenced self-beliefs into separate self-aspects) to perfect integration (i.e., organizing positively and negatively valenced self-beliefs into the same self-aspects). Evaluative organization has been linked to a variety of outcomes including mood (Showers, Abramson, & Hogan, 1998; Showers & Kling, 1996), eating disorders (Showers & Larson, 1999), childhood maltreatment (Showers, Zeigler-Hill, & Limke, 2006), narcissism (Rhodewalt, Madrian, & Cheney, 1998), self-esteem instability (Zeigler-Hill & Showers, 2007), and bipolar disorder (Taylor, Morley, & Barton, 2007). However, the card sorting task used to measure evaluative organization is costly in terms of the time it requires to be administered and may capture a relatively transient form of evaluative organization rather than the general style of the respondents. To complement the card-sorting task, we developed the Positive and Negative Compartmentalization Inventory (PNCI). The PNCI is a brief self-report measure consisting of a compartmentalization subscale and a self-concept content subscale. Analyses utilizing these subscales are consistent with recent research suggesting that compartmentalization may have hidden vulnerabilities (cf. Zeigler-Hill & Showers, 2007). More specifically, the compartmentalization subscale was found to be associated with an array of negative outcomes (e.g., depression, low self-esteem, and low psychological well-being) even when self-concept content was controlled.

#### A193

**CLARITY VERSUS CONFUSION: EFFECTS ON THE SELF AND ROMANTIC RELATIONSHIPS** Natalie Nardone<sup>1</sup>, Gary W. Lewandowski, Jr.<sup>2</sup>; <sup>1</sup>Stony Brook University, <sup>2</sup>Monmouth University – Writing about the self, makes contents of the self-concept more salient and specifically promotes greater usage of self-relevant ideas (Setterlund & Niedenthal, 1993). However, research has not connected this self-concept saliency with clarity of the self-concept, or potential benefits, such as increased quality of one's romantic relationships. To examine this, the present study randomly assigned 78 participants to one of two conditions; self-concept clarity (where they wrote about how their behaviors matched adjectives previously rated as descriptive of them) or self-concept confusion (where they wrote about adjectives that were not descriptive of them). Participants also completed (pre/post manipulation) measures of relationship quality (satisfaction, commitment, investments and quality of alternatives) along with inclusion of the other in self. In addition, participants completed measures of self-concept clarity, self-esteem, the inclusion between their desired and current self, and knowledge/understanding of the self. We conducted a series of ANCOVAs, with pre-test levels of variables as covariates. Participants in the self-concept clarity condition reported significantly higher self-concept clarity, self-esteem, inclusion between desired and current self, knowledge/understanding of self, satisfaction, commitment, investments, and lower quality of alternatives. These analyses show that increasing clarity of the self-concept has a positive effect on one's ideas about their self and about their romantic relationship.

#### A194

**EVALUATIVE ORGANIZATION OF SELF-STRUCTURE: THE DISADVANTAGES OF COMPARTMENTALIZATION FOR SELF-CONCEPT CLARITY, PERSONAL NEED FOR STRUCTURE, AND INFORMATION PROCESSING STYLE** Patrick B. Mayfield<sup>1</sup>, Alicia Limke<sup>1</sup>, Virgil Zeigler-Hill<sup>2</sup>; <sup>1</sup>University of Central Oklahoma, <sup>2</sup>University of Southern Mississippi – The basic model of evaluative organization of self-knowledge (Showers, 1992) states that when positive self-aspect categories are important, compartmentalization (i.e., segregating positive and negative self-attributes into distinct self-aspect categories) will be associated with the most positive mood, whereas integration (i.e., mixing positive and negative self-attributes within self-aspect categories) will be related to more positive mood when negative self-aspect categories are salient. However, recent research has suggested that compartmentalization may have hidden vulnerabilities (Showers & Zeigler-Hill, 2007; Zeigler-Hill & Showers, 2007). To investigate this further, 70 participants completed the Positive and Negative Compartmentalization Inventory (PNCI; Limke, Zeigler-Hill, & Mayfield, 2010), the Self-Concept Clarity questionnaire (SCCQ; Campbell et al., 1996), Personal Need for Structure scale (PNS; Neuberg & Newsom, 1993), and the Rational-Experiential Inventory (REI; Pacini & Epstein, 1999). Results were consistent with those of previous studies that have suggested certain disadvantages associated with utilizing compartmentalization as a general style for organizing self-knowledge. More specifically, as compartmentalization increased in the present study, self-concept clarity decreased ( $r = -.58, p = .000$ ), personal need for structure increased ( $r = .25, p = .03$ ), and reliance on a rational style of information processing decreased ( $r = -.27, p = .02$ ). Discussion focuses on the possible reasons for the vulnerabilities associated with evaluative compartmentalization, the possible advantages that may stem from encouraging integration as a coping technique, and suggestions for future research.

#### A195

**I LOVE MY MULTIPLE SELVES, BUT WHICH ONE IS MY FAVORITE: MOTIVATIONAL PRIMACY OF THE TRIPARTITE SELF** Michelle Luke<sup>1</sup>, Constantine Sedikides<sup>1</sup>, Lowell Gaertner<sup>2</sup>, Erin O'Mara<sup>2</sup>, Lydia Eckstein Jackson<sup>2</sup>, Huajian Cai<sup>3</sup>, Quiping Qu<sup>3</sup>; <sup>1</sup>University of Southampton, UK, <sup>2</sup>University of Tennessee, US, <sup>3</sup>Henan University, CN – Past research evidenced stronger reactions of the individual than collective self to both threat and enhancement, suggesting the motivational primacy of the individual self (Gaertner, Sedikides, Vevea, & Iuzzini, 2002). Absent, however, was consideration of the relational self. The current research rectified that absence, thus expanding our theoretical model while enriching the empirical assessment of primacy. Research, conducted in the US and China, tested the relative primacy of the individual, relational, and collective self. Participants were primed with a particular self before listing 12 future goals. Subsequently, they indicated the importance of each goal and indicated whether a given goal represented their individual, relational, or collective self. The evidence supported a three-tiered motivational hierarchy among the selves, with the individual self at the top of the hierarchy, followed by the relational self, and trailed at the bottom by the collective self. This hierarchy may reflect a fundamental structural pattern of the human self—a pattern whose outline was drawn by evolutionary forces.

#### A196

**I AM MORE HUMAN THAN MY FRIENDS: CROSS-CULTURAL INVESTIGATION OF SELF-HUMANIZING IN COMPARISONS WITH SPECIFIC OTHERS** Joonha Park<sup>1</sup>, Nick Haslam<sup>1</sup>, Yoshi Kashima<sup>1</sup>, Gyuseog Han<sup>2</sup>; <sup>1</sup>The University of Melbourne, Australia, <sup>2</sup>Chonnam National University, South Korea – Research has shown that people see themselves as more human than others, independent of their tendency to self-enhance (e.g., Haslam, Bain, Douge, Lee, & Bastian, 2005). Previous studies have investigated this self-humanizing effect in comparisons with non-specific others (e.g., the average person) or hypothetical individuals. The present study extends this work by examining more concrete comparisons in which people compare themselves with specific others, and by doing so

in different cultures. Seventy European Australian and 97 Korean undergraduates in each country were asked to think about a significant other (a close friend) and a non-significant other (a non-close acquaintance), and to judge themselves compared with these others on 56 personality traits. They also rated these traits on the extent to which each trait is part of human nature, uniquely human, and socially desirable. In both cultures, participants attributed traits considered human nature to themselves more than to both significant and non-significant others. Self-humanizing was stronger in comparison to close friends than to acquaintances among Korean but not Australian participants. Korean participants also attributed uniquely human traits to themselves more than to both others. Self-enhancement effects were also found in Korea only. This study suggests that self-humanizing is cross-culturally robust, but also that it varies subtly across cultures.

#### A197

**WHAT DOES THE PERFECT WOMAN LOOK LIKE? WOMEN'S PERCEPTIONS OF THE IDEAL.** Louise Wasylkiw<sup>1</sup>, Kathryn Poirier<sup>2</sup>, Amber Emms<sup>3</sup>, Anna MacKinnon<sup>1</sup>, Sarah Smith<sup>1</sup>, Michael Currie<sup>1</sup>; <sup>1</sup>Mount Allison University, <sup>2</sup>University of Alberta, <sup>3</sup>University of Victoria – Researchers and clinicians alike accept that mass media is a key source of promoting what is desirable and attractive in women. The literature that describes media representations of women tends to focus on weight and body size and neglects other aspects of appearance that are also promoted. Rather than analyzing the content of media images, we were interested in the perceptions that young women have of what is ideal and expected that young women's descriptions of ideal women would conform to media ideals. In Study 1, we analyzed the content of descriptions that young women (N = 44) wrote in response to the question "What does the perfect woman look like?" Although the majority of women included attributes specific to body size, a large number failed to describe the perfect woman as conforming to the thin ideal presented in the media. Moreover, a number of descriptions included physical attributes that denote health and fertility. Despite the leading question, descriptions were not limited to physical attributes. In Study 2, women (N = 56) described their own perceptions of the perfect woman as well as what they perceived to be the ideal from 4 different viewpoints including: media's, men's, mother's, and friends'. Women's own views corresponded closely to the views they perceived their mothers and friends held whereas women's perceptions of the cultural ideal corresponded to what they perceived to be men's views. Results from this investigation highlight that women's perceptions of perfection are multi-faceted and deserving of more research attention.

#### A198

**THE IMPACT OF PERCEIVED DISCRIMINATION AND ACCULTURATION STRATEGIES ON IDENTITY CHANGE** Miguel Ramos<sup>1</sup>, Clare Cassidy<sup>2</sup>, Stephen Reicher<sup>2</sup>, S. Alexander Haslam<sup>1</sup>; <sup>1</sup>University of Exeter, <sup>2</sup>University of St. Andrews – The focus of this paper is on identity change among international students as they make the transition from first to second year in UK universities. We followed a cohort of 164 international students over a period of approximately one year. Specifically, we drew on the rejection-identification model (Branscombe et al., 1999) to examine the impact of experiences of discrimination on existing identities (e.g., nationality) and the development of new identities (e.g., international student, student of X University). Our data highlighted the importance of examining differing aspects of identification when modelling identity change but also when examining other important outcomes, such as well-being and academic performance. Importantly, our data also pointed to the role of chronic acculturation attitudes - individual preferences, beliefs and behaviours about contact with the minority ingroup and majority. These attitudes moderated the impact of discrimination on identity change and on other outcomes. To understand the implications of discrimination for minority group members, it is important to specify the conditions under which rejection does and does not lead to identification.

#### A199

**THINKING DIFFERENTLY ABOUT DEATH: A TEST OF DUAL-EXISTENTIAL SYSTEMS IN THE CONTEXT OF ATTENTION AND PERCEPTION** Laura E. R. Blackie<sup>1</sup>, Philip J. Cozzolino<sup>1</sup>, Panagiotis Rentzelas<sup>1</sup>, Nick R. Cooper<sup>1</sup>, Marco Perugini<sup>2</sup>; <sup>1</sup>University of Essex, <sup>2</sup>University of Milan – Reminders of our own mortality change the way we think and behave (Greenberg, Pyszczynski, & Solomon, 1986). The dual-existential systems model proposed by Cozzolino (2006) posits that unspecific reminders of mortality (mortality salience; MS) are processed via an abstract system, which focuses attention on external representations of the self such as cultural worldviews. Alternatively, individuated mortality reminders (death reflection; DR) are processed via a specific system, which focuses attention on self-specific structures such as personal values and goals. The model further predicts differential information processing styles once individuals are engaged in these self-focused or external-focused states. In Study 1, we examined the EEG gamma-wave activity of participants who had experienced MS, DR, or a control condition. Numerous studies have linked enhanced gamma oscillations to intense states of self-focus and self-consciousness, as well as bottom-up and top-down cognitive processing. DR participants were found to have significantly greater gamma oscillations in a two-minute post-manipulation reflection period, compared to MS or control participants. In Study 2, DR participants showed a significant attentional bias toward gain-related information in a bottom-up cognitive task that involved estimating the final monetary outcome of a series of gamblers. In Study 3, DR participants were significantly more accurate in the 'framed-line test', a task involving top-down attentional processing, compared to MS and control participants. These studies suggest that DR facilitates heightened states of self-focus, and leads to cognitive processing styles that foster better performance on difficult cognitive tasks that require individuals to 'bind' together complex information.

#### A200

**SELF-AFFIRMATION AND PERCEIVED EFFICACY IN REDUCING UNREALISTIC OPTIMISM** Megan Davidson<sup>1</sup>, Leandre Fabrigar<sup>1</sup>, Kelsey Smart<sup>1</sup>; <sup>1</sup>Queen's University – People tend to believe that they are better than others. In encouraging people to adopt healthier behaviors, one problem often faced is their unrealistic optimism about health outcomes. Research has examined the use of self-affirmation in reducing unrealistic optimism, but results have been mixed. Perceived efficacy is demonstrated to be an important variable in determining whether individuals practice a particular health behaviour, and its correlational relationship with risk perception is encouraging. Thus together, these two variables may act in conjunction to produce a powerful effect on risk perception and subsequent behaviour change. Participants were 274 undergraduate students who were randomly assigned to a self-affirmation manipulation (self-affirmation; no self-affirmation) and a perceived efficacy manipulation (high perceived efficacy; low perceived efficacy; baseline perceived efficacy), followed by exposure to negative health risk information (risk of a heart attack prior to the age of 50). Analyses indicated that in isolation, self-affirmation significantly increased risk perception, while perceived efficacy had no causal effect on risk perception. There was a significant interaction between the 2 variables, such that perceived efficacy affected risk perception only in those participants that did not self-affirm: attempts at both increasing perceived efficacy and decreasing perceived efficacy caused increased perceptions of risk. There were no differences in risk perception among the efficacy conditions in participants who did self-affirm. Finally, greater perceived efficacy was associated with greater behavioural change.

#### A201

**MAN IN THE MIRROR: SELF RECOGNITION ABILITY AS A MEASURE OF GROUP IDENTIFICATION FOLLOWING SOCIAL IDENTITY THREAT** Pamela J. Sawyer<sup>1</sup>, Brenda Major<sup>1</sup>; <sup>1</sup>University of California, Santa Barbara – One method for coping with social identity threat is to modulate identification with one's social group. Research suggests that individuals who are initially high in group identification tend to increase identification

following threat, while those initially low in identification tend to disidentify further. In the current studies, we demonstrate that this change in identification can occur at the perceptual level, such that individuals perceive their own face as appearing more or less prototypical of the social group following threat to the group's social standing. In study one, Asian participants read information suggesting that their group either was or was not frequently the target of prejudice in America. They then completed a self recognition task, in which they were asked to distinguish their own photo from images of their own face morphed to varying degrees with prototypical ingroup and outgroup faces. Relative to participants who did not experience a social identity threat, those who read that their group faced pervasive discrimination showed an increased tendency to perceive their face as appearing prototypical of the outgroup, suggesting these individuals may have perceptually decreased identification with the threatened ingroup. Study 2 replicated these findings with female participants, and further demonstrated that initial implicit group identification moderates self recognition ability, such that those initially high in identification perceive their face to appear more prototypical of the ingroup following threat, while the inverse is true for those initially low in identification. Implications for social identity and intergroup interactions are discussed.

#### A202

##### **I-SHARING VERSUS ME-SHARING IN INTERPERSONAL ATTRACTION; THE EFFECT OF SEX-PAIRING AS AN INTERPERSONAL CONTEXT** Hwaryung

Lee<sup>1</sup>, Eunkook M. Suh<sup>1</sup>; <sup>1</sup>Yonsei University, Seoul, Korea. – One of the basic principles of attraction is the similarity of self-concept. Pinel, Long, Landue, Alexander and Pyszczynski (2006) have recently introduced the concept of I-sharing – the subjective sense of sharing and identical inner feeling with another person – and found that this phenomenon tends to increase people's attraction to others more than me-sharing – sharing a similarity with the another person. The role of I-sharing on interpersonal attraction could be considered with sex-pairing information of dyadic entities because basic expectations toward others are determined whether other people's sex is the same with them or not – same-sex or opposite-sex, then having a great influence on perceiving and interpreting both oneself and other people. The authors conducted this study in a face-to-face situation to examine the moderating effects of sex-pairing on attraction; likeness toward same-sex partner versus opposite-sex partner. In this study, results showed that participants interacting with an opposite-sex partner reported greater attraction on I-sharers, whereas participants interacting with a same-sex partner preferred me-sharers. In additional analysis, I-shared participants tended to predict that their similarity with their interacting partner is limited only in the aspect of I-sharing experience; which is to say, a subjective experience. Unlike I-sharers, me-sharers forecasted that they have high possibility to I-share with their me-sharing partners. This research implies that the more attractive aspect of self sharing with others can be moderated by information from interpersonal context. Also, distinctive features of I-sharing compared to me-sharing were explored.

#### A203

##### **WHO USES THE SELF AS AN ANCHOR TO IDENTIFY WITH THE GROUP? A STUDY ON SELF-ANCHORING AS COGNITIVE ROUTE TOWARDS IDENTIFICATION AND ITS MODERATION BY INDIVIDUAL DIFFERENCES**

Ruth van Veelen<sup>1</sup>, Sabine Otten<sup>1</sup>, Nina Hansen<sup>1</sup>; <sup>1</sup>University of Groningen, The Netherlands – Migration is a highly relevant issue in nowadays societies. Merely bringing cultures together does not automatically lead to a common identity. Thus, research on social identification within diverse groups is very important. A precondition for social identification with any group, is the formation of a link between the self and the group. Recent research has shown that this link can not only emerge via self-stereotyping (i.e., the self depersonalizes towards group prototypes), but also via self-anchoring (i.e., the assimilation of the group representation to the self). Self-anchoring should be especially beneficial for social identification in diverse groups, because members can feel a bond with the group, while also feeling acknowledged for their uniqueness. Our first

goal was to provide evidence for a link between self-anchoring and social identification. Furthermore, with self-anchoring, high emphasis is placed on the role of the individual. Cultures differ in the extent to which people express their individuality in groups. Therefore, our second goal was to investigate how differences in interdependence and uniqueness influence self-anchoring. In two studies, we provided evidence for a link between self-anchoring (based on profile and distance scores) and social identification using two different social categories and different measures. Furthermore, we found that people scoring high on both interdependence and uniqueness showed higher levels of self-anchoring. In sum, self-anchoring can instigate social identification and is most facilitated among those who can express their personal self, while also being interdependent. Implications for optimizing identification in diverse groups are discussed.

#### A204

##### **WHEN IGNORANCE IS BLISS: TESTING MOTIVATIONS TO AVOID INFORMATION** Wendi Malone<sup>1</sup>, James Shepperd<sup>1</sup>; <sup>1</sup>University of Florida –

Despite widespread endorsement of the maxim "knowledge is power", people sometimes choose to remain ignorant. One possible reason is that information can threaten a cherished belief (e.g., that one is attractive, healthy, or intelligent). We tested this explanation by offering participants (N = 102) an opportunity to learn how attractive others rated them and varying the level of threat inherent in those ratings. On arriving for the study, participants were photographed then viewed, via a computer, photos of seven other people ostensibly participating simultaneously in the study. Participants learned that all participants were evaluating one another on several dimensions including physical attractiveness. In the high threat condition, the photos depicted white students described as from the participants' university. In the low threat condition, the photos depicted Indian students described as from Mumbai University in India. We reasoned that participants would perceive students from their own university who looked like them to be more threatening than students from a distant university who did not look like them. At the end of the experiment, participants were offered an opportunity to learn how attractive they were rated by their fellow participants. More women (37.2%) than men (12.0%) chose to avoid learning their attractiveness ratings,  $\chi^2 = 5.60$ ,  $p < .05$ . Consistent with predictions, more women opted to avoid learning their attractiveness ratings in the high threat (46.2%) than in the low threat condition (23.1%),  $\chi^2 = 4.58$ ,  $p < .01$ . These findings have broad theoretical and applied implications.

#### A205

##### **THE DOUBLE-EDGED SWORD OF HARMONIOUS IDENTITIES IN MENTAL HEALTH**

Takuya Tabata<sup>1</sup>, Tomoko Ikegami<sup>1</sup>; <sup>1</sup>Osaka City University – The present study examines how multiple identities affect psychological well-being and resilience. Recent literature on the effects of multiple identities suggests that having many identities leads to greater psychological well-being if the identities are harmonious with each other. Harmonious identities are beneficial for mental health because they expect similar behaviors. However, the self-complexity model proposes that the number and distinctiveness of self aspects is associated with better mental health because it inhibits spillover from negative events in one dimension of the self to other dimensions. From this perspective, it is predicted that harmonious identities, overlapping with each other and being less distinctive, lead to fragility of the self and less resilience against negative events. Thus, we hypothesize that having harmonious multiple identities enhances psychological well-being but at the same time reduces psychological resilience. In order to test this hypothesis, we conduct a questionnaire study in which 221 Japanese university students served as respondents. Respondents first listed their current identities (i.e., group memberships and social roles) and indicated the degree of harmony between them as well as their importance. They then completed a scale of psychological well-being (i.e., happiness) and a scale of psychological resilience (i.e., recovery from being hurt emotionally). Multiple regressions revealed that a greater number of identities were more strongly associated with psychological resilience when identity

harmony was low rather than high. It was also found that greater identity harmony enhanced psychological well-being regardless of the number of identities. Strengths and weaknesses of harmonious identities were discussed.

#### A206

**THE 'WHAT' OF DOING: LAY PERCEPTIONS OF ACTION AND ILLUSORY INTENTIONS TO ACT** Christopher C. Berger<sup>1</sup>, Margaret T. Lynn<sup>1</sup>, Travis A. Riddle<sup>2</sup>, Ezequiel Morsella<sup>1,3</sup>; <sup>1</sup>San Francisco State University, <sup>2</sup>Columbia University, <sup>3</sup>University of California, San Francisco – Ideomotor approaches to the study of action production propose that 'goal-based representations' (e.g., action effects) rather than 'means representations' (e.g., motor programs/control) are essential in the execution of voluntary action. From this standpoint, in action production, one should be more aware of the perceptual consequences (or the 'what') of an action than of the sources (or the 'how') of an action. Though well-accepted, this view has never been demonstrated empirically. Hence, we demonstrated for the first time in a series of experiments ( $n = 125$ ) that, when performing various actions (e.g., humming), participants perceive action consequences (e.g., vibrations in the mouth) as more responsible for causing the action than the primary source of the action (e.g., vocal cords). Consistent with the view that lay perceptions of action production are inaccurate, another experiment demonstrated that participants themselves report that their foreknowledge about the sensory consequences of a simple future action (e.g., touching a surface) was inaccurate. Last, in a novel paradigm ( $n = 18$ ) without the shortcomings of the 'rubber-hand illusion' paradigm, we showed that, by systematically manipulating perceived action outcomes, participants can be deluded into believing that they intended to perform an action (e.g., moving a cursor by using a brain-computer-interface) that they in fact did not intend and was produced by a computer program. Together, these basic findings shed light on the complex relationships among voluntary action, action production, and action perception.

#### A207

**THE EMOTIONAL DIMENSION OF WORKING CLASS UNIVERSITY STUDENTS' SOCIAL CLASS IDENTITY IS LINKED TO GREATER SELF-ENHANCEMENT AND EXPECTATIONS OF UPWARD CLASS MOBILITY** Nassim Tabri<sup>1,2</sup>, Michael Conway<sup>1,2</sup>; <sup>1</sup>Concordia University, <sup>2</sup>Centre for Research in Human Development – The present research examined how working class university students' social class identity relates to their values and expectations of upward class mobility. Social class identity was defined within social identity theory (Tajfel & Turner, 1986) by three dimensions: emotional attachment, perceived similarity, and positive esteem. In Study 1, working class students ( $N = 61$ ) completed the Portrait Values Questionnaire (Schwartz et al., 2001) and a social class identity scale developed for the present research. Emotional attachment was positively correlated with achievement and self-enhancement values. In Study 2, we examined how working class university students' social class identity relates to their expectations of upward class mobility. On the basis of Study 1, we hypothesized that the emotional attachment dimension would support expectations of upward class mobility. Working class students ( $N = 137$ ) completed self-report measures of identity and mobility. Structural regression analysis was conducted (Kline 2005). The model provided a good fit ( $\chi^2(38) = 48.10, p = .13, CFI = .97, RMSEA = .04$ ). The three dimensions of social class identity were positively correlated. As expected, greater emotional attachment to one's working class background predicted greater expectations of upward class mobility. In contrast, the other dimensions of social class identity predicted less expectations of upward class mobility. Furthermore, expectations of upward class mobility were positively correlated with perceptions of success in university; perceptions of success were also correlated with self-reported GPA. The findings of studies 1 and 2 were distinct to working class students only compared to middle class students.

#### A208

**WILL THE REAL SELF-ENHANCEMENT MOTIVE PLEASE STAND UP? OTHER MOTIVES MAY UNDERLIE THE QUEST FOR POSITIVITY** Tracy Kwang<sup>1</sup>, William Swann<sup>1</sup>; <sup>1</sup>The University of Texas at Austin – Contemporary versions of self-enhancement theory assume people want to think well of themselves, even if they know such evaluations are unwarranted. Advocates of the theory suggest the motive is both pre-potent and pancultural (see Sedikides & Gregg, 2008). It is possible, however, that self-enhancement effects may reflect related, but distinct motives, such as self-verification strivings or other rivals such as agency or communion. We tested the relative merits of self-enhancement versus self-verification approaches through a meta-analysis of all available studies. We searched the published research literature for critical tests of self-verification and self-enhancement as well as emailed appropriate listservs contacting researchers for access to any papers that might have been missed otherwise. Statistically, self-enhancement is reflected by a main effect of the evaluation factor in an ANOVA or regression. In contrast, self-verification theory is reflected in an interaction between self-view and evaluation in an ANOVA or regression. Results were standardized to Pearson's  $r$  effect size and corrected for sampling error. We conducted independent meta-analyses of studies that used distinct dependent measures, such as feedback seeking, interpersonal behaviors, relationship outcomes, and cognitive and affective processes. Overall, findings suggest that self-verification effects were equal to or somewhat stronger than self-enhancement on all outcome measures except for affective responses. Although our findings reveal a tie on cognitive reactions, the indices of feedback seeking and relationship quality favored self-verification. This finding lends force to the possibility that most demonstrations of self-enhancement strivings are actually other rival motives.

#### A209

**THE COST OF BEING CLOSE: SELF-OTHER OVERLAP AND DOMESTIC VIOLENCE** J. Anna Bell<sup>1</sup>, Sara D. Hodges<sup>1</sup>; <sup>1</sup>University of Oregon – Greater self-other overlap has generally been considered a desirable trait in romantic relationships, but past research has mainly focused on amicable couples, and not relationships that are less than ideal, such as those marked by domestic violence. This study explores the possible negative consequences that may be associated with greater self-other overlap in abusive relationships, such as greater intent to return to the abusive partner and lower levels of well-being. Twenty-one women in a domestic violence center who had recently left abusive male partners completed measures of self-other overlap, including Aron's "Inclusion of Other in Self" measure [IOS; made up increasingly overlapping circles] and Davis et al.'s (1996) trait adjective overlap measure. Participants who reported previously having greater self-other overlap on the IOS with their former partners also reported greater intent to return to those partners. For trait overlap, the effects of overlap differed by trait valence: Women who described themselves as sharing a greater percentage of positive traits with their former partners had lower self esteem, suggesting that self image may suffer when positive aspects of the self overlap with an abusive partner. Conversely, women who described themselves as sharing a greater percentage of negative traits with their former partners had higher self esteem, which is consistent with the idea that these shared negative self traits have less of a negative impact on self concept when the partner is no longer present. Together these results indicate that greater self-other overlap takes on new meaning in unhealthy relationships.

#### A210

**WHEN AFFIRMING THE SELF FAILS: AN EXAMINATION OF FRIENDSHIP CONTINGENT SELF-ESTEEM, FRIENDSHIP FAILURE, AND SELF-AFFIRMATION** M. Janelle Cambron<sup>1</sup>; <sup>1</sup>University of Alabama, Texas A&M University – Self-affirmation as a strategy for overcoming the deleterious effects of experiencing failure in an unrelated domain has received vast empirical support. The current research aimed to examine the effect of a self-affirmation manipulation following failure for individuals whose

self-esteem is highly contingent on the failure domain. Specifically, would individuals whose self-esteem is based on their friendship quality ("friendship contingent self-esteem") benefit from affirming themselves in another domain when they experienced a friendship failure? To answer this question, 103 participants were led to believe that their friend had unspoken complaints against them, then randomly assigned to either a self-affirmation or control condition. After rank ordering 11 values from most important to least important, participants in the affirmation condition were asked to write about why the highest ranked value was important to them and to describe a time when it was particularly important. Participants in the control condition were asked to write about why their ninth-ranked value was important to the average college student. Participants then completed measures of state self-esteem and the desire to seek out excessive reassurance from their friend. Results revealed no effect of self-affirmation on high friendship contingent self-esteem individuals. In both conditions, high friendship contingent self-esteem individuals experienced lower state self-esteem and a greater desire for reassurance following the rejection compared to low friendship contingent self-esteem individuals. These findings suggest that affirming the self in an unrelated domain following "failure" in a domain on which one's self-esteem is dependent is not an effective strategy for these individuals.

#### A211

**PROTECTING THE UNCERTAIN SELF: THE ROLE OF SITUATIONAL VARIABLES IN SELF-HANDICAPPING AND OVERACHIEVEMENT** Matthew Braslow<sup>1</sup>, Robert Arkin<sup>1</sup>; <sup>1</sup>The Ohio State University – Research has revealed two strategies that establish or preserve an appearance of competence: self-handicapping and overachievement. Self-handicapping involves creating obstacles to one's success (Jones & Berglas, 1978), as in effort withdrawal, whereas subjective overachievement involves exerting heroic amounts of effort in order to ensure success (Oleson et al., 2000). Although previous research identified self-doubt as one variable that motivates these strategies, researchers know relatively little about other variables that contribute to the adoption of these strategies. The present research examined how situational variables might create behavioral patterns consistent with self-handicapping and overachievement. Participants (N=80) were given either easy or difficult analogies on a practice test and told that either success or failure on the final test would be meaningful (diagnostic of their ability). The dependent measure came from a second practice, during which participants could attempt as many problems as desired. When told that failure on the test would be meaningful, people low in chronic self-doubt were unsurprising, practicing more for a more difficult test. However, people high in chronic self-doubt showed the opposite behavior, practicing more for an easy test and less for the challenging test (interaction  $t = 2.029$ ,  $p < .05$ ). This ironic pattern, for individuals with high self-doubt, suggests that the failure-meaningful test inspired overachievement on an easy task, but self-handicapping on a difficult task. For individuals poised to protect an uncertain self, circumstances of the situation moderate the use of self-protective strategies and yield behavior as dramatically different as heroic effort and effort withdrawal.

#### A212

**REMPIND ME WHO I AM: INDIVIDUALS PREFER INFORMATIONAL SUPPORT AFTER AN IDENTITY THREAT** Erica Slotter<sup>1</sup>, Wendi Gardner<sup>1</sup>; <sup>1</sup>Northwestern University – When their identity has been threatened, individuals often look to others in their social world for confirmation of who they are (Gollwitzer, 1986). We propose that, when a specific aspect of individuals' identities is threatened, they seek others who can provide them with information that confirms the threatened aspect of their identity. Individuals should prefer this informational support over emotional support, or warmth, which may make them feel better, but does not confirm the threatened aspect of their identity. Two studies tested this hypothesis. In a pilot study, participants recalled a time that their identity had been threatened. They also recalled one person who provided them with support during this time. Overwhelmingly, participants

recalled others who the participants believed knew them well, and thus could provide information to confirm their threatened identity. In a second study pre-medical students' "physician" identities were either threatened or confirmed. After threat, participants overwhelmingly chose to interact with a novel target, who had previously been given information about the participants' GPA (identity relevant information), over a novel target who had been given information about the participants' non-academic interests. Importantly, the latter target was constrained to be objectively warmer than the former target. These results suggest that, when an aspect of their identity has been threatened, individuals prefer to interact with others who possess information that can help them confirm their threatened sense of self over those who cannot—irrespective of emotional warmth. This informational support may be helpful in repairing individuals' damaged sense of self.

#### A213

**EFFECTS OF EMBODIED EXPERIENCE ON SELF-UNDERSTANDING** Kendall Eskine<sup>1</sup>, Elisabeth Brauner<sup>1</sup>; <sup>1</sup>Brooklyn College and The Graduate Center, The City University of New York – Can the material body influence thoughts about the immaterial self? Does physically looking up to others increase how we think about them or ourselves? Drawing from theories of embodied cognition, which was defined here as the degree to which bodily feedback shapes cognitive processes, the present experiment explored different forms of self-understanding (e.g., academic self-efficacy and perspective taking). Participants (N = 84) were directed to look up or down while thinking about an instructor in whose class they were performing well or poorly. It was hypothesized that looking up would increase perspective taking, causing participants' academic self-efficacy to vary as a function of the instructor about whom they were thinking. Specifically, it was predicted that thinking about the instructor in whose class they were performing the best would increase academic self-efficacy. It was also predicted that looking down would decrease perspective taking and have little effect on efficacy. The results revealed that participants' embodiment (looking up) increased perspective taking. However, the highest levels of academic self-efficacy were reported by participants who were thinking about the instructor in whose class they were performing the worst. Further, there was a significant negative correlation with height and perspective taking in which taller participants were worse at perspective taking than shorter participants. Future directions are discussed with respect to embodiment, perspective taking, and self-understanding. We propose a follow up experiment focused on head posture and affect.

#### A214

**RELIGIOUS DISCRIMINATION: A TWOFOLD THREAT TO BELIEFS AND SOCIAL IDENTITY** Renate Ysseldyk<sup>1</sup>, Kimberly Matheson<sup>1</sup>, Hymie Anisman<sup>1</sup>; <sup>1</sup>Carleton University, Ottawa, Ontario, Canada – A social identity threat may evoke varying degrees of distress depending on which group membership is targeted. The stress associated with religious discrimination may be twofold, even compared with threats to other identities of great importance, given the concurrent attack on the social group and belief system therein. The present study examined how identification with a religious versus ethnic group evoked different appraisal-coping processes following identity threats, as well as the emotions elicited. Community participants (N=420) completed measures assessing ethnic and religious identification, appraisals and coping strategies following ethnic or religious discrimination, and emotional responses to that event. Regression analyses indicated that individuals who highly-identified with their religion or ethnicity appraised threats targeting those groups as more threatening and challenging, and were more likely to use problem-focused and emotion-focused strategies to cope compared with low-identifiers. Group identification was also associated with greater sadness, anger, and fear following both threat types, and these relations were mediated by threat appraisals and emotion-focused coping. However, a threat to religious identity was unique, relative to an ethnic identity threat, in that appraisal-coping and emotional responses were magnified. In addition, following a religious threat, challenge appraisals

appeared to elicit greater strength, whereas such appraisals elicited greater anger following an ethnic threat. Thus, although both ethnic and religious identity threats may evoke powerful responses when individuals identify with their group, religious discrimination appears to evoke a stronger and broader set of responses. Moreover, religious identification may uniquely offer strength to deal with threats targeting the group.

#### A215

**COGNITIVE DISSONANCE AND THE MEANING MAINTENANCE MODEL; DISSONANCE INCREASES MOTIVATION TO SEEK PATTERNS** Daniel Randles<sup>1</sup>, Steven Heine<sup>1</sup>, Travis Proulx<sup>2</sup>, Samuel White<sup>1</sup>; <sup>1</sup>University of British Columbia, <sup>2</sup>University of California, Santa Barbara – The Meaning Maintenance Model (Heine, Proulx, & Vohs, 2006) argues that humans have a need to create and maintain organizing schemas to understand the world. When these schemas are threatened or disrupted in an irreparable way, the individual will affirm other schemas that are still intact or will abstract new schemas. Past evidence has supported this theory with regards to many "meaning" disruptions and has found a consistent pattern of responses, including reinforcing pre-existing world views and a heightened sensitivity to-and motivation to seek-patterns. This study investigates whether meaning maintenance responses are observable in a traditional cognitive dissonance paradigm. Student participants in the "free choice" condition (N=24) were asked to write a paragraph in favor of increasing tuition that would be considered by the university board of governors. Those in the "no choice" condition (N=28) were explicitly told that they must write the paragraph. After this, both groups completed an implicit grammar task designed to tap implicit learning of-and motivation to identify-patterns. Groups also completed a standard post-dissonance rationalization measure. Results show the "free choice" group showed both significantly greater motivation to identify patterns and were more favorable of a tuition increase. These results support the effect of meaning maintenance, showing that before a damaged schema is repaired, individuals may be primed to reinforce other mental connections. Future studies are needed to determine if meaning-maintenance actually reduces dissonance, or if it is part of a defensive response employed until dissonance is reduced through rationalization.

#### A216

**"HOMEOSTATIC BELIEFS" MODERATE REACTIONS TO INCREASED MORTALITY SALIENCE** Caitlin Burton<sup>1</sup>, Jason Plaks<sup>1</sup>; <sup>1</sup>University of Toronto – Homeostatic beliefs reflect the extent to which individuals believe that positive and negative life events "even out" in the long term. Because homeostatic beliefs assume a return to the status quo after disrupting events, we hypothesized that belief in homeostasis would buffer the effects of mortality salience. To prime "homeostatic" or "non-homeostatic" beliefs, participants were presented with a computerized tutorial on either negative feedback systems (in which destabilizing influences have only transient effects) or positive feedback systems (in which destabilizing forces cause large and lasting deviations from a baseline). Subsequently, participants wrote about either their own death (mortality salience prime) or about grocery shopping (control). Finally, participants were asked to imagine themselves as judges and post bail for a hypothetical prostitute. Previous studies have found that participants generally post higher bail bonds following a mortality salience prime, suggesting that individuals are more protective of their culture's predominant values after pondering their own deaths. The current study revealed significant main effects of mortality salience condition and positive/negative feedback system condition on bail bond values, and a significant two-way interaction, such that participants in the negative feedback system condition posted significantly lower bail bonds than participants in the control or positive feedback system conditions following the mortality salience prime; participants who wrote about grocery shopping showed no significant effects of the positive/negative feedback primes. These results suggest that individuals who believe that disturbing events will have only transient effects on their lives may not have strong defensive reactions to mortality salience cues.

#### A217

**COGNITIVE, AFFECTIVE, AND EXISTENTIAL CONSEQUENCES OF THREATENED CIVIL LIBERTIES** Panagiotis Rentzelas<sup>1</sup>, Philip J. Cozzolino<sup>1</sup>, Marco Perugini<sup>2</sup>; <sup>1</sup>University of Essex, <sup>2</sup>University of Milan – Three studies in support of a new model of the psychology of liberty examined the psychosocial consequences of restricting civil liberties. Employing a new 'liberty threat' (LT) manipulation, we asked participants (via scenario) to imagine a series of civil liberty restrictions, based on actual policies implemented in the US and UK. In Study 1, 117 participants completed a thought-accessibility task composed of 14 target word-fragments that could be completed in the context of liberty ('F\_E\_' = free or fled); participants in the LT condition solved significantly more target words with the liberty option than did control participants, indicating the activation of a broader liberty construct post-manipulation. Study 2 (N=40) established the existential consequences of threatened civil liberties, in that participants revealed significantly lower scores on a measure of self-awareness after LT, compared to controls; the same study revealed no differences between the groups on a measure of the participants' perception of choice in their behavior. Finally, Study 3 (N=67) assessed attitudinal effects of LT in that participants were asked to read a news story in which the liberties of an online social network user were infringed. Results revealed the lowest levels of approval for the infringement among those LT participants who also revealed high levels of attachment to the ideals of freedom and democracy. Across all three studies, LT participants reported significantly higher levels of negative affect, compared to controls. Full results from all studies will be presented, along with a discussion of theoretical and practical implications.

#### A218

**TWO SIDES TO EVERY TRAUMA: THE ROLE OF POSTTRAUMATIC GROWTH AND DECLINE ON WELL-BEING** Danay Novoa<sup>1</sup>, Anne Wilson<sup>1</sup>; <sup>1</sup>Wilfrid Laurier University – Research clearly demonstrates how traumatic events can damage psychological and physical health (Janoff-Bulman, 1992). However, Tedeschi and Calhoun (2004) argue that posttraumatic growth can also occur following adversity. Although largely well-received, their theory and the posttraumatic growth inventory (PTGI) have been critiqued as well. For instance, Wortman (2004) argues that Tedeschi and Calhoun give insufficient consideration to the negative consequences of traumatic events. Concurring with Wortman, we contend that the PTGI, constructed to measure only growth, does not allow participants the opportunity to report decline in any domain. This scale design may artificially inflate the apparent occurrence of posttraumatic growth while neglecting the challenges that may co-occur. In the current research, we adapted the PTGI to more fully capture respondents' experiences of both growth and decline. In two studies, participants recalled a significant negative event and completed our adapted version of the PTGI (the post-traumatic growth and decline inventory or PTGDI). In Study 2, participants were randomly assigned to complete the original PTGI or our revised PTGDI. In both studies, participants reported experiencing both growth and decline concurrently. Furthermore, up to 26% of participants completing the PTGDI reported more decline than growth, whereas participants in the PTGI condition were unable to report any decline. Moreover, measuring both growth and decline allowed us to better predict a variety of well-being indicators than measuring growth alone. Results demonstrate the importance of investigating the co-occurrence of positive and negative consequences of adverse life events to better understand current experience.

#### A219

**INFLUENCE OF GROUP TYPE ON THE GROUP-REFERENCE EFFECT** Craig Johnson<sup>1</sup>, Maria Paasivirta<sup>1</sup>, Anthony Iacovelli<sup>1</sup>, Kristin Perret<sup>1</sup>; <sup>1</sup>Hofstra University – This work was designed to gain an understanding of what types of groups can facilitate memory for information encoded in reference to the group (the group-reference effect). Johnson et al. (2002) found that referencing participants' family or university produced better recall than a comparison semantic task and facilitated memory to the

same degree as self-referencing. However, referencing gender or religion did not result in the same memory advantage. Applying Lickel et al.'s (2000) typology, that work included an intimacy group (family), a loose association (students at a university), and two social categories (gender, Jews). The fourth group type presented by Lickel et al. was a task group. In the current work, we include a task group (sports team) along with a number of alternative intimacy, social category, and loose association targets. All studies utilized a similar paradigm in which participants were presented with a series of adjectives, each paired with one of three encoding questions (self-reference, group-reference, or semantic), followed by a free recall test. The results indicated that encoding information in reference to one's sports team facilitated recall to the same degree as self-reference. Across studies, evidence for the group-reference effect was strongest with intimate and task groups, mixed with loose associations, and weakest with social categories. Among a variety of possible candidates (e.g., group size, familiarity, entitativity, identity importance, prototype vs. exemplar representations), the existing data suggest that a combination of features must be considered to best understand when a group will facilitate memory.

## Stereotyping/Prejudice

### A220

**SHUN THE NONBELIEVER: PRIMING RELIGION AND ITS EFFECTS ON ATHEISTIC PREJUDICE** Megan K. Johnson<sup>1</sup>, Jordan LaBouff<sup>1</sup>, Wade C. Rowatt<sup>1</sup>; <sup>1</sup>Baylor University – The sparse amount of literature on religion and its effect on attitudes towards atheists demonstrates that various measures of religiosity are associated with prejudice towards atheists. Despite the strong prejudice religious individuals hold against atheists, this area of prejudice has been largely ignored by the field of social psychology. While some studies have examined how manipulating religion via priming methods influences various social attitudes and behaviors such as cheating and prosocial behavior, the effects of priming religion on attitudes towards derogated out-groups - specifically atheists - have not been examined. This study investigated the effect of priming individuals with religion words on ratings of atheists relative to Christians. Participants who were subliminally primed with religious words reported significantly more negative attitudes towards atheists relative to Christians than those who were primed with control words. These effects persisted even when controlling for right-wing authoritarianism (RWA), a measure strongly associated with various types of prejudice. In examining what drove this result, we found that priming individuals with religion words both increased the ratings of Christians and decreased the ratings of atheists, making the relative measure (between Christians and atheists) significantly different between the religious and control conditions. These results, when examined in conjunction with results demonstrating that priming religion leads to an increase in prejudice towards African Americans and homosexuals (see Johnson, LaBouff, & Rowatt, in prep.), indicate that priming religion may lead to an increase in in-group favoritism and out-group derogation.

### A221

**RACISM, SEXISM, AND IDEOLOGY IN VOTE CHOICE DURING THE 2008 DEMOCRATIC PRIMARIES** Elizabeth R. Salib<sup>1</sup>, Sean T. Stevens<sup>1</sup>, Florette Cohen<sup>2</sup>, Lee Jussim<sup>1</sup>, Sheldon Solomon<sup>3</sup>; <sup>1</sup>Rutgers University, <sup>2</sup>The College of Staten Island, <sup>3</sup>Skidmore College – The historic 2008 Democratic Primaries offered social psychologists a unique opportunity to investigate the impact of race and gender in American politics. Neither major political party had ever nominated an African-American or a woman as its presidential nominee, yet the frontrunners for Democrats were Barack Obama and Hillary Clinton. Symbolic racism argues that American politics are primarily divided along racial lines and that African-American candidates are at a significant disadvantage. Women candidates do not face this disadvantage since politics is not divided over gender issues. Yet, other research suggests that political ideology is the main source of division in American politics and consistently the best predictor of candidate

evaluation and vote choice, particularly in Presidential elections. The current study was designed to test these competing hypotheses and investigate whether symbolic racism or ideology had a greater impact in the Democratic Primaries. Participants were randomly placed in one of two conditions (Obama or Clinton) in the week prior to the New Jersey Primary. Excerpts from victory speeches (South Carolina for Obama; Florida for Clinton) were presented followed by questions evaluating the candidate and a likelihood of vote measure. Symbolic racism, sexism, ideology, and party affiliation were also measured. Ideology emerged as the best predictor of candidate evaluation and vote choice in both conditions. Sexism did not significantly impact Clinton and consistent with symbolic racism theories, racism did indeed reduce support for Obama. Much of this influence, however, occurred indirectly; conservatism mediated much of the effect of racism on support for Obama.

### A222

**STIGMA ACKNOWLEDGEMENT: DIFFERENTIAL OUTCOMES FOR VISIBLE AND INVISIBLE STIGMAS** Jeffrey A Goodman<sup>1</sup>, Susan Darling<sup>2</sup>, Scott Eidelman<sup>3</sup>; <sup>1</sup>University of Wisconsin-Eau Claire, <sup>2</sup>University of Maine, <sup>3</sup>University of Arkansas – Acknowledgment of a visible and uncontrollable stigma during social interaction leads to more positive evaluations of stigmatized individuals (e.g., Hastorf, Wildfogel, & Cassman, 1979; Hebl & Kleck, 2002), yet relatively little is known about disclosure of an invisible stigma. Our research considers benefits and costs of acknowledgment/disclosure by targets with visible and invisible uncontrollable stigmas. In a study on "forming first impressions," participants were led to believe they were interacting with another student (in reality a confederate). The participant and confederate exchanged personal information and a photograph. For some, the photo depicted a confederate with facial scars; for others the confederate did not have scars. In addition, half of the participants also received acknowledgment information from the confederate including mention of his scars, their cause (a non-contagious genetic disorder), and an indication that he was comfortable talking about his stigma. Consistent with previous research, acknowledgment of a visible stigma lead to more positive interaction expectations and more favorable impressions of the stigmatized individual. Conversely, disclosure of an invisible stigma led to less positive interaction expectations and less favorable impressions. Interaction expectations partially mediated the effects of the Visibility by Disclosure interaction on impressions of the target. These findings suggest that while acknowledgment of a visible stigma can be an effective social strategy, the disclosure of an invisible stigma entails costs.

### A223

**YOU'RE GOOD FOR A GIRL: SHIFTING STANDARDS AS SUBTLE SEXISM** Jill Wagaman<sup>1</sup>, Jessi L. Smith<sup>2</sup>; <sup>1</sup>University of Nebraska- Lincoln, <sup>2</sup>Montana State University – Women athletes were recruited to investigate the experience of 'shifting standards.' Shifting standards occurs when people use stereotypes to make a relative judgment about performance or behavior. Whereas past research has examined shifting standards from the perceiver's perspective, the current project investigates shifting standards from the target's perspective. To inform our hypotheses, we relied on stereotype threat literature (Stone et al., 1999) and the motivational model for stereotyped tasks (Smith, Sansone & White, 2007). Using athletics as the stereotyped domain, highly-identified college and community women athletes were recruited using a pre-screen questionnaire. Participants (n = 77, 15.6% community) were then blocked on stigma consciousness (SC) as a woman athlete, resulting in a 2 (SC: high, low) x 3 (feedback: positive, shifting standards, no feedback) between-subjects design. After first engaging in an ambiguous athletic test, participants received the feedback manipulation. Then, a second unambiguous test was administered to measure performance, and participants completed post-test measures assessing intrinsic motivation. Stigma consciousness moderated the effect of feedback on performance and motivation. Women high in SC receiving shifting standards feedback showed significantly higher gender stereotype activation, lower performance, and lower interest compared to women high in SC receiving positive feed-

back (all  $p$ 's < .05). In addition, compared to women low in SC, women high in SC showed significantly higher gender stereotype activation ( $p < .05$ ), somewhat lower performance ( $p = .066$ ) and lower interest ( $p < .05$ ) when receiving shifting standard feedback. Theoretical and practical implications for the experience of shifting standards are discussed.

#### A224

##### **THE PRESENCE OF A BLACK FEMALE AMPLIFIES KILLING IN MALES**

Lydia Eckstein Jackson<sup>1</sup>, Lowell Gaertner<sup>1</sup>, <sup>1</sup>University of Tennessee – Utilizing a bug killing paradigm (Martens et al., 2007), we intended to manipulate different mechanisms of moral disengagement (Bandura, 1999) to assess their effects on killing across four experiments (N=329). After experiencing a given disengagement manipulation, participants could purportedly kill 0 to 20 bugs. Unanticipated and unrelated to the manipulations, sex and race of the experimenter affected the extent to which male (but not female) participants killed bugs. Male participants (the vast majority of whom were white) killed significantly more bugs after interacting with a black female experimenter ( $M = 12.69$ ) than after interacting with either a white female ( $M = 7.17$ ) or a white male experimenter ( $M = 8.72$ ). Although unpredicted, this finding is provocative in that it suggests that race (at least for males) increases willingness to kill in a context and toward a target that is apparently unrelated to race and has the markings of displaced aggression (Marcus-Newhall et al., 2000) engendered by either explicit or implicit prejudices.

#### A225

##### **IMPLICIT AND EXPLICIT MOTIVATION TO CONTROL PREJUDICE AND THEIR RELATIONS TO SELF-ESTEEM**

Elizabeth Mokyr<sup>1</sup>, Jack Glaser<sup>1</sup>, Sang Hee Park<sup>2</sup>, <sup>1</sup>University of California, Berkeley, <sup>2</sup>Indiana University – This poster reports new research on implicit motivations, specifically, an Implicit Motivation to Control Prejudice (IMCP). People high in IMCP are relatively effective at controlling spontaneous discriminatory behavior (Glaser & Knowles, 2008). In this most recent study, we develop an explicit analogue for IMCP, dubbed Explicit Motivation to Control Prejudice (EMCP). In addition, we begin to explore the role of self-esteem in these implicit and explicit motivations. IMCP is measured through reaction times and EMCP is measured through a questionnaire. IMCP and EMCP are both calculated as the product of two associations [Negative Attitude toward Prejudice (NAP) and Belief that Oneself is Prejudiced (BOP)]. Previous studies of IMCP revealed a weak negative relationship between NAP and BOP. We hypothesized that this relationship might be moderated by self-esteem, as being high in NAP and BOP requires associating oneself with a trait one finds undesirable, while being high in one and low in the other might actually promote or buffer self-esteem. When tested through implicit associations, we found no evidence that self-esteem moderated the NAP-BOP relation. However, when measured explicitly, the inverse NAP-BOP relationship was quite robust ( $\beta = -.047$ ,  $p = .000$ ), and the strength of the relationship appears to have been partially explained by self-esteem. Further, the finding that implicit and explicit measurements have different properties and predictive values indicates discriminant validity and a need for concurrent exploration.

#### A226

##### **STIGMA ACKNOWLEDGEMENT IN GRADUATE APPLICATIONS: TOO PERSONAL FOR THE PERSONAL STATEMENT?**

Jennifer L. Wessel<sup>1</sup>, Nao Hagiwara<sup>1</sup>, Ann Marie Ryan<sup>1</sup>, <sup>1</sup>Michigan State University – Individuals may decide not to acknowledge their stigmas in certain situations for fear of discrimination and/or social disapproval. However, non-acknowledgement of stigmas can lead to negative inter- and intra-personal outcomes due to constant, effortful self-monitoring around others, leaving individuals with stigmas in a difficult situation where they have to decide whether they should or should not acknowledge aspects of their identities. In this study, we examine the antecedents of stigma acknowledgement in the graduate school application context, adapting Ragins's (2008) model of stigma disclosure, which proposed that characteristics of the stigma, individual, and environment significantly relate to acknowledgment decisions, mediated through perceived costs of acknowledging.

Ninety-two participants applying to six graduate programs completed a web-based survey concerning stigma acknowledgement decisions in the personal statement portion of the graduate application. Hierarchical linear modeling (HLM) revealed that having heard of another's positive acknowledgement experience significantly related to stigma acknowledgement ( $b = 1.97$ ,  $p < .05$ ), mediated through perceived social costs of acknowledgement. Among non-acknowledgers, perceived stigma visibility and controllability significantly interacted ( $b = .85$ ,  $p < .01$ ), such that individuals with stigmas perceived as highly visible were more likely to have future acknowledgement plans when their stigmas were also perceived as low in controllability, as compared to high in controllability. These results support the importance of social costs and stigma-related characteristics (i.e. visibility and controllability) in present and future acknowledgement decisions. Furthermore, results suggest that students' stigma-related experiences during the application process may indirectly influence acknowledgement decisions of future graduate applicants.

#### A227

##### **REDUCING HOMOPHOBIA WITH A SINGLE TOUCH**

Erin Devers<sup>1</sup>, Ann-Elise Bryant<sup>1</sup>, <sup>1</sup>Gordon College – It has long been documented that men engage in less same-sex touch than women and that this difference can be accounted for by the higher levels of homophobia documented among men (Roese, Olson, Borenstein, & Martin, 1992; Floyd, 2000). This experiment tests the hypothesis that same-sex touch between men increases comfort in viewing homosexual behavior and reduces homophobia. While participants engaged in an unrelated task, a male or female experimenter either touched or did not touch the participant on the shoulder when complimenting their work. Next participants viewed a series of pictures displaying affectionate behavior and were asked to rate how comfortable they were with each picture. Then participants completed the Homosexuality Attitude Scale (Kite & Deaux, 1986). Results replicate previous findings that men ( $M = 60.52$ ) report more homophobia than women ( $M = 54.61$ ),  $t(91) = 2.36$ ,  $p < .05$ . More interestingly, men who are touched are touched by a male experimenter report more comfort with viewing homosexual behavior ( $M = 100.13$ ) than men who are not touched by a male experimenter ( $M = 77.73$ ),  $t(26) = 2.73$ ,  $p = .01$ . Likewise, men who are touched by a male experimenter report less negative attitudes toward homosexuality ( $M = 53.31$ ) than those who are not touched ( $M = 63.50$ ),  $t(26) = 2.56$ ,  $p = .02$ . No significant results emerge for women who are touched by a female experimenter, which is consistent with research suggesting that women touch more frequently and report less homophobia than men. Taken together, the results suggest that increased frequency of touch between men can reduce homophobia.

#### A228

##### **BUT ISN'T THAT WHAT THEY'RE FOR? SEXISM AND THE SEXUALLY OBJECTIFIED MATERNAL BREAST**

Kristin E. Hawkinson<sup>1</sup>, Jessi L. Smith<sup>1</sup>, <sup>1</sup>Montana State University – Women's reproductive capacity often serves as a threatening cue of inferiority engendering sexism (Cox et al., 2007; Hebl et al., 2007). Our own past research confirms this finding, whereby a perceived breastfeeding mother was viewed as less competent than a bottlefeeding mother. We hypothesized that this sexism may be due to the objectification of the breast (Fredrickson & Roberts, 1997; Johnston-Robledo et al., 2007) and the norms that render motherhood and sexuality orthogonal (Friedman et al., 1998; Sterns, 1999). We tested this hypothesis in two phases. First, participants ( $n = 62$ , 68% female) evaluated a series of advertisements, one of which depicted a woman endorsing nipple cream with a randomly assigned use: for nursing mothers' sore nipples (breastfeeding condition); for joggers' chafed nipples (non-sexualized condition); or to refresh nipples for intimate relations (sexualized condition). ANOVA results showed the woman endorsing the breastfeeding and sexualized creams were rated as significantly less capable and intelligent than the endorser of the nonsexualized cream ( $p$ 's < .05). In phase two, participants wrote about the "day-in-the-life" of the endorser in the advertisement before rating their own math ability

(Galinsky et al., 2008). Results showed taking the perspective of either the breastfeeding or sexualized endorser led people to rate themselves as significantly less good at math compared to the non-sexualized endorser ( $p's < .05$ ), suggesting assimilation to feminine stereotypes. Findings support our hypothesis that it is the sexual nature of the objectified breasts that result in sexism against mothers who breastfeed. Implications for actual breastfeeding mothers are discussed.

**A229**

**EXAMINING THE CULTURAL STEREOTYPE OF ATHEISTS** Julie A. Woodzicka<sup>1</sup>, Benjamin W. Mooneyham<sup>1</sup>, Emily F. Coyle<sup>1</sup>, Kelly L. Harrison<sup>1</sup>, <sup>1</sup>Washington and Lee University – A 2003 Gallup poll found that 10.6% of American adults identified with no religion, atheist, or agnostic. Despite that fact that more than 10% of Americans self-identify as nonreligious, little psychological research has focused on perceptions of this group. The present study examined the content and favorability of the cultural stereotype of Atheists, along with participants' personal beliefs regarding Atheists. Christians were included as a comparison group. Eighty one participants (64% female, 56% self-identified as "Religious") completed measures of Christian Orthodoxy and Religion as Quest. Cultural stereotypes and personal beliefs were assessed using Devine and Elliott's (1995) methodology. Participants were asked to use a list of 161 adjectives to identify the cultural stereotypes and their personal beliefs about Atheists and Christians. A diffuse, slightly unfavorable stereotype of Atheists was found; personal beliefs regarding Atheists were equally diffuse, but significantly more favorable. The Atheist cultural stereotype was found to be significantly less favorable than the Christian cultural stereotype. In addition, participants scoring low on Christian Orthodoxy generated a more negative cultural stereotype, but reported more positive personal beliefs, than those scoring high on Christian Orthodoxy. Religion as Quest did not predict favorability of the Atheist stereotype or personal beliefs about Atheists. Education level and age were both positively correlated with favorable personal beliefs about Atheists, but not with a favorable stereotype. These results support research that suggests Atheists are targeted based on their group membership.

**A230**

**THINKING ABOUT RACE AND CLASS, BUT NOT AFFIRMATIVE ACTION: DO OUR IMPRESSIONS SHIFT WHEN PREFERENTIAL SELECTION IS OUT OF THE PICTURE?** Jonathan Iuzzini<sup>1</sup>, Morgan Hopkins<sup>1</sup>, Madeleine Fugère<sup>2</sup>, Amy Nadel<sup>1</sup>, Katherine Mancuso<sup>1</sup>; <sup>1</sup>Hobart and William Smith Colleges, <sup>2</sup>Eastern Connecticut State University – Our previous research has demonstrated that the preferential selection stigma is typically applied to Black affirmative action beneficiaries but not to White legacy beneficiaries. In the present research we did not include this manipulation, so that we could test the hypothesis that people would be less likely to express negative attitudes about people from disadvantaged backgrounds without this socially acceptable way (i.e., the affirmative action stigma) of doing so. The present study also explores the extent to which modern racism, social dominance orientation, and color-blind racial attitudes influence perceptions of college applicants of various race and class backgrounds. White participants provided ratings of a college applicant using information provided on a mock Common Application. We manipulated the applicant's race (White vs. African American) and socioeconomic status (high vs. low), but held qualifications (GPA, SAT scores) constant. Participants also completed measures of modern racism, social dominance orientation, and color-blind racial attitudes. Participants provided consistently higher ratings of intelligence, work ethic, and competence for African American applicants (regardless of socioeconomic class) than for White applicants. This pattern was especially strong among participants with lower scores on modern racism, social dominance orientation, and color-blind racial attitudes, who seem to be attempting to overcompensate in their ratings of African American applicants. These data lend further support to the notion that affirmative action may serve as a "socially acceptable" outlet for the expression of racial prejudice, and that in other contexts individuals may inflate their perceptions of people from disadvantaged backgrounds to avoid appearing prejudiced.

**A231****RACIST AND GRUMPY? GLOBAL NEGATIVITY IN MODERN RACISTS**

Paul B. Hutchings<sup>1</sup>, Geoffrey Haddock<sup>2</sup>; <sup>1</sup>Swansea Metropolitan University, <sup>2</sup>Cardiff University – The current study examines whether individual differences in prejudice influence participants' level of arousal upon viewing in-group and out-group faces, measured by utilising a temporal perception paradigm (Droit-Volet et al., 2004). Participants were trained to respond to short (400ms) and long (1600ms) presentations of a neutral stimulus before being presented with Black and White target faces displaying happy, angry, sad, and neutral emotions for varying lengths of time (between 400ms and 1600ms). Participants' task was to report each presentation as short or long, with overestimation of emotion displays compared to neutral displays indicating increased arousal (see Droit-Volet et al., 2004). Measures of implicit and explicit prejudice were also taken and, using a dual-process model of prejudice (see Son-Hing et al., 2008), it was found that participants high in explicit prejudice (modern racists and principled conservatives) showed greater arousal for in-group displays of anger and sadness and out-group anger. However, these two groups diverged when viewing out-group happiness, with only principled conservatives showing arousal for this display. Furthermore, truly low prejudiced individuals (those scoring low on implicit and explicit measures) exhibited little arousal for any displays of emotion. These findings suggest that people with differing levels of implicit and explicit prejudice may be aroused by different displays of emotion displayed by in-group and out-group members. In particular, modern racists might be 'tuned in' to negative emotions that may be felt to threaten their state of well-being, but remain unaffected by emotion displays that will not impact upon them.

**A232****CAUSAL UNCERTAINTY AND STEREOTYPING: INVESTIGATING THE UNDERLYING COGNITIVE PROCESSES**

Kristen I. Capuozzo<sup>1</sup>, Stephanie J. Tobin<sup>1</sup>; <sup>1</sup>University of Houston – Causal uncertainty (CU), an individual's doubts about understanding the causes of events in the social world, affects the extent to which that individual will make stereotypic judgments (Weary, Jacobson, Edwards, & Tobin, 2001). This study investigated whether CU is associated with unique underlying cognitive processing styles that may explain this effect. Because of their greater motivation for accuracy (Weary & Edwards, 1996), high CU individuals were predicted to show greater relative right hemispheric activation (Bourgeois, Christman, & Horowitz, 1998) and a local processing bias. A scrambled sentence task was used to prime participants with high or low CU (Wichman, Brunner, & Weary, 2008). They then completed one of two (randomized) cognitive processing measures. The line-bisection task measured individuals' left or right-side bias in perception thereby indicating relative hemispheric activation. The Navon (Navon, 1977) task measured individuals' global or local bias in perception, thereby indicating a preference for general or detailed stimuli. Participants next read an impression formation scenario about a student in a stereotyped or non-stereotyped category and rated his typicality. Participants then completed the second cognitive processing measure. Individuals primed with high (versus low) CU found the stereotyped category student less typical, indicating a reduced use of stereotypes. More importantly, high CU primed participants showed significant left-side bias on the line-bisection task, indicating relative right hemispheric activation. These individuals also evidenced a local processing bias on the Navon task, indicating a preference for detail. These results reveal a new and interesting connection between CU and differential cognitive processing styles.

**A233**

**STIGMA AND PREJUDICE CONFRONTATION: PERCEIVED STIGMA CONTROLLABILITY MODERATES DEEMING PREJUDICE URGENT AND WORTHY OF CONFRONTATION** Cheyenne M. Dunbar<sup>1</sup>, Sisi Yu<sup>2</sup>, Stephanie A. Goodwin<sup>2</sup>, Leslie Ashburn-Nardo<sup>3</sup>, Kathryn A. Morris<sup>4</sup>; <sup>1</sup>San Diego State University, <sup>2</sup>Purdue University, <sup>3</sup>Indiana University-Purdue University Indianapolis, <sup>4</sup>Butler University – According to the CPR Model (Goodwin et al., 2009), people are unlikely to confront prejudice that is perceived insufficiently urgent. We explored whether perceiving stigmas to be controllable undermines perceptions that prejudice is harmful, unjust, and urgent, with implications for whether confrontation is deemed necessary. Across two studies, male and female participants (Ps) read scenarios wherein actors expressed prejudice about either homosexual men (Study 1; N=262), or someone with a mental illness (Study 2; N=71) perceived to be low (schizophrenia) vs. high (addiction) in perceived controllability. Ps reported perceptions of the comment, interest in confronting, and perceived controllability of the stigma. Results from both studies support our hypotheses. In Study 1, perceptions that homosexuality was a personal choice (i.e., controllable rather than biologically determined) were negatively related to perceiving hostile anti-gay prejudice to be harmful ( $r=.26$ ), urgent ( $r=.47$ ) and to reported interest in confronting ( $r=.38$ ), all  $ps<.05$ . In Study 2, schizophrenia was rated less controllable and, in turn, anti-schizophrenic prejudice was perceived more harmful, unjust, and urgent than anti-addiction prejudice (all  $ps<.05$ ). Importantly, perceived harm, injustice, and urgency positively predicted interest in confronting both prejudices (all  $ps<.01$ ). Together, these data suggest that lay theories about stigma controllability may promote blaming the stigmatized for experiencing prejudice, in turn influencing whether people contemplate confronting prejudice when it occurs. Implications for prejudice reduction are discussed.

**A234**

**SUCCESSION, IDENTITY, AND CONSUMPTION: DIMENSIONS OF CONTROL IN AGE-BASED PREJUDICE** Michael S. North<sup>1</sup>, Susan T. Fiske<sup>1</sup>; <sup>1</sup>Princeton University – Despite the salience of age in interpersonal judgments, age-based prejudice research has paled in comparison to racism and sexism. Moreover, theoretical explanations have been limited. A novel theory of age-based prejudice takes into account the ambivalent nature of ageist stereotypes, the uniquely intergenerational nature of ageism, and the impact of societal structure in fostering age-based resentment. We posit three dimensions of prescriptive, interdependence-oriented biases, whereby younger people are motivated to maintain the low-status image of older people, while maintaining and improving their own social standing. The first dimension, Succession, represents resentment for older people's active control of enviable resources (wealth, prestige). The second, Identity, aims to keep older people away from activities and roles reserved for the young (computers, nightclubs). The last, Consumption, resents older people's passive depletion of shared resources (public space, government funding). Tests of SIC theory used separate vignette studies, one for each SIC dimension. Studies utilized a 2x2 design, whereby the age of the vignette character described (24 or 71) and his behavior (adhering to vs. violating one of the SIC prescriptions) were manipulated. In all studies, as expected, younger participants (30 and under) viewed the SIC-violating older man more negatively than the SIC-adhering older man, whereas the same behaviors made no difference in reactions to the young character. This suggests that the SIC prescriptions are indeed unique to older people. These preliminary data promise initial support of our SIC framework in attempting a more robust conceptualization of ageism.

**A235**

**EFFECTS OF CONSTRUAL LEVEL MINDSET ON STEREOTYPING OF SELF AND OTHERS** Sean McCrea<sup>1</sup>, Frank Wieber<sup>1</sup>, Andrea Myers<sup>1</sup>; <sup>1</sup>University of Konstanz – Construal level theory suggests that objects can be represented at differing levels of abstraction. High-level representations involve consideration of superordinate goals and broad categorizations,

whereas low-level representations involve consideration of subordinate goals and narrow categorizations. Social targets (including the self) can be represented as individuals or more broadly as members of a group. Because levels of construal tend to be associated, placing individuals into relatively more abstract mindsets via an unrelated task should encourage group-level representations of social targets. In Study 1, male participants were asked to consider how (concrete mindset) or why (abstract mindset) they would try to maintain important friendships. They were then asked to evaluate equivalent male and female applicants for a stereotypically masculine job (software programmer). As expected, participants more positively evaluated the male than the female candidate in the abstract (why) mindset condition, but not in the concrete (how) mindset condition. In three subsequent studies, individuals provided their gender following the construal level manipulation. As predicted, men rated themselves more stereotypically masculine, and women rated themselves more stereotypically feminine, when placed into an abstract compared to a concrete mindset. Moreover, these effects were obtained regardless of whether the construal level manipulation involved maintaining friendships or health. Finally, men also outperformed women on a math test when placed into an abstract mindset, but not when placed into a concrete mindset. In summary, placing individuals into a more abstract mindset leads to increased stereotyping of others, as well as greater self-stereotyping in trait ratings and performance.

**A236**

**THE IMPACT OF SOCIAL ROLES ON GENDER STEREOTYPING: A CROSS-CULTURAL COMPARISON OF GERMANY AND JAPAN** Janina F. Steinmetz<sup>1</sup>, Janine Bosak<sup>2</sup>, Sabine Sczesny<sup>3</sup>, Alice H. Eagly<sup>4</sup>; <sup>1</sup>University of Heidelberg/Germany, <sup>2</sup>Dublin City University/Ireland, <sup>3</sup>University of Bern/Switzerland, <sup>4</sup>Northwestern University/USA – Social-role-theory postulates that gender stereotypes are not applied in judgments if men and women occupy the same role (Eagly, 1987). Instead, the shifting-standards-model (Biernat, 2003) proposes that people tend to judge men and women by within-sex standards on subjective scales which might mask sex differences. Moreover, culturally determined gender-role-attitudes might moderate the influence of social roles on stereotype reduction. To test these assumptions, 288 participants (144 Japanese, 144 Germans) evaluated a male or female target described in a male-dominated role, a female-dominated role or without role information regarding communal and agentic attributes. Participants responded on subjective rating scales that allow for standard shifts and on common rule measures that restrain these. For agency, on subjective scales, participants in both countries evaluated men as more agentic than women if no role information was given and judged men and women in the same role as similarly agentic. On common rule scales, no sex difference emerged in both countries. For communion, on subjective scales, German participants evaluated women and men in female-dominated roles as similarly communal, but judged women as more communal than men without role information and in male-dominated roles. Japanese participants perceived men and women as similarly communal. On common rule measures, German participants judged men and women described without role information or in male-dominated roles as similarly communal, whereas Japanese participants judged women as more communal than men without role information. On agency, the results support social-role-theory in both cultures. On communion, shifting standards were evident in the German sample.

**A237**

**COMPLAINING ABOUT A COMPLIMENT? EVALUATING ATTRIBUTIONS OF POSITIVE OUTCOMES TO DISCRIMINATION** Kate J. Diebels<sup>1</sup>, Alexander M. Czopp<sup>1</sup>; <sup>1</sup>Western Washington University – Attributing a negative outcome to discrimination can allow a stigmatized individual to maintain self-esteem (Crocker, Voelkl, Testa, & Major, 1991). However, Kaiser and Miller (2001) have suggested that there may be social costs that weigh against the protective benefits for the individual making this attribution. Specifically, they found that participants evaluated an African American target who attributed a failing test grade to discrimination less favorably

and as more of a complainer than when he attributed the outcome to answer quality or test difficulty. This was true regardless of the objective likelihood that discrimination occurred. The present study examined whether similar social costs exist for a stigmatized individual who attributes a positive outcome to discrimination in the context of positive stereotypes. Positive stereotypes are evaluatively favorable and are less recognized as forms of prejudice and might render perceptions of an attribution to discrimination as inappropriate or invalid. One hundred and twenty-nine participants read an excerpt of an Asian student who attributed an unexpectedly high essay grade to discrimination, writing quality, or easy grading. Participants evaluated the student less favorably and as more hypersensitive when he attributed the positive outcome to discrimination compared to when he attributed the outcome to writing quality or easy grading. Implications for claiming and confronting discrimination in the context of positive stereotypes are discussed.

### A238

#### STEREOTYPE THREAT: INDIVIDUAL DIFFERENCES IN SELF-MONITORING, ANXIETY, AND PERCEPTION OF BARRIERS

Farrah Anne Pompilus<sup>1</sup>;

<sup>1</sup>University of North Florida – Stereotype threat is a process whereby individuals threatened by a stereotype relating to their target group cause poor performance in a relevant situation because of the fear of confirming that negative stereotype. The current study investigated the effect of stereotype threat on cognitive performance across African Americans, European Americans, and Other minorities (N = 422). The study also examined if performance variations were caused by individual differences in participants' self-monitoring, anxiety, and perception of barriers. Contrary to the hypotheses, results indicated African Americans performed better in a stereotype threat condition than African American in a no stereotype threat condition. In the no stereotype threat condition European Americans performed better than African Americans. Individual differences in self-monitoring did not predict performance; however, test anxiety and perception of barriers had significant effects under various conditions. Plausible explanations for increased performance among the target group were discussed.

### A239

#### RACE AND GENDER ACKNOWLEDGMENT IN THE PRESIDENTIAL ELECTION 2008: WHEN DID A STIGMA ACKNOWLEDGMENT HURT OR BENEFIT THE CANDIDATES?

Nao Hagiwara<sup>1</sup>, Jennifer L. Wessel<sup>1</sup>, Ann Marie Ryan<sup>1</sup>; <sup>1</sup>Michigan State University – Acknowledging one's stigma in evaluative contexts leads to positive consequences, such that it reduces interaction strains between individuals with and without stigmas, reduces perceptions of stereotypes associated with stigmas, and leads to favorable evaluations of acknowledgers. However, recent studies have shown that stigma acknowledgment can also increase negative evaluations of acknowledgers. In the present study, we examined the moderating effect of evaluators' attitudes toward the social group to which acknowledgers belong in the context of race and gender acknowledgements in the 2008 U.S. Presidential election. Participants who had previously completed the Attitudes toward Blacks Scale, Ambivalent Sexism Inventory, and a measure of attitudes toward Obama and Palin watched experimentally manipulated speeches (i.e., Obama and Palin either did or did not acknowledge their stigmatized identities). Participants were then asked to report their feelings toward each candidate. All responses were collected before the actual election. When Obama acknowledged his race, White voters felt less positive about him as compared to when he did not acknowledge his race. Furthermore, voters' attitudes toward Blacks moderated the effects of race acknowledgment, such that high-prejudiced White voters, as compared to low-prejudiced voters, reported that Obama made them feel less positive when he acknowledged his race. In contrast, low- and high-prejudiced White voters felt the same toward Obama when he did not acknowledge his race. In contrast, Palin's gender acknowledgement did not have any effects on male voters. Our findings highlight the importance of a person x situation approach in examining the effects of stigma acknowledgment.

### A240

#### STEREOTYPES OF WARMTH BUT NOT COMPETENCE EMERGE AS JUSTIFICATIONS OF PREJUDICE

Angela Nierman<sup>1</sup>, Christian Crandall<sup>1</sup>;

<sup>1</sup>University of Kansas – The Justification-Suppression model of prejudice (Crandall & Eshleman, 2003) argues that stereotypes serve as justifications of prejudice. We investigated whether all negative stereotypes serve as equally valid justifications for prejudice, or whether stereotypes related to a particular domain of social judgment (warmth or competence) are more suitable as justifications. We experimentally created affective associations toward two unfamiliar target groups and then measured stereotype traits in the domains of warmth and competence (Fiske, Cuddy, & Glick, 2007). We used a supraliminal affective conditioning paradigm adapted from Olson and Fazio (2001, 2002). Eritrea and Mauritania were used as target groups. Negative and positive pictures and words were used as unconditioned stimuli. When a country was paired with negative-affect stimuli, its inhabitants were stereotyped as lower in warmth, compared to the inhabitants of the country paired with positive-affect stimuli. No such effect was found on perceived competence. We found that stereotypes with specific content – traits associated with a lack of warmth – develop to make sense of a newly formed negative affective association. These findings are consistent with research that suggests warmth is the most primary dimension in person perception (Kelly, 1950; Yzerbyt et al., 1997). Information about a group's warmth carries with it unambiguous behavioral implications (approach vs. avoidance), whereas information about a group's competence may depend on other contextual factors such as whether or not the group is an ally or an enemy. In the absence of any real knowledge about a target group, warmth-related stereotypes are used to justify negative affective reactions.

### A241

#### A CROSS-CULTURAL INVESTIGATION OF MINORITY CHILDREN'S ATTITUDES TOWARDS RACIAL OUTGROUPS: EXAMINING THE IMPACT OF GROUP STATUS AND PROXIMITY

Amanda Williams<sup>1</sup>, Elaine Tay<sup>1</sup>, Jennifer

Steele<sup>1</sup>; <sup>1</sup>York University – A great deal of theory and research has examined explicit racial prejudice among predominantly White children (see Quintana & McKown, 2008 for a review), however far less research has examined the emergence and universality of implicit racial biases, particularly among minority children (c.f., Dunham, et al., 2007). Research conducted to date, which has focused almost exclusively on children's attitudes towards a racial outgroups relative to their own racial ingroup, supports the intriguing possibility that, at least from middle childhood, children's implicit racial attitudes reflect knowledge of status differences between groups. In the current research, using a child-friendly IAT we examined the emergence of implicit racial biases towards the racial outgroups of "White" and "Black" among minority children who were not members of either of these groups. Participants included children of East and Southeast Asian descent living in a racially diverse area in Canada (Study 1) and Chinese children and adults living in an urban center in Brunei (Study 2). Results indicate that minority children in both settings displayed a relative pro-White bias (Canada:  $D = .12$ ,  $SD = .39$ ,  $t(48) = 2.19$ ,  $p = .03$ , Brunei:  $D = .24$ ,  $SD = .40$ ,  $t(19) = 2.71$ ,  $p = .014$ ), however in line with a social-cognitive-developmental model of prejudice, this was more pronounced among younger (4- to 7-year-old) compared to older (9-year-old) children. These results support the possibility that implicit preferences for higher status groups emerge quite early in life, but also suggest greater development-based malleability than was previously thought.

### A242

#### STEREOTYPE THREAT IN THE EYES OF OTHERS: THE EFFECTS OF GAZE CUES ON WOMEN'S MATH IDENTITIES

Yusuke Karouji<sup>1</sup>, Takashi Kusumi<sup>1</sup>;

<sup>1</sup>Kyoto University – This research examined whether nonverbal cues signaling evaluation (i.e. gaze cues) could induce the stereotype threat. Stereotype threat is thought to be evaluation apprehension that one could behave in such a way as to confirm negative stereotypes in the eyes of

others, which induces negative thinking about one's own abilities. Two experiments demonstrated that women's negative math identities (e.g., I am not good at math) were activated "in the eyes of others". Thirty-two female undergraduates (Experiment 1) and 24 female undergraduates and graduates majoring in science-related domains (Experiment 2) completed two Implicit Association Tests (IAT): the math identity IAT (self-math) and the stereotype IAT (gender-math). All the while participants completed the math identity IAT, a schematic face either with a direct gaze or an averted gaze was presented at the bottom of the screen. In two experiments, the participants showed weaker math identities in the direct gaze condition than in the averted gaze condition. Moreover, a multiple regression analysis revealed that the participants who had stronger male-math stereotypes showed weaker math identities in the direct gaze condition, but not in the averted gaze condition (Experiment 1). In addition, the negative effects of direct gaze cues on women's math identities were obtained regardless of the social identity salience, which was manipulated by asking participants to indicate either their gender or major before the math identity IAT (Experiment 2). These results suggest that mere exposure to gaze cues can invoke stereotype threat. The effects of nonverbal cues on stereotype threat are discussed.

#### A243

**DECOMPOSING PREJUDICE: IDENTIFYING THE BASIS OF PERSONALITY-PREJUDICE RELATIONS** Nazar Akrami<sup>1</sup>, Bo Ekehammar<sup>1</sup>, Robin Bergh<sup>1</sup>; <sup>1</sup>Uppsala University – In two studies, aimed to examine the concept of generalized prejudice and the relationship between personality and prejudice, we found that attitudes toward various national and ethnic groups including a fictitious, an unknown, and a well-known group were significantly correlated (Study 1,  $N = 113$ ). In Study 2 ( $N = 861$ ), we found significant intercorrelations between four types of prejudice. More important, we made a theoretical and a statistical distinction between an abstract and a group-specific component of prejudice and found that personality variables explained a substantial proportion of the variance of the abstract part but a very small share of the group-specific component. The findings support the existence of a generalized prejudice tendency and a substantial relationship between personality and prejudice, and show that personality is related to prejudice at an abstract rather than specific level. The outcome is discussed in the light of the personality and social psychological explanations of prejudice.

#### A244

**RAISED EXPECTANCIES: AN INTERVENTION APPROACH FOR REDUCING STEREOTYPE THREAT** Harriet E.S. Rosenthal<sup>1</sup>, Emma L. Seddon<sup>1</sup>; <sup>1</sup>Durham University, UK – Previous research has established that performance expectancies are a potential mediator of stereotype threat (Cadinu, Maass, Frigerio, Impagliazzo & Latinotti, 2003; Rosenthal, Crisp, & Suen, 2007). An experiment was conducted to test whether an intervention method designed to increase performance expectancies could subsequently reduce stereotype threat. Male and female participants were given two math tests. Following the first math test participants received either a control (absence of threat), threat (informed genders would be compared), or intervention manipulation. The intervention manipulation consisted of informing participants that their performance on the previous math test was above average, before receiving the threat (informed genders would be compared). On the second math test, female participants were found to underperform in the threat condition compared to the control condition in line with stereotype threat. The performance for those in the intervention condition fell between that of participants in the control and threat conditions, suggesting that the intervention raised performance relative to the threat condition. Mediation and indirect effects for performance expectancies were supported. For men, some evidence for choking under pressure was found, suggesting that public expectations can have detrimental effects for positively stereotyped group members. The results offer preliminary support for raising expectancies as a potential intervention approach for reducing

stereotype threat, while also offering support to the hypothesis that choking under pressure occurs for public, but not private, expectations (Baumeister, Hamilton, & Tice, 1985; Cheryan & Bodenhausen, 2000).

#### A245

##### UNDERSTANDING INTERPERSONAL DIFFERENCES: PERCEPTIONS OF ETHNIC CATEGORIES IN RELATION TO ESSENTIALISM Saori

Tsukamoto<sup>1</sup>, Minoru Karasawa<sup>1</sup>; <sup>1</sup>Nagoya University – The present study examined the role that essentialist inferences play when ethnic categories are made salient. Past research revealed a tendency among lay people to apply their belief about intergroup difference in core essence in order to explain subtle interpersonal differences (e.g., Prentice & Miller, 2006). We investigated whether ethnic categories play such inductive roles. Japanese undergraduates participated in our experiment, ostensibly paired with an international student (i.e., confederate). Firstly, participants performed a dot estimation task individually and were given feedback about their own perceptual style. The similarity within each pair was manipulated by informing them that their styles were either the same or different. They were then asked to perform the dot estimation task again. After completing these tasks, participants were asked to estimate the prevalence of their own perceptual style among Japanese students (i.e., in-group) and among international students (out-group). They then rated to what extent they believed in essential characteristics of "Japanese". The results revealed Japanese participants' tendency to persist on the original perceptual style especially when their perceptual style was different from the international student's. They presumably inferred that essential differences of ethnicities caused the interpersonal perceptual differences. Furthermore, the strength of the belief in essence of being "Japanese" was correlated with the estimated difference between the groups in perceptual style. The role of lay essentialist beliefs in explaining disagreement between groups and its implications for the study of intergroup conflict are discussed.

#### A246

##### STEREOTYPE THREAT AND STEREOTYPE ACQUIESCENCE IN FEMALES' MATHEMATICAL PERFORMANCE Vincent Fogliati<sup>1</sup>, Kay Bussey<sup>1</sup>;

<sup>1</sup>Macquarie University – According to Steele and Aronson (1995), the salience of negative stereotypes leads to stereotype threat: the fear of confirming a negative stereotype as self-characteristic. This threat is suggested to produce anxiety that results in performance decrements. Despite much research demonstrating the effect of stereotype threat on performance, there is little direct empirical support for anxiety as a mediator of this effect. The present study examined whether some individuals acquiesce to, rather than attempt to disconfirm, self-relevant negative stereotypes. Also examined was the effect of a stereotype threat manipulation on within-group and between-group social comparisons. Female undergraduate psychology students ( $n = 130$ ) were told that they would perform a math test. Participants were allocated to either a stereotype condition or no-stereotype condition. Females in the stereotype condition reported lower performance expectancies and aspirations (relative to the expected performance of males), than did those in the no-stereotype condition. Females in the stereotype condition also showed more pre-test concern with their performance relative to other females than with their performance relative to males. Among females high in self-rated ability and low in gender identity, those in the stereotype condition performed significantly worse on the test than did those in the no stereotype condition. Finally, following completion of the test, females in the stereotype condition reported a greater interest in making within-gender comparisons than did females in the no stereotype condition. These results provide preliminary evidence that some individuals acquiesce to self-relevant stereotypes and compare their performance with other negatively-stereotyped individuals.

**A247****STIGMA SALIENCY AND PERCEPTION OF REJECTION AND ACCEPTANCE-RELATED FACIAL EXPRESSIONS**

Jennifer Guadagno<sup>1</sup>, Laura Richman<sup>1</sup>,  
<sup>1</sup>Duke University – Individuals are considered to be stigmatized if they are treated differently on the basis of a personal characteristic or belief such as their race, gender, or sexual orientation. Making stigmatized individuals aware of their stigmatized group membership has been found to evoke the threat of unfair treatment, which may lead to increased vigilance to potential signs of rejection and a decreased ability to notice social signs of acceptance. The purpose of the current study was to examine how stigmatized individuals process threatening and accepting social stimuli in their environment. Participants' stigmatized identity was made salient by having them write about an experience where they had been treated unfairly based on some aspect of their identity (Study 1) or participants were made to think they had been treated differently by a biased experimenter based on their university affiliation (Study 2). Participants viewed a short video clip of a male and female face that slowly morphed from a neutral expression to an expression of either contempt or acceptance and were asked to indicate when they first noticed the expression of contempt or acceptance appear on the faces. Across both studies, participants whose stigmatized status was made salient were slower to detect acceptance displayed by females compared to participants whose stigmatized status was not made salient. Stigmatized individuals whose stigmatized status was made salient did not show heightened attention to contemptuous expressions. These results suggest that when remembering or encountering incidents of discrimination, stigmatized individuals are slower to notice signs of social acceptance.

**A248****THE EFFECTS OF DIVERSITY GOALS ON STEREOTYPES, EMOTIONS AND BEHAVIORS TENDENCIES TOWARD OLDER WORKERS**

Caroline Iweins de Wavrans<sup>1</sup>, Donatienne Desmette<sup>1</sup>, Vincent Yzerbyt<sup>1</sup>,  
<sup>1</sup>Université Catholique de Louvain – Recent studies on stereotypes have investigated the fundamental dimensions of warmth and competence and the process of compensation that links them (i.e., a positive stereotype on one dimension is associated with an unflattering stereotype on the other). However, few empirical efforts analyse how social perceptions are influenced by their structural context and which are their emotional and behavioural consequences. Building on the Bias Map Model, we investigated this issue by manipulating the competence dimension via a personnel selection policy that focused either on diversity or on personal merit of an "older worker". Participants (n=66) responded to a questionnaire about an older target in one of two conditions (diversity vs. merit). We hypothesized that participants would perceive the target as less competent and, because of compensation, warmer in the diversity condition than in the merit condition. We also predicted more paternalistic emotions and cooperative behaviors under the promotion of diversity rather than merit. In line with predictions, competence was lower and paternalistic prejudice was stronger in the diversity condition than in the merit condition. Our study also lends some support to the BIAS Map Model regarding the pattern of emotions and behaviors related to stereotypes. As a set, our findings contribute to a better understanding of the processes linking social structural factors in real life settings on the one hand and perceptions and attitudes on the other.

**A249****SOCIETAL STEREOTYPES AND THE PERMISSIVENESS OF INTERGROUP BEHAVIORS: A TEST OF THE BIAS MAP**

Frank Asbrock<sup>1</sup>, Chris G. Sibley<sup>2</sup>,  
 Claire Nieuwoudt<sup>2</sup>, John Duckitt<sup>2</sup>,  
<sup>1</sup>Philipps-University of Marburg, Germany,  
<sup>2</sup>University of Auckland, New Zealand – Recent research indicates that specific intergroup behaviors are based on warmth and competence stereotypes (BIAS Map; Cuddy, Fiske, & Glick, 2008). In the present study we extended previous research and tested whether societal stereotypes of warmth and competence can also predict differences in the perceived permissiveness of behaviors directed toward stereotyped groups, i.e.,

the prescriptive normative function of warmth and competence for behavior. We tested our hypotheses in two community samples in New Zealand. A pilot study (N = 98) identified social groups that fit each of the four high-low warmth competence domains in the New Zealand context. In the main study (N = 103) participants indicated the permissiveness of active and passive harm and facilitation toward 16 groups. Here we applied Multilevel Random Coefficient Modeling as our strategy of analysis. As expected from the BIAS Map, we found that it is more acceptable to show more active facilitation toward warm and incompetent groups and less passive facilitation toward cold and incompetent groups. For harm, however, we detected linear rather than interactive effects of warmth and competence: it is more acceptable to show more active harm toward cold groups and competent groups, and more passive harm toward cold groups. For harmful behaviors this indicates noteworthy differences between the ways groups should be treated (prescriptive stereotypes) and groups actually are treated (descriptive stereotypes). Results strongly support the notion that the BIAS Map allows for predictions about the normative functions of fundamental stereotypes.

**A250****THE RELATIONSHIP OF RACIAL COLORBLINDNESS TO IMPLICIT AND EXPLICIT PREJUDICE**

Philip Mazzocco<sup>1</sup>,  
<sup>1</sup>Ohio State University at Mansfield – More and more Americans appear to support the principle of racial colorblindness. Though some have lauded this development as a harbinger of the end of racial conflict in America (e.g., Disouza, 1995), others believe that racial colorblindness is just the most recent instance of an ideology that systematically harms racial minorities (e.g., Bonilla-Silva, 2006; Carr, 1997). According to Bonilla-Silva (2000) a key component of racial colorblindness is its lack of association with affective racial prejudice. Instead, racial colorblindness is presumed to be based on rationalistic beliefs and value orientations. In the present study involving 72 white college students, a four-item measure of racial colorblindness (Mazzocco, 2009) was included alongside several measures of black prejudice; specifically, two measures of implicit prejudice, two measures of explicit old-fashioned prejudice, and two measures of modern prejudice (the modern and symbolic racism scales). Confirming Bonilla-Silva's presumption that racial colorblindness is not driven by affective prejudice, null correlations were found between the colorblind scale and all measures of implicit and old-fashioned prejudice ( $-.10 < r < .10$  for all). Despite these null correlations, the colorblind scale consistently predicted attitudes toward a variety of racial policy programs. The colorblind scale was found to be significantly correlated with both modern ( $r = .24$ ) and symbolic ( $r = .32$ ) prejudice, perhaps due to a similar set of value orientations underlying all three constructs. These findings have important implications regarding both the nature of racial colorblindness, and also how such an ideology might be undermined.

**A251****THE EFFECTS OF SOCIAL CLASS AND MONEY REMINDERS ON PERFORMANCE**

Sarah J. Gervais<sup>1</sup>,  
<sup>1</sup>University of Nebraska-Lincoln – This research examined how reminders of money and socioeconomic status (SES) affect emotions and cognitive performance for students from different social class backgrounds. Recent research shows that money reminders lead to perceptions of control and self-sufficiency (Vohs, Mead, & Goode, 2006). We argued, however, that students' responses to money may vary as function of their social class. To consider this possibility, we asked undergraduates (158 females, 63 males) to indicate their parents' income (SES prime), the money in their pocket (money prime) or the number of their siblings (control prime). Participants were then given 20 minutes to complete 25 word problems and asked to complete a 14-item money worry measure ( $\alpha = .70$ ). Consistent with predictions, a main effect of SES,  $F(1, 220) = 5.62$ ,  $p < .0043$ , revealed that low SES students were more worried about money ( $M = 2.83$ ,  $SD = .78$ ) than middle ( $M = 2.53$ ,  $SD = .86$ ) and high ( $M = 2.45$ ,  $SD = .74$ ) SES students and a significant SES X Prime interaction,  $F(1, 220) = 2.46$ ,  $p < .0468$ , revealed that low SES students were more worried about money when reminded of money or SES, than medium and high SES students. Somewhat ironically, how-

ever, a significant SES X Prime interaction,  $F(1, 220)=2.84$ ,  $p<.0253$ , further revealed that low SES students performed better when reminded of money or SES, whereas medium and high SES students performed worse. Money concerns also partially mediated the relationship between prime and performance for low SES participants. We discuss these findings in the context of ongoing research which examines the impact of social class and money on emotions, cognitive functioning, and social interactions.

#### A252

##### "I (DON'T) FEEL YOUR PAIN!": EFFECTS OF AUDIENCE RACE AND NEED TO BELONG ON REPORTS OF WHITE PRIVILEGE

Joshua D. Meadors<sup>1,2</sup>, AnGelica Alsbrooks<sup>2</sup>, Johanna Labadie<sup>2</sup>, Laurie O'Brien<sup>2</sup>; <sup>1</sup>University of California, Riverside, <sup>2</sup>Tulane University – Pervasive group inequality between White and Black Americans has traditionally been framed as Black disadvantage. Framing inequality as White privilege threatens Whites' collective self-worth and increases collective guilt, leading to a tendency to deny privilege (Lowery et al., 2007; Powell et al., 2005; Unzueta & Lowery, 2008). Drawing upon past research (e.g., Carvallo and Pelham, 2004; Postmes et al., 1999), the goal of the present study is to examine factors that affect Whites' reports of privilege. We expected Whites' reports of personal privilege would be lower than group privilege—a personal/group discrepancy (PGD). We hypothesized that the PGD would be larger in the presence of a Black experimenter because Whites would attempt to differentiate themselves from the rest of their group. Furthermore, we hypothesized that with Black experimenters, the PGD would be largest when need to belong was high and participants wanted the acceptance of the experimenter. We hypothesized that the reverse would be true for White experimenters. Following a priming task that manipulated need to belong, participants reported personal and group privilege. Consistent with our hypothesis, participants reported more group than personal privilege. Furthermore, the PGD was larger in the presence of a Black experimenter. Regardless of experimenter race, reports of both personal and group privilege were larger when need to belong was high. Additional research is needed to understand why need to belong increases reports of both types White privilege, regardless of the audience. The current research suggests avenues for interventions to increase White's awareness of their privilege.

#### A253

##### THE EFFECTS OF AMBIVALENT STEREOTYPES TOWARD DISABLED PEOPLE ON ATTITUDES AND PERCEPTION OF SOCIAL SYSTEM

Tokika Kurita<sup>1</sup>, Takashi Kusumi<sup>1</sup>; <sup>1</sup>Graduate School of Education, Kyoto University – Disabled people seemed as high warmth and low competence (Fiske et al., 2002). We investigated the effects of activation of such ambivalent stereotypes toward disabled people on attitudes and perception of social system. Forty-one participated in the experiment. Participants saw a picture and they asked to write down words they associated. They were assigned three activation conditions. 1) In the positive stereotype condition, they saw a picture of disabled person and associated of personality of the person. 2) In the negative stereotype condition, they saw a picture of disabled person and associated competence of the person. 3) In the control condition, they saw a picture of sofa (i.e. neutral picture). They activated one of three concepts and then conducted the Implicit Association Test (IAT) to measure their prejudice toward disabled people and questionnaire of perception of social system concerning welfare of disabled people. The results showed that the participants who activated negative stereotype were higher implicit prejudice toward disabled people than the control condition, however perceived the social system as negative that is, they considered it more necessary to improve. On the other hand, the participants who activated positive stereotype seemed the social system as positive that is, they considered it less necessary to improve. The ambivalent stereotype toward disabled people has the ironic results as for attitudes and social system. Negative stereotype about disabled people's competence may improve social system for disabled people. Positive stereotype about personality of disabled people may improve their attitudes toward disabled people.

#### A254

##### ACCENTUATE THE POSITIVE! THEORIES OF GENDER DIFFERENCE AND SELECTIVE STEREOTYPING

Jill Coleman<sup>1</sup>; <sup>1</sup>Roosevelt University – Previous research on essentialist theories of gender has shown that individuals who endorse essentialist, biologically based explanations for gender differences are also likely to endorse gender stereotypes (Brescoll & LaFrance, 2004) and to positively evaluate stereotypically feminine traits (Coleman, manuscript in preparation). The goal of the present study was to examine how these explanations of gender differences might lead individuals to differentially endorse positive and negative traits as descriptive of women and men. Female students ( $N = 47$ ) participated in an experiment described as a reading comprehension study. After reading an article on one of the two gender difference explanations (biological, social), the participants reported the extent to which a list of approximately eighty traits applied to women and men. The results indicated that participants who read the article on biological explanations were more likely to endorse positive traits (e.g., loyal, affectionate) as being descriptive of women, while participants reading about social explanations were more likely to endorse negative traits (e.g., gullible) as being descriptive of women. Additionally, participants who read about social explanations were more likely than participants who read the biological article to endorse masculine traits, particularly positive masculine traits (e.g., self-reliant, ambitious), as being descriptive of women. These results suggest that women who endorse essentialist, biologically based explanations for gender differences are more likely to view stereotypically feminine characteristics positively, while those endorsing social explanations are more likely to view both feminine and masculine stereotypes in a more balanced manner.

#### A255

##### PREJUDICE ENHANCES INCLUSION OF CRIMINAL FACES IN STIGMATIZED CATEGORY

Ron Dotsch<sup>1</sup>, Daniel Wigboldus<sup>1</sup>, Ad van Knippenberg<sup>1</sup>; <sup>1</sup>Behavioural Science Institute, Radboud University Nijmegen – People who are highly prejudiced towards Moroccan people (a highly stigmatized immigrant group in the Netherlands) expect Moroccan faces to look more criminal (Dotsch, Wigboldus, Langner, & van Knippenberg, 2008). Therefore, criminal faces should fit the category of Moroccans better for highly prejudiced people (Bruner, 1957; Oakes, 1987; van Knippenberg & Dijksterhuis, 2000). If this is the case, highly prejudiced people should include more criminal faces in the Moroccan category than people low in prejudice. This hypothesis was tested using a task in which participants were instructed to categorize Moroccan faces and criminal Moroccan faces into the categories Moroccan and non-Moroccan. Prejudice was assessed using a Single Target Implicit Association Test (Bluemke & Fries, 2008). The results showed that while all participants categorized a greater percentage of criminal Moroccan faces than Moroccan faces as Moroccan,  $F(1, 76) = 24.35$ ,  $p < .01$ , partial  $\eta^2 = .24$ , this effect was stronger for highly prejudiced participants than for participants low in prejudice,  $F(1, 76) = 5.58$ ,  $p = .02$ , partial  $\eta^2 = .07$ . Our results support the idea that prejudice biases the categorization process on the level of category applicability. Social categorization (Allport, 1954) has proven to be an important concept in explaining prejudice (Fiske, 2005). Ample research has shown the influences of prejudice on the consequences of categorization. The current research clearly demonstrates the effect of prejudice on the categorization process itself.

#### A256

##### TIRED OF PREJUDICE: THE SELF-REGULATORY EFFECT OF DISCRIMINATION ON HEALTH-RELATED BEHAVIORS

Elizabeth Pascoe<sup>1</sup>; <sup>1</sup>University of Northern Colorado – Within a self-regulatory framework, three studies examined the causal effect of discrimination on health-related behaviors. In study 1, reflection upon a past personal experience of discrimination led to more unhealthy food-related decision-making. Study 2 revealed increased endorsement of unhealthy food items following a discriminatory experience for individuals who experienced low levels of past-year discrimination. Individuals reporting high levels of

discrimination within the past year endorsed high numbers of unhealthy foods regardless of experimental condition. Also, individuals who decided to accept a snack from the experimenter were marginally more likely to select an unhealthy option after experiencing discrimination. Finally, study 3 found that the anticipation of conversing with an individual who espoused benevolently sexist attitudes marginally increased individuals' willingness to accept a snack from an experimenter than did the anticipation of hostile sexism. For individuals who accepted a snack, higher levels of gender identification were found to protect individuals from choosing an unhealthy snack over a healthy one. These results provide initial evidence that the experience of discrimination over several temporal formats can result in a reduced ability to refrain from unhealthy eating behavior. These findings represent an important advance in framing how exactly discrimination may affect health through interruptions in individuals' ability to self-regulate in health behavior-related domains.

#### A257

**RAISING STUDENT AWARENESS THROUGH EXPOSURE TO CAMPUS BIAS** Heather D. Hussey<sup>1</sup>, Bethany K. B. Fleck<sup>1</sup>, Rebecca M. Warner<sup>1</sup>; <sup>1</sup>University of New Hampshire – Prejudice and acts of bias have become an increasingly popular social issue demanding attention on many college campuses today. These harmful actions (e.g., physical assaults, biased speech, and vandalism) have been shown to have short and long term negative effects on minority group members. However, many majority group members are not aware of the impact of these biased actions and words. The current study examined the impact of exposure to collected artifacts from biased incidents on campus over the past five years on students. After viewing the "Bias Gallery", students' affective reactions and comments were measured as well as their commitment to becoming an ally. Results suggest that exposure to artifacts of campus bias affected females and males differently. Females scored significantly higher on anger, whereas males scored significantly higher on feelings of satisfaction and contentment. There were no gender differences for ally commitment. Rather, students with greater feelings of anger and guilt were more likely to commit to being an ally after viewing the Bias Gallery. Five months later, the majority of students reported greater awareness of the bias on campus and monitoring their own biased language. Written comments support previous literature in that many students reported surprise and even alarm that such actions happen around them. Results also showed that every student spoke with someone (e.g., friends, family, and teachers) about the Bias Gallery, suggesting that interventions exposing students to the truth of bias on their campus can be effective in raising student awareness and engendering important discussions.

#### A258

**OBAMA'S WIN IS A GAIN FOR AFRICAN AMERICANS? CHANGES IN IMPLICIT RACIAL PREJUDICE FOLLOWING THE 2008 US PRESIDENTIAL ELECTION** Michael Bernstein<sup>1</sup>, Steven Young<sup>1</sup>, Heather Claypool<sup>1</sup>; <sup>1</sup>Miami University – Did Barack Obama's victory in the 2008 Presidential election impact racial prejudice in the US and, if so, were implicit and explicit attitudes differentially affected? Witnessing the historic victory of Obama could result in a number of different outcomes in terms of attitude change. Because exposure to positive group exemplars has been shown to produce favorable changes in attitudes on both explicit and implicit measures, both might be more positive following Obama's election. On the other hand, for social desirability reasons, participants may report very favorable attitudes toward African Americans at all times on explicit measures because they are so easy to control, which might result in no apparent improvement in explicit racial attitudes post election. Finally, if participants subtype Obama, no changes (in either explicit or implicit attitudes) might be observed. This study was designed to investigate these possibilities. A sample of forty White participants reported their explicit and implicit prejudice toward African Americans in two sessions, one immediately prior to and one immediately following the 2008 US Presidential election. A paired-samples t-test on the implicit measure (a racial IAT) showed that implicit bias was significantly

smaller after the election ( $M=301.78$ ,  $SD=227.90$ ) than before ( $M=427.61$ ,  $SD=385.42$ ),  $t(41)=2.26$ ,  $p=.029$ , whereas a paired-samples t-test on the explicit measure (the Attitudes Toward Blacks Scale) revealed no change in explicit bias ( $p>.45$ ). These results indicate that implicit prejudice decreased following Obama's election, whereas explicit prejudice remained unchanged. The possible mechanisms that gave rise to these results will be discussed.

#### A259

**STEREOTYPES OF LATINA/O PROFESSORS BASED ON ETHNICITY, GENDER, TEACHING STYLE, AND COURSE TYPE** Kristin J. Anderson<sup>1</sup>, Shauna M. Curtis<sup>1</sup>; <sup>1</sup>University of Houston-Downtown – Much of the research on discrimination of people of color has focused on whites' discrimination of African Americans. Less is known about discrimination directed at other ethnic groups. This study examined students' perceptions of Latina/o and Anglo professors based on professor ethnicity, gender, teaching style, and type of course taught. An ethnically diverse sample of undergraduates ( $N = 594$ ) rated hypothetical professors on several dimensions including perceived warmth, professional competence, and difficulty. Evidence consistent with response amplification and expectancy violation theories was found. Women's and Latina/os' ratings were, in some cases, based on their teaching style, while Anglo men's were not. Implications for women and Latina/os in the academy are discussed.

#### A260

**ALLOCATION OF DRUG BENEFITS TO HIV POSITIVE PATIENTS: INFLUENCE OF METHOD OF DISEASE TRANSMISSION, PATIENTS' SEXUAL ORIENTATION, AND BELIEFS REGARDING SEXUAL ORIENTATION AS A CHOICE** Renee Murray<sup>1</sup>; <sup>1</sup>Iowa State University – The present study examined method of disease transmission, sexual orientation, and beliefs regarding sexual orientation as a choice as predictors of attitudes toward people with HIV/AIDS. Based on attribution theory, I expected participants to respond negatively to controllable infections (e.g., unsafe sex), regardless of target sexual orientation. However, based on just world theory, when infection was uncontrollable (e.g., infected medical equipment), I expected participants who view sexual orientation as a choice to respond more negatively to gay than to heterosexual targets as a means to explain the infection. Student participants ( $n=267$ ) read a vignette describing either a gay or heterosexual man applying for free drug coverage whose HIV infection was either controllable or uncontrollable. Afterward, participants completed measures of support for admittance and beliefs regarding whether sexual orientation is a choice. A 2(Orientation)X2(Transmission Method)X2(Orientation as Choice) ANOVA revealed that when the target was heterosexual, participants who believe sexual orientation is a choice reported greater support for admittance when infection was uncontrollable. However, transmission method did not influence support for admittance for gay targets. I hypothesized that when infection was uncontrollable these participants would respond more negatively to gay targets, but did not expect that transmission method would have no influence on gay targets. These findings suggest attribution theory may not predict reactions to gay targets when participants believe sexual orientation is a choice. Consistent with just world theory, when infection was uncontrollable, participants who believe sexual orientation is a choice likely used the gay targets' sexual orientation to explain infection.

#### A261

**THE EFFECTS OF ALCOHOL ON NEGATIVE STEREOTYPES IN A BAR POPULATION** Kristen Konkel<sup>1</sup>, Toni Bisconti<sup>2</sup>; <sup>1</sup>Colorado State University, <sup>2</sup>The University of Akron – Extensive research has shown that stereotypes are used in everyday situations, but there is a limited amount of work looking at how they relate to alcohol consumption. Past research has shown that after the consumption of alcohol, participants are less able to inhibit stereotypical responses in a laboratory setting (Bartholow, Dickter, & Sestir, 2006). The present research extended this work by exploring the effects of alcohol consumption on stereotype use (particularly nega-

tive stereotypes) in a real-world setting. In this experiment, 88 participants were recruited from a Northeast Ohio bar to complete a short word-association task. After passing a measure of cognitive impairment and completing a survey used to estimate blood alcohol levels, participants responded to a series of single-word stimuli with the first word that came to mind. Responses were coded as a negative stereotype, a non-negative stereotype, or neither (e.g., stimulus word blonde and response word dumb is a negative stereotype). Unexpectedly, results showed that as blood alcohol levels increased, subjects were no more likely to use negative stereotypes,  $r = .09$ ,  $p = .43$ . However, subsequent analyses revealed an important gender difference. As women drank more, they used significantly more stereotypes,  $r = .39$ ,  $p < .05$ . No such association was documented for men. Findings supported past research that alcohol may affect cognitive control over stereotype use, but only in women, not men.

#### A262

**EXAMINING THE SEPARATION OF CHURCH AND STATE: THE AMERICAN=CHRISTIAN EFFECT** Jayson Carvalho<sup>1</sup>, David A. Butz<sup>2</sup>; <sup>1</sup>University of Massachusetts, Amherst, <sup>2</sup>Morehead State University – Although many Americans are committed to increasing diversity in the United States, at the same time they may retain prototypical views of the social groups that most strongly represent the American identity. For example, Devos and Banaji's (2005) work revealed that Americans more strongly associate the American identity with Whites/Caucasians than with other ethnic groups. The current research extends previous work by examining the role of religion in the prototypical American identity. We predicted that Americans would more strongly associate the American identity with Christian than with non-Christian religious groups. Strong "American=Christian" associations were expected to result in responses on resource allocation tasks that favored Christian relative to non-Christian religious groups. Ninety-five participants completed an Implicit Association Test (IAT) modified to assess the strength of implicit "American=Christian" associations. In addition, during the course of the session participants allocated resources to Christian and non-Christian campus groups and completed explicit measures of the extent to which a range of religious groups were regarded as American. Results indicated that participants strongly associated the American identity with Christianity at both an implicit and explicit level, and these associations were stronger among Christian compared to non-Christian participants. Moreover, strong explicit American=Christian associations were associated with responses on resource allocation tasks that favored Christian groups. This work will be discussed in terms of its implications for broadening work on American prototypes and developing approaches to create more inclusive representations of the American identity.

#### A263

**EFFECTS OF THE AMERICA FLAG ON BIAS AND STEREOTYPING** Shanette Porter<sup>1</sup>, Melissa Ferguson<sup>1</sup>; <sup>1</sup>Cornell University – Cognitive and social psychological research suggests that there are numerous, sometimes conflicting, associations tied with concepts in memory; upon activation of a particular concept, these associations can affect an individual's beliefs and attitudes (e.g., Bargh, 2007). We examined how the activation of America, specifically through nonconscious exposure to a national cue, alters attitudes toward, and beliefs about, Blacks. We derived two potential hypotheses. First, both empirical research and well-known prescriptive norms suggest a link between America and egalitarianism, indicating that implicit activation of America could lead to more positivity toward Blacks (Butz et al., 2007). Alternatively, given a descriptive historical trend of unequal treatment of Blacks, as well as recent research finding that America was more readily associated with Whites than other ethnicities, beliefs about Blacks could become more negative upon activation of America (Devos & Banaji, 2005). In study 1, participants were primed with the American flag or a control image, then completed an IAT measuring attitudes toward Blacks and Whites. We found that attitudes toward Blacks were significantly less positive in the experimental condition. In study 2, participants were primed with

the flag or control image, then completed an IAT measuring stereotyping of Blacks. There was significantly more stereotyping of Blacks in the experimental condition. In study 3, which combined the methodologies used in the first two studies, we found evidence for a mediational path in which activation of America lead to negative stereotyping of Blacks, which led to negative bias against Blacks.

#### A264

**HOW CAN EXPOSURE TO PERVASIVE GROUP DISCRIMINATION LEAD SOME WOMEN TO FEEL BETTER? EXAMINATION OF A GROUP DISCREPANCY ACTIVITY AND ITS EFFECT ON WOMEN'S WELLBEING AFTER EXPOSURE TO GROUP DISCRIMINATION** Brandon Cosley<sup>1</sup>, Shannon McCoy<sup>1</sup>, Joseph Wellman<sup>1</sup>, Ellen Newell<sup>1</sup>, Ryan Pickering<sup>1</sup>; <sup>1</sup>University of Maine – Many theoretical perspectives predict that when members of low status groups are exposed to evidence of pervasive group discrimination their wellbeing will suffer (see Major, Quinton, & McCoy, 2002 for a review). It has been argued that evidence of group discrimination highlights the group's inadequacies, which leads to the internalization of one's own inferiority (Allport, 1954). The present studies sought to examine how women exposed to clear evidence of group discrimination subsequently think about their group, and how those thoughts influence their mood and self esteem. Across 2 studies we show the counter intuitive relationship that women who identify inadequacies with their group (i.e. group discrepancy activity) after exposure to evidence of clear discrimination against their group feel better (study 1 & study 2), have higher self esteem (study 2), and feel more in control over their future outcomes (study 2) compared to women who perceive fewer group discrepancies. We also show that this effect does not emerge when women are not given an opportunity to consider their group's inadequacies (study 2), nor when they are exposed to information regarding mere group inequality (study 1 and study 2). Ironically, across two studies, when women focused on the discrepancy between how women are and how they ought to be they felt better in the face of sexism. Potential mediators and explanations for this counterintuitive finding are discussed.

#### A265

**PSYCHOLOGICAL CORRELATES OF RACIAL BIAS IN CONSCIOUS AND UNCONSCIOUS THINKERS** Madelijn Strick<sup>1</sup>, Ap Dijksterhuis<sup>1</sup>, Rick Van Baaren<sup>1</sup>; <sup>1</sup>Radboud University Nijmegen – This study explored whether thinking consciously or unconsciously reduces racial bias. Participants were asked to imagine having to find a new roommate, and were subsequently presented with the descriptions of four candidates. Each description comprised both verbal information and a picture of the roommate's face. All roommates were white, but two of them had African facial features, whereas the other two had Caucasian facial features. In the immediate condition, participants evaluated each roommate directly after information presentation. In the conscious condition, participants evaluated the roommates after carefully thinking about them. In the unconscious thought condition, participants evaluated the roommates after being distracted with an anagram task. Finally, implicit prejudice (using the IAT), explicit attitude toward Africans, and Motivation to Control Prejudice of all participants were assessed. The results showed that only participants in the immediate condition were racially biased, i.e., preferred Caucasians over Africans, whereas participants in the other two conditions were not. Furthermore, across the thought conditions, the level of racial bias correlated with different psychological constructs. In the immediate condition, racial bias was correlated with implicit prejudice. In the conscious thought condition, racial bias was correlated with the explicit attitude toward Africans. In the unconscious thought condition, prejudice was correlated with the motivation to control prejudice. In conclusion, both conscious and unconscious thought reduce racial bias, but through different psychological mechanisms. Whereas conscious thought helps to act in line with explicit racial attitudes, unconscious thought helps to fulfill the goal to control prejudice.

**A266**

**IMPLICATIONS OF TIMING OF SEXUAL ORIENTATION DISCLOSURE FOR INTERGROUP INTERACTIONS** David Buck<sup>1</sup>, E. Ashby Plant<sup>1</sup>, <sup>1</sup>Florida State University – Because sexual orientation is not necessarily identifiable, homosexual individuals often have the option of revealing or concealing their group identity until they feel comfortable disclosing. The current study sought to determine whether timing of the disclosure of sexual orientation, be it immediate or delayed, might influence impression formation. We were further interested in how impression formation might influence factors typically relevant to the course and quality of intergroup interactions. Participants were led to believe that they would soon be interacting with another person after sharing information about one another via videotaped interviews. Participants watched a videotaped interview of a male confederate. The sexual orientation of the confederate and the timing of disclosure of sexual orientation were manipulated. After watching the video, participants' reactions toward the confederate and the pending interaction were assessed. Results showed a three-way interaction between participant sex, timing of disclosure, and sexual orientation of the confederate. Timing of disclosure did not matter for the straight confederate or for the female participants across orientation conditions. However, when the confederate identified as gay early, male participants disliked him more and perceived him as more stereotypic than when he identified as gay late in the interview. In addition, male participants were more interested in avoiding the interaction and had negative expectations about the interaction with the gay confederate who identified early versus late. Responses to the upcoming interaction were mediated by the stereotypicality of participants' impression of the confederate.

**A267**

**CAPITALIZING ON MULTIPLE SOCIAL IDENTITIES TO PREVENT STEREOTYPE THREAT: THE ROLE OF SELF-ESTEEM** Kathryn Boucher<sup>1</sup>, Robert Rydell<sup>1</sup>, <sup>1</sup>Indiana University – Activation of negative stereotypes about women's math ability decreases their math performance (i.e., stereotype threat; Steele, 1997). However, stereotype threat-related performance decrements can be eliminated when a social identity with positive stereotypes for math performance (i.e., college students) is concurrently available (Rydell, McConnell, & Beilock, 2009). In two experiments, we examined if self-esteem could predict whether stereotype threat impacted women's performance when both a positive and a negative social identity related to math performance were available. We expected women with greater self-esteem to benefit more from an available positive social identity in a threatening situation, allowing them to identify less with their gender and to retain cognitive resources necessary for successful math performance. After completing a trait self-esteem scale (Rosenberg, 1965), participants were told: no stereotypic information, "college students are good at math," "women are bad at math," or "college students are good at math" and "women are bad at math" (multiple identities condition). Participants completed a measure of gender identification (Experiment 1) or working memory capacity (WMC) (Experiment 2) and solved difficult math problems. In the multiple identities condition, there was a positive relation between: self-esteem and performance in each experiment, self-esteem and reduced gender identification, and self-esteem and increased WMC. WMC mediated the relation between self-esteem and performance. These results demonstrate self-esteem's buffering potential as the combination of high self-esteem and a positive, self-relevant stereotype about math ability eliminated the impact of stereotype threat on performance and WMC.

**A268**

**DISTORTING REALITY?: THINKING ABOUT PRESIDENT OBAMA LEADS PEOPLE TO DISCOUNT SOCIETAL AND PERSONAL RACIAL BIAS** Jill Lybarger<sup>1</sup>, Margo Monteith<sup>1</sup>, <sup>1</sup>Purdue University – We examined the effects of priming President Obama on perceptions of societal and individual level racial bias. Believing they were designing magazine covers, participants (N=104) were instructed to create taglines for either a photo of

Obama or a control image. After this, participants completed various measures relating to bias. Participants also completed the implicit association test (IAT), were given fixed feedback suggesting they had a preference toward Whites, and were asked about the validity of the test. Our results indicated that participants creating taglines for Obama were more likely to report that Blacks could get ahead if they just worked harder and that discrimination is no longer a problem in the United States, relative to the control tagline condition. Participants who created taglines for Obama also perceived the IAT as a less valid test of racial bias. However, our manipulation was unrelated to participants' reports of their internal or external motivations to control prejudice or to their level of racial bias on the IAT. These findings indicate that thinking about our country's newly elected first Black President did not shift participants' explicit beliefs about controlling their racial prejudice, nor did it affect their implicit racial attitudes. However, it did cause participants to discount the possibility that racial bias operates in society and themselves. Discussion focuses on how such distortions of reality may have negative implications for Blacks.

**A269**

**IMPLICIT PREJUDICE AND UNINTENTIONAL INTERRACIAL BEHAVIORAL COORDINATION** Tamra E. Beckman<sup>1</sup>, Alen Hajnal<sup>1</sup>, Virgil Zeigler-Hill<sup>1</sup>, Kenji Noguchi<sup>1</sup>, Jonathan D. Walker<sup>1</sup>, <sup>1</sup>University of Southern Mississippi – Implicit prejudice has been shown to be associated with a variety of spontaneous interracial behaviors (e.g., Fazio, Jackson, Dutton, & Williams, 1995). The purpose of the present study was to examine whether implicit prejudice would predict unintentional interracial behavioral coordination. Unintentional coordination has been demonstrated in various tasks such as walking in pairs (van Ulzen, Lamothe, Daffertshofer, Semin, & Beek, 2008) and rocking in rocking chairs (Richardson, Marsh, Eisenhower, Goodman, & Schmidt, 2007). The principles that govern this collective behavior remain largely unknown. We asked pairs of naïve participants sitting side-by-side in rocking chairs to rock at their individually preferred tempos. Data were collected from 66 undergraduate students (6 White men, 26 White women, 7 Black men, and 27 Black women). The racial compositions of the dyads were White-Black (12 pairs), White-White (10 pairs), and Black-Black (11 pairs). Following the rocking chair task, participants were asked to complete measures of implicit prejudice and explicit prejudice. The racial composition of these dyads was not found to influence the degree of behavioral coordination between the participants constituting each dyad,  $F(2,30) = 1.67$ , ns. However, the implicit prejudice levels of the White participants in the White-Black dyads were associated with the degree of behavioral coordination between themselves and their Black partners ( $r = .70$ ,  $p < .05$ ). These results show that higher levels of implicit prejudice among White participants predicted greater behavioral coordination with Black participants. Discussion will focus on the role of implicit prejudice in social interactions between White and Black individuals.

**A270**

**OUTSIDERS IN ACADEMIA: SEX-STEREOTYPING OF WOMEN PROFESSORS IN "FEMALE APPROPRIATE" CONTEXTS** Katherine E. Briley<sup>1</sup>, Karen Z. Naufel<sup>1</sup>, Michael B. Pyle<sup>1</sup>, <sup>1</sup>Georgia Southern University – Women are seen as less competent than men in various contexts even when achieving the same performance level as men (Foschi, 2009). In academia, women's teaching ability is judged to be of lower quality than men's, as men are still seen as the "typical" college professor (Etaugh & Riley, 1983). In the present study, we examined if such stereotypical attitudes prevailed in contexts in which women's expertise were valued. Specifically, we examined how female professors are viewed in stereotypically female versus male departments, and how female professors are viewed by female students. First, we hypothesized that male professors would be rated higher than female professors at coeducational colleges. However, because women's colleges foster an environment in which women can thrive in stereotypically male fields (Kinzie, Thomas, Palmer, & Umbach, 2007), we also hypothesized that female professors would be rated higher than male professors at women's colleges. Public

student ratings for 3066 professors from 46 women's colleges and 54 coeducational colleges were analyzed. For each professor, professor gender, professor department (stereotypically female versus male), and the rating of instructor quality were recorded. Partially supporting the first hypothesis, male professors had significantly higher quality ratings than female professors at coeducational colleges, but the effect was unique to professors in stereotypically female departments. Against the second hypothesis, male professors were also rated higher than female professors at women's colleges. These results suggest that women are still seen as outsiders in academia even in stereotypically female contexts.

#### A271

**HOW DOES STEREOTYPE THREAT INFLUENCE MARKETPLACE DECISIONS: IMPACTS OF THE NEGATIVE INGROUP STEREOTYPE ACTIVATION ON SELECTION OF TRANSACTION PARTNERS AND INVESTMENT OPTIONS** Kyoungmi Lee<sup>1</sup>, Hakkyun Kim<sup>2</sup>, Kathleen Vohs<sup>3</sup>; <sup>1</sup>Kansas State University, <sup>2</sup>Concordia University, <sup>3</sup>University of Minnesota – We tested whether stereotype threat affects decisions with long-term implications for well-being. Given that stereotype threat evokes avoidance tendencies and prevention goals (e.g., Brodish & Devine, 2009; Seibt & Forster, 2004), we proposed that consumers for whom a negative ingroup stereotype is made salient will make poorer decisions and we tested this in the financial realm. We predicted that stereotype-threatened women would lower intentions to engage with outgroup members, even if they could help participants make wise financial decisions, and display a cautious investment style. Four experiments supported these predictions. Experiment 1 found that women (but not men) who were reminded of a negative stereotype about women and math lowered their intentions to interact with outgroup members who were known experts in financial decisions. Experiment 2 replicated the effect and found that such avoidance occurred because of heightened mistrust in outgroup members and was particularly prominent among women with low self-esteem. Experiments 3 and 4 found that women under stereotype threat adopted more cautious investment styles than when not under threat. Specifically, women reminded of the math-gender stereotype preferred Treasury bonds versus stocks (Exp. 3) and low-volatility stocks, which over the long-term underperform high-volatility ones (Exp. 4). Together, these decisions can be viewed as prevention-focused and, more importantly, poor selections for long-term financial health. These four experiments therefore demonstrate that stereotype threat impairs decision making in a manner that could harm financial well-being, the importance of which cannot be underscored given the current economic climate.

#### A272

**THE PERSPECTIVE-TAKING--PREJUDICE LINK: EMPATHY, SELF-OTHER OVERLAP, AND ATTRIBUTIONS AS MEDIATORS** Caroline Mann<sup>1</sup>, Michael Olson<sup>1</sup>; <sup>1</sup>University of Tennessee – This study extends the perspective-taking literature to mental illness stigma and examines multiple mediational pathways between perspective-taking and reductions in prejudice. Previous research has shown that perspective-taking leads to decreased prejudice (e.g., Batson, Early, & Salvarani, 1997; Galinsky & Moskowitz, 2000), but questions remain as to how perspective-taking creates such effects. Mediators such as empathy, self-other overlap, and attributions are the big theoretical players, but have rarely been tested in unison. This study employed a 3x2 factorial design, with participants (n=185) randomly assigned to perspective-taking, objective, or “no instruction” conditions, and then exposed to a narrative of a student with bipolar disorder or AIDS. Afterward, participants completed a social distance scale and funds allocation task (outcome variables) as well as measures tapping potential mediators such as empathy, self-other overlap, and attributions. Results indicated that prejudice toward the individual and the group was reduced, and that empathy, self-other overlap, and attributions all partially mediated the relationship for prejudice toward the individual. However, for attitudes toward the group, empathy was the only significant mediator. Testing different path models in SEM, those in

which self-other overlap acted upon empathy (which in turn predicted prejudice) were the only models with sufficient goodness of fit. These results speak to how competing theories of perspective-taking (i.e. empathy vs. self-based) may operate in conjunction with each other, underwriting the effects of perspective-taking. More research needs to examine these theories in a collaborative manner, as they are likely not orthogonal.

#### A273

**A TEST OF TMT: MORTALITY SALIENCE AND AVOIDANCE OF WORLDVIEW THREATS** Taylor Wadian<sup>1</sup>, Helen C. Harton<sup>1</sup>; <sup>1</sup>University of Northern Iowa – Years of research on terror management theory suggests that people cling more adamantly to their worldviews when mortality is salient, causing individuals to prefer those who support these worldviews (e.g., Schimel et al., 1999). However, very little research has examined how this increased preference for worldview-validating information influences behavior (c.f., McGregor et al., 1998). In this study, participants wrote about either their own death or dental pain and then played a simulated game of catch (Cyberball) over the internet with three fictitious African American targets that were manipulated to appear to be consistent, neutral, or inconsistent with common African American stereotypes. Participants tossed the ball less often to the stereotype consistent African American than either the neutral or stereotype inconsistent targets regardless of mortality salience or participants' level of need for closure. Participants also rated the stereotype consistent target more positively on attitude and trait ratings. Interestingly, however, participants in the mortality salience condition who were high in need for closure rated the stereotype consistent target less favorably than those lower in need for closure. Results suggest that stereotypes do influence behavioral interaction with and favorability toward African Americans, and that these effects seem to be apparent regardless of mortality salience. Given the effects of social exclusion (e.g., Williams, 2008), avoidance of an African American based on his or her consistency with prominent African American stereotypes may in fact evoke behaviors that validate these negative stereotypes (i.e., hostility, social loafing, and decreased cognitive ability) and thus perpetuate these stereotypes further.

#### A274

**AMBIGUITY TOWARD SEXUAL ABUSE VICTIMS** Erin D. Solomon<sup>1</sup>, Amy M. Garczynski<sup>1</sup>, Ruth Warner<sup>1</sup>, Nyla Branscombe<sup>2</sup>, Ghazaleh Fouladi<sup>1</sup>; <sup>1</sup>Saint Louis University, <sup>2</sup>University of Kansas – In two studies, we explore how people react to a victim of childhood sexual abuse compared to a nonvictim, when they have a rationalization for expressing prejudice against them—in that the target has harmed another person—or do not. According to two-factor theories of prejudice, prejudice is only expressed when there is sufficient justification (Crandall & Eshleman, 2003). Research has explored the expression of prejudice based on justifications for groups such as African-Americans and the obese (Gaertner & Dovidio, 1986; King, et al., 2006). However, victims of sexual abuse are unique from these groups in that other theories suggest that their victim status would act as a mitigation factor if they harmed someone else (Barnett, Brodsky, & Davis, 2005). In both studies, participants read vignettes regarding a fictional hiring scenario and evaluated applicants on expected job performance and social distance. The results of both studies show that nonvictims who did harm were rated higher on expected job performance and lower on social distance than victims who did harm. There was no difference on judgments of job performance and social distance between victims and nonvictims when they did not do harm. Additionally, Study 2 showed that the order in which the victimization history and harm-doing were presented had no effect. In summary, harm-doing victims are judged more harshly than harm-doing nonvictims. The results support the two-factor theories of prejudice.

**A275**

**BOOSTING OLDER PEOPLE'S PERFORMANCE** Hannah Swift<sup>1</sup>, Dominic Abrams<sup>1</sup>; <sup>1</sup>Centre for the Study of Group Processes, University of Kent – According to stereotype threat theory, (Steele & Aronson, 1995) people underperform on tasks when a negative self-relevant stereotype is activated. In contrast, stereotype lift occurs if a relatively positive self-stereotype is activated because the stereotype casts doubt upon the ability of a comparison group, thereby, enhancing own performance (Walton and Cohen, 2003; Marx and Stapel, 2006). Stereotype lift can also be achieved by directly activating a positive self-relevant stereotypic expectation, denoting high achievement on a relevant task. This research examined the mediating role of anxiety in the relationship between positive and negative stereotypic expectations on older people's cognitive performance. The research also explored whether stereotype lift can be extended to, and experienced by older people, by directly activating a self-relevant social identity with a high-achievement expectation on performance. Study one, a nationally represented survey (N=2113), demonstrated that there are clear age related expectations about specific competencies, positively and negatively associated with old age stereotypes. Study two, an experiment (N=120), investigated the effect of stereotype threat and stereotype lift on a range of stereotype relevant cognitive tasks for older participants. Participants in the stereotype threat condition underperformed on all tasks compared to the control and the lift condition. However, optimum performance was shown in the stereotype lift condition on an old-age positive stereotyped task, where participants out-performed those in the control. This effect was mediated by anxiety, demonstrating that older people's performance can be boosted when the task is associated with stereotypically positive domain of competence.

**A276**

**"DO UNTO OTHERS": EFFECTS OF PRIMING THE GOLDEN RULE ON BUDDHISTS' AND CHRISTIANS' ATTITUDES TOWARD GAY PEOPLE** Oth Tran<sup>1</sup>, Nicole Lindner<sup>1</sup>, Brian Nosek<sup>1</sup>; <sup>1</sup>University of Virginia – The Golden Rule, a core precept of many religions, emphasizes the importance of treating others with compassion (Wattles, 1996). However, religious adherents inconsistently apply its message to different social groups. For example, religious people are more prejudiced against sexual minorities than racial minorities (Herek, 1987). The present study examined whether priming Golden Rule messages would influence Buddhists' and Christians' attitudes toward gay people and perceptions that homosexuality is a choice. In a priming task, participants filled in missing words for popular quotations including two Golden Rule messages that were attributed to either Buddha or Jesus in the experimental conditions. Christians (N= 585) in the Buddha-attributed Golden Rule condition showed stronger explicit anti-gay attitudes and were more likely to agree that homosexuality is a choice than Christians in the Jesus-attributed or control conditions,  $\eta$ -partial<sup>2</sup>= .01,  $p$ =.035, even after controlling for political orientation and religiosity. Buddhists (N= 394) showed no variation in attitudes across priming conditions,  $\eta$ -partial<sup>2</sup>= .001,  $p$ =.782. Our results suggest that although the Golden Rule has an important influence on believers, its message of compassion may backfire by increasing prejudice if it comes from an outgroup source.

**A277**

**SOCIAL DOMINANCE ORIENTATION, PROTESTANT WORK ETHIC, AND ATTRIBUTIONAL COMPLEXITY PREDICT IMPLICIT THEORIES ABOUT PREJUDICE** Rekha Tiwari<sup>1</sup>, Dorian M. C. Cowan<sup>1</sup>, Devin L. Wallace<sup>1</sup>; <sup>1</sup>Towson University – Much research has examined the extent to which people possess naïve or implicit theories about human characteristics (Molden & Dweck, 2006). People whose implicit theory reflects the belief that human characteristics are fixed and stable are entity theorists, while those who conceive of traits as malleable and fluid are dubbed incremental theorists. Research has examined the relationship between implicit theories and stereotyping (Levy, Stroessner, & Dweck, 1998), but none has tested whether perceivers possess implicit theories about prejudice

as a character trait. To this end, we measured implicit theories about prejudice and some factors that predict their endorsement. Data were collected from a sample of 139 White undergraduates at a large, public university in the Mid-Atlantic. Implicit theories about prejudice were predicted from a regression model including social dominance orientation, Protestant work ethic, and attributional complexity. Responses to the implicit theories about prejudice items demonstrated strong internal consistency ( $\alpha$  = .86). In addition, social dominance orientation and Protestant work ethic significantly predicted entity theories about prejudice ( $\beta$  = .281 and .252, respectively,  $ps$  < .03). Attributional complexity negatively predicted entity theories about prejudice ( $\beta$  = -.336,  $p$  < .001). We discuss Whites' implicit theories about prejudice in terms of ideologies that justify inequity between majority and minority groups. In the service of favorable intergroup relations, future research will examine behaviors predictable from implicit theories about prejudice for both high and low-status groups.

**A278**

**THE SELF-FULFILLING EFFECT OF A SOCIAL STEREOTYPE: ACCUMULATION EFFECTS ACROSS PERCEIVERS** Marie Lane<sup>1</sup>, Stephanie Madon<sup>1</sup>, Max Guyll<sup>1</sup>, Kyle Scherr<sup>1</sup>, Jennifer Willard<sup>2</sup>; <sup>1</sup>Iowa State University, <sup>2</sup>Kennesaw State University – This research provided the first test of the hypothesis that the self-fulfilling effect of a social stereotype can accumulate across perceivers. We examined the stereotype that overweight people lack willpower and self-control (Crandall, 1994). Participants (N=723) were randomly assigned to groups (N=241) comprised of one target and two perceivers each. Groups were randomly assigned to an expectation condition in which (a) both perceivers believed the target was overweight (N=82), (b) one perceiver believed the target was overweight whereas the other did not (N=76), or (c) neither perceiver believed the target was overweight (N=82). A photograph manipulated perceivers' expectations. Perceivers judged the target's willpower and self-control and selected an amount of candy for the target to eat. These questions were embedded within filler items. Then, as part of a bogus taste test, targets received the total amount of candy selected for them by both perceivers in their group. Study procedures encouraged all targets to take candy home. The amount of candy each target took was recorded. Results indicated that perceivers judged the target as having less willpower and self-control when they believed the target was overweight versus not ( $M$ s<3.58/4.20 vs. 3.95/4.67),  $p$ <.001, and also selected more candy for the target to eat ( $M$ odes=20 vs. 8 pieces),  $U$ =12279;  $p$ <.001. Targets, responding to this differential behavior, took more candy home when two perceivers believed they were overweight ( $M$ =4.76) than when only one did ( $M$ =2.99),  $p$ <.001. This last finding provides evidence that the overweight stereotype had cumulative self-fulfilling effects on targets' behavior.

**A279**

**THE MODULATION OF PERSON PERCEPTION BY STEREOTYPIC GENDER BELIEFS** Susanne Quadflieg<sup>1</sup>, Natasha Flannigan<sup>1</sup>, Bruno Rossion<sup>2</sup>, Laurence Dricot<sup>2</sup>, Gordon Waiter<sup>1</sup>, David Turk<sup>1</sup>, Gagan Wig<sup>3</sup>, Neil Macrae<sup>1</sup>; <sup>1</sup>University of Aberdeen, UK, <sup>2</sup>Universite Catholique de Louvain, Belgium, <sup>3</sup>Harvard University – Based on the idea that perception is an inherently constructive process, it was hypothesized that person perception is fundamentally shaped by a perceiver's stereotypic expectations. Using functional magnetic resonance imaging (fMRI), we measured neural activity while participants viewed a series of photographs depicting men and women in gender-stereotype congruent or incongruent professions (i.e., a female nurse vs. a female firefighter). For each photograph, participants either judged a target's gender (male, female) or the color of a dot (orange, purple) randomly placed on the target. As expected, response times revealed that only under a person categorization goal responding towards people in stereotype-incongruent rather than congruent occupational roles was impeded. Additionally, stereotype-incongruent gender judgments were accompanied by increased neural activity in areas associated with the detection of expectancy-violations (e.g., dorsolateral pre-

frontal cortex) and in regions implementing person perception (e.g., fusiform face area, extrastriate body area). The strength of the observed differences in neural activity between stereotype-congruent and stereotype-incongruent gender judgments was correlated with participants' chronic need to evaluate. These findings elucidate how the formation of a coherent and accurate person representation can be impoverished when targets fail to confirm common gender stereotypes.

#### A280

##### **BENEFICIAL EFFECTS OF INTERRACIAL INTERACTIONS ON IMPLICIT ATTITUDES AND EXECUTIVE FUNCTIONING** Lisa Haisfield<sup>1</sup>, Kareem Johnson<sup>1</sup>; <sup>1</sup>Temple University

Previous research has found that individuals often hold implicit prejudices towards those outside of their own racial group. Additionally, interactions with outgroup members have been shown to deplete attentional resources for those with strong biases towards outgroup members. Although past studies have had participants discuss controversial topics during an interracial interaction, few studies have looked at interactions designed to foster closeness. The present study examined whether engaging in an interpersonal closeness task with an outgroup member could reduce implicit outgroup biases and result in less of a strain on executive functioning than previously found. Twenty-one Black and White female participants completed an Implicit Association Test (IAT) measuring trust/mistrust of outgroup members and a Stroop color naming task measuring attentional resources. Approximately one week later, participants engaged in an interpersonal closeness activity with an interviewer of the same race or a different race after which participants again completed the IAT and Stroop task. Results showed that participants who engaged in the interpersonal closeness task with an outgroup member showed more implicit outgroup trust relative to those who interacted with an ingroup member controlling for initial levels of implicit trust. Additionally, those interacting with the outgroup member had improved Stroop performance compared to their performance during the first session, relative to those interacting with an ingroup member. In conjunction with previous research these findings suggest that the nature of interracial interactions may affect the direction of changes in implicit attitudes and executive functioning.

#### A281

##### **CARDIOVASCULAR EVIDENCE FOR DISENGAGEMENT UNDER CONDITIONS OF STEREOTYPE THREAT** Mark D. Seery<sup>1</sup>, Shannon P. Lupien<sup>1</sup>, Kimberly B. Arnold<sup>1</sup>, Jessica L. Almonte<sup>1</sup>; <sup>1</sup>University at Buffalo, The State University of New York

The motivational consequences of stereotype threat have received relatively little empirical attention. One such consequence is psychological disengagement from the task at hand. We investigated disengagement by measuring cardiovascular responses during a difficult intellectual test. Black and White participants either (1) were primed with their racial identity and heard that the test had shown previous racial differences (Biased condition); or (2) were not primed with their racial identity and heard that the test had not shown previous racial differences (Fair condition). Results revealed a pattern of cardiovascular responses consistent with disengagement for Blacks in the Biased condition relative to the Fair condition. The implications for understanding disengagement as a response to stereotype threat are discussed.

#### A282

##### **SOCIO-ECONOMIC STATUS THREAT AND RISKY DECISIONS** Rusty McIntyre<sup>1</sup>, Eric Fuller<sup>1</sup>; <sup>1</sup>Wayne State University

The current recession has affected consumer confidence and created economic panic internationally. The psychological implications for groups varying in socio-economic status (SES) have yet to be delineated. Stereotype threat research indicates that negative stereotypes impair performance and domain identification (Steele & Aronson, 1995), but can also improve the performance of contrasting groups (Walton & Cohen, 2003). It is possible then, that the economic recession will have lasting implications for how high and low SES groups behave in situations invoking threat where group

image is relevant. We examined threat by making SES salient for students high and low in SES. Students were told they would complete a measure of financial risk assessment, under high salience conditions (asked to indicate SES prior to an assessment portrayed as diagnostic of financial ability) or under low salience conditions (students did not indicate SES, survey was described as a pilot measure). A crossover interaction was found,  $F(1, 39) = 7.53, p < .05$ . Low SES individuals were more cautious (less risky) when SES was salient than when SES was not salient,  $p < .05$  (demonstrating threat). High SES individuals, in contrast, were less cautious when SES was salient, than high SES individuals when SES was not salient,  $p = .10$  (demonstrating lift). Additionally, threat-relevant concerns and confidence were also seen for members low in SES. The results are seen as indicating that threat may cause a change in task perceptions for members who are negatively stigmatized, but may lead to benefits for members of positively stigmatized groups.

#### A283

##### **THE ROLE OF MOTIVATION IN SUBTLE STEREOTYPE THREAT** Allison E. Seitchik<sup>1</sup>, Jeremy P. Jamieson<sup>2</sup>, Stephen G. Harkins<sup>1</sup>; <sup>1</sup>Northeastern University, <sup>2</sup>Harvard University

Jamieson and Harkins (in press) have found support for the motivation-based, mere effort account of stereotype threat performance effects on GRE-Q items. This account proposes that threat motivates females to want to perform well, which potentiates prepotent responses. On GRE-Q problems, the prepotent response is to apply a solving approach: Applying known rules and equations to compute an answer (Gallagher & DeLisi, 1994). On solve-type problems the prepotent response is correct, and consistent with the mere effort account, threatened females' performance was facilitated. On the other hand, on comparison-type GRE problems the prepotent response is incorrect, and performance was debilitated. However, Stone and McWhinnie (2008) have argued that although blatant manipulations of stereotype threat, like the one used by Jamieson and Harkins (in press), may work through motivational mechanisms, subtle threat manipulations may operate through a different mechanism, working memory deficits (e.g., Schmader, Johns, & Forbes, 2008). Research has shown that working memory deficits undermine performance on even simple math problems (e.g., Logie, Gilhooly, & Winn, 1994). Thus, subtle threat should debilitate performance on both comparison and solve problems. To test this hypothesis, we used a subtle threat manipulation modeled on Schmader and Johns's (2003), and asked females to complete Jamieson and Harkins's (in press) GRE test. Once again, consistent with a motivational explanation, we found facilitation on the solve problems and debilitation on the comparison problems. Additionally, potentiation of the prepotent solving approach mediated the relationship between subtle threat and performance on the comparison problems.

#### A284

##### **IMPLICIT RACIAL ATTITUDES AND PERFORMANCE ON A SIMULATED SHOOTER TASK: RESULTS FROM POLICE CADETS AND COLLEGE STUDENTS** Katherine Knight Tuttle<sup>1</sup>; <sup>1</sup>University of Michigan

Recent cases of unarmed Black men being shot by police by mistake have stimulated research on how racial bias and stereotyping may affect shooting decisions. The current study examined how both implicit and explicit racial attitudes predicted performance on a simulated shoot task. Samples of police cadets and college students completed a Race IAT, the Modern Racism Scale (MRS), a simulated Shooter Task, and a questionnaire about other topics related to law. Examining cadets allowed comparison to past research (Correll, et al., 2007) to see if potential differences between the populations were a result of training or present at the time of hiring. Police cadets had a significantly higher implicit and explicit bias against Blacks than college students. Consistent with past research, Black "targets" yielded the fastest reaction times and there was a moderately significant interaction between the race of the target and weapon presence in both groups. IAT scores were not correlated with the number of mistakes made during the shooter task or with reaction time on the task. However, MRS scores were significantly related to the number of mistakes made when a target was Black and unarmed, and a

marginal relationship to the racial bias score calculated from the Shooter Task. These results suggest that measures of explicit racism may be more predictive of biased behavior in shootings than implicit measures. In addition, future directions for research comparing police and civilian populations are suggested.

#### A285

**HOW SUBTLE DIFFERENCE IN LANGUAGE USE INFLUENCES STEREOTYPIC JUDGMENTS: A JAPAN-US COMPARISON.** Sayaka Suga<sup>1</sup>, Heejung Kim<sup>2</sup>, Minoru Karasawa<sup>1</sup>, Arabo Beiki<sup>2</sup>, Munehisa Kaneda<sup>1</sup>; <sup>1</sup>Nagoya University, <sup>2</sup>University of California, Santa Barbara – Recent studies on the relationship between language use and person perception have demonstrated that abstract terms such as trait adjectives trigger top-down, expectancy-based information processing about a person. In contrast, concrete terms such as action verbs facilitate bottom-up processing. In this study, we proposed that descriptions of stereotype-relevant information using abstract terms would affect stereotypic judgments regarding vocational aptitude. Furthermore, we predicted that there would be a cultural difference in the effect of linguistic abstraction on stereotypic judgments. In the experiment, European American and Japanese undergraduate students were presented with a description of a "professor" containing either stereotype-consistent (SC) or stereotype-inconsistent (SI) information. The level of abstraction was manipulated by describing the target either in an abstract term (e.g., She is intelligent) or in a concrete verb (e.g., She answered a difficult question correctly). The participants rated the target's vocational aptitude as a professor. The results showed that SC information led to ratings of higher vocational aptitude of the target, particularly when the stimulus description was written in an abstract rather than a concrete term. In contrast, SI information resulted in lower vocational aptitude rating, especially when it was written in a more abstract term. The predicted cultural difference was not seen. However, there was a cultural difference in the level of perceived informativeness of adjectives and verbs. These results indicate that the abstract terms facilitated an expectancy-based judgment regarding the target's vocational aptitude. The role of linguistic abstraction in stereotypic judgment under a communicative context is discussed.

#### A286

**HOW TO APPROACH IMPLICIT PREJUDICE: THE ROLE OF APPROACH TRAINING IN REDUCING PREJUDICED BEHAVIOR** Annemarie M. Wennekers<sup>1</sup>, Rob W. Holland<sup>1</sup>, Daniël H. J. Wigboldus<sup>1</sup>, Ad Van Knippenberg<sup>1</sup>; <sup>1</sup>Behavioural Science Institute, Radboud University Nijmegen, the Netherlands – In this research, we start from the idea that implicit prejudice is largely based on (irrational) fear of outgroup members, and we focus on the implications of this link between fear and prejudice for understanding successful prejudice-reducing methods. Exposure therapy research has shown that approaching feared objects can help people to overcome fear and related avoidance. In line, it could be expected that approaching outgroup members can help to reduce fear and prejudice. Indeed, Kawakami et al. (2007) showed that approach movements toward outgroup members can reduce prejudice and prejudice-related behaviors. However, from this study it is not clear whether participants simply learn to approach outgroup members, or to decrease fear and unlearn to avoid outgroups. The goal of our study was to investigate this process by focusing on individual differences in prejudice level. Based on the proposed link between prejudice and fear, we expected that approach training would particularly reduce avoidance responses of highly prejudiced individuals. Our study revealed first evidence for this hypothesis. Participants were trained to either repeatedly approach or avoid pictures of outgroup members with a joystick. Then, participants were guided to a waiting room where a jacket and bag indicated the presence of an outgroup participant (c.f. Amodio & Devine, 2006). As compared to avoidance training, approach training decreased seating distance toward the outgroup member, but only for highly prejudiced

participants (measured by an IAT). Overall, with this study we have started to unravel the mechanism by which approach training can reduce prejudice.

#### A287

**INDIVIDUATION THROUGH EMERGENT ATTRIBUTE APPLICATION IN INCONGRUENT SOCIAL CONJUNCTIONS** Russell Hutter<sup>1</sup>, Chantelle Wood<sup>1</sup>, Rhiannon Turner<sup>1</sup>; <sup>1</sup>University of Leeds – The augmented application of emergent attributes (attributes associated with a social category conjunction, but not the constituents) in descriptions of incongruent social conjunctions (e.g., a male midwife) is a robust effect (e.g., Hastie, Schroeder, & Weber, 1990; Kunda, Miller, & Claire, 1990). Recently, Siebler (2008) and Hutter, Crisp, Humphreys, Waters, and Moffitt (2009) have shown that perceivers do not immediately generate emergent attributes on encountering an incongruent conjunction. This is at odds with the processes outlined in Kunda et al.'s (1990) impression formation model. Instead, consistent with Hastie et al.'s (1990) two-stage model, emergent attributes appear to be applied during a second processing stage involving complex reasoning, following failed attempts to fit a target to the constituents. Using an attribute generation task, we found that the application of emergent attributes to incongruent conjunctions is mediated by the degree to which a target is viewed as an individual (cf. as a group member). Specifically, the more the target was individuated, the more emergent attributes were applied, suggesting that Hastie et al.'s, 1990 two-stage model is compatible with broader models of impression formation (e.g., Fiske & Neuberger's, 1990 continuum model). Additionally, the application of emergent features was found to occur earlier in incongruent (cf. congruent) conjunctions. This relationship was mediated by how descriptive of the target perceivers considered each emergent attribute to be. This original work shows that emergent attributes are the result of complex reasoning based on explanatory individuation and furthermore, that emergence is crucial, although understudied in person construal.

#### A288

**THE QUICKER WE PROCESS, THE LESS WE'RE PREJUDICED?** Amy C. Moors<sup>1</sup>, Joseph E. Mosley<sup>2</sup>, Elizabeth L. Haines<sup>3</sup>, Bruce J. Diamond<sup>3,4</sup>; <sup>1</sup>University of Michigan, <sup>2</sup>Montclair State University, <sup>3</sup>William Paterson University, <sup>4</sup>University of Medicine and Dentistry of New Jersey – On the Implicit Association Test (IAT) categorization of highly associated concepts is more rapid than non-associated concepts. Greater implicit bias is associated with slower executive processing (Payne, 2005) and increased activity in executive control brain regions (Richeson et al., 2003). The role of speed in the IAT computation has been questioned (e.g., Blanton et al., 2006). Therefore, objectives were: (1) to evaluate relationships between multiple measures of speed and IAT performance (2) to extend findings to a socially neutral IAT. Fifty-two Caucasian adults ( $M = 23.8$ ,  $SD = 7.4$ ) completed a 3-back Processing and a Dual 2-Back Reaction Time Task, as well as a simple reaction time (SRT) measure. The Race IAT and a neutral flower-insect IAT were administered. There were correlations between the 3-back and the flower-insect IAT D-score ( $\rho = .24$ ,  $p = .05$ ) and with race IAT D-scores at the upper and lower quartiles ( $\rho = .356$ ,  $p = .029$  and  $\rho = .40$ ,  $p = .05$ ), respectively. Speed was correlated with latencies on the incompatible (R-IAT:  $\rho = .51$ ,  $p = .001$  and neutral:  $\rho = .47$ ,  $p = .003$ ) and compatible (R-IAT:  $\rho = .41$ ,  $p = .01$  and flower-insect:  $\rho = .41$ ,  $p = .01$ ) conditions of the race and neutral IATs, respectively. SRT was not correlated with any IAT measures. Higher-level processing speed, but not SRT, was related to lower implicit bias across both IAT tasks. The relationship between higher-order processing and race and neutral IAT D-scores and latencies may reflect a distinct processing style with associated neurophysiological correlates.

**A289****PREJUDICE AGAINST THE RELATIVELY SIMILAR: INTERGROUP ANNOYANCE, NOT ANXIETY, PREDICTS NEGATIVE ATTITUDES TOWARD CANADIANS**

Jennifer Hunt<sup>1</sup>, Alexis Luttrell<sup>2</sup>; <sup>1</sup>SUNY College at Buffalo, <sup>2</sup>SUNY University at Buffalo – The recent downturn in the U.S. economy is one of several factors that may have fostered negative attitudes toward Canadians among residents of U.S. border communities. The current study examined whether residents of one border community, Buffalo NY, have negative attitudes toward Canadians, and if so, what factors predict such prejudice. Consistent with Integrated Threat Theory (ITT), we hypothesized that prejudice against Canadians would be associated with perceptions of realistic threat (e.g., the strong Canadian dollar), symbolic threat (e.g., Canada's liberal social policies), and negative stereotypes (e.g., that Canadians are cheap). However, given the regular contact and cultural similarities between U.S. and Canadian residents, we did not expect intergroup anxiety to predict attitudes toward Canadians. Instead, we predicted those attitudes would be associated with intergroup annoyance, the feeling that interactions with Canadians were irritating. 150 participants (69% women, 74% White, 73% employed) completed a survey about their attitudes and beliefs about Canadians. Results confirmed that participants had more negative attitudes toward Canadians than U.S. residents,  $t(149)=3.39$ ,  $p<.005$ . Bias against Canadians was correlated with realistic threat,  $r=.45$ , symbolic threat,  $r=.51$ , and negative stereotypes,  $r=.54$ , as well as other factors, such as concerns about distinctiveness,  $r=.52$ , all  $ps<.001$ . As predicted, intergroup annoyance was more strongly correlated with attitudes about Canadians,  $r=.56$ , than was intergroup anxiety,  $r=.16$ . In addition to providing an initial assessment of prejudice against Canadians, these findings suggest that the intergroup anxiety component of ITT may not apply to situations in which outgroups are considered to be relatively similar.

**A290****REVISITING THE EFFECTS OF POLITICAL ORIENTATION ON PREJUDICE TOWARD MINORITY GROUPS**

Mason D. Burns<sup>1</sup>, Russell J. Webster<sup>1</sup>, Donald A. Saucier<sup>1</sup>; <sup>1</sup>Kansas State University – Much research shows that political conservatives overtly report more negative attitudes toward various outgroups when compared to liberals (Whitley & Kite, 2006). However, just as conservatives report more prejudice toward groups who violate their worldviews (e.g., Webster et al., 2009), we reason that liberals will likely report more prejudice toward groups perceived as violating liberal worldviews (i.e., support for social change and equality; Jost, 2006), particularly Christian fundamentalists (CFs). CFs are likely perceived as resisting social change (e.g., opposition to evolution) and supporting inequality (e.g., opposition to same-sex marriage), stances which align with conservative worldviews. Thus, we hypothesized that liberals would report more prejudice toward CFs, even after controlling for both measures of self-religiosity and attitudes toward religion/Christianity. In total, 120 undergraduates completed measures of: political orientation, self-religiosity, attitudes toward religion/Christianity, prejudice toward CFs, prejudice toward social groups that conflict with conservative ideology (Arabs, gay men, lesbians, and feminists), and prejudice toward a "control" group (Belgians) that is not likely perceived as violating/upholding liberal or conservative beliefs. As predicted, liberalism was negatively related to attitudes toward CFs and positively related to attitudes toward Arabs, gay men, lesbians, and feminists even after controlling for religiosity. Further, political orientation did not predict prejudice toward Belgians. These findings suggest that liberals/conservatives report more prejudice depending on the target, while political orientation does not predict prejudice in some cases. Future research should ascertain whether violations of liberals'/conservatives' ideology (support/opposition to change and equality) do indeed underpin the relationship between political orientation and prejudice.

**A291****DISCREPANCIES BETWEEN GENERAL AND SPECIFIC STANDARDS: POTENTIAL PREJUDICE REDUCTION AMONG HIGHLY PREJUDICED PEOPLE**

Patrick Schnarrenberger<sup>1</sup>, Patricia Devine<sup>1</sup>; <sup>1</sup>University of Wisconsin-Madison – Although extensive research has examined the processes and implications of prejudice reduction among low-prejudice individuals, far less research has examined prejudice reduction among high-prejudice individuals. The present study attempts to break ground in this area through examining the interactions between prejudice, fairness values, and standards for treating others. Fairness values can be defined either according to equality of treatment (i.e., people should treat others equally) or according to equality of effort (i.e., peoples' outcomes should be commensurate with their effort) (Monteith & Walters, 1998; Feldman, 1988; Lipset, 1979). Equality of treatment implies endorsing standards that generally proscribe unequal treatment (general standards); these are usually stricter than high prejudice people's standards for their treatment of stigmatized group members (specific standards). The present study develops a scale to measure discrepancies between participants' general and specific standards. High-prejudice individuals who endorse equality of treatment should exhibit discrepancies between these standards. These discrepancies constitute violations of fairness values to which these individuals feel obligated, resulting in feelings of guilt when the discrepancies are made salient. Individuals in the general population completed the scale, and the relationships between the novel scale and prejudice, affect, and fairness values were assessed. For high-prejudice individuals, discrepancies between general and specific standards predict differing patterns of affect, depending on the individual's fairness values. The results point to a potential route for prejudice reduction among a subgroup of high-prejudice individuals who define fairness according to equality of treatment.

**A292****ARE ALL WHITES RACIST? STEREOTYPE THREAT EFFECTS ON EXPLICIT RACISM**

Rachel E. Tennial<sup>1</sup>, Jana Hackathorn<sup>1</sup>, Melinda Bullock<sup>1</sup>, Amy Garczynski<sup>1</sup>, Erin Solomon<sup>1</sup>, Richard D. Harvey<sup>1</sup>; <sup>1</sup>Saint Louis University – Traditionally stereotype threat research has focused on the effect threat has on task performance among minorities (Steele & Aronson, 1995). Recent stereotype threat research has investigated Whites' fears of appearing prejudiced on both an implicit level (Frantz et al., 2004) and with behavioral measures (Goff et al., 2008). The current study sought to expand this research by measuring Whites' fears of appearing prejudice explicitly. However, because measures of racism prime threat themselves, we measured racism indirectly by examining correlates of prejudice such as the Protestant Work Ethic (Feather, 1984). White participants ( $N=88$ ) were instructed by a White researcher that they would be engaging in a conversation with either a White or Black discussion partner on either a neutral (senior comprehensive exams) or race-related topic (racial profiling). Results indicated that participants anticipating a conversation with a Black discussion partner scored higher in Protestant Work Ethic compared to participants anticipating a conversation with a White discussion partner,  $F(1,83) = 5.38$   $p <.05$ . Also, participants anticipating discussion of a neutral discussion topic reported more positive affect than participants anticipating discussion of a race-related topic as measured via the Positive and Negative Affect Scale,  $F(1,83) = 4.48$   $p <.05$ . Present findings suggest that a White individual's mere anticipation of engaging in a conversation with a Black individual increases scores on a correlate of racism and anticipation of discussion of a race-related topic decreases positive affect.

**A293**

**WHEN EXPECTING THE BEST LEADS TO SUFFERING THE MOST: OPTIMISTIC EXPECTATIONS, DISSONANCE, AND THE CONFRONTATION OF PREJUDICE** Heather Rasinski<sup>1</sup>, Andrew Geers<sup>1</sup>, Alexander Czopp<sup>2</sup>, Jackie Smoktonowicz<sup>1</sup>; <sup>1</sup>University of Toledo, <sup>2</sup>Western Washington University – Cognitive dissonance can arise when targets of prejudice remain silent after hearing a biased statement from another individual. Prior research shows that targets can reduce this dissonance by evaluating the perpetrator more positively (Rasinski & Czopp, 2009). We tested whether dispositional optimism moderates this confrontational dissonance effect. We propose that, because optimists expect to be active in the face of threats and challenges (Rasinski & Geers, 2009), they expect themselves to confront prejudiced others. Consequently, high optimists should experience greater dissonance from not confronting than low optimists. Two studies were conducted to test this hypothesis. In Study 1, 168 female participants were exposed to a male confederate who made a sexist comment. Afterwards, participants were given an opportunity to confront the confederate or not (no confrontation actually occurred in either study). Consistent with the dissonance theory prediction, high optimists were more likely than low optimists to rate the sexist confederate positively—but only in the opportunity to confront condition. In Study 2, 40 female participants interacted with a male making a sexist comment over an instant messenger program. All participants were given the opportunity to confront. Before rating the male, half of the participants were given a chance to self-affirm, whereas the other half were not. Results in the no-affirmation condition replicated the findings of Study 1—optimists showed greater dissonance reduction. However, in the self-affirm condition, this effect was reduced to non-significance. Taken together, these two studies demonstrate that high optimists generate stronger confrontational dissonance effects than low optimists.

**A294**

**THE NEGATIVE EFFECT OF DOMAIN RELEVANT SELF-AFFIRMATION ON PREJUDICE** Brian Collisson<sup>1,2</sup>, Luis Rivera<sup>1</sup>, Nilanjana Dasgupta<sup>3</sup>; <sup>1</sup>California State University, San Bernardino, <sup>2</sup>University of Florida, <sup>3</sup>University of Massachusetts - Amherst – Situations that provide self-affirmation decrease negative intergroup attitudes presumably because affirmations buttress one's positive self-image and thus satisfy self-image maintenance needs (e.g., Fein & Spencer, 1997). The current study examines the limitations of the beneficial effect of self-affirmation on intergroup attitudes by testing the conditions under which self-affirmation can exacerbate prejudice. We hypothesized that self-affirmation increases prejudice when an ingroup quality is affirmed followed by an opportunity to evaluate an outgroup that is stereotyped as deficient in terms of that quality. To test this hypothesis, heterosexual men received affirming feedback about one of two masculine-related domains – toughness or success – or did not receive any feedback. Then, participants completed measures of prejudice, similarity to gay men, and identification with men in general. Results showed that participants who received an affirmation in the domain of "toughness" expressed greater antigay prejudice and in turn perceived less similarity between themselves and gay men when compared to those in the "success" affirmation and control conditions. In line with our hypothesis, affirming participants' masculinity by highlighting their toughness increased antigay prejudice because this attribute is directly applicable to gay stereotypes whereas affirming masculinity by highlighting their career ambition did not influence attitudes because it is not applicable to gay stereotypes. Furthermore, participants' identification with men did not vary as a function of feedback condition, which suggests that the results cannot be explained by mere identity salience. Together with past research, we illustrate the conditions under which self-affirmation and its motivational processes influence intergroup attitudes.

**A295**

**CHANGING BEHAVIORS BY CHANGING ATTITUDES: THE IMPACT OF TRAINING TO REDUCE PREJUDICE ON IMMEDIACY BEHAVIORS DURING INTERRACIAL INTERACTIONS** Curtis Phillips<sup>1</sup>, Kerry Kawakami<sup>1</sup>; <sup>1</sup>York University – Research has demonstrated that implicit prejudice is related to behavior during interracial interactions such that greater levels of implicit prejudice are associated with increased negative nonverbal or spontaneous behavior. Though many interventions for reducing implicit prejudice have been investigated, very little research has examined the impact of these interventions on actual behavior during interracial interactions. The goal of the present research, therefore, was to investigate the impact of one intervention designed to reduce implicit prejudice – extensive training to associate positive concepts with Blacks – on an important behavior during interactions – immediacy behaviors. The absence of immediacy behaviors during interracial interactions have been shown to have important negative consequences for Blacks (Word, Zanna, & Cooper, 1974). Participants in this study were randomly assigned to one of two training conditions in which they either learned to associate positive or negative concepts with Blacks before completing an Implicit Association Test (IAT) to assess implicit prejudice. Once the IAT was complete participants completed a task with either a Black or White confederate. During this task participants' immediacy behaviors toward the confederate were measured. The results showed that participants trained to associate positive rather than negative concepts with Blacks sat closer to and directly faced their partner to a greater extent when completing the task with a Black confederate but not a White confederate. In addition, the effect of the training on subsequent immediacy behaviors with a Black confederate was mediated by implicit prejudice.

**Social Judgment/Decision-Making****A296**

**CHILDREN AND THE LENIENCY BIAS** Jacqueline Pope<sup>1</sup>, Christine Kelley<sup>1</sup>, Nola Schmidt<sup>1</sup>; <sup>1</sup>Western Kentucky University – The current research focuses on the leniency bias and children. Previous research has found that adults tend to be more lenient in their sentencing decisions, particularly in regards to physical attractiveness, gender of victim, gender of defendant, social status, and race (Darby & Jeffers, 1988; Efran, 1974, LaFrance & Hecht, 1995, Landy & Aronson, 1969, Mazzella & Feingold, 1994). We suspect that this leniency bias is also apparent across various types of settings, not only the courtroom. We proposed that academic status and popularity would influence guilt and punishment recommendations in young people in a school setting. Middle school students (i.e., grades 6-8) read scenarios that contained information about a hypothetical student who allegedly engaged in some illegal behavior (i.e., stealing or cheating on a test). Following the scenarios, students were asked to determine what action the teacher should take to handle the situation. Result showed that participants were more likely to assign less blame and a less harsh penalty to those students considered popular/good students. Additional results, along with the implications of the findings will be discussed.

#### **PRESENTING THE SELF AS AN ALCOHOL USER: THE ROLE OF IMPRESSION MOTIVATION AND IMPRESSION CONSTRUCTION** Megan

Alison O'Grady<sup>1</sup>; <sup>1</sup>Colorado State University – Many negative consequences occur each year due to alcohol misuse among college students in the United States, particularly those in their first year (Hingson et al., 2005). The purpose of this study was to investigate underage college freshmen alcohol use behavior from the perspective of the two-component model of impression management (Leary & Kowalski, 1990). This model suggests that self-presentational behavior is affected by two components: impression motivation and impression construction. These components can be influenced by both situational and dispositional factors. In this study (n = 232), situational impression motivation (low vs. high) and situational impression construction (alcohol norm vs. control) were manipulated. The dependent variable, alcohol self-presentation, was dichotomized based on whether participants presented themselves as an alcohol user in a profile they created to introduce themselves to a group they believed they were being assigned to. It was predicted that participants in the high situational impression motivation condition, who were also in the alcohol norm situational impression construction condition, would have the highest likelihood of being an alcohol self-presenter. Dispositional measures related to impression motivation (e.g., self-monitoring) and alcohol-related impression construction (e.g., alcohol expectancies) were also assessed. Logistic regression analyses suggested that situational alcohol impression construction led to increased alcohol self-presentation. Neither situational impression motivation alone, nor the interaction between situational impression motivation and alcohol impression construction were significant predictors of alcohol self-presentation. Also, several dispositional variables were significant moderators. Results confirm the importance of interpersonal factors, particularly social image factors, in the study of alcohol use.

### B2

#### **THE EFFECT OF EXPOSURE TO SMOKING SCENES IN FILMS ON IMMEDIATE SMOKING: A CONTROLLED LABORATORY STUDY** Dikla

Shmueli<sup>1</sup>, Judith Prochaska<sup>1</sup>, Stanton Glantz<sup>1</sup>; <sup>1</sup>University of California, San Francisco – Smoking is extremely prevalent in contemporary movies made in the United States. Research has shown an association between onscreen smoking and smoking attitudes and behaviors. The goal of the current experiment was to investigate the direct effect of exposure to smoking scenes in a movie montage on subsequent smoking behavior in a sample of young adult smokers. Participants were 100 smokers recruited from the San Francisco Bay Area. They were randomly assigned to watch a movie montage comprised of clips that either did or did not contain smoking scenes. All participants were then given a 10-minute break, and whether or not they smoked during the break served as the primary dependent variable. They were not aware that a primary goal of the study was to measure their smoking behavior during the break, so as not to influence their decision to smoke. Results confirmed a causal relationship between exposure to smoking scenes in the film clips and subsequent smoking behavior. Smokers who watched the montage with smoking scenes were more likely to smoke during the break than those who watched the smoke-free montage (OR 3.32, 95% confidence interval [CI] 1.12-9.85). Greater prior exposure to smoking in movies, greater level of nicotine dependence, and earlier stage of readiness to quit smoking predicted smoking during the break. The results may have

implications for individuals attempting to reduce their smoking and for the necessity of preventative steps by the U.S. film industry to reduce the impact of exposure to smoking on screen.

### B3

#### **TRANSPERSONAL EFFICACY AND AUTOMATIC EFFORT ALLOCATION IN TEAMS AND COMPETITIONS** Kyle Emich<sup>1</sup>; <sup>1</sup>Cornell University – Groups

are omnipresent in modern organizations. Due to this, individual motivation loss in groups has been a perennial topic of study in the organizational literature. Traditionally, this topic has been studied from a practitioner viewpoint focused on environmental and structural interventions. The current poster instead focuses on automatic individual judgment processes that occur during group formation by integrating findings from the social psychological literature into this traditionally organizational topic. Specifically, transpersonal efficacy, or one's confidence in another's ability to produce a given attainment, is introduced and used to explain patterns of individual effort allocation in group tasks and competitions. Two studies find that individuals with high self-efficacy decrease their transpersonal efficacy in teammates and increase their transpersonal efficacy in opponents in order to allocate effort to areas they believe themselves to be skilled in. The opposite attributions are found to be made by those with low self-efficacy in order to avoid putting effort into areas they believe themselves to be poor in. Effort and performance are then shown to be linked to these transpersonal efficacy attributions. Results are discussed in the context of effort allocation attributions made during group formation and how individual level interventions based on social psychological findings can produce similar effects to environmental interventions while incurring fewer costs.

### B4

#### **BUYING-IS-FOR-BELONGING BELIEFS AND MATERIALISTIC VALUES AS PREDICTORS OF COMPULSIVE BUYING: A MEDIATIONAL MODEL** Paul

Rose<sup>1</sup>, Stephanie Comstock<sup>1</sup>; <sup>1</sup>Southern Illinois University Edwardsville – People frequently use buying as a means of achieving social goals. Recent research suggests that one of the social goals some people believe they can achieve through their buying is greater social acceptance (or belonging). In this study we examined whether people who believe that buying can enhance their belonging might be at greater risk for compulsive buying (a tendency to buy so excessively that it results in personal and interpersonal difficulties). On the basis of past research, we also examined whether materialism (the valuation of wealth and luxury) mediates the relationship between buying-is-for-belonging beliefs and compulsive buying. One hundred undergraduates completed well-validated measures of compulsive buying, buying-is-for-belonging beliefs, materialism and social desirability. As predicted, buying-is-for-belonging beliefs were positively associated with compulsive buying and materialism mediated this relationship. The predicted relationships held when social desirability was controlled. The mediational model suggests that buying-is-for-belonging beliefs may predispose consumers to problematic buying habits by increasing their valuation of wealth and luxury, which in turn increases the amount they buy. Inducing skepticism about the effectiveness of buying as a means of belonging may be an effective way to help those who buy excessively.

**B5**

**PAY ME NOW – PAY ME LATER: HOW THE STRUCTURE OF CRIMINAL INTERROGATIONS CAPITALIZES ON A ‘HERE AND NOW’ BIAS TO ELICIT CONFESSIONS FROM CRIMINAL SUSPECTS.** Stephanie Madon<sup>1</sup>, Max Guyll<sup>1</sup>, William Exley<sup>1</sup>, Holly Figueroa<sup>1</sup>, Roy Molina<sup>1</sup>, Kellie Olson<sup>1</sup>, Kyle Scherr<sup>1</sup>; <sup>1</sup>Iowa State University – Confessions are one of the most persuasive forms of evidence in criminal trials, and interrogations are designed to increase suspects’ willingness to confess to crimes. Drawing on research showing that immediate consequences influence behavior more than distal ones, we hypothesized that suspects confess to crimes to escape the immediate consequences associated with continued denials during an interrogation even though doing so increases their risk for worse consequences later (e.g., imprisonment). Participants (N=82) were assigned to one of three conditions that manipulated the consequences they faced for responses to an interview that assessed whether or not they had ever committed 21 different crimes. Participants in the confession condition answered repetitive questions every time they denied having committed a crime, but risked meeting with a police officer if they tended to confess to the crimes. Participants in the denial condition answered the repetitive questions every time they confessed to a crime, but risked meeting with the police officer if they tended to deny the crimes. Control participants did not have any consequences for their responses. Results indicated that confession rates were highest in the confession condition (M=7.92 vs. Denial M = 4.57, Control M = 5.52),  $p < .02$ , and that this effect was strongest for crimes that appeared in the second half of the interview,  $p < .001$ . These findings suggest that police interrogations capitalize on people’s tendency to focus on the here and now and that this bias becomes stronger as suspects repeatedly face immediate and negative consequences for continued denials during an interrogation.

**B6**

**AN INTEGRATION OF THE PROTOTYPE/WILLINGNESS MODEL AND TERROR MANAGEMENT THEORY IN THE EXPLANATION OF SEXUAL BEHAVIOR.** Kristina Wilson<sup>1</sup>, Megan A. O’Grady<sup>1</sup>; <sup>1</sup>Colorado State University – Prior Terror Management Theory research suggests that mortality salience (MS) leads to increased willingness to engage in sexual risk behaviors (Taubman-Ben-Ari, 2004). The current study sought to extend research examining the influence of MS on sexual risk behavior by incorporating the Prototype/Willingness model (Gibbons & Gerrard, 1995). Specifically, we examined whether MS interacts with perceptions of the prototypical young adult who engages in unprotected sex to predict willingness to engage in unprotected sex and the appeal of engaging in sexual risk behaviors. It was hypothesized that the effects of MS would be moderated by prototype perception, such that the effects of MS would be stronger for those individuals who hold favorable prototype perceptions. Gender was also examined as a moderator. Participants (n = 159) completed a 12-item measure assessing perceptions of the typical young adult who engages in unprotected sex. Participants were randomly assigned to a MS or control condition. Willingness to engage in unprotected sex was assessed with 3-items ( $\alpha = .75$ ) and appeal of engaging in sexual risk behaviors was assessed with 5-items ( $\alpha = .80$ ). Results suggested that prototype perception and the interaction between prototype perception and gender significantly predicted willingness to engage in unprotected sex and the appeal of engaging in sexual risk behaviors. However, prototype perception did not moderate the effects of MS as hypothesized. Findings suggest that the Prototype/Willingness model does not add additional insight into how MS affects sexual risk behavior, but confirms that prototypes are important predictors of behavioral willingness.

**B7**

**HUMANIZING NONHUMANS: THE ROLE OF MIMICRY IN HUMAN-ROBOT INTERACTION** Friederike Eyssel<sup>1</sup>, Gernot Horstmann<sup>1</sup>, Claudia Wagner<sup>1</sup>, Hegel Frank<sup>1</sup>; <sup>1</sup>University of Bielefeld, Germany – In recent years, social psychologists have become increasingly interested in the study of anthropomorphism, the tendency to ascribe uniquely human characteristics to nonhumans. Would a robots’ nonverbal response (emotional vs. neutral) during human-robot interaction (HRI) affect the degree to which it is humanized? We tested this in an experiment that investigated the attribution of human traits and emotions to the iCat (Philips Research, Eindhoven). The iCat is a zoomorphic robot with human-like facial features that can be operated by a "Wizard of Oz" to form various emotional expressions (e.g., fear, happiness). Participants were instructed to read passages of a fairy-tale with vital emotional expression to the iCat. We experimentally manipulated the robots’ nonverbal responses to the text passages: That is, in the experimental condition, the iCat displayed motor mimicry, whereas in the control condition, the iCat displayed neutral emotional responses (e.g., eye blink). Results showed that generally, participants perceived the iCat as capable of experiencing emotions. Importantly, however, as predicted, participants ascribed both more primary emotions and human nature traits to the robot in the mimicry vs. in the control condition. Furthermore, response congruency led to higher perceived likeability of the robot than a neutral reaction. Our results document the importance of the interplay of form and function in the attribution of humanness to robots. Ultimately, this contributes to smoother HRI and an increased usability of robots in applied settings. These and further implications of our findings will be discussed.

**B8**

**SEX AND CONFIDENCE AS MODERATORS OF THE ASSOCIATIONS AMONG ONE’S OWN APPROVAL, PERCEIVED PEER APPROVAL, AND ALCOHOL CONSUMPTION** Clayton Neighbors<sup>1</sup>, Kristen Lindgren<sup>2</sup>, Angelo DiBello<sup>2</sup>, Megan Jensen<sup>1</sup>, Andy Kurz<sup>1</sup>; <sup>1</sup>University of Washington, <sup>2</sup>University of Richmond – Alcohol consumption among young adults is strongly influenced by one’s own attitudes and perceptions of peer approval, with some evidence suggesting men are more sensitive to peer approval than women are (Prentice & Miller, 1993). The present research was designed to evaluate sex and confidence in both one’s own approval and in the estimates of one’s friends’ approval of drinking as moderators of the associations between attitudes and perceptions of peer approval, and drinking behavior. Data were drawn from a longitudinal intervention trial and included three time points at six month intervals. Participants included 818 (58% female) college students from a large Pacific Northwest university who reported at least one episode of heavy drinking in the past month at screening. Assessments were completed over the internet and included measures of one’s own approval of drinking, confidence in own approval, perceptions of friends’ approval of drinking, confidence in friends’ approval, and self-reported drinking behavior. Data were analyzed using hierarchical generalized linear modeling, where drinking was Poisson distributed. Results indicated that confidence augmented associations between one’s own attitudes and perceived friends’ approval, and drinking. Perceptions of friends’ approval was most strongly associated with drinking for men who were confident in their estimates of friends’ approval and least strongly associated with drinking for women who were confident in their own attitudes about drinking. Results suggest consideration of alternative emphases on self for women, and friends’ for men, when discussing peer influences on drinking in the context of brief alcohol interventions.

**B9**

**ANTECEDENTS AND CONSEQUENCES OF COMMITMENT TO THE NATURAL ENVIRONMENT** Anthony Coy<sup>1</sup>, Jody Davis<sup>1</sup>, Ben Le<sup>2</sup>; <sup>1</sup>Virginia Commonwealth University, <sup>2</sup>Haverford College – The present research focuses on the connection between individuals’ relationships with the environment and their environmental behavior. Recent research derived from interdependence theory introduced the concept of commitment to

the natural environment (Davis, Green, & Reed, 2009), which we define as psychological attachment to and long-term orientation toward the natural world. Close relationships research has identified three key antecedents to commitment: satisfaction, alternatives, and investments (Rusbult, 1980; Le & Agnew, 2003). In the present research, we developed new versions of these measures in order to explore whether these antecedents apply to commitment to the environment. Factor analysis of potential scale items revealed three factors with desirable factor structure. In a regression analysis, satisfaction and investments (but not alternatives) predicted commitment. Commitment, in turn, predicted an established measure of general ecological behavior as well as our new measure of willingness to sacrifice for the environment, even when controlling for ecological worldview, inclusion of nature in the self, connectedness to nature, and environmental identity. Moreover, commitment mediated the effects of satisfaction and investments on general ecological behavior and willingness to sacrifice. Individuals who are satisfied with and invested in the natural world are likely to be committed to the environment, and to move beyond self-interest and act with the well-being of the environment in mind.

### B10

**ILLEGITIMATE LEADER: IMPACT ON SUBORDINATES' PERCEPTION AND BEHAVIOR IN LEADER-SUBORDINATE INTERACTION** Annick Darioly<sup>1</sup>, Marianne Schmid Mast; <sup>1</sup>University of Neuchâtel – People do not leave companies, they leave bosses, and one reason they do so is because they perceive their superior as incompetent. Expectation States Theory (EST) posits that if leaders lack task competence, they are in a situation of illegitimacy. In 2 studies we focused on leader task incompetence and how subordinates perceive such illegitimate leaders and how they behave towards them. In both studies, 80 participants in a subordinate role interacted with either a legitimate (task-competent) or an illegitimate (task-incompetent) leader on a problem-solving task. Legitimacy of the leader was manipulated in both studies by indicating that the leader was either an expert in the matter to discuss (legitimate) or a novice (illegitimate). In Study 1, participants interacted via email with a bogus male leader (a scripted computer program). In Study 2, participants were involved in a face-to-face interaction with a trained male confederate as leader. Results showed that subordinates interacting with an illegitimate leader perceived him as less dominant, behaved more dominantly, resisted more to the leader's influence, but were not more task involved. Perceived leader dominance mediated the relation between leader competence and subordinate dominance behavior, and between leader competence and subordinate resistance (only in Study 1). Finally, task performance was worse when interacting with an illegitimate leader. Thus, having an illegitimate leader affects the subordinates' perception of the leader, affects how the subordinate interacts with the leader, and has detrimental effects on performance although some aspects of this illegitimacy can be compensated by the subordinate.

### B11

**WHEN SIMILARITY MAKES A DIFFERENCE: PREDICTING ADHERENCE BEHAVIOR WITHIN EXERCISE GROUP SETTINGS.** William L. Dunlop<sup>1</sup>, Mark R. Beauchamp<sup>1</sup>; <sup>1</sup>The University of British Columbia – Although the similarity-attraction hypothesis has received considerable support within the domain of social psychology, very little work has explored its potential applicability to the explanation of adherence behaviours within exercise class settings. The current study sought to address this gap in the literature. At the end of the second and eighth week of their respected courses, participants (N = 402) from 46 registered group-based exercise courses completed a questionnaire assessing the level of perceived similarity between themselves and the other group members. Perceptions of global similarity (assessed by the proportion of the group that members believed were very similar to themselves) taken after the second week of the program were found to predict adherence behaviors over the 8-week period studied. A secondary purpose of this study was to identify the compositional attributes of the group that contributed to this global perception. Measures of surface-level (i.e., observable quali-

ties such as age and gender) and deep-level (i.e., non-observable qualities such as attitudes and previous life experiences) similarity were also administered during the two data collection periods. Perceptions of surface-level similarity (i.e., age, physical condition, and appearance) were found to significantly predict global perceptions of similarity at both times. Perceptions of deep-level similarity did not contribute to this prediction during either time point. These results highlight the importance of considering perceptual similarity and class composition when attempting to design effective group-based exercise programs. The findings also highlight the exercise group as a potentially fruitful subject for the application of social psychological theories.

### B12

#### **PERFORMANCE ANXIETY, PERFORMANCE EXPECTATION AND PERSONALITY VARIABLES AS PREDICTORS OF SPORTS PERFORMANCE FLUCTUATIONS** Sindhuja Sankaran<sup>1</sup>; <sup>1</sup>Cardiff University – Evidence

exists suggesting the presence of two groups– those who perform better during training (Training Champions) and those who perform better during competition (Competition Champions). This has led many researchers to investigate the factors that could lead to such performance fluctuations. The present study was designed to understand these fluctuations as a result of personality characteristics and performance anxiety. One hundred and twenty sports persons, both male and female were chosen from India belonging to various individual sports categories. They were assessed using the Sports Competition Anxiety Test (SCAT) and the NEO-FFI. The sample was then divided into two groups – those who rated their performance better during training and those who rated their performance better during competition. In general, training champions showed higher levels of performance anxiety, higher levels of Neuroticism and lower levels of Conscientiousness than the competition champions. The study was further extended to assess the effect of priming on performance expectancies amongst thirty elite track and field athletes. An objective measurement of the performance was taken during the athlete's training period and was compared to previous competition timings to categorize the athletes as Training or Competition champions. Positive and negative primes were then introduced. The primes included giving performance related information about one's ingroup. An objective measurement of the post prime performance was taken again. In general, training champions showed lower performance expectancies and were more susceptible to a negative prime and less susceptible to a positive prime affecting objective performance than Competition champions.

#### **PSYCHOSOCIAL MEDIATORS OF THE RELATION BETWEEN EARLY SEXUAL ONSET AND SUBSEQUENT RISKY SEXUAL BEHAVIOR** Amy E. Houlihan<sup>1</sup>, Frederick X. Gibbons<sup>2</sup>, Meg Gerrard<sup>3</sup>, Lynn Fahey<sup>1</sup>; <sup>1</sup>Texas A&M University - Corpus Christi, <sup>2</sup>Dartmouth College, <sup>3</sup>Dartmouth Medical School – Adoles-

cents who become sexually active at early ages are at an increased risk for subsequent risky sexual behavior, sexually transmitted infections, and unintended pregnancy. Little previous research, however, has identified the mechanisms through which early sexual onset influences later sexual behavior. Thus, the goal of this research was to examine psychosocial mediators of this relation. Data from the Family and Community Health Study (FACHS), a longitudinal study of factors affecting the mental and physical health of African American families, were used to test the hypothesis that sexual attitudes, prototypes, and behavioral willingness mediate the effect of early sexual onset on later risky sexual behavior. Over 6 years and 4 waves of data collection, adolescents reported: age of sexual onset (early onset = before Time 2, age 12.5), favorability of sexual prototypes (Time 1, age 10, and Time 4, age 18.5), attitudes toward casual sex and infidelity, willingness to engage in risky sex, and risky sexual behaviors (Time 4). Regression analyses revealed that, controlling for Time 1 prototype favorability, early sexual onset was associated with more favorable attitudes toward casual sex and infidelity, more favorable images of the typical peer who has casual sex, and more willingness to be unfaithful to a partner. Each of these variables medi-

ated the effect of early onset on adolescents' sexual behavior. These findings suggest that early sexual onset is a risk factor for subsequent unsafe sexual behavior in part because of its association with favorable sexual attitudes, prototypes, and willingness regarding casual sex and infidelity.

#### B14

##### **WHEN PERFORMANCE BEGINS TO SLIP: HOW STEREOTYPES AND STANDARDS AFFECT INFERENCES OF INCOMPETENCE** Kathleen

Fuegen<sup>1</sup>, Monica Biernat<sup>2</sup>, Diane Kobrynowicz<sup>3</sup>; <sup>1</sup>Northern Kentucky University, <sup>2</sup>University of Kansas, <sup>3</sup>University of Texas – We distinguish between minimum and confirmatory standards of incompetence and hypothesize that for groups stereotyped as relatively competent (e.g., White men), confirmatory standards of incompetence are higher (more information is required to confirm incompetence), but minimum standards of incompetence are lower (suspicion of incompetence occurs earlier, as it less expected), relative to groups stereotyped as relatively incompetent. In Study 1, participants indicated either the MINIMUM number of behaviors necessary to SUSPECT that a person may be incompetent, or the TOTAL number of behaviors necessary to CONFIRM that a person is incompetent. Men were held to lower minimum but higher confirmatory standards than women. In Studies 2 and 3, participants role-played the position of Director of a corporate training program. They were exposed to a poor-performing White male or female (Study 2) or Black or White male (Study 3) trainee and were asked to record "notable" behaviors in either their "informal notes" (instantiating a minimum standard) or a "formal performance log" (instantiating a confirmatory standard). As expected, fewer negative behaviors were recorded in the formal log, but more negative behaviors were recorded in informal notes, for White male trainees. Firing decisions mimicked these patterns and were partially mediated by attention to negative behaviors.

#### B15

##### **FREQUENT FACEBOOK USE: MALADAPTIVE ADDICTION OR HEALTHY SOCIAL STRATEGY?** Neetu Abad<sup>1</sup>, Kennon Sheldon<sup>1</sup>, Chris Hinsch<sup>1</sup>;

<sup>1</sup>University of Missouri – Online social networking tools such as Facebook have become increasingly used by many individuals. Many commentators have extolled the benefits of these social networking sites as a way to connect people with one another. However, others have suggested that frequent Facebook use may be a maladaptive addiction that can actually make people lonelier. We examined these issues using a measure of the need for relatedness (or belongingness), distinguishing between the presence of satisfaction (connectedness; positively worded items) and the absence of satisfaction (loneliness; negatively worded items). Paradoxically, three studies found positive associations between the amount of Facebook use and both loneliness and connectedness, although loneliness and connectedness are negatively associated themselves. We attempted to explicate this pattern via a longitudinal process perspective, finding in Study 2 that loneliness prompts people to cope by using Facebook, rather than suggesting that Facebook use causes loneliness. Study 3 asked users to "quit" for 48 hours, and found that increased loneliness during this period predicted greater Facebook use upon return, which in turn predicted increased connectedness at the end of the study. These results suggest that Facebook use is an adaptive coping response which can produce enhanced relations with others. Implications for theories of psychological needs are considered, as well as possible moderators that might pinpoint for whom frequent Facebook use really is a problem.

#### B16

##### **ASSESSING THE FEEDBACK LOOP: A LONGITUDINAL EXAMINATION OF HIV/AIDS DISCLOSURE** Stephenie Chaudoir<sup>1</sup>, Diane Quinn<sup>2</sup>, Jeffrey

Fisher<sup>2</sup>, Stephanie Milan<sup>2</sup>; <sup>1</sup>Bradley University, <sup>2</sup>University of Connecticut – Disclosure is a critical component of the lives of individuals who live with a concealable stigmatized identity. The disclosure process may be particularly complex in the context of HIV/AIDS, where disclosing renders people vulnerable to severe stigmatization but can also yield psy-

chological benefits and aid in the prevention and treatment of HIV/AIDS. While many theorists have hypothesized that discrete disclosure events affect each other through a hypothesized feedback loop (Clair et al., 2005; Greene et al., 2006; Ragins, 2008), no known research has examined this possibility. In the current study, we conducted a longitudinal survey of 238 people living with HIV/AIDS residing in various parts of the U.S. At 2 time points (6 months apart), we asked our participants to recall their most recent disclosure experience, evaluate how positive the event was (i.e., disclosure positivity), and rate the antecedent factors they considered in making their disclosure decision. Results indicate that disclosure positivity at Time 1 predicted greater likelihood of disclosure at Time 2. Moreover, disclosure positivity at Time 1 predicted changes in the antecedent factors determining disclosure at Time 2, including greater feelings of social support and less perceived communication difficulties and negative HIV-related thoughts. These results demonstrate that the positivity of discrete disclosure events can affect both future disclosure likelihood and the degree to which specific antecedent factors are considered in the decision-making process.

#### B17

##### **AN EXTENSION OF IMPLICIT THEORIES TO AN APPLIED CONTEXT: SELF-REGULATION AND WEIGHT MANAGEMENT** Jeni Burnette<sup>1</sup>, Eric VanEpps<sup>1</sup>;

<sup>1</sup>University of Richmond – The current work extended the implicit theory approach (Dweck & Leggett, 1988) to the area of weight management and merged it with value expectancy theory. Specifically, we examined how beliefs about the malleability of body weight influenced participants' regulatory strategies in response to challenges to personal dieting goals. To examine these relations, we recruited individuals currently trying to lose weight to participate in a longitudinal study. Participants (N = 287) completed measures at two time periods. At time 1, we assessed participants' dieting goals, implicit theory, and constructs related to successful dieting (e.g., self-efficacy, self-control). Eight weeks later at time 2, we asked participants about their goal achievement thus far. Participants also self-reported height and weight at both time periods. After controlling for a number of variables related to successful dieting goal achievement, results indicate that individuals who perceived weight as fixed (entity theory), relative to malleable (incremental theorists), engaged in more avoidant coping in the face of challenges to goal pursuits. Expectations about future success mediated the implicit theory-avoidant coping relation. Specifically, entity theorists, relative to incremental theorists, reported lower success expectations which in turn predicted more avoidance. We also predicted that individuals with more entity-oriented beliefs, because they expect failure and cope with avoidance would struggle to achieve weight-loss goals. Results supported this proposition indicating that coping mediated the implicit-theory-weight loss achievement relation. Results are discussed in terms of how social cognitive beliefs are relevant predictors of self-regulation and weight management.

#### B18

##### **THE "AMERICAN DREAM" AT LAKE WOBEGON: HOW INDIVIDUALS PERCEIVE ECONOMIC OPPORTUNITY FOR THEMSELVES AND OTHERS.** Wendy R. Williams<sup>1</sup>, <sup>1</sup>Marshall University – The belief that social class is

fluid and that upward mobility can be achieved through individual effort is a central tenet of the "American Dream" (Hochschild, 1995). Recent research, however, suggests that there is far less mobility than most Americans believe (Economic Mobility Project, 2007; Scott & Leonhardt, 2004). Despite current data, many Americans still believe that economic mobility is possible. Because social class boundaries are seen as permeable (regardless of whether they are or not), it may be difficult for individuals to see that there are impediments to individual mobility. In the current study, participants were given factual information about economic opportunity in the United States, with half of the participants reading information that reinforces the "American Dream," whereas the other half read information that challenges the "American Dream." The results indicate that although participants recognize that others' current and future opportunity may be affected by their social class, their belief

in their own economic opportunity is robust, even after examining data that contradict their beliefs. In addition to illustrating the application of basic social psychological principles (e.g., the better-than-average effect) to a core American belief, these results are most important because of their implication for creating support for policies that address growing economic inequality.

### B19

**PSYCHOLOGICAL UNDERPINNINGS OF SUCCESSFUL CONFLICT MEDIATION** Ryan Gonzalez<sup>1</sup>, Corrie Hunt<sup>1</sup>, Marti Hope Gonzales<sup>1</sup>; <sup>1</sup>University of Minnesota – There are over 300 Victim-Offender Mediation (VOM) programs around the nation. VOM involves a two-stage process. First, crime victims meet with a trained mediator to discuss the crime and its impact. Pending the outcome of individual meetings, most victims meet for a facilitated face-to-face exchange with offenders (i.e., mediation), during which victims describe their experiences, offenders listen, and both parties arrive at a mutually acceptable restitution plan. Social work research has revealed that these alternatives to the traditional justice system reduce recidivism, and that victims and offenders alike are satisfied with their experiences. However, this evaluation research neglects the psychological underpinnings of successful mediation. We drew from VOM procedures to design a longitudinal analog experiment to assess the effects of a two-stage conflict mediation intervention, including measures of psychological change (e.g., forgiveness, affect, physical health symptoms) that might develop over time as a function of participation. Participants were randomly assigned to one of three experimental conditions: (1) wait-list control, (2) one-on-one with mediator, and (3) mediation. Repeated measures ANOVA revealed significant main effects for condition: Mediation participants reported significantly more forgiveness compared to those in the other groups. However, participants in the one-on-one group experienced greater happiness as a result of their participation. Participants in all conditions experienced significant reductions in health symptoms across time, and reduced dejection and agitation. Additional results illustrate the power of mediation to transform conflicts and relationships. We address implications for VOM practitioners and the contribution of this research to social psychology.

### B20

**THE MULTIDIMENSIONAL STRUCTURE OF IMPLICIT CONDOM ASSOCIATIONS AND EXPLICIT CONDOM ATTITUDES** Michelle Broadus<sup>1</sup>, Angela Bryan<sup>2</sup>; <sup>1</sup>Center for AIDS Intervention Research, Medical College of Wisconsin, <sup>2</sup>University of New Mexico – Inherent limitations of explicit measures highlight the need for health researchers to incorporate implicit measures into their models of behavior, especially in the context of condom use. Moreover, the multidimensional nature of condom attitudes has been clearly demonstrated in explicit condom attitudes, and this perspective needs to be applied to implicit condom attitudes as well. Specifically, condoms are associated with disease, sex, the self, and one's partner. Results from two studies with different populations using survey research and multiple IATS confirm the multidimensional nature of implicit condom attitudes, the distinct constructs of implicit and explicit condom attitudes, and that an implicit condom + disease association may be detrimental to condom use. However, in Study 2, neither implicit associations nor explicit attitudes correlated with a behavioral measure of comfort with condoms. Gender differences in implicit associations and explicit attitudes are discussed. Future research will seek to understand the association between evaluative implicit attitudes and individual implicit condom associations and how to incorporate issues of implicit attitudes and associations in intervention efforts to promote safer sex.

### B21

**THE EFFECTS OF INDIAN-ACCENTED ENGLISH AND NEED FOR COGNITION ON MESSAGE EVALUATION: A FIELD STUDY** Duoc Nguyen<sup>1</sup>, Helen C. Harton<sup>1</sup>; <sup>1</sup>University of Northern Iowa – Research has shown that Americans rate non-accented English speakers more favorably than accented English speakers (e.g., Birch & McPhail, 1997), although there has been little research on the Indian accent. In this study, we examined whether evaluations of this accent may be moderated by individual differences in need for cognition (NFC; (Cacioppo & Petty, 1982) and argument strength, using the Elaboration Likelihood Model (Petty & Cacioppo, 1986). It was hypothesized that people with low NFC would use the Indian-accent as a negative peripheral cue and evaluate an Indian-accented sales pitch more negatively than a Midwestern-accented one, regardless of argument strength, and that people with high NFC would evaluate a sales pitch with strong arguments more positively than one with weak arguments, regardless of accent. Community members listened to 1 of 16 different sales pitches recorded by 2 male and 2 female Midwesterners and 2 male and 2 female natives of India and reported their evaluations. People with low NFC were affected by accent type as expected, giving more negative evaluations of sales pitches with Indian accents. They also evaluated pitches with weak arguments more negatively than those with strong arguments. On the other hand, people with high NFC did not differentiate their evaluations by accent type or argument strength. Message evaluation was more strongly related to intentions to buy solar panels than were attitudes toward solar panels. These results suggest that the recent trends of outsourcing call centers to foreign countries may have a negative effect on consumers' purchase decisions.

### B22

**THE INFLUENCE OF JUST WORLD BELIEFS ON AGGRESSIVE DRIVING BEHAVIOR** Sunde Nesbit<sup>1</sup>, Kevin Blankenship<sup>2</sup>; <sup>1</sup>University of Northern Iowa, <sup>2</sup>Iowa State University – Just-world theory suggests that, in general, people believe that good things happen to good people and bad things happen to bad people. Despite a number of negative consequences associated with believing the world is just, recent research suggests positive outcomes are also associated with this belief. For example, individuals high in belief in a just world (BJW) are better able to cope with anger-provoking situations (Dalbert, 2002). This research examines the relationship between BJW and aggressive driving. It was hypothesized that BJW may buffer against aggressive behavior within provoking driving situations, especially when such beliefs are violated. Participants read a driving scenario in which they imagined an SUV tailgating them; half of participants were told that the SUV was later pulled over by police (no BJW violation), whereas half was told that the SUV was not pulled over (BJW violation). Participants then rated the likelihood of engaging in various aggressive driving behaviors, and completed the BJW scale. As expected, BJW moderated the effect of the violation manipulation on aggressive driving outcomes [ $b = -.12, t(93) = -2.3, p = .024$ ]. At one standard deviation below the mean of BJW scores, the violation manipulation did not influence aggressive driving outcomes. However, at one standard deviation above the mean, participants reported less aggression toward the target driver in the scenario when BJW beliefs were violated vs. not. This is consistent with previous work arguing for the buffering effect of just world beliefs on anger within provoking situations.

### B23

**ACCESSIBLE POSSIBLE SELVES INFLUENCE EXERCISE FREQUENCY** Robert Hessling<sup>1</sup>, Dietlinde Heilmayr<sup>1</sup>, Kristin Flora<sup>2</sup>; <sup>1</sup>Hendrix College, <sup>2</sup>Franklin College – Possible selves may help us better understand how people motivate themselves to exercise (Markus & Nurius, 1986). Prior research on possible selves and health has used measures that assess the presence or absence of these images of oneself in the future, but the findings have been mixed. Measures in which people are asked to list possible selves may not provide information about their cognitive

accessibility, and as Ouellette et al (2005) demonstrated, a possible self may only gain its power to motivate behavior when it is accessible. The purpose of the present study was to determine if accessibility of health-related possible selves, rather than presence or absence, was a better predictor of exercise behavior. College students reported their exercise frequency and intentions, and they completed both accessibility and presence measures of health-related possible selves. Controlling for prior exercise and intentions to exercise, participants who thought frequently about hoped-for possible selves related to fitness were more likely to report exercising one week later. The presence of possible selves did not predict exercise frequency. The findings have both theoretical and practical implications. The presence assessment of possible selves has been the mainstay of research in this area, but these findings suggest that future work needs to expand how possible selves are assessed. Furthermore, interventions should focus on making people think about themselves as successfully exercising in order to change exercise behavior, rather than just creating a hoped-for possible self.

**B24**  
**GAINING THE SELF-EFFICACY TO LIVE WELL: AN ONLINE NUTRITION AND PHYSICAL ACTIVITY INTERVENTION IN THE WORKPLACE** Anne E. Bergen<sup>1</sup>, Melissa MacKay<sup>2</sup>, Jennifer McCriston<sup>2</sup>; <sup>1</sup>University of Guelph, <sup>2</sup>Wellington-Dufferin-Guelph Public Health – Over the past 30 years, self-efficacy has emerged as a key variable in behaviour change. Online health education tools increasingly facilitate the development of interventions to target self-efficacy through multiple modalities. The current research was performed to determine whether an online nutrition and physical activity education tool could change self-efficacy beliefs and self-reported behaviour in a sample of participants recruited from workplaces in South-Western Ontario. The Live Well website was developed as an interactive tool, including self-testing, self-paced learning, and virtual and vicarious modelling of choices related to nutrition and physical activity behaviours. A non-equivalent control group pre/post/post design was used. Online surveys were used to assess knowledge of nutrition and physical activity recommendations, self-efficacy beliefs, and behaviour before exposure to the website, immediately after viewing the website, and at 6-week follow-up. The control group completed the same surveys at 6-week intervals, but did not view the website. At pre-test, no differences were found between experimental and control groups. Exposure to the website led to increases in knowledge and self-efficacy beliefs regarding Canadian nutrition and physical activity recommendations. In addition, after exposure to the website, self-reported physical activity rates increased from pre-test levels. For the experimental group, all changes were maintained at 6-week follow-up. Results suggest that interactive online health education tools targeting self-efficacy can support behaviour change. Recommendations for health promotion websites and online tools are discussed.

**B25**  
**UNREALISTIC OPTIMISM ABOUT PROBLEMS WITH ALCOHOL PREDICTS SUBSEQUENT NEGATIVE EVENT EXPERIENCES** Amanda Dillard<sup>1</sup>, Amanda Midboe<sup>2</sup>, William Klein<sup>2</sup>; <sup>1</sup>University of Michigan & VA HSR&D, Ann Arbor, MI, <sup>2</sup>University of Pittsburgh – Unrealistic optimism is the mistaken belief that one's chances of experiencing problems are lower than those of other people (Weinstein, 1980). Researchers have often debated about whether unrealistically optimistic beliefs promote or deter risk-reduction behaviors (Armor & Taylor, 1998; Weinstein & Klein, 1996). The goal of the present study was to test whether unrealistic optimism about having long-term problems with alcohol in the future placed college students at risk for experiencing various short-term alcohol-related negative events. We identified unrealistic optimism in college students by comparing their risk perceptions for experiencing the long-term problems to their self-reported alcohol consumption. Unlike the majority of studies on unrealistic optimism, we assessed the bias at the individual rather than the group level. We also used a prospective rather than a cross-sectional design. Participants completed measures at four time points, each separated by a period of 4-6 months. Findings showed that unrealistic opti-

mism at Time 1 was associated with a greater number of negative events at Times 2, 3, and 4. For example, compared to participants who were realistic or unrealistically pessimistic, unrealistically optimistic participants were more likely to report having experienced events such as hangovers, missed classes, arguments with friends, and other events, because of their drinking. Similarly, unrealistic optimism at Time 2 was associated with more negative events at Times 3 and 4. In all cases, the relationships were significant when controlling for previous negative events, suggesting the effects of unrealistic optimism can mount over time.

**B26**  
**PERSONNEL SELECTION, FACEBOOK, AND THE DILUTION EFFECT: IS MORE INFORMATION REALLY BETTER?** Paige J. Deckert<sup>1</sup>, Neal J. Roese<sup>2</sup>; <sup>1</sup>The Pennsylvania State University, <sup>2</sup>Northwestern University – Employers admit to checking applicant profiles on social networking websites before hiring, and 9% of companies plan to start checking these social networking sites as a way to review potential employees (Skinner, 2009). Further, the same survey said that 33% of employers had decided not to extend a job offer based on information located in Facebook profiles. Conversely, 24% of employees decided to hire someone based on their social networking profile—but were they the best candidate for the job? The information provided from these profiles can be problematic when those in charge of making decisions are presented with too much information (e.g., Smith, Stasson, & Hawkes, 1999) regarding the possible choices. This investigation tested whether the non-diagnostic information provided by Facebook profiles, (such as music and movie preferences), served to dilute diagnostic information contained by resumes (see also Nisbett, Zukier, & Lemley, 1981 for an overview of the dilution effect). Three conditions (résumé only, low dilution, and high dilution) were created to manipulate the levels of applicant information provided to participants. Results indicated that including Facebook profiles reduced effective final hiring. Employers viewing potential employees Facebook profiles appears to be relatively common practice, but this study shows that can decrease hiring of quality employees.

**B27**  
**THE EFFECTS OF SELF-REGULATORY FOCUS ON SAFE-SEX DECISION MAKING** Karen Wilson<sup>1</sup>, Eddie Clark<sup>2</sup>; <sup>1</sup>College of Staten Island and St. Francis College, <sup>2</sup>Saint Louis University – The purpose of this study was to investigate the role of self-regulatory focus on safe-sex decision-making. Self-regulatory focus theory proposes that people have one of two types of self-regulatory focus: promotion or prevention. Individuals with a promotion focus approach desired outcomes while those with a prevention focus try to avoid negative outcomes. Participants were randomly assigned to either a promotion or prevention focus priming task (Freitas, Liberman, & Higgins, 2002). Participants were also given a hypothetical scenario and asked to imagine themselves in a romantic relationship with an individual in the scenario and make judgments regarding the individual's emotional and physical safety, STD and HIV risk, and condom use with the individual. The scenarios differed based upon whether information about the target's prior sexual history was present or absent. Previous research has found that prevention focused individuals tend to have a conservative bias in decision making thus it was hypothesized they would rate the target as being riskier, less emotionally and physically safe, and be more likely to use condoms with the target. Participants were 43 undergraduate students. As hypothesized individuals in the prevention focused condition were more likely to report using a condom with the target than were individuals in the promotion focused condition,  $F(1, 39) = 4.03, p < .05$  ( $M_{prevention} = 96.80; M_{promotion} = 87.59$ ). This finding supports the conservative decision-making bias associated with a prevention focus.

This finding supports the conservative decision-making bias associated with a prevention focus.

**B28****THE ROLE OF INITIAL IMPRESSIONS WHEN EVALUATING CREDIBILITY IN THE OBSERVERS-PATIENTS RELATIONSHIP** Patrice Rusconi<sup>1</sup>, Paolo Riva<sup>1</sup>, Lorenzo Montali<sup>1</sup>, Paolo Cherubini<sup>1</sup>; <sup>1</sup>University of Milan-Bicocca –

Research on impression formation suggests that information acquired early might have a much greater impact on the credibility attribution made by a judge than subsequent evidence. This is relevant in the medical context, where subjective experiences, as pain, requires the observers to evaluate the credibility of the patients to assess pain severity and decide treatment options. We aimed at investigating the credibility attribution process in the observer-patient relationship by considering the role of the judges' first impressions. We thus determined whether or not initial judgments were revised after knowing the patient's self-report of pain. A sample (N = 423) of physicians, nurses, medical students and nursing students participated to a computerized task which showed 16 vignettes featuring fictitious patients. In the experimental condition participants were asked to evaluate the patient's pain severity and hypothesize prescriptions before and after knowing the patient's rating, which was systematically varied as a function of the first participants' estimates, whereas in the control condition participants were shown all the information about the patient at the same time and required to make judgments in a unique stage. The results showed that in 46% of the responses participants didn't revise their initial pain ratings and they confirmed their first prescriptions in 63% of cases. Also, we found that physicians were less miscalibrated, but more affected by the initial impressions than the other groups. Overall, these findings show how the initial impressions can serve as an "anchor" for the observers in the credibility attribution process.

**B29****TELEVISION CONTENT AND FOOD INTAKE AMONG RESTRAINED VERSUS UNRESTRAINED EATERS** Mitsuru Shimizu<sup>1</sup>, Brian Wansink<sup>1</sup>; <sup>1</sup>Cornell University –

There is accumulating research suggesting that television (TV) viewing is associated with increased food intake (e.g., French et al., 2001). However, research on the relation between TV content and food intake is limited. This study examined whether a TV program's effect on food intake was moderated by people's dieting status. We hypothesized that unrestrained eaters were less likely to eat while watching a food-related TV program, because it increased awareness of the amount of food they were eating (Wansink & Payne, 2007). On the other hand, we hypothesized that restrained eaters were more likely to eat while watching a food-related TV program, because food-relevant stimuli undermined their self-control (Herman & Polivy, 1980; Stroebe et al., 2008). To test those hypotheses, we asked participants to watch 30-minute TV programs (SpongeBob SquarePants) that had either food-related content or non-food-related content after assessing their restrained eating by using Restraint Scale (Herman & Polivy, 1975). While watching the TV programs, participants were allowed to eat two types of candies (Snickers and Hillside Candy Go Lightly). As expected, the results indicated that unrestrained eaters were less likely to eat those candies while watching a food-related TV program. In contrast, restrained eaters were more likely to eat while watching a food-related TV program. Possible implications are discussed.

**B30****THE EFFECTS OF CALORIE INFORMATION ON EATING BEHAVIOR** Laura Girz<sup>1</sup>, Janet Polivy<sup>1</sup>, C. Peter Herman<sup>1</sup>, Veronique Provencher<sup>2</sup>, Adam Palanica<sup>1</sup>, Helen Lee<sup>1</sup>; <sup>1</sup>University of Toronto, <sup>2</sup>Laval University –

There is currently proposed legislation that would require calorie information to be presented on the menus/menu boards of restaurants with more than 20 outlets. To test the possible impacts of such legislation, the present study examined the effects of calorie information on the food selection and intake of restrained and unrestrained eaters. Method: 143 female students were presented with a menu containing two items, a salad and a pasta dish. The menu had either no calorie information, information that the salad was 600 and the pasta was 1200 calories, or information

that the salad was 1200 calories and the pasta was 600 calories. Participants selected either the salad or the pasta dish from the menu and were given 15 minutes to complete their meal. Results: There was no effect of Condition on the food chosen. For participants who chose pasta, those in the 600-calorie and 1200-calorie pasta conditions ate significantly less than those in the control condition. For participants who chose salad, those in the 1200-calorie salad condition ate significantly more than those in the control condition. Discussion: Results of the present study indicate that the provision of calorie information does not alter food choice but does influence the amount people eat. Although the salad and pasta contained the same number of calories, calorie information decreased the consumption of pasta, but increased the consumption of salad. Overall, these results tentatively suggest that posting calorie information on menus may have the unintended consequence of increasing the consumption of certain foods.

**B31****INTENTION OF THE PUBLIC TO PARTICIPATE AS JURORS UNDER THE NEW JURY SYSTEM IN JAPAN** Naoya Takahashi<sup>1</sup>; <sup>1</sup>Japan Society for the

Promotion of Science – In Japan, the saiban-in system (jury system) took effect in May 2009. Under this system, selected members of the general public participate in trials as jurors. Psychosocial factors affecting the intention to participate as jurors were analyzed before the new system was introduced. Two surveys were conducted with students and attitudes regarding the new jury system, familiarity with the new system, political attitudes, the image of judges, and emotional empathy were investigated. Study 1 was conducted one year before the new system was inaugurated. Path analysis using multiple regression analysis indicated that expectations about the new system and empathy with the system directly increased the intention to participate, whereas distrust of the new system inhibited it. Also, negative images of judges indirectly inhibited the intention to participate. Determination coefficient for the intention to participate was .15. Study 2 was conducted just before the system was introduced and the identical analysis as in Study 1 indicated that expectations and familiarity with the new system directly increased the intention to participate, whereas apathetic attitudes about the new system inhibited it. Determination coefficient for the intention to participate was .28. A comparison of factors regulating the intention to participate observed in the two studies suggested that as the date of inaugurating the system approached, factors such as ambiguous images about the law and judges were replaced by specific knowledge about the new jury system.

**B32****SENSE OF COMMUNITY MEDIATES LINK BETWEEN TRAUMA EXPOSURE AND RESOURCE GAIN: IMPLICATIONS FOR MENTAL HEALTH** Robert

Blagg<sup>1</sup>; <sup>1</sup>Claremont Graduate University – Research supports resource loss and gain as indicators of psychological stress and mental health following trauma. Maintenance of key resources has been found to be associated with strong psychological sense of community (PSC). This analysis explores PSC as a mediator of links between trauma exposure and resource loss and gain, and examines health correlates of resources loss and gain among residents of New Orleans, three years after hurricane Katrina. Participants (N = 234) completed multiple item measures of exposure to disaster, PSC, resource loss and gain, stress, depression, anxiety, and life satisfaction ( $\alpha's > .89$ ). Results of regression analyses showed that exposure to disaster was significantly related to PSC ( $\beta = -.35, p < .001, \Delta R^2 = .09$ ) and PSC was related to resource gain ( $\beta = .23, p < .01, \Delta R^2 = .04$ ), but not resource loss. PSC mediated the link between exposure to disaster and resource gain. The significance of the indirect effect was supported by a Sobel test ( $Z = 2.96, p < .01$ ). Correlation analyses revealed resource loss was positively associated with stress, depression, and anxiety ( $r's > .33, p < .001$ ), and negatively related to life satisfaction ( $r > -.20, p < .01$ ). Resource gain was positively related to stress, depression, and anxiety ( $r's > .17, p < .05$ ). This examination highlights the important role PSC may play in the lives of individuals resid-

ing in communities affected by disaster, and supports previous research finding resource loss and gain to be significant indicators of psychological stress and mental health.

## Gender

### B33

#### THE DIFFERENCE A TIGHT OUTFIT MAKES: THE EFFECTS OF OBJECTIFYING VS NON-OBJECTIFYING REPRESENTATIONS OF CELEBRITIES ON MOOD AND CONCERNS ABOUT APPEARANCE

Christopher John Hunt<sup>1</sup>, Elizabeth Rieger<sup>2</sup>; <sup>1</sup>The University of Sydney, Sydney, Australia, <sup>2</sup>Australian National University, Canberra, Australia – Objectification theory (Fredrickson & Roberts, 1997) holds that contemporary, Western culture encourages women to self-objectify, meaning that they evaluate their self-worth primarily in terms of their appearance, rather than in terms of their abilities, emotions or thoughts. This is proposed to lead to several negative outcomes for women, including disturbances in mood and body image. Objectification theory also holds that the objectifying representations of women presented through the mass media are a major source of pressure that leads women to self-objectify. Whilst objectification theory was developed to explain the experiences of women in contemporary culture, current research indicates that men are also being increasingly exposed to objectifying pressures, and are experiencing growing dissatisfaction with their bodies. The present study aimed to investigate the impact that objectifying media representations have on both males and females. Participants were shown sets of images with accompanying written material concerning well-known celebrities that were designed to be either objectifying or non-objectifying. The impact of these images on mood and appearance anxiety was then examined. The results demonstrated a positive effect from viewing objectifying images on mood for both males and females, a marginally significant effect on participants of both genders using appearance-related terms to define themselves, and no effect on appearance anxiety for either gender. In addition, no significant differences were found between males and females on appearance anxiety. These findings with regards to mood are consistent with a "fantasy effect" of exposure to media images similar to that previously found for females.

### B34

#### MIRROR, MIRROR ON THE WALL, WHO IS THE THINNEST OF THEM ALL? SEXUALLY SUGGESTIVE TV COMMERCIALS AND THEIR IMPACT ON SELF-ESTEEM AND BODY PERCEPTION IN WOMEN OF DIFFERENT RACES

Malgorzata Skorek<sup>1</sup>, Yarrow Dunham<sup>1</sup>; <sup>1</sup>University of California, Merced – Exposure to unrealistic body portrayals of women in advertising is known to have powerful effects on self-esteem and body dissatisfaction, but little research investigates these effects across race. Racial minorities tend to idealize larger bodies than Whites (Parnell et al., 1996) and so might respond differently to media influences. We investigated whether exposure to unrealistic portrayals of women's bodies in TV commercials has different effects on women of different races. Sixty-two female undergraduates (White, Asian, Hispanic) watched sixteen TV commercials with sexy portrayals of women (priming condition) or watched no ads (control condition). Afterwards, subjects' implicit self-esteem was measured using the Implicit Association Test, and a questionnaire assessed subject's body satisfaction, perception of weight-related health risks, and explicit self-esteem. Women exposed to sexist ads saw their bodies as thinner compared to control subjects. In addition, the effect of ads on implicit self-esteem differed by race: Asian and Hispanic but not White women had lower implicit self-esteem after viewing ads. Finally, body ideals and perceptions of health risks differed across race. White women indicated the thinnest while Hispanic women the largest own-body ideal, and Hispanic women considered only large bodies to be at health risk whereas White and Asian were also concerned with thinner ones. This study provides evidence that media exposure interacts with culturally-local body ideals and so can produce difference effects in dif-

ferent ethnic groups. It also suggests that exposure to media has different effects on women of different races, which could have important implications for interventions.

### B35

#### THE BLACK HOLE OF MOTHERHOOD: A DECREASE IN PERCEIVED COMPETENCE AND HIRABILITY FOR FEMALE PHYSICS JOB CANDIDATES WITH CHILDREN

Jessica Liddell<sup>1</sup>, Kathryn Oleson<sup>1</sup>; <sup>1</sup>Reed College – Women are under-represented in the sciences and in physics especially. The present research explores the possibility that this under-representation may be influenced by unconscious bias in the hiring and evaluation of women. Previous research suggests that women may be penalized and be perceived as less competent when they have children while men are not. Some researchers also propose that individuating information suggesting that a candidate engages in hobbies that are congruent with the gender of the job being applied for can reduce the effect of gender stereotypes. To explore further the evaluation of females entering typically masculine fields, a 2 (target gender: female, male) X 2 (children: no, yes) X 2 (hobbies: masculine, feminine) design was used. Participants were 142 college students from Reed College and Portland State University who read about a job candidate applying for a position as a physics professor. Participants evaluated the candidate on measures of perceived warmth, competence, and hirability. Consistent with previous literature, female job candidates without children received both higher hirability and competence ratings than female candidates with children. Males were not seen as significantly more or less hireable or competent based on their parental status. After controlling for ratings of competence, women with and without children were equally likely to be hired, suggesting that reductions of perceived competence may underlie the decrease in hirability of female job candidates who are mothers. These findings have implications for policies aimed at increasing women's participation in fields where women have traditionally been under-represented.

### B36

#### COMPETENT, NOT BITCHY: CAN INGRATIATION COUNTERACT BACKLASH AGAINST AGENTIC WOMEN?

Sanne Nauts<sup>1</sup>, Laurie A. Rudman<sup>2</sup>, Roos Vonk<sup>1</sup>, Susan T. Fiske<sup>3</sup>; <sup>1</sup>Radboud University Nijmegen, <sup>2</sup>Rutgers University, <sup>3</sup>Princeton University – Women who strive for leadership roles face a Catch-22: they have to self-promote during job interviews to be perceived as competent (to counter the stereotype that women are not qualified to lead) but if they do, they are disliked (social backlash) and less likely to be hired than their male counterparts (economic backlash; Rudman, 1998). Because ingratiation can profoundly increase liking (Gordon, 1996; Vonk, 2002), we investigated whether women can counteract backlash effects by flattering interviewers and seeking common ground with them. To do so, Rutgers University students (N = 136) interviewed a male or female confederate ostensibly applying for a marketing manager position. Confederates answered interview questions according to a script that was either self-promoting or mixed self-promotion with ingratiation. Participants rated female applicants as equally competent, but less likeable and less hireable than male confederates, demonstrating social and economic backlash. New to the present study, social backlash was fully mediated by perceptions that female applicants violated feminine proscriptions, suggesting that female applicants were disliked because they were perceived as too high in status-enhancing traits such as dominance, arrogance and self-centeredness. However, women who mixed self-promotion with ingratiation were not rated as violating female proscriptions (i.e., they were competent but not bitchy). And while they suffered social and economic backlash, the effect sizes were much smaller than for self-promoting women. In concert, the findings suggest that ingratiation has the potential to improve interview outcomes for female managerial applicants.

**B37**

**MASCULINITY, FEMININITY, AND WELL-BEING: A META-ANALYTIC APPROACH** Christopher Garris<sup>1</sup>; <sup>1</sup>University of Kentucky – Two ongoing meta-analyses were conducted on studies testing the relationship between gender roles (masculinity and femininity) and well-being. Comprehensive searching yielded 191 articles for possible inclusion in the analysis., of which 69 percent were excluded from the meta-analyses due to irrelevant or insufficient reported information, leaving 75 eligible articles for analysis. Requests for unpublished data were made by contacting potentially relevant data from dissertations. Effects sizes ( $r$ s) were extracted from the articles, weighted using inverse variance, and combined. Results based on the studies coded by the time of poster submission indicate that the combined effect size for the relationship between masculinity and well-being was  $r = .11$  (95% CI = .05 - .15;  $Z = 4.06$ ;  $p = .00$ ;  $N = 1562$ ). Femininity, on the other hand, had an effect size of  $r = .03$  (95% CI = -.053 - .11;  $Z = 0.68$ ;  $p = .50$ ;  $N = 700$ ). Therefore, based on this summary, higher levels of self-reported masculinity seem to be positively related to self-reported well-being, while femininity does not. Year of publication and type of well-being measure used were significant moderators of both relationships, with masculinity being a stronger predictor of well-being in older studies. Comprehensive analyses and general conclusions will be discussed.

**B38**

**ATTITUDES ABOUT OLDER WOMEN, FEMINIST IDENTITY, AND AGING ANXIETY AMONG FEMALE COLLEGE STUDENTS** Ada Diaconu Muresan<sup>1</sup>, Mary White Stewart<sup>1</sup>; <sup>1</sup>University of Nevada, Reno – Anxiety about aging constitutes a significant source of psychological distress, and younger individuals have been consistently found to exhibit higher levels of aging anxiety than older people. Young women are particularly likely to experience aging anxiety, perhaps as a reflection of the double standard of aging that characterizes Western culture. In this study, we examined attitudes about older women and feminist identity as potential predictors of aging anxiety in a sample of 116 female college students. Our measures included Henley et al.'s (1998) Feminist Perspectives Scale, a modified version of Lasher and Faulkender's (1993) Fear of Old People subscale, Cantwell and Barrett's (2002) Personal Aging Anxiety Scale, and three independent items used by Barrett and Robbins (2008) to assess aging anxiety. Negative attitudes toward older women were positively correlated with several measures of aging anxiety, supporting the hypothesis that young women's prejudices against older women may increase anxiety about their own aging (of course, the correlational nature of the data could also support alternative formulations). Feminist identity was not associated with aging anxiety, suggesting that endorsement of feminist beliefs does not protect young women against aging concerns. Considering the established role of feminist identity in reducing problematic occurrences such as body image concerns, we discuss the methodological and conceptual factors that may have contributed to the present results and outline the complexity of women's aging process compared to other issues addressed within feminist scholarship.

**B39**

**THE MEDIATING EFFECT OF SYSTEM JUSTIFICATION ON THE RELATIONSHIP BETWEEN FUNDAMENTALIST RELIGIOSITY AND HOSTILE SEXISM** Nuray Sakalli-Ugurlu<sup>1,2</sup>, Nilüfer Ercan<sup>1</sup>; <sup>1</sup>Middle East Technical University, <sup>2</sup>The Scientific and Technological Research Council of Turkey-TÜBİTAK scholar – The question of how religiosity is relevant to hostile attitudes toward women has been an important topic for social psychologists. Religiosity was a significant predictor of benevolent sexism rather than hostile sexism in predominantly Christian Western countries. However, when benevolent sexism was controlled, religiosity was a significant correlate of hostile sexism for males whereas it was not a significant correlate of hostile sexism for females in Turkey. In addition, researchers have presented an association between system justifying tendencies and religion. All these studies lead us to examine how system justification which is a motivation to rationalize the social, economic and political

arrangements can mediate the relationship between fundamentalist religiosity and hostile attitudes toward women in a Muslim country, Turkey, to understand the generative mechanism through which fundamentalist religiosity is able to influence hostile attitudes toward women. 157 male and 228 female participants (university students and nonstudents) completed measures of Hostile Sexism (Glick & Fiske, 1996), Gender-related System Justification (Jost & Kay, 2005), and Fundamentalist Religiosity. Following Baron and Kenny (1986), three simple regression analyses were conducted and then a multiple regression analysis was conducted with Fundamentalist Religiosity and System Justification predicting Hostile Sexism for both females and males. Sobel  $z$  test was 3.94 for males, and 2.95 for females. The significant partial mediations indicated that system justification was a significant mediator between Fundamentalist Religiosity and Hostile Sexism for both males and females. Although the mediation is significant for both men and women, the effect sizes were much larger for men.

**'PSYCHOLOGY OF WOMEN' VERSUS 'PSYCHOLOGY OF GENDER': THE IMPACT OF VARYING DIVERSITY COURSE TITLES ON STUDENT INTEREST** Justin J. Lehmillier<sup>1</sup>, Jennifer R. Spoo<sup>2</sup>; <sup>1</sup>Colorado State University, <sup>2</sup>University of Queensland – Diversity enhancement courses are increasingly common throughout higher education (Humphreys, 1997). Within social psychology, such courses often focus on gender-based prejudice. No research has examined what factors are likely to attract a broad range of open-minded students to such classes. Courses that appear to focus on disadvantaged groups may threaten potential students because they anticipate the class will challenge their beliefs or suggest ways in which they are complicit in perpetuating prejudice. For example, aversive sexists (i.e., people who hold egalitarian gender beliefs, but unconsciously harbor negative feelings toward women; Dovidio & Gaertner, 2004) might avoid such courses in order to maintain a non-prejudiced self-image. This experiment examined whether titling a diversity-related course with the traditionally disadvantaged group (e.g., 'Psychology of Women') would influence students' perceptions of course content and likelihood of enrollment compared to a broader title (e.g., 'Psychology of Gender'). Participants ( $N=127$ ) were randomly assigned to read one of two prospective course offerings. The course descriptions were identical; only the title was varied (i.e., Psychology of Women vs. Gender). Participants indicated whether the course content appeared biased and their willingness to enroll. Participants perceived the Women course as more biased ( $p < .001$ ) and were less willing to take it ( $p < .05$ ) compared to the Gender course. Furthermore, perceptions of biased content mediated the effect of course title on willingness to enroll ( $p < .01$ ). These results have practical implications for social psychologists teaching diversity-related courses and suggest that titles emphasizing disadvantaged groups may be evaluated negatively and could potentially restrict enrollment.

**B41**

**AMBIVALENT SEXISM AND EVALUATIONS OF POSITIVELY AND NEGATIVELY SEXUALLY SUBTYPED WOMEN** Sianna Ziegler<sup>1</sup>, Kathryn Oleson<sup>1</sup>; <sup>1</sup>Reed College – The present study explores the effects of mortality salience and sexual subtype information on hostile and benevolent attitudes toward women in general as well as evaluations of individual women. Ambivalent sexist attitudes and evaluations of a female target conforming to a positive (chaste) or negative (promiscuous) sexual subtype were examined under mortality salient and control conditions. Thirty-six female and 32 male participants evaluated the target's competence and warmth and completed measures of ambivalent sexism. Participants were randomly assigned to one of four conditions in a 2 (mortality salience: present vs. absent)  $\times$  2 (target subtype: promiscuous vs. chaste) between-subjects factorial design. No effects of mortality salience were found. Among women, the promiscuous target elicited more hostile sexism and lower competence ratings than did the chaste target. Men's hostile sexism and competence ratings, however, did not differ by target description. Within the chaste condition, women rated

the target as more competent than did men. Overall, men expressed more benevolent sexism than women regardless of target subtype. Finally, the chaste target was rated as warmer than the promiscuous one regardless of participant gender. The way a woman is perceived in terms of sexual promiscuity influences how she is perceived in other domains, particularly when the perceiver is another woman. Additionally, exposure to a sexually subtyped female target affects immediate attitudes toward women as a whole. Taken together, these findings illustrate the pervasiveness of traditional standards of female sexuality.

#### B42

**EXPANDING THE RELATIONSHIP BETWEEN BODY DISSATISFACTION AND OBJECTIFICATION BEYOND WEIGHT** Nicole M. Overstreet<sup>1</sup>, Diane M. Quinn<sup>1</sup>, V. Bede Agocha<sup>1</sup>; <sup>1</sup>University of Connecticut – Objectification theory posits that the sexual objectification of women contributes to a preoccupation with physical appearance and the internalization of an outsider's perspective on the self, a process known as self-objectification (Fredrickson & Roberts, 1997). Self-objectification, mostly examined as a consequence of societal pressures of thinness, leads to a multitude of negative outcomes including body dissatisfaction (Harper & Tiggemann, 2008). Although thin idealization increases body dissatisfaction with regards to weight, a curvaceous but thin body ideal (i.e., smaller waist and hips with a larger bust line) is another cultural standard of feminine beauty that may influence body dissatisfaction beyond thinness. The present study (N = 145) examined whether self-objectification (indexed by body surveillance and body shame) influenced dissatisfaction with breast size, buttock size, and weight among women. Results indicated that both body shame and body surveillance were significant predictors of weight, breast, and buttock size dissatisfaction, such that more body shame and surveillance was associated with more dissatisfaction. Additionally, given recent research suggesting that appearance contingent self worth may lead to negative consequences when cultural ideals of physical attractiveness are not met (cf., Crocker & Wolfe, 2001), we examined whether basing one's self-worth on appearance also influenced dissatisfaction. Analyses indicated that appearance contingent self-worth significantly predicted weight, breast, and buttock size dissatisfaction; however, these effects were mediated by body shame and surveillance. These findings stress the importance of considering dissatisfaction with other aspects of women's bodies as a consequence of an objectified body consciousness, specifically body shame and body surveillance.

#### B43

**THE SCIENTIFIC GENDER GAP: GENDER BIAS IN FACIAL INFERENCES THAT PREDICT SCIENTIFIC INFLUENCE** Emily Kim<sup>1</sup>, Joan Chiao<sup>1</sup>; <sup>1</sup>Northwestern University – Although the number of female scientists earning graduate degrees in science, technology, engineering and math (STEM) fields has increased steadily in the past 15 years, the gender gap in higher echelons of science has remained. What psychological factors underlie the scientific gender gap at the highest levels of STEM fields? From politics to business, facial appearance has been shown to play a pivotal role in predicting an individual's success. Here we examine the possibility that facial appearance may contribute to scientific success and, in particular, to a gender gap in scientific influence as measured by h index. Twenty-one participants viewed 110 greyscale facial photographs (55 females) of professors at Tier I science, engineering, and math departments. All facial photos were standardized for background color, size, luminosity and age. Participants viewed each face for one second and judged how dominant, attractive, approachable and competent the face seemed on a 7-point Likert scale. Across all faces, perceived competence was a negative predictor of h index. Critically, distinct facial inferences predicted scientific influence for men and women. For male scientists, perceived competence was a negative predictor of h index, whereas for female scientists, perceived approachability was a negative predictor of both h index and amount of federal grant funding. These

results indicate that shallow decision heuristics, such as facial inferences, play an important role in scientific influence and may contribute to the perseverance of gender gaps in STEM fields.

#### B44

**GENDERING OBJECTS: THE REPERCUSSIONS OF USING GENDERED PRONOUNS WHEN REFERRING TO OBJECTS.** Kelly Danaher<sup>1</sup>, Iva Katzarska-Miller<sup>2</sup>, Monica Biernat<sup>1</sup>; <sup>1</sup>University of Kansas, <sup>2</sup>Transylvania University – Using gendered pronouns to refer to an object is common in conversation, writing, and other expressions of language (Wales, 1996). The current research explores whether gendering objects produces stereotype-consistent perceptions of the object. In Study 1, participants rated 14 objects (e.g., TV, boat, computer) on gender-stereotypical traits and pronoun labels—ranging from 1 “definitely she” to 7 “definitely he” with a midpoint of 4 “definitely it”. Pronoun ratings were positively correlated with male trait ratings,  $r(12) = .64$ ,  $p < .05$ , and negatively correlated with female trait ratings,  $r(12) = -.71$ ,  $p < .05$ . To further explore the directionality of this relationship, participants in Study 2 read passages about personified objects where half were referred to as “she” and half as “he”. Between-subject ANOVAs revealed that TV, boat, and desk were rated as more feminine when referred to as “she” compared to “he,”  $F(1, 47) > 8.99$ ,  $ps < .01$ , and cell phone was viewed as more masculine in the “he” condition than in the “she” condition,  $F(1, 39) = 4.26$ ,  $p < .05$ . Logistic regressions revealed that for car, boat, ipod, and cell phone the odds of giving the object a male name versus a female name were greater in the “he” condition compared to the “she” condition,  $c2(2, Ns = 43-44) > 6.66$ ,  $ps < .05$ . As predicted, using gendered pronouns when referring to objects influences how that object is viewed.

#### B45

**ARE LESS INTELLIGENT WOMEN MORE DESIRABLE? THE ROLE OF GENDERED ROMANTIC PREFERENCES** Lora Park<sup>1</sup>, Jordan Troisi<sup>1</sup>, Ariana Young<sup>1</sup>; <sup>1</sup>University at Buffalo, The State University of New York – The present research examined whether college students' romantic preference (RP) for dating smarter partners predicted personal and societal beliefs regarding women's intelligence in masculine vs. feminine domains, and their subsequent romantic desirability. One-hundred twelve undergraduate students initially reported their preference for dating someone smarter than themselves. They later completed questionnaires assessing their desire to date someone in stereotypically masculine (e.g., math, science) vs. feminine (e.g., arts, humanities) domains, and their personal and societal beliefs regarding women's intelligence in these domains and their subsequent romantic desirability. Results of regression analyses revealed significant interactions between gender and RP, such that women who preferred smarter partners wanted to date partners who were more intelligent than themselves in traditionally masculine domains, whereas this effect was not found among men who preferred smarter partners. Women's RP did not extend to a preference for dating partners who were smarter than themselves in traditionally feminine domains. Moreover, women who preferred smarter partners believed – on both a personal and societal level – that women who are less intelligent than men in math/science are more romantically desirable. Women who preferred smarter partners also endorsed the societal belief that women who are smarter than men in math/science are less romantically desirable, whereas women who are smarter than men in the arts/humanities are more romantically desirable. Implications of women's RP for the gender gap in math/science performance and persistence are discussed.

#### B46

**THEY'RE NOT KIDDING: GENDER, MARITAL STATUS, AND THE MOTIVATIONS FOR CHOOSING INTENTIONAL CHILDLESSNESS** Vincent Ciaccio<sup>1</sup>; <sup>1</sup>Rutgers University – The purpose of this study was to determine what motivates people to choose to be childfree. Participants (N=432) were primarily recruited via Internet message boards that catered to the childfree; the study was fielded online. Participants were asked to rate forty items on nine-point Likert-type scales, indicating to what degree

each item motivated them to choose childfreedom, where higher values indicated greater influence. They were also asked to select the motivator that was most influential in their lifestyle choice. The highest scoring items for the total sample were: "Do not want to sacrifice privacy/personal space for kids" ( $M=7.78$ ,  $SD=1.93$ ), "No compelling reason to have kids" ( $M=7.64$ ,  $SD=2.25$ ), "Do not want to sacrifice time for children" ( $M=7.55$ ,  $SD=2.02$ ), and "Actively do not want children around" ( $M=7.45$ ,  $SD=2.24$ ). Additionally, one of those four items was selected by 59.5% of the total sample as their most influential motivator. A 2 (gender) by 3 (marital status: single; single, but in a relationship; married) ANOVA was performed on each motivator, revealing significant differences in 14 items for gender and 11 items for marital status (all  $p<.05$ ). For all but one item showing statistically significant differences by gender, women have higher means scores versus men; there is no similar pattern when examining the corresponding items by marital status. Results are discussed in particular regard to gender roles.

#### B47

**GENDER ROLE IDENTITY PREDICTS ENDORSEMENT OF CULTURAL STANDARDS OF THINNESS** Susan Darlow<sup>1</sup>, Marci Lobel<sup>1</sup>; <sup>1</sup>Stony Brook University – Thin ideal internalization, or endorsing cultural standards of thinness, is associated in women with body dissatisfaction, concerns about eating and weight, and anxiety. It is unknown why some people are more likely than others to internalize thinness standards. In addition, thin ideal internalization in men has largely been ignored. Female and male undergraduates ( $N = 244$ ) completed measures of thin ideal internalization (Heinberg, Thompson, & Stormer, 1995) and masculine and feminine traits (Spence & Helmreich, 1978). In women, those with masculine traits were less likely to report that they were trying to lose weight. This association was mediated by lower scores on the thin ideal internalization measure. In male students, neither feminine nor masculine traits were associated with trying to lose weight. Separate hierarchical regression analyses examining the influence of gendered traits on thin ideal internalization were conducted for men and women. Results indicated that endorsing cultural standards of thinness was least common in women who are androgynous (high on both feminine and masculine traits) or undifferentiated (low on both feminine and masculine traits), and in men who identify strongly with masculine but not feminine traits. Endorsement of thinness ideals was most common in women who are high in masculine or feminine traits, and in androgynous men. Findings suggest that concerns about weight are associated with gender role identity for both men and women. Women with strong masculine or feminine orientation and androgynous men may be at highest risk for the mood and behavioral consequences of preoccupation with appearance.

#### B48

**THE CULTURAL CONSTRUCTION OF MATH AND SCIENCE AND THE GENDER GAP IN PERFORMANCE: IS CRITICAL CONSCIOUSNESS A SOURCE OF RESILIENCE FOR WOMEN?** Alison Blodom<sup>1</sup>, Sharon Dzieszietnik<sup>1</sup>, Laurie T. O'Brien<sup>1</sup>; <sup>1</sup>Tulane University – The present study investigated how the cultural construction of Science, Technology, Engineering, and Mathematics (STEM) fields as "masculine" contributes to the gender gap in STEM performance by creating social identity threat for women and social identity privilege for men. In addition, the present study examined critical consciousness as a potential source of resilience to the social identity threats encountered by women in STEM domains. Critical consciousness is a multi-faceted construct that includes the belief that gender differences are illegitimate, unstable, and that women share a common fate. Undergraduates ( $N=105$ , 65% female) completed the perceived masculinization of STEM IAT, a math and science test, ratings of enjoyment of STEM and Humanities courses, interest in visiting science and art museums, and a measure of critical consciousness. Results suggest that the cultural construction of STEM may indeed contribute to the gender gap in STEM fields. For women, perceived masculinization of STEM was associated with poorer performance on the test whereas for men perceived masculinization was associated with better performance.

The results also suggest that critical consciousness may be a source of resilience for women in STEM fields: women who scored high in critical consciousness were less likely to perceive STEM as masculine, scored higher on the test, reported greater enjoyment of science (but not humanities) courses, and indicated more interest in visiting science (but not art) museums. Future research should experimentally investigate whether increasing critical consciousness among women is a viable strategy for diminishing the gender gap in STEM fields.

#### B49

##### **WHAT'S THE SKINNY ON BODY IMAGE?: THE EFFECTS OF EXPOSURE TO AVERAGE AND IDEAL MODELS ON WOMEN'S BODY DISSATISFACTION**

Alison S. Carson<sup>1</sup>, George E. Schreer<sup>1</sup>; <sup>1</sup>Manhattanville College – Research examining the influence of media on women's body dissatisfaction has hypothesized that ideal images of women's bodies portrayed in the media may have a negative effect on body image, leading to increases in body dissatisfaction. Based on the meta-analytic findings and recommendations of Groesz, Levine, and Murnen (2002), the current study uses a pre/post design to experimentally examine the immediate effects of exposure to "ideal" or digitally manipulated "average" images of female bodies on body dissatisfaction. White female participants ( $N = 35$ ) completed two measures of body dissatisfaction before and after exposure to the images. Participants also completed a measure of socio-cultural awareness and internalization of Western body ideals (SATAQ) and a measure of appearance schematicity (ASI). It was hypothesized that women exposed to the ideal images would show a greater increase in body dissatisfaction than women in the Average condition. While differences were found between the Ideal and Average conditions on the visual analog scale of body dissatisfaction, they were only marginally significant. Additionally, it was predicted that high scores on the SATAQ and ASI would also lead to greater change in body dissatisfaction. Multiple regression analysis revealed that change in body dissatisfaction was best predicted by the participant's internalization of the sociocultural norms toward appearance and their level of appearance schematicity. Discussion focuses on the measurement of state changes in body dissatisfaction, moderators of body dissatisfaction (e.g., appearance schematicity), and future directions of research (e.g., ethnicity and the role of acculturation).

#### B50

##### **SEXISM IN THE MEDIA: COVERAGE OF THE 2008 DEMOCRATIC PRIMARY SEASON** Annie B. Fox<sup>1</sup>, Valerie Earnshaw<sup>1</sup>, Mary Crawford<sup>1</sup>;

<sup>1</sup>University of Connecticut – Subtle sexism in media portrayals of candidates could have a profound effect on the course of an election. These portrayals may be shaped by the gender of the writer as well as that of the candidate. Male and female authors may focus on different aspects of a candidate or bring different perspectives to political coverage. Additionally, male and female candidates may receive differential treatment in the media. In order to explore sexism in political coverage, we examined the language used by male and female authors of newspaper editorials written during the 2008 Democratic primary election. We collected 1094 editorials appearing in eight different major newspapers across the country (e.g., USA Today, New York Times) from December 2007 to June 2008. Newspaper articles were analyzed using the Linguistic Inquiry and Word Count program (LIWC 2007). Only 23% of the articles were written by women and only 35% were written about Clinton. Female authors wrote articles containing more words that were categorized as social, familial, body-related, or sexual; articles written by men contained more words related to work, money, and achievement. In examining the focus of the article, articles written about Clinton contained more words related to affect and sadness than articles written about other candidates. Overall, these results indicate that there is less coverage of female candidates, there are fewer women than men writing editorials, and that there appears to be a divide in what men and women wrote about when covering Clinton and Obama.

**B51  
SIMILARITIES AND DIFFERENCES IN MEN'S AND WOMEN'S  
RESPONDING TO STRESS: PHYSIOLOGY AND CONCEPT  
ACCESSIBILITY** Elaine Perea<sup>1</sup>, Michelle Shiota<sup>1</sup>; <sup>1</sup>Arizona State

University – Researchers have suggested that men and women have somewhat different automatic responses to stress (Taylor, et al., 2000). One possibility is that the "fight or flight" response is more pronounced among men, whereas a tendency to affiliate, or "tend and befriend," may be more pronounced among women. However, the nature and degree of sex differences in physiological and psychological stress responding is still uncertain. We used a laboratory-based mental arithmetic task to explore sex differences in stress-related physiological reactivity (heart rate) and accessibility of stress-related constructs (Wegner & Smart, 1997). A lexical decision task assessed effects of the stress task on fight/flight and tend/befriend concept accessibility. The stress manipulation led to increased heart rate from baseline among both men and women, as well as increased accessibility of fight/flight concepts. The effect on fight/flight concept accessibility was significantly greater among men than women, and heart rate effects showed a trend in this direction as well. The stress manipulation also increased cognitive accessibility of tend/befriend words among men, but women displayed significant slowing of reaction times to tend/befriend words after the stress manipulation. This was unexpected, as it suggests reduced accessibility of tend/befriend constructs when women are stressed. These findings suggest that men's and women's responses to stress are similar in some ways and different in others. A careful analysis of construct accessibility, combined with future analyses of individual differences, will yield a more complex understanding of the interaction of sex and affiliative tendencies in stress responses.

**B52  
YOU CAN'T READ MY PAIN FACE: HOW GENDER AFFECTS THE DECODING  
OF FACIAL EXPRESSIONS OF PAIN** Paolo Riva<sup>1</sup>, Simona Sacchi<sup>1</sup>,  
Alessandra Frigerio<sup>1</sup>, Lorenzo Montali<sup>1</sup>; <sup>1</sup>University of Milan-Bicocca – Evolutionary theories suggest that decoding facial expressions of pain may be crucial in eliciting empathic behaviors towards the individual experiencing pain (Williams, 2002). Among the several factors which affect the judgment of facial expression of suffering, gender is particularly relevant (e.g., Simon, 2006), even if little is known about its role in affecting observers' inferences. The present research addresses the issue of whether people are faster and/or more accurate in detecting the expression of suffering on male or female faces. In two experimental studies, we devised a set of stimuli using virtual human technology. In Study 1, a prototypical female and male avatar were displayed with different expressions (pain, anger, disgust, and neutral) while subjects' (N = 34) accuracy and latency of expressions discrimination were recorded. In Study 2, participants had to categorize an androgynous avatar face showing different expressions as either female or male in a gender discrimination task. Results showed that participants, regardless of their gender, were significantly less accurate in recognizing pain expressions (but not the other expressions) when displayed on female faces. Further, androgynous faces displaying painful expressions were categorized less as female than male. These results are interpreted by taking into account the shared views that considered women as more likely to express their pain together with the existence of the "cheating detection mechanism", that is the evolutionary tendency to systematically put into question the expression of pain, which might lead observers to be less able to accurately detect suffering in women.

**B53  
EXPLICIT VERSUS IMPLICIT ASSOCIATIONS OF WOMEN WITH  
WORKPLACE SUCCESS** Ashley C. Myers<sup>1</sup>, Ioana M. Latu<sup>1</sup>, Tracie L. Stewart<sup>1</sup>, Claire G. Lisco<sup>1</sup>, Sarah Beth Estes<sup>2</sup>, Dana K. Donohue<sup>1</sup>; <sup>1</sup>Georgia State University, <sup>2</sup>University of Arkansas at Little Rock – Research reveals that women in the workplace are viewed more positively than ever before, and often more positively than men, yet data also suggest that

gender inequalities in the workplace persist. We investigated this contradiction and proposed that a better understanding of such inconsistency might lie in disentangling explicit and implicit attitudes towards women in the workplace. Thus, we developed a novel implicit measure which contextualized bias within the workplace, the Successful Manager IAT (SM-IAT), to assess the degree of implicit association between gender and successful/unsuccessful manager traits. In two studies, 371 college students completed (1) the SM-IAT, (2) the General Attitude IAT, (3) several individual difference measures (Hostile Sexism, Benevolent Sexism, Internal/External Motivation to Respond Without Sexism), (4) a gender bias outcome measure, (5) and an explicit evaluation of male and female managers. Analyses revealed that male participants were more likely to implicitly associate men with successful manager traits and women with unsuccessful manager traits, compared to reversed pairings. Female participants, individuals low in hostile sexism, and individuals both high in internal motivation to respond without sexism and low in external motivation to respond without sexism demonstrated the least bias. No bias against women was found on either explicit evaluations of managers or the implicit general gender attitudes measure. A test of the SM-IAT's predictive ability revealed that greater implicit association of men with successful manager traits, and women with unsuccessful manager traits, predicted greater workplace rewards assigned to male managers by both male and female participants.

**B54  
SHE DESERVES A PUNISHMENT: PERCEPTION OF GENDER VIOLENCE  
AND THE EFFECT OF AMBIVALENT SEXISM WHEN WOMAN CHALLENGES  
TRADITIONAL ROLES** M. Carmen Herrera<sup>1</sup>, Inmaculada Valor-Segura<sup>1</sup>,  
Francisca Expósito<sup>1</sup>, Miguel Moya<sup>1</sup>; <sup>1</sup>University of Granada – The existence of violence against women is closely linked to ambivalent sexism. Lay theories of the causes of relationship violence may affect whether women challenge or uphold traditional roles within relationships. We have designed two studies to analyze the influence of sexism of the perceivers and characteristics of the situation on judgments of a gender aggression. In study 1, 293 participants estimated the probability that the man would feel threatened and become violent as a result of challenge of traditional roles relationship within the couple. In study 2, 197 participants estimated the blame of victim and exonerate of perpetrator in different aggression episodes. Results in study 1 showed that benevolently sexist women were especially likely to view the male partner as threatened, which in turn, mediated women's perceptions of increased likelihood that the man would aggress. Results in study 2 showed differences in the reactions of observers depending on the cause that triggered the aggression. We also found effects of sexism perceivers, in the perception of situations of aggression. We suggest that sexism may lead women to embrace traditional roles in relationships to avoid antagonizing male partners.

**Individual Differences**

**B55  
CONSCIENTIOUSNESS AND SELF-MOTIVATION AS MUTUALLY  
COMPENSATORY PREDICTORS OF UNIVERSITY-LEVEL GPA** Wen  
Cheng<sup>1</sup>, William Ickes<sup>1</sup>; <sup>1</sup>University of Texas at Arlington – To help account for variability across studies in the predictive utility of conscientiousness, we proposed that conscientiousness and self-motivation mutually compensate for each other in predicting university-level academic performance. Consistent with this expectation, we found evidence of such mutual moderation in a sample of 377 college undergraduates. First, we found that conscientiousness and self-motivation compensated for each other in predicting university GPA: Students who were either high in conscientiousness or high in self-motivation had better academic performance (GPA) than those who were low in both conscientiousness and self-motivation. Second, these findings were still evident after we controlled for the students' previous academic performance (high school rank) and academic ability (SAT/ACT). The study of mutually compen-

satory predictors not only offers the potential of developing better predictive models; it also helps to account for why some "main effect" predictors of university GPA are variable across studies in their degree of predictive utility.

**B56**

**PERSONALITY AND ONLINE SOCIAL ENVIRONMENTS** Jason D. Ferrell<sup>1</sup>, Alicia Limke<sup>1</sup>; <sup>1</sup>University of Central Oklahoma – The purpose of this project was to quantify a hypothesized difference in participants' general personalities compared to their personalities during online social interactions. 157 undergraduate General Psychology students from the University of Central Oklahoma participated to receive credits toward their class research requirement. They completed a self-report 44-item Big Five Inventory (BFI; John, Donahue, & Kentle, 1991) assessing the Big Five personality factors (i.e., openness, conscientiousness, extraversion, agreeableness, and neuroticism) twice – one version included the typical instructions and the other version included modified instructions in which participants were directed to answer the items referring specifically to their online social interactions. Participants also completed the Self-Monitoring Scale (Snyder & Gangestad, 1986) and the Self-Concept Clarity Scale (Campbell, Trapnell, Heine, Katz, Lavallee, & Lehman, 1996). The absolute differences between BFI and OnlineBFI scores were used in one-sample t-tests to test the hypothesis that there are significant differences in personalities (in general) and personalities online. This hypothesis was supported. That is, when individuals are interacting with others online, their personalities are different from their personalities in general. Moreover, individual differences in self-monitoring and self-concept clarity predict the extent of the actual differences between BFI and OnlineBFI scores.

**B57**

**THE DYNAMICS OF DEATH AND MEANING: THE EFFECTS OF DEATH-RELEVANT COGNITIONS AND PERSONAL NEED FOR STRUCTURE ON PERCEPTIONS OF MEANING IN LIFE** Matthew Vess<sup>1</sup>, Clay Routledge<sup>2</sup>, Mark Landau<sup>3</sup>, Jamie Arndt<sup>1</sup>; <sup>1</sup>University of Missouri, <sup>2</sup>North Dakota State University, <sup>3</sup>University of Kansas – Although terror management theory emphasizes the importance of transcendent meaning for the mitigation of existential distress, few studies have directly examined how mortality concerns influence perceptions of meaning in life. The present research proposes that death-relevant thought has divergent effects on meaning perceptions depending on individuals' personal need for structure (PNS), or dispositional desire for structured knowledge. In prior research, high-PNS individuals primed with mortality employ clearly structured conceptions of reality and were thus expected to show stable or even bolstered meaning perceptions under heightened death-thought activation. Low-PNS individuals do not show this tendency and were therefore expected to show decreased meaning perceptions when death-thought was active. Using three different measures of meaning in life, three distinct control conditions, and two operationalizations of death-focused cognitions, the results of Studies 1a – 1d support these hypotheses. Study 2 examined how low-PNS individuals might reaffirm meaning, and showed that activated death-thought increased their willingness to explore novelty. Studies 4 and 5 directly tested the meaning-conferring function of novelty-seeking among low-PNS individuals, showing that they affirmed the meaningfulness of their lives after contemplating mortality and considering novel interpretations of the world and their experience. These findings suggest that individuals predisposed toward unambiguous interpretations of the world experience bolstered perceptions of meaning when death-thoughts are activated. Individuals not so disposed, on the other hand, experience threats to life's meaning but are able to overcome these threats when given the opportunity to actively explore unfamiliar and novel interpretations of both the world and themselves.

**B58**

**SEARCHING FOR A VULNERABLE AND DARK TRIAD: COMPARING VULNERABLE NARCISSISM, SECONDARY PSYCHOPATHY, AND BORDERLINE PERSONALITY DISORDER** Brittany Gentile<sup>1</sup>, Joshua Miller<sup>1</sup>, Ally Dir<sup>1</sup>, Lauren Wilson<sup>1</sup>, Lauren Pryor<sup>1</sup>, W. Keith Campbell<sup>1</sup>; <sup>1</sup>University of Georgia – Previous research has shown substantial covariance between personality disorders and pathological personality styles. This comorbidity has most notably been exemplified by Paulhus and colleague's "Dark Triad" which identified relationships between narcissism, psychopathy, and Machiavellianism. The current study further examines the heterogeneity found in narcissism and psychopathy to determine the existence of a second, complementary triad, composed of emotional vulnerability and dark traits (i.e., the Vulnerable and Dark Triad; VDT). A sample of 361 undergraduates was used to examine the interrelationships between composite measures of vulnerable narcissism, secondary psychopathy, and Borderline Personality Disorder (BPD). Additionally, we examined the relationships of these three constructs to measures of personality, parent reports of personality, etiological factors, and current functioning (e.g. affect, self-esteem, externalizing behaviors). The three members of the VDT were shown to be significantly related to each other and to exhibit similar nomological networks, providing support for the existence of a second dark triad. Significant relationships were also found between the three constructs and aspects of negative emotionality and antagonistic interpersonal styles. Although vulnerable narcissism was related to primary psychopathy, the VDT constructs were otherwise quite distinct from the original dark triad.

**PSYCHOLOGICAL UNDERPINNINGS OF POLITICAL ORIENTATION: A FOCUS ON POLITICAL LIBERALISM** Becky L. Choma<sup>1</sup>, Carolyn L. Hafer<sup>2</sup>, Sid J. Segalowitz<sup>2</sup>, Jane Dywan<sup>2</sup>; <sup>1</sup>Wilfrid Laurier University, <sup>2</sup>Brock University – Psychological research on political ideology has focused disproportionately on the conservative rather than liberal end of the liberal-conservative continuum. Consequently, researchers might have overlooked certain motivational underpinnings of political orientation, especially those that might relate to political liberalism. That is, most of the qualities thought to underlie political ideology were originally proposed because they were indicative of conservatives (i.e., a disparate focus on political conservatism). To address this imbalance, the present research builds on previous work investigating psychological variables that underlie political ideology (e.g., Block & Block, 2006; Jost, Glaser, Kruglanski, & Sulloway, 2003) by concentrating on needs that underlie political orientation, with a theoretical and methodological focus on political liberalism. A review of various literatures led us to hypothesize that needs for Inclusiveness, Change, and Understanding, would relate to political liberalism. In addition, drawing on theories of ideology arguing that different factors promote liberal and conservative orientations (Higgins, 1997; Tomkins, 1963), we tested whether the three proposed needs were distinctly related to political liberalism. Canadian undergraduates (N=245) completed measures of political ideology (using a liberal-conservative continuum, and separate measures of political liberalism and conservatism) and individual difference scales indicative of the proposed needs (Inclusiveness, Change, Understanding). Results from partial correlations and regressions showed that political liberalism was positively associated with Inclusiveness, Change, and Understanding (controlling for political conservatism); however, political conservatism was unrelated to these needs (controlling for political liberalism). Results suggest that some of the underpinnings of political liberalism and political conservatism are distinct, not just opposite.

**B60**

**PERSONALITY CORRELATES OF THE SELF-PRESENTATION TACTICS SCALE** Namia C. Worth<sup>1</sup>, Angela S. Book<sup>1</sup>; <sup>1</sup>Brock University – The purpose of this study was to examine the relationships between the Self-Presentation Tactics scale (S. Lee et al., 1999) and six broad personality traits (using the HEXACO Personality Inventory; K. Lee & Ashton, 2004). The

Self-Presentation Tactics scale consists of 12 tactics reflecting ways that individuals can manipulate the image they project to others (S. Lee et al., 1999), but it is not clear how these different tactics relate to general personality traits. Self-report data from 147 university students showed that total self-presentation tactics scores were negatively correlated with honesty-humility, agreeableness, and conscientiousness, but were uncorrelated with emotionality, extraversion, and openness to experience. A multiple regression analysis found that total scores were predicted by honesty-humility (negatively) and emotionality (positively). Negative correlations were observed between the honesty-humility factor and 10 tactics, suggesting that these tactics are used more often by those who are generally manipulative and insincere. Lower levels of agreeableness were associated with more frequent use of seven tactics, including the more obviously 'aggressive' tactics (e.g., intimidation and blasting), but also other tactics (e.g., excuses) that do not contain overtly disagreeable content. Results suggest that the nature of the different self-presentation tactics can be explained in terms of their relationships with the six broad personality traits, and that overall self-presentation tactics are generally deceptive behaviours. However, the two tactics (apologies and self-handicapping) that were largely uncorrelated with honesty-humility may sometimes be authentic expressions of feeling rather than tactics designed to alter one's image.

### B61

**MORAL IDENTITY AND THE EXPERIENCE OF MORAL ELEVATION IN RESPONSE TO ACTS OF UNCOMMON GOODNESS** Karl Aquino<sup>1</sup>, Brent McFerran<sup>1</sup>, Marjorie Laven<sup>1</sup>; <sup>1</sup>University of British Columbia – Two studies examine whether people whose moral identity is highly self-defining are more susceptible to experiencing a state of moral elevation after being exposed to acts of uncommon moral goodness. Moral elevation consists of emotional, cognitive, and physiological responses that motivate prosocial action tendencies (Freeman, Aquino, & McFerran, 2009; Haidt 2000; 2003). Study 1 used a representative sample of the Canadian population obtained from a professional polling organization. Participants were asked if they had ever witnessed an unexpected and extraordinary act of human goodness, kindness, or compassion, and if so to briefly describe the event. Results showed that people higher in moral identity centrality reported experiencing more intense elevating emotions, had more positive views of humanity, and were more desirous of becoming a better person after witnessing an act of uncommon goodness, but not positive emotions in general. These elevating experiences fully mediated, self-reported prosocial behavior in an estimated path model. Study 2 replicates the effect of moral identity on these elevation states as well as on physiological responses using an experimental paradigm. University student participants were exposed to a video that was designed to elicit moral elevation or a control video. Results showed an interaction between video and moral identity such that those high in moral identity centrality reported heightened reactions to the elevating, but not non-elevating video, whereas those low in moral identity did not differ as a function of the stimuli. Together, the findings suggest that individual differences in moral identity influence reactions to witnessing moral goodness.

### B62

**TRAIT ATTENTION TO EMOTION INFLUENCES THE EFFECT OF MOOD ON DECISION MAKING** Elizabeth L. Foreman<sup>1</sup>, Kristen L. VonWaldner<sup>1</sup>, Carol L. Gohm<sup>1</sup>; <sup>1</sup>University of Mississippi – Psychological research has well supported the idea that people use their current affective states as informative cues when evaluating and making decisions about their environments (e.g., Gouaux, 1971; Schwarz & Clore, 1983; Clore, 2001). Recent studies conducted in our lab suggest that individual differences may influence these effects of mood on judgment. One such personality trait is attention, which is the extent to which an individual monitors and values his/her emotions. It seems plausible that people who pay attention to their emotions would be more strongly influenced by their emotions when making decisions. The present study sought to investigate the influence of attention to emotion on the effects of mood on outcome

decisions in an interactive story. Of concern to this study is whether being high in attention to emotion leads individuals to better use their current affective state when making positive or negative outcome decisions following a mood manipulation. Participants' moods were induced by watching a positive or negative movie clip. They then read seven interactive paragraphs about a character named Ally and had to make positive or negative outcome decisions about what happened next in her story. Attention to emotion was obtained by calculating the mean of two attention scales. A mood by personality trait interaction revealed that persons low in attention to emotion did not differ in outcomes made across movie conditions, but that highs did. Thus, this data provides support for the idea that personality traits, specifically attention, can be influential factors in decision making.

### B63

#### **THE EFFECT OF COGNITIVE LOAD AND IMPULSIVITY ON BASE RATE NEGLECT IN LEARNING-BASED PROBABILITY JUDGEMENTS** Kristen Blackler<sup>1</sup>; <sup>1</sup>Queen's University – Research has repeatedly found that human judgements deviate substantially from logical probability rules such as Bayes's Theorem and instead exhibit predictable, systematic biases. Base rate neglect is a common bias that occurs when participants fail to utilize prior probabilities, or base rates, when making probability judgments. The purpose of this study was to examine the effect of a personality factor, cognitive impulsivity, as well as varying levels of cognitive load on base rate neglect. Participants completed a computer task where they were responsible for estimating the probability that oil would be found on plots of land. Participants completed training trials where a cue was presented (level of bacteria) along with an outcome (oil was/not found). Participants then completed test trials where they were presented with a cue and indicated the probability that the current plot contained oil. Participants completed half of the test trials under high cognitive load and half under low cognitive load. We found no effects for the load manipulation; however, for the individual difference, those who were low in cognitive impulsivity were more prone to use base rate information and thus made more accurate judgements than did those who were high in impulsivity. In addition, overall probability estimates were accurate in the high base rate condition but much too high in the low base rate condition even though participants had acquired an accurate understanding of the low base rate. These results suggest an optimism bias where individuals are prone to optimistically interpret low base rate situations.

Participants then completed test trials where they were presented with a cue and indicated the probability that the current plot contained oil. Participants completed half of the test trials under high cognitive load and half under low cognitive load. We found no effects for the load manipulation; however, for the individual difference, those who were low in cognitive impulsivity were more prone to use base rate information and thus made more accurate judgements than did those who were high in impulsivity. In addition, overall probability estimates were accurate in the high base rate condition but much too high in the low base rate condition even though participants had acquired an accurate understanding of the low base rate. These results suggest an optimism bias where individuals are prone to optimistically interpret low base rate situations.

#### **UNVEILING THE MECHANISMS UNDERLYING INDIVIDUAL DIFFERENCES IN SITUATION-AFFECT PROFILES** Joeri Hofmans<sup>1</sup>, Iven Van Mechelen<sup>1</sup>; <sup>1</sup>University of Leuven – Emotional intensity is subject to between- and within-individual differences. A thorough understanding of it implies a simultaneous account of both kinds of heterogeneity. Three groups of questions may provide a hold to arrive at such an understanding: (1) Do individual differences in emotional intensity exist, and, if yes, do they correspond to a pattern expected on the basis of a trait concept? (2) Do situational differences in emotional intensity exist, and, if yes, what are the relevant situational features to which it is sensitive? (3) Do individual differences show up in the sensitivity to situational features (differential sensitivity), and, if yes, what is the nature of these differences? The results of studies on anger, shame, and guilt suggest that: (1) emotional intensity is subject to individual differences and the observed patterns of such differences comply with a trait account; (2) intensity is subject to situational differences in that it is sensitive to emotion-specific situational features. In particular, for shame and guilt, those differences can be reduced to a single underlying dimension (viz., the extent to which the situation implies a revelation of a weakness or incompetence of the subject, and the extent to which the situation induces self-blame, respectively), while for anger, a multidimensional account is needed; and (3) differential sensitivity occurs, with the nature of this differential sensitivity being emotion-dependent. Beyond this, a rich variety of situational

Emotional intensity is subject to between- and within-individual differences. A thorough understanding of it implies a simultaneous account of both kinds of heterogeneity. Three groups of questions may provide a hold to arrive at such an understanding: (1) Do individual differences in emotional intensity exist, and, if yes, do they correspond to a pattern expected on the basis of a trait concept? (2) Do situational differences in emotional intensity exist, and, if yes, what are the relevant situational features to which it is sensitive? The results of studies on anger, shame, and guilt suggest that: (1) emotional intensity is subject to individual differences and the observed patterns of such differences comply with a trait account; (2) intensity is subject to situational differences in that it is sensitive to emotion-specific situational features. In particular, for shame and guilt, those differences can be reduced to a single underlying dimension (viz., the extent to which the situation implies a revelation of a weakness or incompetence of the subject, and the extent to which the situation induces self-blame, respectively), while for anger, a multidimensional account is needed; and (3) differential sensitivity occurs, with the nature of this differential sensitivity being emotion-dependent. Beyond this, a rich variety of situational

sensitivity structures is revealed, including a threshold model, and gradual models with both equal and unequal feature contributions to emotional intensity.

### B65

**DO YOU TWO KNOW EACH OTHER? TRANSITIVITY, HOMOPHILY, AND THE NEED FOR (NETWORK) CLOSURE** Francis Flynn<sup>1</sup>, Ray E. Reagans<sup>2</sup>, Lucia E. Guillory<sup>3</sup>, <sup>1</sup>Administrative Science Quarterly, Management Science, Academy of Management Journal, <sup>2</sup>Administrative Science Quarterly, Organization Science, <sup>3</sup>Academy of Management, Society for Personality and Social Psychology – We investigate whether need for closure affects how people judge the existence of social relations. In Study 1, we find that people who have a high need for closure were more likely to assume that their social ties were connected to each other (i.e., transitivity) when this was not the case. In Study 2, we find evidence of a presumed racial homophily effect: participants with a high need for closure were more inclined to believe that two individuals from the same racial category (e.g., African-American) were more likely to be friends than people who were racially dissimilar. Finally, in Study 3, individuals with a high need for closure were more likely to make errors when judging physical proximity among a racially-mixed group of people: specifically, they recalled racially similar people sitting closer together than they had originally appeared.

### B66

**NARCISSISM IS ON THE RISE BOTH NATIONALLY AND LOCALLY** Erin Gallivan<sup>1</sup>, Jean Twenge<sup>2</sup>, Jennifer Boutwell<sup>1</sup>, Joshua Foster<sup>1</sup>; <sup>1</sup>University of South Alabama, <sup>2</sup>San Diego State University – Several recent high-profile studies have produced conflicting results regarding a possible rise in narcissism in American college students during the past 30 years. We suggest that some of the studies that reported no increase in narcissism were confounded because their sources of data (i.e., college campuses) varied systematically across time. That is, students from certain college campuses were more heavily sampled at specific time periods (e.g., UC Davis students were heavily sampled in recent time periods). In this poster, we report two studies demonstrating that removing this confound reveals significant generational increases in narcissism. In Study 1, we update a previously published meta-analysis and show that statistically controlling for college campus reveals a significant nationwide increase in narcissism between the years 1982 and 2008 ( $k = 110$ ;  $N = 51,268$ ;  $d = .36$ ). In Study 2, we methodologically control for college campus by examining narcissism trends within a specific university (i.e., University of South Alabama) and again demonstrate a significant increase in narcissism between the years 1994 and 2009 ( $N = 4,152$ ;  $d = .37$ ). In sum, these results reveal detectable increases in narcissism when college campus is controlled for either statistically or methodologically.

### B67

**APPLYING THE INTERPERSONAL CIRCUMPLEX TO THE STUDY OF ANIMAL PERSONALITY** Lauren Highfill<sup>1</sup>, Virgil Zeigler-Hill<sup>2</sup>; <sup>1</sup>Eckerd College, <sup>2</sup>University of Southern Mississippi – Research concerning animal personality has become increasingly popular during the past few decades. However, researchers continue to have difficulty finding a model of animal personality that can be used to adequately capture the individual differences between members of the same species as well as being broad enough to apply to a range of species. The purpose of the present study was to examine whether the interpersonal circumplex (e.g., Leary, 1957) could be applied to animals in such a way that it would improve our understanding of their behavioral styles. The interpersonal styles of 555 pet owners were assessed along with the behavioral styles of their pets (449 dogs and 106 cats). Consistent with the interpersonal circumplex, we found that the behavioral styles of household pets conformed to a circular structure. We also found evidence for complementarity such that cat owners reported more positive attitudes toward their pets when they perceived reciprocity between themselves and their pets on the dominance dimension (e.g., dominant behavior from the owner elicited submissive behavior from their pet). In contrast,

the attitudes of owners for their dogs were not associated with the degree of complementarity between their pets and themselves. For the warmth dimension, both dog and cat owners reported more positive attitudes when they perceived greater correspondence between themselves and their pets (e.g., warm behavior from the owner elicited warm behavior from the pet).

### B68

**BROAD AND SPECIFIC MEASURES OF IMPLICIT BELIEFS ABOUT STABILITY AND CHANGE: A CONSTRUCT VALIDITY STUDY** Jamie Hughes<sup>1</sup>; <sup>1</sup>New Mexico State University – Implicit theories are beliefs about the relative stability or malleability of human characteristics. Individuals can hold these beliefs about intelligence, morality, or personality. Further, the particular belief one holds (entity beliefs versus incremental beliefs) are shown to predict a particular pattern of behavior. However, it is not known whether beliefs about broad domains such as intelligence, are consistent with beliefs about specific domains such as mathematical ability. Ninety-five participants completed the eight-item implicit belief measures regarding persons, intelligence and morality. They also completed a series of four-item implicit belief measures about specific domains related to the broad domains. Finally, participants completed questionnaires regarding their perceived stress, moral beliefs, and political orientation. The order of broad domains, and whether participants received the broad or specific items first was counter balanced using a Latin square. Results indicated that most participants endorsed incremental beliefs. The classification of participants into entity theorists, incremental theorists, or neither revealed that approximately 70 percent of participants were unclassified or incremental theorists. Analysis of the correlations between broad and specific domains showed significant and positive associations. Finally, correlations between implicit belief measures and theoretically unrelated measures proved non-significant. Discussion centers on the construct, convergent, and discriminant validity of implicit beliefs.

### B69

**REDUCED COLLECTIVISM IN VERY SMALL COMMUNITIES AND LARGE METROPOLITAN AREAS: THE CURVILINEAR EFFECT OF HOME TOWN SIZE ON COLLECTIVISM** Jared L. Ladbury<sup>1</sup>, Verlin B. Hinsz<sup>2</sup>; <sup>1</sup>North Dakota State University – Previous research (Kashima, et al., 2004) demonstrated that people living in regional population centers (population approximately 100,000) tend to be more collectivistic than people living in metropolitan areas (population greater than one million). This effect occurs regardless of East/West culture membership. However, the nature of the effect in very small populations is not well understood. Theories predict that people from small communities will be more traditional and collectively oriented because survival often depends on relying on and getting along with one another. Alternatively, people from very small communities could be forced to become more self-reliant and thus less collectivistic because there are too few people to form a collective community. To compare these hypotheses, 696 students participated in a mass questionnaire. This questionnaire included estimates of home town size on a logarithmic scale. Participants also completed the Individualism-Collectivism scale (Hui, 1988). Multiple regression analysis with home town size as linear and curvilinear predictors of collectivism showed support for a curvilinear relationship. Those from very small towns and large metropolitan areas had the lowest collectivism scores with those from regional population centers having the highest. Results lend support to the hypothesis that living in very small and very large communities reduces reliance on others and encourages an individualistic mindset. This study also reiterates the impact within-culture variables can have on individualism and collectivism.

**B70**

**LONGITUDINAL EFFECTS OF CAUSAL UNCERTAINTY AND IMPORTANCE OF CAUSAL UNDERSTANDING ON UNCERTAINTY REDUCTION IN SAME-SEX FRIENDSHIPS** Eliane M. Boucher<sup>1</sup>, Jill A. Jacobson<sup>2</sup>; <sup>1</sup>University of Texas of the Permian Basin, <sup>2</sup>Queen's University – High causally uncertain (CU) people experience doubts about their ability to determine the causes of social events (Weary & Edwards, 1994). These individuals tend to perceive their conversations with others negatively (Boucher & Jacobson, 2007) and report interpersonal difficulties, including greater roommate rejection (Passey, 2006). Recent research suggests that their difficulties during interactions with strangers stem from an inability to reduce uncertainty about themselves and others (Boucher & Jacobson, 2008). However, it is unclear if a lack of uncertainty reduction also accounts for their difficulties in close relationships. The purpose of the current study was to examine the relationship between causal uncertainty and uncertainty reduction in same-sex friendships over time, and to explore if the degree to which people perceive causal understanding as important moderates this relationship. Friend pairs completed measures of uncertainty reduction, causal uncertainty, and causal importance (CI) at Time 1 and again after six weeks. Although high CU participants reported more uncertainty about their future behavior, their friend's future behavior, their feelings toward their friend, and their friend's feelings toward them, causal uncertainty was not associated with such heightened uncertainty six weeks later. However, high CU participants with lower levels of CI reported less uncertainty reduction about their own future behavior after six weeks. Furthermore, people with high CU friends reported less uncertainty reduction about their friend's feelings toward them. Therefore, high CU people might engage in behaviors that eventually make their friends question their feelings, resulting in the reported interpersonal problems and rejection.

**B71**

**THE EPISTEMIC FUNCTION OF FAMILIARITY VS. NOVELTY SEEKING IN TERROR MANAGEMENT** Todd Williams<sup>1</sup>, Murat Usta<sup>2</sup>, Jeff Schimmel<sup>2</sup>, Gerald Haubi<sup>2</sup>; <sup>1</sup>Grand Valley State University, <sup>2</sup>University of Alberta – According to terror management theory (TMT; Greenberg, Pyszczynski, & Solomon 1986), the existential anxiety that arises from our implicit awareness of our own mortality plays a pivotal role in the extent to which we embrace novelty as a potential source of self-expansion and excitement or eschew it as a potential threat to our existing self-concept and beliefs. Recently, TMT research has shown that when mortality is salient, individuals who are high in personal need for structure (PNS; Neuberg & Newsom, 1993) prefer simplistic interpretations of both their material and social world (Landau et al., 2004, Landau et al., 2006, Landau et al., 2008). Extending this previous research, we examined whether these effects would generalize outside of a social domain and whether the amount of structure present in the choice context would further moderate the extent to which individuals would avoid or seek novelty. In two studies, mortality (vs. pain) was made salient and participants completed a simulated choice task in which they were asked to select food items from a restaurant menu. The amount of structure in the choice environment was manipulated by changing the organization of menu items. The following results were observed when mortality (vs. pain) was salient. When high PNS individuals perceived less structure in the choice environment, they avoided novelty (Study 1). When low PNS individuals perceived greater structure in the choice environment, they sought novelty (Study 2). These results suggest that high and low PNS individuals engage in different terror management strategies. Implications are discussed.

**B72**

**WHEN I LOOK AT THE TELEVISION, I WANT TO SEE ME STARING RIGHT BACK AT ME: INTRODUCING THE 16-ITEM DESIRE FOR FAME INVENTORY** Graeme Haynes<sup>1</sup>; <sup>1</sup>The University of Western Ontario – A surprisingly high number of today's youth (collectively referred to as the Millennial Generation or Generation Me) believe that they will become

famous someday (Twenge and Campbell, 2009). The fame frenzy has been fueled by the explosion in popularity of reality television shows, entertainment gossip shows and websites, as well as internet vehicles for showcasing one's talent such as YouTube and Myspace. A scale was designed to measure individual differences in people's desire to become famous. Forty scale items were created by the experimenter and administered to a group of 141 undergraduate students at a mid-size North-eastern American university. The items were subjected to a factor analysis and reduced to a psychometrically sound 16-item Fame Inventory ( $\alpha = .89$ ) comprised of two factors: 1) Fame Achievement (11 items; e.g., "It would be great to have everyone recognize me when I walk down the street,") and 2) Vanity (5 items; e.g., "My life story would make an interesting novel or movie.") Participants' scores on the Fame Achievement subscale correlated positively with narcissism and extraversion, while scores on the Vanity subscale were associated with narcissism, Rosenberg self-esteem, extraversion and openness to experience. Potential applications of the inventory are discussed.

**B73**

**INDIVIDUAL DIFFERENCES IN ADAPTIVE PERFORMANCE** Raelynn Wheeler<sup>1</sup>, Kirby Gilliland<sup>1</sup>; <sup>1</sup>University of Oklahoma – Adaptability can be broadly defined as "an effective change in response to an altered situation (White et al., 2005)." This construct is noteworthy because "individuals, teams and organizations must be able to continuously adapt their knowledge and skills in order to remain competitive in environments which [sic] are fluid, often ambiguous, and where multiple pathways to goal attainment exist (Burke, Pierce & Salas, 2006)." Previous research has focused on defining the major components of adaptability and predicting adaptability with identified correlates. What is novel about the current study is that adaptability is defined by one's adaptive performance on a behavioral test. Individual differences are then evaluated between those who display efficient and inefficient adaptive performance. Participants (N=154) filled out a battery of personality measures as well as a battery of computerized cognitive ability tests. They also participated in an air traffic control simulation task as a measure of adaptive performance. It was found that efficient adaptors had faster reaction times on all six cognitive tests, and a higher percent correct on two of the five cognitive tests, relative to inefficient adaptors. Efficient adaptors are also less likely to use emotion-focused coping strategies, are lower in extraversion, and more open to experience, relative to inefficient adaptors. We conclude that cognitive ability and personality are related to adaptive performance. Individuals who fit a behavior-based efficient adaptor profile may be better suited to complex environmental situations, relative to inefficient adaptors.

**B74**

**NEED TO EVALUATE AS A MODERATOR OF MNEMIC NEGLECT** Daria Bakina<sup>1</sup>, Leonard Newman<sup>1</sup>; <sup>1</sup>Syracuse University – Research on mnemonic neglect (Sedikides & Green, 2004) reveals that when presented with positive and negative information about the self (but not others), individuals have better recall for positive, favorable feedback than negative, unfavorable feedback. However, individual differences moderating mnemonic neglect – which could shed light on the processes mediating the effect – have rarely been explored. The Need to Evaluate (NE; Jarvis & Petty, 1996) is an individual difference reflecting people's tendency to engage in evaluative processing and responding. If the self-protective pattern of recall found in past studies reflects differential processing of evaluatively significant self-related and other-related personality feedback, it should be less pronounced among participants chronically motivated to consider the evaluative implications of social information regardless of its valence or referent (i.e., participants high in NE). In the present study, participants were asked to read a series of positive and negative statements either about themselves or an individual named Chris. After a distracter period, the participants were asked to recall the statements. Finally, they completed the NE questionnaire. Analyses revealed a significant three-way interaction ( $p < .05$ ) between NE (high, low), Valence of statement (positive, negative), and Referent of statement (self, other).

A pattern of recall consistent with past research—more recall of positive than negative feedback for the self but not for another person—was found only for low NE participants. The results indirectly support the idea that mnemonic neglect depends on people's willingness and ability to redirect attention away from some kinds of evaluatively significant self-relevant information.

**B75**

**AN UMBRELLA OF DOMINANCE? AN EXAMINATION OF OPPRESSIVE BELIEFS IN THE CONTEXT OF RAPE** Jericho Hockett<sup>1</sup>, Sara Smith<sup>1</sup>, Cathleen Klausung<sup>1</sup>, Donald Saucier<sup>1</sup>; <sup>1</sup>Kansas State University – Research has demonstrated that negative perceptions of rape victims may vary based on characteristics such as the victims' race (e.g., Estrich, 1987; Wyatt, 1992). This study examined rape from feminist (e.g., Collins, 1991; hooks, 2003) and Social Dominance Theory (SDT; e.g., Pratto, 1996; Sidanius, 1993) perspectives to assess the relationship between individuals' social dominance orientation (SDO) and differences in their attitudes toward rape victims of differing races. After reading newspaper-style vignettes describing the rape of either a White or Black victim, participants (N = 83) completed measures assessing their levels of rape myth acceptance (RMA), gender role beliefs, SDO, racism, and social desirability. Results indicated that participants' SDO scores significantly predicted their perceptions of the triviality of the rape. Specifically, when participants' SDO scores were higher, they perceived the rape as less trivial for White victims. However, participants higher in SDO did not perceive the rape of Black victims as being either more or less trivial. Consistent with previous research, this study also found that negative attitudes toward women significantly predicted overall negative perceptions of both the Black and White rape victims (e.g., Hockett et al., in press) and that individuals perceived the Black rape victims as less credible than the White rape victims (Wyatt, 1992). These results contribute to our understanding of the relationships among individuals' attitudes about power, race, and rape by offering support for feminist theories about the relationship between rape and power, as well as for SDT and feminist theories regarding the structure of dominance.

**B76**

**LEFT-WING RADICALISM AND PREJUDICE** Daniel Miller<sup>1</sup>, Kenneth Bordens<sup>1</sup>; <sup>1</sup>Indiana University - Purdue University, Fort Wayne – The study of prejudice has examined how personality characteristics are correlated with prejudice almost since the beginning of the field. One of the most studied personality correlates of prejudice is right-wing authoritarianism (RWA; Altemeyer, 1981). People high in RWA tend to be politically conservative, and prejudiced against a wide variety of groups including feminists (Duncan, Peteron & Winter, 1997), lesbians and gay men (Whitley & Lee, 2000), Native Americans (Altemeyer, 1998), immigrants (Quinton, Cowan & Watson, 1996), and fat people (Crandall, 1994). Thus, research using RWA has been quite successful in identifying prejudice personalities on the right of the political spectrum. However, psychologists have often debated whether prejudiced personalities exist only on the right-wing side of the political spectrum or whether prejudiced personality traits can also be detected at the extreme left-wing end of the political spectrum. The goal of this research is to develop a scale, which will identify those on the extreme left of the political spectrum (left-wing radicals) who are more likely to express prejudice against groups that violate left-wing values (e.g. Fundamentalist Christians). The results of several studies indicate that those high in left-wing radicalism have quite positive attitudes toward traditional minority groups (Blacks, Muslims, and Homosexuals). However, this same group has quite negative attitudes toward groups that violate left-wing values (Conservatives, Christians, and Israelis). The implications of these findings are discussed.

**B77**

**UNEQUAL OPPORTUNITY: SOCIAL DOMINANCE ORIENTATION AND PROSOCIAL RESOURCE ALLOCATION** Reehan K. Bari<sup>1</sup>, Paul K. Piff<sup>1</sup>, Andres G. Martinez<sup>1</sup>, Amanda Purcell<sup>1</sup>, Dacher Keltner<sup>1</sup>; <sup>1</sup>UC Berkeley – Social dominance orientation (SDO) assesses an individual's preference for social hierarchies and group-based dominance. We examined the antisocial consequences of social dominance for the allocation of resources in two social settings. Participants (N = 112) completed an online task (Social Values Orientation, SVO) in which they chose between prosocial and selfish responses for nine hypothetical resource allocation scenarios. In a laboratory setting, these same participants completed a behavioral measure of altruism: the dictator game. Here, participants were instructed to divide a sum of money between themselves and an anonymous partner. Across tasks, a consistent pattern of antisocial behavior emerged. Specifically, SDO was associated with heightened selfishness in SVO and decreased altruism in the dictator game. We argue that SDO is a dimension of a more global anti-egalitarian belief system. This worldview may cause individuals to disregard the needs of others and act in favor of their own self-interest.

**B78**

**TESTING A DUAL PROCESS MODEL OF MOTIVATION AND COGNITION: EXPERIMENTAL MANIPULATION OF DISTINCT SOCIAL CONTEXTS** Miriam Matthews<sup>1</sup>, Shana Levin<sup>2</sup>; <sup>1</sup>Claremont Graduate University, <sup>2</sup>Claremont McKenna College – This research examined the extent to which a socially threatening context and a socially competitive context affect the ideological attitudes of right wing authoritarianism (RWA) and social dominance orientation (SDO), respectively. Building from Duckitt's (2001) dual process model of motivation and cognition, two experimental studies utilized structural equation modeling (SEM) to demonstrate that these distinct social contexts operate through separate mechanisms to affect ideological attitudes. In Study 1, participants first read a scenario that depicted either a chaotic or a stable future. Afterward, they responded to a series of questions as if this future were true. Results demonstrated that the effect of a socially threatening context on expressions of RWA and one's view of the world as a competitive jungle are mediated by a view of the world as a dangerous and chaotic place. In Study 2, participants read a news article that either described various aspects of the United States (e.g., the job market) as involving fierce competition or described general trends in these aspects, with no mention of competition. Results of this study further supported the dual process model's proposition that the effects of a competitive social context on expressions of SDO and a dangerous worldview are mediated by a competitive jungle worldview. The findings of these studies emphasize the importance of considering both the unique aspects of the situation and the characteristics of the individual when examining the factors that contribute to expressions of prejudice.

**B79**

**THE EFFECTS OF POLITICAL AFFILIATION AND RELIGIOUS CHARACTERISTICS ON ACCEPTABILITY OF IVF FOR NON-TRADITIONAL WOMEN** Alexandra E. Sigillo<sup>1</sup>, Monica K. Miller<sup>1</sup>, Dana A. Weiser<sup>1</sup>; <sup>1</sup>University of Nevada, Reno – Individuals have increasingly utilized in vitro fertilization (IVF) to bear children. Controversy surrounds the use of IVF, especially by non-traditional women (e.g., lesbians). This research expands on previous studies that have investigated the relationship between personality traits and attitudes toward IVF. This study explores individuals' perceptions of morality and whether doctors should refuse IVF for a variety of non-traditional women. Three-hundred-three students (women = 156, men = 101; M age = 20.9) completed online questionnaires assessing sociodemographics, political and religious affiliations, and religious characteristics (e.g., fundamentalism). Using a 5-point Likert scale, participants also rated perceptions of morality and whether doctors should refuse IVF for four types of women: a single woman, a woman with Alzheimer's, a man who had a sex change, and a lesbian. Multiple regression models significantly predicted moral-

ity and doctor refusal for a single woman; morality for a woman with Alzheimer's; doctor refusal for a man who had a sex change; and morality and doctor refusal for a lesbian. Results indicated Democrats, compared to Republicans, rated three of the four scenarios as more moral and all scenarios as less supportive of doctor refusal. There were no significant effects for religious affiliation. However, individuals higher in devotionism, fundamentalism, and evangelism rated some scenarios as less moral and were more supportive of doctor refusal. Individuals higher in extrinsic-personal religiosity rated some scenarios as more moral and were less supportive of doctor refusal. In conclusion, political affiliation was a better predictor of scenario ratings compared to religious affiliation and characteristics.

#### WHO ARE YOU ON FACEBOOK? THE ROLE OF PERSONALITY AND GENDER IN ONLINE SOCIAL NETWORKING SITES

Nicole Muscanell<sup>1</sup>, Rosanna Guadagno; <sup>1</sup>The University of Alabama – In the last few years there has been a rapid growth in the use of the Internet as a means of communicating with others socially (Lenhart, January, 2009). Because many popular social networking sites are relatively new, there is still a paucity of psychological research on the ways in which individuals use social such sites. The present study examined whether or not individual differences such as personality and gender influence individuals' use of online social networking websites such as Facebook and MySpace. Participants were 238 undergraduate students who completed an online survey about their experiences with and use of social networking sites. All participants reported being members of Facebook, MySpace, or both. Based on prior research in online behavior, we expected to find different patterns of behavior for men and women and that Big 5 personality scores would also moderate behavior. Our results indicated that personality and gender both moderated individuals' use of social networking sites. Additionally, we found significant interactions between personality and gender that predicted how often individuals made blog postings, engaged in live chat/instant messaging, and played games through social networking sites. As such, we conclude that it is important to examine individual differences when examining certain types of online behavior.

### B81

#### DO NARCISSISTS ENVY, AND IF SO, WHICH DO?

Omesh Johar<sup>1</sup>, Zlatan Krizan<sup>1</sup>; <sup>1</sup>Iowa State University – Although clinical conceptualizations of narcissism emphasize both the grandiose-exhibitionistic and hypersensitive-vulnerable features, more recent research distinguishes between grandiose- and hypersensitive-narcissisms. A deeper insight into the distinct features of narcissism is offered by the unpleasant emotion of envy. For instance, clinical theorists propose envy as a critical motivator of exploitativeness and hostility of grandiose narcissists, but not of hypersensitive narcissists. However, implicit in more recent trait theories is the notion that grandiose narcissists' high self-esteem should minimize opportunities for feeling envious, whereas hypersensitive narcissists' emotional vulnerability should make them more likely to envy. We examined these contradictory notions along with the extent to which narcissistic traits are able to predict emotional components of envy. In Study 1 we collected self-reports of narcissism, envy, schadenfreude, grandiosity, hostility, and entitlement. In study 2, in addition to these self-reports, students' close peers provided informant reports of the same personality characteristics. Grandiose and hypersensitive narcissism were assessed using the Narcissistic Personality Inventory and the Hypersensitive Narcissism Scale, respectively. Furthermore, Study 2 participants recalled and wrote about an intense envy experience. Subsequently, they rated it on multiple envy-related thoughts and emotions. Grandiose narcissism was unrelated to experience of envy ( $r = -0.17$ ). Neither did it predict stronger emotional reactions (e.g., feelings of injustice, inferiority, and anger) during an envy episode. However, hypersensitive narcissism was strongly related to feelings of envy and schadenfreude

( $r_s > .50$ ), and was indicative of more intense emotions during an envy episode. These findings support conceptualization of narcissism offered by recent trait theories.

### B82

#### SOCIAL RANK STYLES AND PERFORMANCE IN SMALL WORK GROUPS

David Zuroff<sup>1</sup>, D. S. Moskowitz<sup>1</sup>, Stéphane Côté; <sup>1</sup>McGill University, <sup>2</sup>University of Toronto – Zuroff, Fournier, Patall, Leybman, and Abela (2008) proposed that an evolutionary personality psychology could be developed by articulating individual differences in each of five evolved systems that regulate social behavior (Bugental, 2000). They developed a 17-item questionnaire measure of three personality variables related to the social rank system: dominant leadership, coalition-building, and ruthless self-advancement. In the present study, 36 leaderless work groups with 3-4 members were composed from 136 employed adults. Groups watched a video describing a hypothetical airplane crash landing in the arctic; the group's task was to prepare a consensus rank-ordering of the survival value of 15 salvaged items. After a 35-minute discussion, participants rated their own performance and the performance of each other member. An objective measure of the group's performance was obtained by comparing the group's final rankings to the rankings of survival experts. Self-ratings and aggregated other-ratings were analyzed using hierarchical linear modeling, with scores for subjects nested within groups. Self-rated performance was positively predicted by dominant leadership. The subject's performance as rated by other group members tended to be positively predicted by coalition-building. For the analysis of objective performance, objective performance scores were regressed on the groups' mean levels of the three personality variables. Objective performance was poorer when the group's mean level of ruthless self-advancement was high, and superior when the group's mean levels of both dominant leadership and coalition-building were high. The results are consistent with theoretical expectations and demonstrate the value of personality variables developed from an evolutionary perspective.

## Intergroup Relations

### B83

#### BLACK SHEEP OR DEVIL PROTECTION? REACTIONS TO INGROUP DEVIANCE IN ANONYMOUS VERSUS PUBLIC SETTINGS

Melisa A. Holovics<sup>1</sup>, Jared B. Kenworthy<sup>1</sup>, Joy Stratton<sup>2</sup>, Rhonessia S. Johnson<sup>1</sup>, Norman Miller<sup>3</sup>; <sup>1</sup>The University of Texas at Arlington, <sup>2</sup>Northern Virginia Community College, Loudoun, <sup>3</sup>University of Southern California – We tested the hypotheses that derogation of ingroup deviants would be stronger in anonymous settings than in public settings, especially by high ingroup identifiers. In two experiments, participants read about an ingroup or outgroup target exhibiting negative behavior, then reported target evaluations either publicly or anonymously. In Experiments 1 and 2, the high (not low) identifiers rated the ingroup deviants more positively in public versus anonymous settings. Also, in both experiments the high identifiers rated the ingroup deviants more negatively than the outgroup deviants – the "black sheep effect" – in the anonymous (not public) settings. When the high identifiers were asked to rate the targets in a public setting, the "black sheep effect" was attenuated. In Experiment 1, there was no difference between the ratings of the ingroup and outgroup deviants in the public setting. In Experiment 2, the ratings of the ingroup and outgroup deviants in the public setting were directionally opposite than the ratings in the anonymous setting. This finding provides support for a "devil protection effect", such that the ingroup deviants will be rated more positively than the outgroup deviants in a public setting. We discuss these findings as an elaboration on and refinement to current theory explaining the black sheep effect.

**B84****THE IMPACT OF THE COLORBLIND AND MULTICULTURAL IDEOLOGIES ON FACILITATING SOCIAL TOLERANCE IN A DIVERSE STUDENT POPULATION** Dina Karafantis<sup>1</sup>, Maria LaPadula<sup>1</sup>, <sup>1</sup>New York Institute of Technology

– Given the increasing diversity of the United States, we face the very same challenges in our land today that threatens the democratic ideals of peace and justice embraced by the world. Social scientists and others have answered this threat by investigating how best to maintain a peaceful coalition without de-fragmenting the racial, ethnic, and gender-specific pieces that make up our culturally, rich society. Anti-discriminative policies promote ideas of equality on political platforms, but fail to maintain equality on economic and social levels. This implies that anti-discriminative interventions should be directed at the cognitive and affective components of inter-group relations, namely stereotypes and prejudice, respectively. In an attempt to combat the pervasiveness of biased views and practices in U.S. society, lay theories related to diversity, such as the colorblind and multicultural theories, have been most influential. The present investigation examined whether brief inductions derived from the multicultural and colorblind theories differ in the extent to which they facilitate social tolerance among a racially diverse group of college students, as indicated by participant responses on measures of prejudice, stereotyping, and discrimination, as well as a measure of empathy. Further, as an actual behavioral measure of social tolerance, participants were provided with the opportunity to donate money to a homeless shelter. Results indicate that both the multicultural and colorblind conditions were successful at facilitating social tolerance; however, participants in the multicultural condition also demonstrated higher levels of stereotyping. Contrary to our hypotheses, no differences in money donated to the homeless shelter were found.

**B85****"WE" ARE FAMILIAR BUT "IT" IS NOT: INGROUP PRONOUNS TRIGGER FEELINGS OF FAMILIARITY VIA POSITIVITY** Meghan Housley<sup>1</sup>, Heather Claypool<sup>1</sup>, <sup>1</sup>Miami University

– Previous work has shown that pairing ingroup pronouns with neutral stimuli makes those stimuli appear more familiar. The purpose of this work is to identify if positivity is the mechanism by which this effect occurs. Some participants initially completed a filler task and were subsequently told that nonsense syllables had been subliminally presented during it (though none actually were). Then, during a judgment phase, they rated how familiar a series of syllables appeared. Other participants first completed the same filler task, though without mention of subliminal presentation, and then completed a judgment phase in which they rated how appealing (positive) they found the same syllables. During the judgment phase for both groups, participants were told that "distractor" words would appear prior to each syllable. These "distractors" were actually ingroup (e.g., "we") and neutral (e.g., "it") pronoun primes. Replicating previous work, ingroup-primed syllables ( $M=3.77$ ) were rated as more familiar than neutrally-primed syllables ( $M=3.29$ ),  $F(1,44)=7.52$ ,  $p=.009$ . Furthermore, syllables primed with ingroup pronouns ( $M=4.04$ ) were rated as more appealing (positive) than those primed with neutral pronouns ( $M=3.76$ ),  $F(1,44)=5.26$ ,  $p=.03$ . Using the bootstrap mediation method (Preacher & Hayes, 2004, 2008) with syllable as the unit of analysis, we tested whether the direct effect of pronoun type on perceived familiarity was mediated by perceived positivity. This analysis yielded a 95% bias-corrected confidence interval for the indirect effect which did not include zero, indicating that the effect was mediated by positivity. Therefore, ingroup-primed syllables are perceived as familiar because of their increased positivity.

**B86****RETRIBUTION AFTER THREAT: EFFECTS OF A RELIGIOUS AFFILIATION PRIME** Karina Schumann<sup>1</sup>, Michael Ross<sup>1</sup>, <sup>1</sup>University of Waterloo, Waterloo, Ontario, Canada

– When people are made anxious by threats and uncertainties, they sometimes attempt to alleviate their anxiety by increasing conviction for their sources of meaning (e.g., Pyszczynski, Rothschild, & Abdollahi, 2008). This compensatory conviction process

often results in antagonistic behavior toward those who threaten or do not share these values and worldviews. We investigated whether making culturally prescribed benevolent values salient prior to a threat can reduce, rather than increase, antagonistic behavior. In the first two studies, we examined the effects of a religious affiliation prime and a mortality salience threat on retributive action following an injustice against an ingroup. In Study 1, all participants received a religion prime ("which religion, if any, do you most identify with?"). Those experiencing the mortality salience threat opted for less retribution than participants not experiencing this threat, suggesting that threat increased adherence to religious convictions. In Study 2, we replicated this pattern and confirmed that participants only chose less retribution after threat when they had been primed with religion. In Study 3, participants exposed to a religion prime prior to a mortality salience threat recalled fewer retributive words than those not primed with their religion. No effects were found for benevolent or neutral words, indicating that the threat and religion prime specifically reduced the accessibility of vengeful concepts. The results of these studies suggest that making benevolent values salient during conflict might help mitigate antagonistic tendencies caused by the compensatory conviction process.

**B87****SYMhedONIA IN INTERGROUP RELATIONS: THE RELATIONSHIP OF EMPATHIC JOY TO PREJUDICE AND ALLOPHILIA** Todd Pittinsky<sup>1</sup>, R. Matthew Montoya<sup>2</sup>, <sup>1</sup>Stony Brook University, <sup>2</sup>University of Dayton

– We conducted two studies to examine how two forms of emotional empathy – sympathy and symhedonia – affect intergroup relations. In a study of American high school students, Study 1 ( $N = 125$ ) found that increased levels of sympathy were associated with reduced levels of disliking for outgroups (prejudice) but not with higher levels of liking for outgroups (allophilia). Study 2 ( $N = 403$ ) found that symhedonia was more strongly associated with increased allophilia for outgroups than with decreased prejudice. Taken together, the studies indicate that sympathy and symhedonia may play distinct roles in intergroup relations. Whereas sympathy is more important to understanding intergroup hatred and negative intergroup relations, symhedonia is more important to understanding allophilia, intergroup liking and positive intergroup relations. More generally, our findings support the study of positive intergroup attitudes independently of negative ones.

**B88****EFFECT OF DISCUSSION INTERVENTION ON INTERGROUP DISCONTINUITY EFFECT** Guihyun Park<sup>1</sup>, Richard DeShon<sup>1</sup>, <sup>1</sup>Michigan State University

– There are robust findings in the intergroup literature that suggest intergroup relationships are more competitive than interpersonal relationships (i.e., group discontinuity effect). Previous studies suggest that allowing intra-group communication increases the group discontinuity effect because having communication among group members strengthens in-group favoritism norms. Drawing on the Information Sampling Theory (Stasser, 1989), we argue that communication among group members sways groups to compete more because members are more likely to focus on sharing more popular opinions to compete than opinions to cooperate. Accordingly, we propose that having a group discussion intervention that facilitates a balanced discussion of both opinions will decrease the discontinuity effect. Specifically, we hypothesized that making groups discuss pros and cons of both cooperative and competitive decisions will make groups become more cooperative. Participants played a Prisoner's Dilemma Game for six trials as an individual or a three-person group. In individual conditions, individuals played PDGs individually. In the control group condition, groups played the PDGs and each trial allowed for two minutes if group discussion. In the intervention group condition, groups played PDGs and group members discussed using a decision guideline for two minutes for each trial. Groups competed more than individuals thereby replicating the group discontinuity effect. Consistent with our prediction, groups with discussion interventions made more cooperative choices than

groups in the control condition. These results suggest that having a group discussion intervention can potentially allow groups to make more cooperative choices and decrease the discontinuity effect.

### B89

**PREDICTION PROCESSES IN INTERGROUP INTERACTION** Sang Hee Park<sup>1</sup>; <sup>1</sup>Indiana University, Bloomington, IN – How do people form expectations about interaction with members of other groups, and decide whether to engage in intergroup interactions? In three studies, I demonstrated the significance of prediction processes in intergroup interaction by showing that they can influence expectations and anxieties involved in such interactions, and affect intentions for future interaction. I hypothesized that when considering an intergroup interaction, people make predictions about the thoughts and behaviors of outgroup members, and use the feelings of difficulty of their predictions as information about what to expect in the interaction. In all studies, I had participants make predictions about outgroup members' behaviors while manipulating the perceived difficulty of the prediction task, and measured their outlook on future interactions with members of the outgroup. In Study 1, I used different descriptions about the target outgroup that directly affected perceptions about the target group members' predictability, and showed that experience of difficulty during prediction task led to more negative outlook of future intergroup interaction. In Study 2, I found that future outlook can be made more positive or negative depending on the situations presented in the prediction task. Lastly, Study 3 demonstrated how knowledge about the outgroup can help the prediction process, and thereby make one have more a positive future outlook of intergroup interaction. This research examined the role of cognitive experience of prediction difficulty in intergroup interaction context, and identified one of the reasons intergroup interactions are often thought of as anxiety-provoking and avoided.

### B90

**INTRAETHNIC DIVERSITY: CONSEQUENCES OF DEVALUING ETHNIC DISTINCTIONS** Natalia Flores<sup>1</sup>, Yuen Huo<sup>1</sup>; <sup>1</sup>University of Los Angeles, California – Our study investigated Asians and Latinos' experiences with ethnic distinction devaluation: a phenomenon which occurs when an interaction partner fails to acknowledge the distinctiveness of an individual's national or cultural group. Distinction devaluation occurs when national or cultural groups are referred to interchangeably (i.e. Chinese=Japanese, Columbian=Mexican). To investigate the social consequences of this experience, we conducted an online study. Participants (N=224) were exposed to one of two scenarios: 1) one in which they encountered distinction devaluation or 2) one in which they encountered distinction recognition. Drawing from previous research on identity neglect (Hornsey & Hogg, 2002; Huo & Molina, 2006), we predicted that encountering ethnic distinction devaluation would result in increased negative emotions and more negative evaluations of the interaction partner. In contrast, encountering ethnic recognition would result in increased positive emotions and more positive evaluations of the interaction partner. As hypothesized, individuals in the recognition condition reported more positive emotions and more positive evaluations (and less negative emotions and less negative evaluations) relative to those in the devaluation condition. Interestingly, these effects seem to be driven by an elevation in positive emotions and positive evaluations among those who experienced identity recognition. Additionally, we found that group identification moderated the relationship between the identity manipulation and reactions to the encounter such that the effect was stronger among those who more strongly identified with their national or cultural group. These findings suggest the prevalence and importance of a seemingly benign form of identity neglect in shaping the outcome of cross-ethnic interactions.

### B91

**MOTIVATIONAL EFFECTS OF NEED TO BELONG ON INTERGROUP MEMORY IN MINIMAL GROUPS** Rachel C. O'Connor<sup>1</sup>, Jay J. Van Bavel<sup>2,1</sup>, William A. Cunningham<sup>1</sup>; <sup>1</sup>The Ohio State University, <sup>2</sup>New York University – Recent research has shown that assigning people to novel mixed-race groups shifts bias on implicit measures from racial groups to the novel in-group. This research makes the assumption that these results occur because, in this experimental context, the new group is relatively more motivationally relevant than racial identity. In the current study, we tested this assumption and examined whether the need to belong might serve as a critical motivator in the encoding and processing of social groups. Research on the need to belong has shown that ostracism can motivate a person to differentially affiliate with groups. In the current study, participants were made to feel included or excluded, randomly assigned to one of two teams, and then learned about faces from both teams. Participants then completed a face recognition task. Participants in the exclusion condition showed the greatest affiliation with their new in-group, expressing greater memory for members of their in-group. This effect was attenuated among participants in the inclusion condition. People who were ostracized appeared especially motivated to encode team members. This research extends prominent theories of social identity and self-categorization by showing that a person's need to belong is an important factor in determining how a person will organize their social identities and perceptions.

### B92

**CHANGING COOPERATION TO COMPETITION DISRUPTS ATTITUDES AND VALENCE: FIRST TEST OF A DYNAMICAL MODEL** Jay Michaels<sup>1</sup>, Larry Liebovitch<sup>1</sup>, Robin Vallacher<sup>1</sup>, Vincent Naudot<sup>1</sup>; <sup>1</sup>Florida Atlantic University – With the cessation of cooperation between groups or individuals comes the threat that temporary competition transforms into destructive intractable conflict. To better understand how intractable conflicts develop, Liebovitch, Naudot, Vallacher, Nowak, Bui-Wrzosinksa, and Coleman (2008, *Physica A*387: 6360-6378) recently developed a non-linear model of two-actor cooperation-competition incorporating interaction feedback and valence. This study tested their model's predictions by investigating attitude and valence change depending on whether a social exchange was cooperative or competitive. In this study, 96 undergraduates completed an attitude survey and then verbally exchanged survey responses with a confederate who followed a script. Depending on the confederate's responses, participants experienced either cooperation, competition, or a mix of the two. We measured attitude change by comparing participants' initial survey responses to the survey completed during the interaction. We dynamically measured valence by having participants move a computer cursor while viewing a video of the interaction. Participants experiencing the interaction that switched from cooperation to competition exhibited greater attitude change than participants in the control or the continuously competitive interaction condition and more valence change than the control or competition switching to cooperation condition. Attitude change and valence were significantly correlated ( $r = -.25, p = .024$ ) implying that greater attitude change is associated with more negative valence. These results support the model's prediction that greater attitude and valence fluctuation manifests in interactions transitioning from cooperation to competition, providing the first verification of the model. These findings offer new insights into how human cooperation and competition evolve over time.

### B93

**MULTICULTURAL FRAME SWITCHING PROMOTES GREATER COGNITIVE COMPLEXITY AND LESS RIGID POLITICAL ATTITUDES** Mujde Peker<sup>1</sup>, Richard J. Crisp<sup>1</sup>; <sup>1</sup>University of Kent, UK – These studies investigated the influence of frame switching (i.e. detection, processing and reacting differently to cultural cues, Benet-Martínez, Lee, & Leu, 2006) and multicultural experience on preference for complexity and rigid political attitudes. In Experiment 1, half of the participants engaged in a frame switching task, and their preference for complexity and political atti-

tudes were measured. Results showed that participants who frame switched (i.e. thought about a different culture, namely Istanbul) preferred complex art to simple art, and showed more liberal political attitudes. However, these effects were limited to participants who were low in intolerance of ambiguity, and/or high in cognitive flexibility. Experiment 2 looked at the interaction between uncertainty and multicultural experience in predicting economically conservative ideology. After reading an economic threat scenario that was either framed in a certain or uncertain way, participants' multicultural experience and confidence was measured, along with their economic system justification. Results showed that participants who had low multicultural experience and confidence justified the uncertain economic system, while participants who had high multicultural experience and confidence did not. Future directions for research on the combined influence of multiculturalism and uncertainty in predicting liberal political ideology are proposed.

#### B94

**LET'S AGREE TO DISAGREE: ACCEPTANCE OF DISSENT IN CHANGING SOCIAL CONTEXTS** Cory Davenport<sup>1</sup>, Yishan Xu<sup>2</sup>, Ken Uehara<sup>2</sup>, Radmila Prislin<sup>2</sup>; <sup>1</sup>Texas Tech University, <sup>2</sup>San Diego State University – Dissent is any challenge to current norms with the goal of norm change (Packer, 2008). Although mostly rejected (Levine, 1989), dissent may also be tolerated or accepted (Filson, 2006; Prislin et al., 2007). We examined acceptance of dissent in the context of social change that occurs when majority and minority factions within a group switch positions. Assuming that acceptance of dissent is a function of one's position within a group, we hypothesized a decrease (increase) of acceptance of dissent upon becoming new majority (new minority). This hypothesis was tested in a 2 (initial position: majority vs. minority) x 2 (stability of initial position: stable vs. change) study in which a naïve participant engaged in a discussion with five other "participants" (confederates). Initial position was established by having three (one) confederates agree with the participant and others disagree. This pattern of (dis)agreement was either kept stable or was reversed when, half way through the discussion, two confederates switched their alliances. Following this discussion, participants completed an acceptance of dissent questionnaire. An ANOVA yielded a significant interaction effect ( $F(1, 104) = 9.05, p < .01$ ) whose decomposition revealed a significant decrease in acceptance of dissent upon becoming a new majority,  $t(100) = 2.63, p < .01$ , but no significant increase in acceptance of dissent upon becoming a new minority,  $t(100) = 1.60, ns$ . Implications for group dynamics in the aftermath of social change are discussed.

#### B95

**I'M NOT WHITE BUT YOU TREAT ME THAT WAY: THE ROLE OF RACIAL AMBIGUITY IN INTERRACIAL INTERACTIONS** Jessica D. Remedios<sup>1</sup>, Alison L. Chasteen<sup>1</sup>; <sup>1</sup>University of Toronto – Interracial interactions are complicated by concerns that both majority and minority group members hold. Although a large body of work has examined interactions between Whites and minorities, no research has examined the complications that racial ambiguity may introduce into these already anxiety-provoking situations. Unlike other minorities, people who belong to multiple racial groups (multiracial people) cannot always be categorized as members of a particular race. Furthermore, their physical ambiguity may have consequences for how they are perceived and how they perceive others. In two studies, we examined the role of racial ambiguity in individuals' expectations for an upcoming interracial interaction. Participants in Study 1 were led to believe that they would interact with a White, Black, or multiracial individual. The results revealed that participants expecting to meet a Black partner rated him more positively and anticipated a more positive interaction than those expecting to meet a White or multiracial partner. In Study 2, multiracial, monoracial non-White and White participants expected to interact with a White person during the study. Multiracial participants expressed the greatest concern that others would be confused by their appearance; the more concern they expressed, the more negative emotions they experienced. Taken together, these findings suggest that although multiracial people express

concerns about how others perceive them, monoracial people ignore these concerns and expect to treat multiracial people in the same way that they would treat White people. The results also imply that monoracial people may not accommodate the worries that multiracial people hold about interracial interactions.

#### B96

**ASSESSING THE ROLE OF PRINCIPLED LEADERSHIP RHETORIC IN INTERGROUP CONFLICT** Fouad Bou Zeineddine<sup>1</sup>, Joseph De Rivera<sup>1</sup>; <sup>1</sup>Clark University, Worcester, MA – Although there is a great deal of research on the topic of attitudes and their role in conflict, the tactical application of certain ideals of principled nonviolence, such as the fostering of positive intergroup attitudes by group leadership, is not adequately explored. Specifically, there is very little known about the role of principled leadership rhetoric in conflict management and prevention. The Leadership, Intergroup Attitudes, and Conflict Simulation (LIACS), an experimental design for an adaptable intergroup conflict simulation addressing this factor, was developed and tested in a conflict scenario. It was found to be a useful tool for examining the relationship between leadership stance and the political communications and behavior of groups under different conditions. Results showed that two personality factors were correlated to increased positivity in groups' political actions; lower Social Dominance Orientation and greater extent of circle of moral regard. The use of principled leadership rhetoric was significantly related to an increase in positivity of communication between groups and to an increase in perceived intergroup similarity.

#### B97

**INTRAMINORITY RELATIONS: DOES THE SALIENCE OF HISTORICAL DISADVANTAGE PROMOTE COMMON CATEGORIZATION OR OUTGROUP DEROGATION?** Maureen A. Craig<sup>1</sup>, Jennifer A. Richeson<sup>1</sup>; <sup>1</sup>Northwestern University – Despite an increasingly diverse population, intergroup research has focused on dominant group-minority group relations and little is known about relations among members of different minority groups. These relations may differ from previous work because a common minority status and similar experiences of discrimination may promote common categorization among minority groups. This research examines the effects of making discrimination against different historically-disadvantaged group members salient on their attitudes toward other minority groups. Fifty-nine Asian American (Study 1) and 44 White female (Study 2) participants read articles outlining social and economic consequences of discrimination against their groups and completed implicit (IAT, Affective Priming Task) and explicit (Feeling Thermometers, Similarity circles) measures of attitudes toward Blacks, Hispanics, and Whites. In Study 1, Asian participants became more implicitly pro-Black and rated Asians as more similar to Blacks after being reminded of racism. These results are consistent with the view that the information about racism promoted a common minority categorization. After being reminded of sexism however, White women became more pro-White in both implicit and explicit attitudes measures. These results are consistent with the view that instead of a common minority categorization, participants sought to maintain positive esteem by derogating minority outgroups. Whereas Asians felt more positive and similar to another racial minority group after being reminded of racism, White women were more negative towards racial minorities after being reminded of sexism. These results suggest that a common "minority" categorization may not easily cross identity dimensions (e.g., between gender and race).

#### B98

**DEFENDING OR CHALLENGING THE STATUS QUO: POSITION EFFECTS ON BIASED INTERGROUP PERCEPTIONS** Emma A. Bäck<sup>1</sup>, Torun Lindholm<sup>1</sup>; <sup>1</sup>Stockholm University – The default ideological position is status quo maintaining (Skitka et al, 2002), and system justifying (Jost et al, 2004). One strategy to maintain the status quo and justify the current system, is to undermine arguments challenging the status quo (O'Brien & Crandall, 2005). Research indicate that outside observers tend to be more biased

against challengers than defenders (O'Brien & Crandall, 2005; Crandall et al., 2009). While challengers are in a vulnerable and exposed position (De Dreu et al., 2008), it is not known whether challengers or defenders of the status quo show more intergroup biases when their own position is considered. In Study 1 we found that challengers undermine, by ascribing more externality and less rationality, the position of defenders to a larger extent than defenders do of challengers' position. Thus, challengers might be aware of the general negative view of them, and hence feel threatened, leading to increased biases. The result may however also be due to challengers by default assuming that they are in minority and defenders assuming being majority. Numerical status was experimentally manipulated in Study 2. No effects of numerical status on intergroup biases were found, but challengers were again more biased than defenders. Being a challenger may make one's group membership highly salient and information about social support for one's position does not decrease biases and intolerance of those who disagree with oneself.

### B99

**IN NEED OF LIBERATION OR CONSTRAINT? HOW INTERGROUP ATTITUDES MODERATE THE BEHAVIORAL IMPLICATIONS OF INTERGROUP IDEOLOGIES** Stacey J. Sasaki<sup>1</sup>, Jacquie D. Vorauer<sup>1</sup>; <sup>1</sup>University of Manitoba – A number of intergroup ideologies have the potential to encourage more positive intergroup relations. However, because these ideologies are multifaceted and open to different interpretations, it seems likely that their effects might depend on the ingoing attitudes of the individuals who are exposed to them. The present study examined how individual differences in prejudice moderate behavioral responses to intergroup ideologies. Anti-racism essentially tells individuals what not to do and is apt to induce evaluative concerns. Thus, we predicted that it would improve higher-prejudice individuals' behavior by prompting them to rein in potentially discriminatory actions but have a harmful effect on lower-prejudice individuals by prompting them to second-guess acting on positive impulses. In contrast, we predicted that the benefits of the outward focus on learning about and from outgroup members that is encouraged by multiculturalism would be more clearly evident for lower- than for higher-prejudice individuals, because higher-prejudice individuals would find the prospect of intergroup differences threatening. Individuals with a European ethnic background whose scores on the Modern Racism Scale (McConahay, Hardee, & Batts, 1981) were in the top and bottom third of the distribution across all introductory psychology students participated in an ostensibly real interaction with an outgroup member. Results were generally consistent with our predictions. Interestingly, color-blindness had a general negative effect not moderated by prejudice. These results suggest that tailoring the ideology promoted in a specific setting to the particular individuals who will be exposed to it might enhance the effectiveness of intervention efforts.

### B100

**COMPARISON OF THE REHEARSAL PROCESSES IN BOTH SIDES OF A LINGUISTIC CONFLICT: THE SEPARATION OF THE UNIVERSITY OF LEUVEN, BELGIUM** Aurelie Mercy<sup>1</sup>, Olivier Luminet<sup>2</sup>, Laurent Licata<sup>1</sup>, Olivier Klein<sup>1</sup>; <sup>1</sup>Free University of Brussels (ULB), <sup>2</sup>Catholic University of Leuven (UCL) – During the 1960's, the quarrel between the French-speaking and the Flemish people in Belgium, which was non-violent, turned into a more brutal conflict. The Flemish students of the Leuven University, which was bilingual but located in a Flemish territory, organized marches to evict the French-speaking students and staff from their University. After years of fight, the French-speakers eventually leaved Leuven to create a new French-speaking University, Louvain-la-Neuve, in a French-speaking territory. The aim of this research was to investigate the collective memory of these events, in a Flashbulb memory theoretical framework (Curci & Luminet, 2006; Er, 2003; Finkenauer, Luminet, Gisle, el-Ahmadi, van der Linden, Philippot, 1998; Conway, 1995; Brown & Kulik, 1977). We worked with a sample (n=124) of people studying in

Leuven during the events. Our correlation analysis of the elements eliciting the rehearsal underlines the role of the negative emotions in the French-speaking group and of the political involvement in the Flemish group. Groups also differ in the impact of the rehearsal on the memory, which is improved in the Flemish group, and decreased in the French-speaking group. These results suggest that the two groups lived the events of Leuven in different ways: for the Flemish, the events were mainly political, and the rehearsal of the facts, elicited by the political involvement in the events, was associated with a better memory. On the other hand, the French-speaking group seems to perceive the events in a more traumatic way, with a rehearsal decreasing the quality of the memory.

**MORTALITY SALIENCE, SELF-ESTEEM, AND DEFENSES AGAINST WORLDVIEW THREAT: AN EXPLORATION INTO DEFENSIVE ACCOMMODATION** Joseph Hayes<sup>1</sup>, Jeff Schimel<sup>1</sup>, Todd Williams<sup>2</sup>, Erik Faucher<sup>1</sup>; <sup>1</sup>University of Alberta, Canada, <sup>2</sup>Grand Valley State University, MI – Although terror management research has focused predominantly on worldview defenses involving derogation of people who espouse alternative worldviews, there are other ways in which worldviews can be defended. The present research explores the accommodation defense, and assesses the roles of mortality salience (MS) and self-esteem in this type of defense. Accommodation is based on compromise rather than conflict, and entails incorporating aspects of the alternative worldview into one's own in order to reduce incompatibility, and diminish the threat of the alternative perspective. In Study 1, participants with a creationist worldview were reminded of death (vs. control) and subjected to a worldview threatening essay arguing in favour of evolution (vs. neutral essay). Without MS, participants in the threat condition displayed more accommodation of evolution than those in the control condition. Under MS, however, self-esteem moderated the effect such that participants with low self-esteem (LSE) increased accommodation in response to threat, while those with high self-esteem (HSE) did not. Study 2 replicated Study 1 using evolutionist participants and a pro-creation threat-essay, and derogation of the essay-author was measured in addition to accommodation of creationism. Once again, threat alone (without MS) increased accommodation relative to control. But when threat was coupled with MS, LSEs responded with increased accommodation while HSEs responded with increased derogation, suggesting accommodation and derogation are alternative defenses against threat. Discussion focuses on the different types of defenses available to people under worldview threat, as well as the moderating role of self-esteem in defensive responses to MS.

### B103

**DO PUBLIC REGARD AND SOCIAL SUPPORT FROM OUTGROUP OR INGROUP MODERATE THE RELATIONS BETWEEN DISCRIMINATION AND EMOTIONAL DISTRESS?** Andrena Pierre<sup>1</sup>, Kimberly Matheson<sup>1</sup>, Hymie Anisman<sup>1</sup>; <sup>1</sup>Carleton University – There is considerable evidence that social support buffers against the negative effects of stressful events. However, in the context of discrimination, the effects of such support may depend on whether it comes from other members of the targeted group who share the experience, or from individuals who belong to the group that has perpetrated the discriminatory event. It was expected that when the outgroup is perceived to hold the ingroup in high regard (high public regard), outgroup support would be experienced positively. When the outgroup is perceived to hold the ingroup in low regard, ingroup support was expected to diminish the relation between discrimination and emotional distress. A community sample of 163 Blacks completed an online questionnaire assessing past discrimination experiences, social support (from ingroup and outgroup), perceived public regard for Blacks, and indices of emotional distress (anger, depressive affect, and anxiety). Hierarchical regression analyses indicated that discrimination

was related to anger only among participants who thought that the dominant outgroup held their group in high regard. However, as expected, high outgroup support was found to diminish this relation. Unexpectedly, ingroup support did not have any direct or moderating effects on negative emotions. These findings suggest that, as social attitudes toward Blacks become more positive, the establishment of reliable social networks or organizations that facilitate positive intergroup contact may provide a mechanism that replicates such attitudes at an interpersonal level. In so doing, group members may be more resilient to the emotional distress caused by discrimination encounters.

#### B104

**WE ARE ALL MULTICULTURAL IN OUR OWN WAY: CULTURAL MODELS OF DIVERSITY IN FLANDERS AND CALIFORNIA** Kaat Van Acker<sup>1</sup>, Heejung Kim<sup>2</sup>, Norbert Vanbeselaere<sup>1</sup>, Batja Mesquita<sup>1</sup>, Karen Phaet<sup>1</sup>; <sup>1</sup>Katholieke Universiteit Leuven, Belgium, <sup>2</sup>University of California, Santa Barbara – In the United States multiculturalism and colorblindness are two competing cultural models of diversity characterized by different clusters of values (Plaut, 2002). The present research studies whether the same diversity models prevail in different cultural contexts and whether they contain similar values. More specifically, we focus on two cultural contexts with different immigration histories and policies: Flanders and California. In a first study we compared Flemish (N = 230) and Californian (N = 250) participants with regard to their endorsement of multiculturalism and colorblindness. After establishing measurement invariance, multiculturalism appeared to be less endorsed in Flanders. Additionally, multiculturalism and colorblindness were highly interrelated in Flanders but not in California. The results suggest that multiculturalism and colorblindness might be not as clearly distinguishable models of diversity in Flanders. Rather, there might be Flanders-specific diversity models. Thus, the second study aimed at uncovering which models of diversity are most prevalent in Flanders and which values constitute them. To avoid using self-reports, we performed a content analysis of cultural products. Political platforms, newspaper articles and online reactions to these articles were analyzed during five months. Results show that several models of diversity co-exist in Flanders that differ from the American models. Some of the values that figure prominently in the Flemish models are less common in American models (e.g., adaptation, secularization); but even values that Flemish and American models have in common cluster differently across cultures (e.g., equality, tolerance). The implications of these differences in diversity models between California and Flanders are discussed.

#### B105

**AT LEAST SHE LIKES ME: THE INTERSECTION OF PREJUDICE AND SOCIAL FEEDBACK ON HORMONAL STRESS RESPONSES DURING INTERGROUP INTERACTIONS** Sarah S. M. Townsend<sup>1</sup>, Pamela J. Sawyer<sup>1</sup>, Brenda Major<sup>1</sup>, Wendy B. Mendes<sup>2</sup>; <sup>1</sup>University of California Santa Barbara, <sup>2</sup>Harvard University – Engaging in an evaluative intergroup interaction is stressful and leads to the activation of stress-responsive biological systems (e.g., the hypothalamic-pituitary-adrenal, HPA, axis). For members of stigmatized groups who are interacting with members of higher status groups, the experience of stress may be exacerbated if the outgroup member holds prejudiced attitudes. However, it is unclear whether receiving positive (relative to negative) social feedback from an outgroup member alters the degree of stress a stigmatized individual experiences in a subsequent evaluative interaction with that person. To answer this question, we examined Latina women's (N = 120) hormonal stress responses (i.e., cortisol reactivity) during an evaluative interaction with a White female confederate who had previously expressed either prejudiced or non-prejudiced attitudes toward minority ethnic groups and who had given the participant positive or negative social feedback. The confederate's attitudes interacted with the valence of the feedback to predict participants' stress responses. Specifically, Latinas who had received rejecting feedback showed significantly higher cortisol reactivity during the interaction if the confederate had expressed prejudiced, compared to non-

prejudiced, attitudes. However, Latinas who had received accepting feedback showed similarly low levels of cortisol reactivity during the interaction regardless of the confederate's prejudice level. Thus, for members of stigmatized groups, receiving negative social feedback from a high status group member who has expressed prejudiced attitudes, leads to the greatest experience of stress. This stress is attenuated if the outgroup member either expresses non-prejudiced attitudes (even coupled with rejecting feedback) or provides accepting feedback (even coupled with prejudiced attitudes).

#### B106

**IN TO WIN? INTERGROUP PROCESSES AND THE EFFECTIVENESS OF MALE VERSUS FEMALE ENDORSEMENTS FOR HILLARY CLINTON** Blair E. Vandegrift<sup>1</sup>, Alexander M. Czopp<sup>1</sup>; <sup>1</sup>Western Washington University – Past research suggests individuals acting against self or group interest are seen as more trustworthy and their cause more veridical; the messages presented by these individuals result in more thorough mental processing as they are seen to be without bias (Petty, Fleming, Priester, & Feinstein, 2001). However, this phenomenon may only influence persuasion when more salient aspects are absent. While fear of racism often elicits feelings of aversion and thus greater message processing, sexism may not be viewed as similarly aversive. In instances involving gender identity, ingroup members may polarize opinions of other ingroup members with either extreme praise or punishment in order to maintain that group identity (Marques, Yzerbyt, & Leyens, 1988). Male and female participants viewed a photograph of either a man or a woman along with a paragraph declaring support for Hillary Clinton for president. Participants evaluated the speaker's competence, the extent to which the speaker was a complainer, and the degree to which they agreed with the speaker. Women rated the male endorsement as more competent, less complaining, and showed more agreement with his arguments. In contrast, men rated the male endorsement as less competent and more complaining. Results are discussed in the context of intergroup processes related to persuasion.

#### B107

**IMPROVING ITALIAN STUDENTS' ATTITUDES TOWARD IMMIGRANTS: BOOK READING AS A NEW DIMENSION OF EXTENDED CONTACT** Loris Vezzali<sup>1</sup>, Sofia Stathi<sup>2</sup>, Dino Giovannini<sup>1</sup>; <sup>1</sup>University of Modena and Reggio Emilia, Italy, <sup>2</sup>University of Kent, UK – According to the extended contact hypothesis (Wright, Aron, McLaughlin-Volpe, & Ropp, 1997), the simple knowledge that an ingroup member has an outgroup friend is sometimes sufficient to reduce prejudice. Recently, strategies based on extended contact have been successfully applied in school settings (Cameron & Rutland, 2006). The aim of this study was to test the effectiveness of extended contact between school students in the Italian context, by examining a new age group and untested mediators of ameliorated intergroup relations. Furthermore, we examined the hypothesis that extended contact would facilitate the desire to engage in future real intergroup interactions. Participants were Italian secondary school students aged 11-13 years; the target outgroup was that of immigrants. There were three conditions. In the first (intercultural reading), participants read, during the summer period, a book with stories involving contact between people with different cultural backgrounds. The other two were control conditions: participants read a book unrelated to intercultural themes (non-intercultural reading) or did not read any book (no-reading). After the summer holiday, participants completed a questionnaire. As expected, in the intercultural reading condition, intergroup attitudes, stereotypes and intended behavior were more positive than in the two control conditions; furthermore, the desire for future intergroup interactions was stronger. Notably, the positive effects of intercultural reading were mediated by IOS (Aron, Aron, & Smollan, 1992), ingroup identification and increased pleasantness of interacting with outgroup vs. ingroup members. Theoretical and practical implications of the findings are discussed.

**B108****THE EFFECT OF INGROUP AUDIENCE ON INTERGROUP VICARIOUS RETRIBUTION** Kengo Nawata<sup>1</sup>, Hiroyuki Yamaguchi<sup>1</sup>, <sup>1</sup>Kyushu University –

Intergroup vicarious retribution is the phenomenon that retaliation takes place on unrelated third parties when an outgroup member do harm to an ingroup member (Lickel et al., 2006). The purpose of this study is to examine the effect of being observed by ingroup audience on intergroup vicarious retribution. We predicted that being observed by ingroup members will enhance vicarious retribution because an agency of vicarious retribution expects that ingroup members admired him or her as a hero. Thus this study is based on 2 premises: (H1) greater intergroup vicarious retribution would occur on the condition of being observed by ingroup members than not being observed by ingroup members.; (H2) Perceived admiration from ingroup members will mediate the relationship between being observed by ingroup members and vicarious retribution. We examined these hypotheses by one-on-one match gaming situation that a winner imposes a fine on a loser. Sixty five undergraduates and graduates (33 men, 32 women) used in the final analysis. As a result, the participants imposed the greater amount of the fine on outgroup member when observed by ingroup member than when not observed by ingroup member. Moreover, pass analysis revealed that being seen by ingroup members has a significant effect on the amount of the fine to outgroup member through perceived admiration from ingroup members and motivation of retaliation. Therefore, both H1 and H2 are supported. The findings of this study suggest that intra-group process, such as being observed by ingroup audience, would escalate intergroup conflict.

**B109****GENERALIZING THE BENEFITS OF I-SHARING: THE ROLE OF EXISTENTIAL ISOLATION IN A BEHAVIORAL EXPRESSION OF PREFERENCE FOR HEAVYWEIGHT INDIVIDUALS** Leslie Crimin<sup>1</sup>, Elizabeth Pinel<sup>1</sup>, <sup>1</sup>The

University of Vermont – I-sharing (i.e., shared subjective experiences) satisfies the needs to know reality and to feel interpersonally connected (Pinel et al., 2004; 2006). Sharing one's subjective experience with another relieves feelings of existential isolation (E.I.) and increases liking for him/her. Research demonstrates that dispositionally high E.I. individuals are particularly sensitive to I-sharing (Pinel et al., 2009). We examined whether the effects of I-sharing with a heavyweight partner generalize to subsequent interactions with other heavyweight individuals. We hypothesized that this is particularly likely for chronically E.I. individuals. The study consisted of two computerized interactions. First, participants exchanged spontaneous responses to a series of inkblots with a heavyweight confederate. I-sharing occurred when two people saw identical images in the inkblots. Participants learned they I-shared, did not I-share, or received no I-sharing information. Subsequently, they rated their liking for their partner. Participants then played a virtual toss-and-catch game with two new partners, one lightweight and one heavyweight. Tossing preferences were recorded. Findings demonstrate that individuals in the I-sharing condition liked their first partner more than participants who did not I-share. Additionally, a marginal interaction between I-sharing and dispositional E.I. emerged for tossing preference. As compared to low E.I. individuals and those who did not I-share, high E.I. individuals who previously I-shared tossed the ball to the novel heavyweight partner more than the lightweight partner. Findings demonstrate I-sharing's power to foster liking for stigmatized others and suggest that high E.I. individuals likely reap the positive effects of I-sharing in subsequent interactions with stigmatized others.

**B110****CURRENT PERSPECTIVES ON AGEISM, RACISM, AND SEXISM: ATTITUDES ABOUT DISCRIMINATION AND THOSE WHO CLAIM TO HAVE EXPERIENCED IT** Crystal Tse<sup>1</sup>, Sonia K. Kang<sup>1</sup>, Alison L. Chasteen<sup>1</sup>, Jessica

D. Remedios<sup>1</sup>, <sup>1</sup>University of Toronto – Although discrimination is an undeniable reality, the degree to which people claim to have experienced discrimination varies widely. Surprisingly, there is little research com-

paring reactions to different types of discrimination claims. The current study sought to learn more about how individuals choose whether or not to make a discrimination claim by assessing attitudes about discrimination and about those who make claims of ageism, racism, and sexism. A large sample of male and female participants from a variety of age and ethnic groups (N = 185) completed a questionnaire assessing reactions to discrimination claims made by men and women, young and older people, and ethnic minority and majority group members. Participants indicated their beliefs about the commonality and seriousness of each type of discrimination, the frequency with which people make claims of each type of discrimination, how legitimate they think these claims are, and the degree to which they think people should report specific types of discrimination. When comparing the traditionally dominant and non-dominant group within each category, participants rated discrimination as more common and serious against non-dominant group members, and the claims made by these individuals as being more frequent and more legitimate. Interesting discrepancies for perceptions about one's ingroup vs. one's outgroup also emerged. Detailed results of this study and implications for those who claim discrimination will be discussed.

**B111****INTERGROUP EMOTIONS AS PREDICTORS OF INTERGROUP AGGRESSION AND RECONCILIATION IN SERBIA** Marija Spanovic<sup>1</sup>, Brian

Lickel<sup>2</sup>, Nebojsa Petrovic<sup>3</sup>, <sup>1</sup>University of Southern California, <sup>2</sup>University of Massachusetts, Amherst, <sup>3</sup>University of Belgrade – Important debate still exists concerning the role of fear in intergroup aggression. For example, Mackie, Devos and Smith (2000) found that fear was not related to aggressing against the outgroup. However, a separate line of research suggests that fear of the outgroup can sometimes be associated with a fight response (Jarymowicz & Bar-Tal, 2006). For example, Israeli 'hawks', who objected to compromises towards peace, were characterized by a higher fear orientation than that of 'doves', who instead tended to support such compromises. We investigated the effects of fear and anger on aggressive tendencies and reconciliation in the context of Serbian-Albanian conflict. Serbian students in Belgrade (N=126), completed a survey that assessed their attitudes towards Albanians. We found that fear was related to aggression. For some of the aggression variables the relationship between fear and aggression was significant even after controlling for anger. Contrary to Jarymowicz and Bar-Tal's (2006) prediction, conflict ethos was not related to fear. Supporting and extending Kugihara's (2005) work, ingroup affiliation and attachment mediated the relationship between fear and aggression. The study also provided the opportunity to assess motives for reconciliation as well as aggression. Motivation for reconciliation (between Serbs and Albanians) had a negative relationship with aggression and anger and a positive relationship to the perceptions of risk, flight, pity, and shame. Reconciliation was also related to the perception of intergroup interdependence, superordinate categorization, and individuation.

**B112****RECONCEPTUALIZING RELATIVE DEPRIVATION WITH ADVANTAGED AND DISADVANTAGED STATUS GROUPS: THE CASE OF SOUTH AFRICANS AND MONGOLIANS** Fabrice Pinard Saint-Pierre<sup>1</sup>, Roxane De la Sablonniere<sup>1</sup>,

Francine Tougas<sup>2</sup>, Donald M. Taylor<sup>3</sup>, Jonathan Crush<sup>4</sup>, David McDonald<sup>4</sup>, <sup>1</sup>University of Montreal, <sup>2</sup>University of Ottawa, <sup>3</sup>McGill University, <sup>4</sup>Queen's

University – Social changes have a dramatic impact on the lives of individuals. Paradoxically, it is not always those who lose the most that are negatively affected by social change. Why some people maintain a positive self-regard in dire situations, whereas others break down remains an unsolved question. The goal of the present research is to test a potential explanation for this phenomenon. Two theoretical perspectives are considered. The first, Relative Deprivation Theory (Davies, 1962; de la Sablonniere, Taylor, Perozzo, & Sadykova, 2009; Grofman & Muller, 1973), focuses on the temporal trajectory of threat resulting of temporal comparisons at the group level. The second, Social Identity Theory (Tajfel, 1978) and the five-stage model of intergroup relations (Taylor &

McKirnan, 1984), points to the importance of group status in predicting group member's reaction to social change. Specifically, our hypotheses are that individuals in a high status group will express more well-being when they perceive the trajectory of their group as stable and improving, because it will secure their situation as a high status group. In contrast, individuals in a low status group will not perceive the instability generated by social change as threatening, but as reinforcing the perspective that group status is not fixed and may be improved. Members of low status groups will experience higher well-being when they perceive the trajectory of their own group as unstable. Results from five studies confirmed our hypotheses with participants from South Africa representing different status groups (Black, White English and White Afrikaans) and from Mongolia.

**B113****IF YOUR BEST FRIEND IS A MUSLIM, HOW DO YOU FEEL ABOUT JEWS? CLOSE INTERFAITH RELATIONSHIPS, DIMENSIONS OF RELIGIOSITY, AND INTERFAITH ATTITUDES** Reeshma Haji<sup>1</sup>, Richard Lalonde<sup>2</sup>;

<sup>1</sup>University of Kent, <sup>2</sup>York University – Dimensions of religiosity (Batson, Schoenrade, & Ventis, 1993) were applied to an investigation of close interfaith relationships. University students in a culturally diverse city (N = 111) were assigned to groups based on whether or not someone from their 5 closest nonfamily relationships belonged to a different religious group. There were a number of significant differences between the groups. Those who had a religious outgroup member among their 5 closest relationships were more favourable to religious outgroups on a variety of measures. This generalised not only to the religious group of the close friend but to other religious outgroups as well. Additionally, attitudes toward religious outgroups were moderated by dimensions of religiosity, specifically the extrinsic and intrinsic dimensions.

**B114****THE EXPERIENCE OF PERCEIVED DISCRIMINATION AMONG SKILLED IMMIGRANTS** Leah K. Hamilton<sup>1</sup>, Victoria M. Esses<sup>1</sup>; <sup>1</sup>University of Western

Ontario – While there is a considerable body of literature examining factors that predict prejudice and discrimination, research on the experiences of targets of discrimination has only recently become a focus of attention. One target group that is important to consider in this context is immigrants, particularly skilled immigrants. During the last few decades, there has been a marked shift in Western nations' perspective on immigration, with a growing focus on acknowledging the need to attract highly skilled immigrants to fill positions in advanced economies. This newfound "race for talent" – competition among nations for skilled labour – means that most industrialized countries have built into their immigration policies a provision for attracting skilled workers (Martinez-Herrera, 2008). Yet upon arrival, skilled immigrants often face prejudice and discrimination, particularly in the workplace (Esses, Dietz, & Bhardwaj, 2006). In this context, we investigated how experiences of discrimination in the workplace affect skilled immigrants' attitudes toward their employment and their immigration decision. Participants were 191 skilled immigrants in Canada who completed a measure of perceived employment-related discrimination, as well as measures assessing their perceptions of their employment and immigration experiences. Participants who reported higher perceived discrimination experienced lower job satisfaction and reported that their pre-migration expectations about working in Canada had not been met. They were also more likely to regret their decision to immigrate to Canada. Implications for understanding the experiences of targets of discrimination are discussed.

**B115****VICARIOUS INTERGROUP CONTACT: THE INFLUENCE OF THE OBSERVATION OF INTERGROUP CONTACT SITUATIONS ON WILLINGNESS FOR CONTACT AND INTERGROUP ATTITUDES** Agostino Mazziotta<sup>1</sup>,

Amélie Mummendey<sup>1</sup>, Stephen Wright<sup>2</sup>; <sup>1</sup>Friedrich-Schiller-University Jena, Germany, <sup>2</sup>Simon Fraser University, Canada – Direct contact between members of different groups influences intergroup attitudes between these groups (Allport, 1954; Pettigrew & Tropp, 2006). Much is already known

about the optimal conditions for direct contact and about the psychological processes that mediate the relationship between direct contact and improvement of intergroup attitudes (Brown & Hewstone, 2005). However, little is known about the conditions and psychological processes that make direct contact between groups more likely and raise the willingness of group members to engage in contact with the out-group. The present contribution examines the influence of vicarious contact (i.e. the observation of successful intergroup contact situations between in-group and out-group members) on willingness to engage in direct intergroup contact and on attitudes towards the out-group. Diverging from previous research on extended intergroup contact (cf. Wright, Aron, McLaughlin-Volpe, & Ropp, 1997) this contribution systematically applies concepts of social-cognitive learning theory (Bandura, 1986) to intergroup research (e.g., behavioral knowledge acquisition, self-efficacy expectation). A series of two video-based experiments, indicate that vicarious intergroup contact increases participants' willingness to engage in direct intergroup contact and improves attitudes towards the out-group. These studies provide evidence that the relation between vicarious contact and willingness to engage in direct contact (and out-group attitudes) is mediated by behavioral knowledge acquisition, self-efficacy expectation, and intergroup anxiety. Implications of these findings for further research on the (indirect) contact hypothesis and their application (e.g., for media design) will be discussed.

## Mental Health

**B116****AGE DIFFERENCES IN POSTTRAUMATIC GROWTH** Rhonda Swickert<sup>1</sup>, Davis Baird<sup>1</sup>, Taylor Owens<sup>1</sup>, Aasha Foster<sup>1</sup>, Meagan Orton<sup>1</sup>, Stephen McGuigan<sup>1</sup>; <sup>1</sup>College of Charleston – Posttraumatic growth can be understood as the occurrence of positive psychological change that can come about when individuals respond to highly challenging life events (Tedeschi & Calhoun, 2004). Growth following trauma has been documented in both young adults and older individuals (Ardelt, Ai, & Eichenberger, 2008; Park, Cohen, & Murch, 1996). However, few studies have directly compared young and older adults regarding differences in growth following trauma. The purpose of this study was to examine this issue. Participants (N=156) were recruited at a retirement community and on a college campus. Sixty-percent of the sample was 35 and younger; the remaining forty-percent of the sample ranged in age from 55 to 100. The sample was predominately White (90%), although both Blacks and Asian were represented (10%). Participants completed a post-traumatic growth measure and provided information regarding their demographic characteristics. Because gender has been shown to influence rates of posttraumatic growth (Swickert & Hittner, 2009), all analyses controlled for this variable. A significant difference was found between growth and age ( $t(133) = -4.05, p = .0001$ ), such that older individuals reported greater levels of growth than did young adults. Specifically, older adults, as compared to young adults, reported a greater compassion towards others, a greater faith in people, a greater sense of community, an enhanced sense of family closeness, and an enhanced feeling of spirituality. These findings are consistent with a burgeoning literature that suggests that older adulthood can be a time of resilience and fortitude (Hamarat, Thompson, Steele, Matheny, & Simons, 2002).
**B117****PERCEPTIONS OF CONTROL OVER TRAUMATIC EVENTS AND TRAUMA OUTCOMES** Nora Keenan<sup>1</sup>, Patricia Frazier<sup>1</sup>, Samantha Anders<sup>1</sup>, Samuel Hintz<sup>1</sup>, Sulani Perera<sup>1</sup>, Sandra Shallcross<sup>1</sup>, The Prospective Study Team; <sup>1</sup>University of Minnesota – The purpose of this study is to provide further evidence for the validity of a new measure of perceived control over stressful life events, which assesses past (control over event occurrence), present (control over current reactions to the event), and future (control over event reoccurrence) control (Frazier et al., in preparation). We focus here on the relations between these three forms of control and distress, PTSD symptoms, and alcohol use following traumatic events. Data were

collected at baseline (T1; N = 1,528) and two months later (T2; N = 1,281) from psychology students at four universities using online surveys. Only data from students who reported a traumatic event between T1 and T2 (n = 264) were included. Distress, PTSD symptoms, and alcohol use were measured pre (T1) and posttrauma (T2). Perceived control over the traumatic event was assessed posttrauma. As predicted, because most events were uncontrollable (e.g., bereavement), past control was associated with more distress and PTSD symptoms posttrauma and with increased distress from pre to posttrauma. Future control also was associated with more distress and PTSD symptoms posttrauma, and with increased alcohol use from pre to posttrauma. In contrast, present control was associated with less distress and fewer PTSD symptoms posttrauma, and with decreased alcohol use and binge drinking from pre to posttrauma. These data support the validity of our measure of perceived control over stressful events, and highlight the differences between these three aspects of control in terms of their relations with distress and unhealthy coping behaviors posttrauma.

**B118****THE EFFECT OF EDUCATION ON FEELINGS OF HOPELESSNESS OF LIFE IN TAIWANESE PEOPLE** Feng-Chun Hsiung<sup>1</sup>, Ruey-Ling Chu<sup>1</sup>, <sup>1</sup>Taiwan University

– This study investigated the influence of education on sense of meaning of life in Taiwanese people, and used personal values and cultural identity as mediators. The data included the answers of the 1,881 participants in the Taiwan Social Change Survey carried out in 2004. The results indicated that: 1. After controlling for age and income, levels of education can still predict sense of meaning of life. 2. People with higher levels of education placed less importance on utilitarian values and expressed more appreciation for their own culture. 3. People placing more importance on utilitarian values felt that life has less meaning; people exhibiting less appreciation for their own culture also felt that life has less meaning. 4. Both utilitarian values and cultural identity partially mediated the effect of education on sense of meaning of life. Overall, as we expected, the influence of education on hopelessness of life was partly through personal values and cultural identity.

**B119****NATURALISTICALLY OBSERVED LAUGHING PREDICTS LOWER DEPRESSION AMONG BREAST CANCER AND RHEUMATOID ARTHRITIS PATIENTS** Megan Robbins<sup>1</sup>, Matthias Mehl<sup>1</sup>, Ana Maria Lopez<sup>2</sup>, Shelley Kasle<sup>3</sup>, <sup>1</sup>University of Arizona, <sup>2</sup>Arizona Cancer Center, <sup>3</sup>Arizona Arthritis Center

– In two naturalistic observation studies using the Electronically Activated Recorder (EAR), we investigated how laughing is related to mental health in the context of coping with breast cancer, an acute, life-threatening disease (Study 1), and rheumatoid arthritis, a chronic, life-changing disease (Study 2). The EAR periodically recorded snippets of ambient sounds while participants were going about their daily lives. In Study 1, 21 breast cancer patients wore the EAR for one weekend and completed self-report measures of coping and depression concurrent with the EAR monitoring and again at a two-month follow-up. In Study 2, 13 rheumatoid arthritis patients wore the EAR for two weekends separated by one month, and completed self-report measures of coping and depression (identical to those in Study 1) concurrent with the EAR monitoring and at a six-month follow-up. All sound files were coded for the presence of participants' laughter, as well as a standard set of social behaviors and interactions. Across both samples, more EAR-observed laughing predicted lower levels of depression. This effect was not accounted for by participants' self-reported coping strategies (including humor). Further, controlling for time spent with others did not attenuate the effect indicating that coded laughing was not merely a proxy for having a social interaction. Finally, laughing in the presence of close others was more strongly related to lower depression than laughing in the presence of strangers. The findings are consistent with the idea that laughing can facilitate coping via promoting positive interactions with important members of the social network.

**B120****FLOCCINAUCINIHIPIPIFICATION AND ITS RELATION TO PERSONALITY AND PSYCHOPATHOLOGY** Ruth Yeh<sup>1</sup>, Sherman A. Lee<sup>1</sup>, Stephen D. Short<sup>2</sup>, Daniel R. Miteer<sup>1</sup>, Jason W. Hart<sup>1</sup>, Jeffrey A. Gibbons<sup>1</sup>, <sup>1</sup>Christopher Newport University, <sup>2</sup>University of Kansas – Floccinaucinihiplification (flocci) is the act or habit of regarding something as worthless. Although defined in the early 18th century, no empirical study has been conducted on this construct and its relation to personality and psychopathology. The goal of the present study was to examine global self-esteem, the big five personality traits, depression, and anxiety and their relation to dimensions of flocci, while controlling for the effects of gender, race, and social desirability with a sample of college students (N = 209). Using the framework from Beck's triadic model (Beck, Rush, Shaw, & Emery, 1979), three flocci scales were developed (self, others, and future focused) and found to demonstrate internal consistency, temporal stability, and factorial validity. Hierarchical multiple regression analyses revealed that depression and global self-esteem were the predominant predictors of flocci, whereas to a lesser degree, unique patterns emerged for gender and personality. Taken together, these findings provide evidence that flocci is a multidimensional construct that is influenced by specific individual difference variables. Continuation of floccinaucinihiplification research as its own unique construct could provide a better understanding of mental health issues for young adults.

**B121****CONTACT HIGH: RISK FOR MANIA AND OVER-ATTRIBUTION OF POSITIVE EMOTIONS TO TOUCHES** Amanda Purcell<sup>1</sup>, Paul K. Piff<sup>1</sup>, June Gruber<sup>2</sup>, Olga Antonenko<sup>1</sup>, Matthew Hertenstein<sup>3</sup>, Dacher Keltner<sup>1</sup>; <sup>1</sup>University of California, Berkeley, <sup>2</sup>Yale University, <sup>3</sup>DePauw University

– Emotion disturbances are common across several clinical disorders (Kring, 2008), yet researchers have only recently begun to explore the role of emotion in mania. In the present study, we examined how risk for mania (i.e., bipolar disorder), as measured using the Hypomanic Personality Scale (HPS; Eckblad & Chapman, 1986), affects the ability to interpret emotional communication through touch. Participants (N = 55) received a series of touches to their forearm by a stranger and were asked to identify the communicated emotion from a list of emotion terms. Risk for mania predicted a positive bias: higher HPS scores were associated with increased identifications of both positive and negative touches as positive. More specifically, risk for mania was associated with increased attributions of love and decreased attributions of sadness across touches. Results held after controlling for current depressive and manic symptoms. Implications for the study of mania and the general study of positive emotion and touch are discussed.

**B122****DO POSTTRAUMATIC GROWTH THEMES IN TRAUMA NARRATIVES MODERATE THE RELATIONSHIP BETWEEN TRAUMA TYPE AND SYMPTOMS?** Courtney E. Mitchell<sup>1</sup>, Anne P. DePrince<sup>1</sup>, Daniel N. McIntosh<sup>1</sup>; <sup>1</sup>University of Denver

– Inconsistencies in the association between posttraumatic growth and post-trauma symptoms may be due to variability in growth themes across trauma types. To examine this variability and its relation to symptoms, the current study examined positive themes in trauma narratives using qualitative methods and drawing on categories from the posttraumatic growth inventory (PTGI; Tedeschi & Calhoun, 1996). Semi-structured interviews were conducted with 72 ethnically diverse adults exposed to a variety of traumatic events (e.g., sexual assault, natural disasters). Self-report questionnaires for posttraumatic stress disorder, depression and dissociation were also administered. Qualitative coding methods were used to examine the frequency of posttraumatic growth (PTG) themes and test whether growth moderates the relationship between trauma type and symptoms. Nearly all narratives (97%) contained at least one posttraumatic growth reference: 92% mentioned increased personal strength, 62% enhanced emotional expression, 59% spiritual change, and 55% a desire to put more effort into relationships. The interrelation of these self-generated themes

differed from the factor structure of the PTGI, suggesting that qualitative coding of PTG themes in narratives may provide a richer understanding of posttraumatic growth than the PTGI alone. Although some characteristics of trauma history significantly predicted symptoms, PTG themes did not moderate this relationship, nor were PTG themes significantly correlated with trauma type or symptoms (including avoidance symptoms). These findings contradict the notion that PTG themes may vary substantially by trauma subgroups, and suggest that PTG may not mitigate symptoms. Implications for understanding the role of reported growth in the aftermath of trauma are discussed.

### B123

**PARENT-CHILD CONFLICT AND ADOLESCENT PROBLEM BEHAVIOUR: MEDIATING MECHANISMS** Kuang-Hui Yeh<sup>1</sup>; <sup>1</sup>National Taiwan University, Academia Sinica, Taiwan – Although research has shown that parent-child conflict is positively related to poor adjustment in adolescents, the underlying processes have been little examined. This study probes some possible mediators (perceive threat, self-blame, rage, and resentment) to clarify how parent-child conflict impacts adolescent psychological maladjustment. To specify these mediation processes in greater detail, we distinguished internalizing from externalizing problem behaviours and examined whether the mediating effects were stronger for perceived threat and self-blame on internalizing problem behaviour, and rage and resentment on externalizing behaviour. A total of 1,107 high school students completed a battery of questionnaires that separated Father from Mother as the focal interaction target. Hierarchical linear modelling was used to test the hypothetical mediating model. The results showed that (1) the result patterns for Father and Mother targets were similar; (2) parent-child conflict positively related to adolescents' internalizing (mainly as psychosomatic complaints and withdrawal) and externalizing (mainly as violent aggression and deviant behaviour) problem behaviours; (3) children's resentment over the conflict was the main mediator of the relationships between parent-child conflict and psychosomatic complaint, withdrawal behaviours, or deviant behaviours; (4) children's wrath from the conflict was the main mediator of the relationship between parent-child conflict and violent aggression.

### B124

**PERCEIVED VALUE IN PERSPECTIVE TAKING IN EXPRESSIVE WRITING** Yi-Tai Seih<sup>1</sup>, James W. Pennebaker<sup>1</sup>; <sup>1</sup>University of Texas at Austin – Writing about emotional upheavals has been found to improve mental health. A number of analytic methods suggest some ways of writing may yield more benefits than others. Particularly promising are findings that indicate those who write from different perspectives subsequently report the greatest health improvements. Two overlapping questions were addressed: Does writing from a particular perspective enhance the perceived value of writing? Does changing perspective over the course of writing affect its perceived value? To explore the possible perspective effects, two studies manipulated writing perspectives wherein people were asked to write about emotional events using either the 1st-person, the 2nd-person, and the 3rd-person singular personal pronouns. In Study 1, 55 students were randomly assigned to one of the three writing perspectives and were asked to write from the same perspective for three times for 5-min each. In Study 2, 129 students wrote three 5-min essays, one from each perspective in a counterbalanced order. Counter to predictions, writing from one perspective or another or changing perspectives had no advantages. Across all conditions, participants reported high self-rated value and meaning from the writing exercise. Interestingly, when people wrote from the different perspective on three occasions, there was a modest preference for writing in the 1st-person perspective and, across all perspectives, a large order effect emerged. The more times a person writes, the more value and emotional the writing was reported to be. These findings related to expressive writing suggest the implication of writing order, writing perspective, and anti-tediousness in a short-term period.

### B125

**TOXICITY AND RETROSPECTIVE ACCURACY OF BORDERLINE PERSONALITY DISORDER SYMPTOMS: AN EXPERIENCE SAMPLING STUDY** Paul Hutman<sup>1</sup>, William Fleeson<sup>1</sup>; <sup>1</sup>Wake Forest University – The purpose of this study was to assess the toxicity of Borderline Personality Disorder (BPD) symptoms and the relationship between symptoms sampled with a range of time frames. Experience sampling methods were used to determine the association between BPD symptomology and negative affect and also the correspondence between momentary manifestation and retrospective reports of symptomology. Participants screened for BPD carried Palm Pilots for a week completing five reports a day. Reports assessed momentary affective and behavioral symptoms outlined by the Diagnostic and Statistical Manual 4th Ed. (TR). Participants also completed written retrospective questionnaires describing the same affective and behavioral symptoms in the last day, week, month, and year of the participants' lives. Multiple regression analyses revealed that momentary manifestation of BPD symptoms were highly toxic, accounting for 61% of the variance in participants' negative affect. All symptoms were significantly and positively associated with negative affect; the criteria of suicidality, identity disturbance, and affect instability had the strongest relationships and no relationship was below .30. Multilevel modeling revealed mixed relationships between the momentary and retrospective reports of BPD symptoms. Three criteria for BPD did not have any relationship while all other criteria had strong and positive relationships, ranging from .53 to .75. These results have important implications into the day-to-day debilitating affects of BPD symptoms as well as the accuracy of diagnosis based on reflective interviews. Results also question where the true nature of BPD lies; in the manifestation of symptoms or in retrospective reflections of symptomology in general?

### B126

**RELATIONAL DISTRESS ASSOCIATED WITH SUB-CLINICAL PERSONALITY PATHOLOGY** Carly Smith<sup>1</sup>, R. Michael Furr<sup>1</sup>; <sup>1</sup>Wake Forest University – Personality pathology's toxicity arises in part from its disruptive effects on interpersonal relationships. These effects might be behavioral (e.g., one partner's pathology-related maladaptive behavior disrupts the relationship) or cognitive (e.g., one partner's pathology-related perceptions are maladaptively discrepant from the other's, creating interpersonal friction). Such effects and their associated interpersonal distress have been documented at clinical levels, but they have not been explored in non-clinical populations. The goal of this study was to examine affective and relational correlates of sub-clinical personality pathology. Specifically, we predicted that relatively negative affective states and relational disruptions will be associated with elevated pathology. Well-acquainted opposite-sex pairs (n=24) of participants engaged in brief interactions, reporting their affect immediately before and after the interaction. In addition, they rated their relationship quality along several dimensions, and they self-reported (MCMI) their levels of Narcissistic, Histrionic and Borderline personality pathology. Results supported our 'disruption' hypothesis: interpersonal disruptions characteristic of personality disorders can be seen in some forms at a sub-clinical level of pathology. We found that people with elevated levels of Narcissistic symptoms reported highly positive interactions regardless of how their partner's rated the same experience. Those reporting Histrionic personality symptoms also reported decreased levels of positive affect following an interaction. In addition, people with relatively high levels of Borderline symptoms had partners who reported lower ratings of perceived closeness – even when controlling for subject's own ratings of perceived closeness. Future research will examine the behavioral mediators of these affective and relational effects.

**B127**

**CONCEALING IS REVEALING: EXPLORING INTERPERSONAL STRATEGIES AMONG INDIVIDUALS WITH MENTAL ILLNESS** Amy Huntington<sup>1</sup>, Valerie Earnshaw<sup>1</sup>, Diane Quinn<sup>1</sup>; <sup>1</sup>University of Connecticut – Individuals with concealable stigmatized identities (CSIs) have been theorized to spend a great deal of time self-monitoring and suppressing discrediting verbal and non-verbal behavior (Pachankis, 2007). The current study manipulated interpersonal disclosure norms for individuals with mental illness (MI) to examine the resulting interaction for explicit and implicit behavioral responses. Fifty participants were recruited. Prior to the interaction, participants were randomly assigned to one of three conditions: Control: No mention of mental illness history was made. Conceal-Specific: Participants were reminded of their MI through a background questionnaire, but were told not to discuss their mental illness history during the interaction. Conceal-Generalized: Participants were reminded of their MI, but were told not to talk about "anything too personal." Participants then entered a brief social interaction with a confederate. Transcript analysis of the interaction provided an array of implicit measures indicating differential use of impression management strategies. During the interaction, participants in the Conceal-Specific condition used the highest proportion of positive affect words and the smallest proportion of negative affect words compared to the Control and Conceal-Generalized conditions. Non-verbal behaviors were affected by condition while self-reports (i.e., self-esteem) remained unaffected. For instance, eye contact made by participants decreased in the Conceal-General condition as compared to the Control and Conceal-Specific conditions [ $F(2,47)=4.677$ ,  $p=.014$ ]. Results indicate that individuals with MI employ different strategies based on social contexts and this may have benefits and consequences. Discussion centers on a variety of implicit measures of interest when studying individuals with CSIs.

**B128**

**THE TIPPING POINT: WHEN INTERPERSONAL CONFLICT LEADS TO ATTEMPTED SUICIDE** Marta Elliott<sup>1</sup>, Barbara Kohlenberg, Yvette Kaunismaki, Morgan Green, Barbara Larsen; <sup>1</sup>University of Nevada, Reno, <sup>2</sup>University of Nevada School of Medicine – The purpose of this study is to demonstrate the conditions under which interpersonal conflict leads people to attempt suicide. The study is based on open-ended interviews with 37 people who were in hospital subsequent to surviving attempted suicide. Subjects were asked to tell the story of their attempt in detail, including their mental health history, as well as their immediate circumstances at the time of their attempt. Most subjects volunteered that an argument or rift with a significant other directly preceded their suicide attempt. However, upon closer inspection, it became apparent that those arguments typically occurred in the context of extreme economic hardship. Survivors describe excruciating emotional pain and utter hopelessness, which comes to make more sense when their interpersonal conflict is put in the context of their concurring financial crisis. Though suicide survivors themselves place little emphasis on their socioeconomic circumstances as an impetus for their behavior, the authors infer from a grounded theory analysis of the interview transcripts that the themes of interpersonal and financial crisis frequently go hand in hand. The results demonstrate the confluence of typical methods of self-harm, socioeconomic and psychosocial circumstances, as well as the often positive short-term result of surviving attempted suicide, at least in terms of close personal relationships. The authors conclude with recommendations for preventing suicidal behavior that extend beyond psychotherapy and medication to addressing the underlying social-structural risk factors that predispose emotionally distraught individuals to attempt suicide.

**Motivation/Goals****B129**

**CREATIVE BECAUSE IT IS FUNCTIONAL** Marieke Roskes<sup>1</sup>, Carsten K. W. De Dreu<sup>1</sup>, Bernard A. Nijstad<sup>2</sup>; <sup>1</sup>University of Amsterdam, <sup>2</sup>University of Groningen – Creativity distinguishes excellent artists or scientists from mediocre ones, but why do some people seek creativity more than others – why would someone bother investing time and energy in such a risky and potentially costly endeavor as being creative. Our research tried to answer this fundamental question from a functional perspective, assuming that human effort traces back to (implicit) survival functions that take one of two forms – approach motivation or avoidance motivation. Interestingly, past work indicates that a focus on getting positive outcomes (approach motivation) leads to more creativity than a focus on avoiding negative outcomes (avoidance motivation). We note that in none of these previous studies being creative served (or not) goal achievement (i.e., achieving gains or avoiding losses). In three studies we manipulated approach versus avoidance motivation, and whether creative behavior was functional or not towards goal achievement. In study 1 and 2 we assessed the originality of words generated in a word-puzzle. In study 3, we assessed creative insights with a Remote Associations Task. During this task a mouse and a cheese (approach) or an owl (avoidance) appeared on the screen. To make creative output functional, the cheese moved closer to the mouse after a correct association (or the owl moved closer after an incorrect association). To make creative output non-functional the cheese (or owl) was moving at random. Across studies, results showed that avoidance motivated people can be as creative as approach motivated people, provided their creativity serves a purpose.

**B130**

**CLOSURE OF AUTOBIOGRAPHICAL MEMORIES MODERATES THEIR DIRECTIVE EFFECT ON BEHAVIOR** Denise R. Beike<sup>1</sup>, Laura P. Adams<sup>1</sup>, Karen Z. Naufel<sup>2</sup>; <sup>1</sup>University of Arkansas, <sup>2</sup>Georgia Southern University – Specific autobiographical memories have been theorized to serve a directive function, whereby the content of the memory directs behavior outside of awareness. The present research tested whether the extent to which a memory feels low in closure, or psychologically not in the past, moderates this directive effect. One hundred sixty-three participants in an online experiment were asked to recollect a specific autobiographical memory of a time they had failed to donate to charity, or were not asked to recollect a memory. Those who recollected a memory were randomly assigned to think of the memory as high versus low in closure. Recollecting an autobiographical memory made to feel low in closure led to more memory-relevant behavior than either recollecting a memory made to feel high in closure, or no memory at all. Moreover, the directive effect of a low-closure memory occurred whether participants were made aware of an upcoming behavioral opportunity or not. Discussion centers on possible processes linking low closure and behavior, as well as implications for the Self-Memory System theory of autobiographical memory.

**B131**

**REGULATORY FOCUS AND CHOICE COMMITMENT** Chin Ming Hui<sup>1</sup>, Daniel Molden<sup>1</sup>; <sup>1</sup>Northwestern University – Two studies examined the relationship between regulatory focus and choice commitment. It was postulated that security-based self-regulation, or a prevention focus, encourages individuals to represent a chosen goal or course of action as a standard that it is necessary to maintain. In contrast, it was postulated that growth-based self-regulation, or a promotion focus, encourages individuals to represent a chosen goal or course of action as just one among several objectives that they hope to attain. Based upon this line of reasoning, it was hypothesized that a prevention focus should result in greater commitment during goal-pursuit. This hypothesis was supported across two different operationalizations of commitment and both when regulatory focus was measured as an individual difference and when it was manipulated. Compared to their promotion-focused coun-

terparts, prevention-focused individuals (a) reported stronger intentions to enact behaviors related to a prioritized goal versus a non-prioritized goal, as well as greater actual enactment of these behaviors 2 days later (Study 1), and (b) remained committed to their chosen course of action even after receiving feedback that it was failing (Study 2). These studies highlight the importance of security-based motivation as an additional determinant of commitment.

### B132

#### ON THE RELATION BETWEEN PERFORMANCE OF ONE'S TEAM AND LIFE SATISFACTION OF SPORT FANS: THE MODERATING ROLE OF PASSION

Marc-André K. Lafrenière<sup>1</sup>, Eric G. Donahue<sup>1</sup>, Robert J. Vallerand<sup>1</sup>, <sup>1</sup>Université du Québec à Montréal – Vallerand et al. (2003) developed a Dualistic Model of Passion wherein passion is defined as a strong inclination toward a self-defining activity that one loves, values, and in which one invests time and energy. Furthermore, the model proposes two distinct types of passion: harmonious (HP) and obsessive (OP) passions that generally predict adaptive and less adaptive outcomes, respectively. In the present research, we were interested in understanding the moderating role of passion for being a sport fan on the relation between victory or defeat of the beloved team and life satisfaction. We hypothesized that fans with an obsessive passion would have their life satisfaction contingent on their team's performance. This is so because ego-invested rather than integrative self-processes are at play (Deci & Ryan, 2000) with obsessive passion leading people to become dependent on their passion. On the other hand, this should not be the case for harmoniously passionate fans. A sample of 77 hockey fans reported their life satisfaction the day after each game of the second round of the 2009 NHL playoffs. HLM analyses showed that the more people had an obsessive passion, the more they experienced accentuated increases in life satisfaction following a victory. Likewise, the more people had an obsessive passion, the more they experienced accentuated decreases in life satisfaction following a defeat. In contrast, harmonious passion was unrelated to this phenomenon. Future research directions are discussed in light of the Dualistic Model of Passion.

### B133

#### MOTIVATION AND GOALS: RELATIONSHIPS BETWEEN EXPLICIT AND IMPLICIT MOTIVES, MOOD, PROGRESS, AND ATTAINABILITY

Emily A. A. Dow<sup>1</sup>, Christopher T. Burke<sup>2</sup>, Michael Bender<sup>3</sup>, Barbara Woike<sup>1</sup>; <sup>1</sup>Barnard College, Columbia University, <sup>2</sup>Lehigh University, <sup>3</sup>Tilburg University – Understanding motivation allows us to tease apart the complex elements that drive behavior, and previous research has shown that both implicit and explicit motives are important when setting and pursuing goals. The current study seeks to understand how such motives relate to daily goal pursuit. Ninety-eight participants created three goals and completed a three-week diary. Using a series of multilevel models, we found that the links between daily achievement goal progress and mood, and daily achievement goal attainability and mood depend on implicit and explicit achievement motives. However, the pattern of the interaction in these two analyses was different. Individuals who scored high in both implicit and explicit achievement motives were most sensitive to increases in achievement goal progress, as indicated by a decrease in negative mood as daily progress increased. In contrast, individuals who scored low in both implicit and explicit achievement were most sensitive to increases in attainability, as indicated by a decrease in negative mood as progress increased. In essence, individuals who are highly motivated by both implicit and explicit factors are impacted emotionally when self-evaluating goal progress. Individuals who are not highly motivated by both implicit and explicit factors are impacted emotionally when self-evaluating goal attainability - they feel better when their goal becomes easier. Taken together, these analyses suggest that implicit and explicit motives are not interchangeable, but rather play distinct roles in the day-to-day processes of goal pursuit.

### B134

#### TERROR MANAGEMENT, RELIGION, AND POLITICAL ATTITUDES: COMBINED EFFECTS OF MORTALITY SALIENCE AND RELIGIOUS FUNDAMENTALISM ON IMPORTANCE OF RELIGIOUSLY-MOTIVATED POLITICAL ISSUES

Dave Weise<sup>1</sup>, Tom Pyszczynski<sup>2</sup>, Jeff Greenberg<sup>1</sup>; <sup>1</sup>University of Arizona, <sup>2</sup>University of Colorado - Colorado Springs – We investigated the combined effects of mortality salience (a death reminder; MS) and religious fundamentalism (RF) on the importance of religiously-motivated political issues to illuminate the political impact reminders of death can have among religious fundamentalists. Terror management suggests MS increases allegiance to central aspects of one's worldview including religious belief in the service of allaying fear of death. This study explored how MS affects high RFs on how important they believe religiously-motivated political issues to be. We randomly assigned participants to either MS or an aversive control prime. Packets contained the 1992 RF scale, MS or control prime, and the dependent variable instructing participants to rank 12 political issues in terms of personal importance (1=most important). The rank items were grouped into four categories: (1) religiously-motivated issues (e.g., abortion), (2) economic (e.g., jobs), (3) security (e.g., airport security), and (4) community issues (e.g., helping disadvantaged people). Participants' (N = 63) average rankings per category were separately regressed on MS, RF, and their interaction. These analyses revealed significant MS × RF interactions on both religiously-motivated issues (p = .01) and community issues (p = .01). MS, relative to the control prime, led high RFs to place more importance on religiously-motivated issues (M = 6.85 and 8.35, respectively) and less importance on community issues (M = 8.29 and 6.48, respectively). In conclusion, MS interacts with RF in affecting importance rankings of religiously-motivated and community focused political issues.

### B135

#### FLEXIBILITY OF HIERARCHICAL GOALS IN CONTEXTUAL CHANGE: GOAL DEACTIVATION BY CONTEXTUAL CONSTRAINTS

Hiroyuki Yoshizawa<sup>1</sup>, Makoto Nakajima<sup>2</sup>, Takuya Yoshida<sup>3</sup>, Chika Harada<sup>3</sup>, Koji Tsuchiya<sup>3</sup>; <sup>1</sup>Gifu Shotoku Gakuen University, <sup>2</sup>Mie University, <sup>3</sup>Nagoya University – Previous research has approved that the adaptation of goal setting flexibility was different between hierarchically superordinate and subordinate goals. However, studies of goal activation in self-regulation have not examined whether superordinate goals that correspond or not correspond to the given situation would be activated or deactivated. In the present study, we tested the hypothesis that superordinate goals would be deactivated by contextual constraints. Without contextual constraints, people tend to hold up as many superordinate goals as possible to achieve them. In contrast, people who face the concrete situation would deactivate them according to contextual constraints to effectively use their cognitive resources. Participants (n = 893) completed the superordinate goal scale (24 items) that was developed based on the taxonomy of human goals (Ford, 1987) in situations with or without (neutral situation) contextual constraints. Constrained situations were composed of the vignettes (buying, eating, antisocial behavior, and interpersonal conflict) where participants needed to regulate their impulse. Consistent with the hypothesis, the results of Dunnett's multiple comparisons test showed that goal activations in any constrained situations were lower than neutral situations in most goal items, while they were higher or equal in a few items theoretically corresponding to the constrained situations. These results indicated that people had the flexibility to adjust their activations of hierarchical goals according to changing situations. This flexibility was also discussed in line with the idea by Kruglanski et al. (2002), which implied that the allocational properties of goal systems were resting on the assumptions of limited mental resources.

### B136

#### CHANGING THE PAST: POWER ALTERS PERSON MEMORY

Mario Weick<sup>1</sup>; <sup>1</sup>University of Kent – Memories are temporary constructions and susceptible to many sources of influence. The present research examines social power as one such source of influence. Drawing on previous

research showing that power promotes stereotyping, two studies tested the hypothesis that power alters person memory, favoring the recall of information that is consistent with stereotypes. Participants read behavioral descriptions of a target, half depicting stereotype-congruent, and half depicting stereotype-incongruent behaviors. Consistently across studies, and using multiple operationalizations of power such as priming (Studies 1 and 2) and measures of individual differences (Study 2), power led to differences in the recall of the target information. Powerful, but not powerless individuals, recalled more stereotype-congruent than stereotype-incongruent information. These effects occurred when power was manipulated before (Study 1) and after (Study 2) the encoding of the target information. These findings importantly extend previous research, showing that power can change people's recollections of the past.

**B137****ARE THE POWERLESS ALWAYS LESS ATTENTIVE TO GOALS THAN THE POWERFUL? IMPACT OF PREVENTION-FRAMED INFORMATION** Yeri

Cho<sup>1</sup>, Jennifer Overbeck<sup>1</sup>; <sup>1</sup>University of Southern California – This research examines the effects of power on attention to goals under conditions of prevention-focused information. Previous research suggests that lack of power reduces attention to goal-relevant information in the environment and even leads to goal neglect. However, questions remain about when the powerless use attentional resources on goals. The authors have extended previous findings by identifying conditions in which low power individuals demonstrate greater attention to goals. The current research focuses on the effect of the framing of goal-relevant-information on using attentional resources, especially prevention-focused framing. The authors argue that the effect of power on using attentional resources on goals depends on how goal-relevant information is framed. In support of the argument, when asked to recall and to prioritize goal-relevant information framed in prevention terms, the powerless attend to goals and distinguish what is goal-relevant and what is not goal-relevant as much as the powerful do. This result supports that the goal framing moderates the relationship between power and attention to goals. Findings from the current research add to the literature of power research on goals and prevention-promotion motivations.

**B138****POWER CORRUPTS: POWERFUL PEOPLE ARE MORE VULNERABLE TO UNCONSCIOUS PLAGIARISM** Aukje Sjoerdsma<sup>1</sup>, Nils B. Jostmann<sup>2</sup>, Ap

Dijksterhuis<sup>1</sup>, Rick B. van Baaren<sup>1</sup>; <sup>1</sup>Radboud University Nijmegen, <sup>2</sup>University of Amsterdam – Unconscious plagiarism (or cryptomnesia) is a mental illusion in which people mistakenly believe that thoughts, words or ideas encountered previously are their own original creations (Brown & Murphy, 1989). In this study, we investigate whether having or lacking power influences the extent to which participants plagiarize others' responses in a generation task. Participants generated items with an ostensible interaction partner, after being primed with either low power, high power, or no power (writing task; Galinsky, Bodenhausen & Magee, 2003). In the item generation task, participants generated words beginning with a certain letter combination (BL-, RO-, WE-, HA-) together with an interaction partner. Next, participants performed a 5-minute filler task, unrelated to the experiment. Subsequently, to measure plagiarism, participants were presented with the words they had generated in the generation task and the words the 'interaction partner' had generated. To measure plagiarism, we asked participants to indicate as fast as possible (within 3 seconds) to indicate whether they had generated the presented word, or whether their interaction partner had generated the word. The number of words that were wrongly attributed to the self (false positives; 'partner' words as own words) served as our dependent measure of plagiarism. Results show that participants primed with high power plagiarized others' responses more than participants primed with low power. Control participants fell in between. The conclusion is that power indeed affects unconscious plagiarism. Having power makes you more susceptible to take credit for other's efforts, or to speak with Lord Ashton: "Power corrupts".

**B139****ACHIEVEMENT, POWER, AFFILIATION: INVESTIGATING RASCH**

**RELIABILITY OF THE OPERANT MOTIVE TEST** Marvin Drosten<sup>1</sup>, Markus Quirin<sup>1</sup>, Julius Kuhl<sup>1</sup>; <sup>1</sup>University of Osnabrueck – Although a great number of studies suggest criterion-based validity of a variety of Thematic Apperception Test (TAT) variants, a major critique refers to reliability. We used a multi-categorical Rasch model to analyze a novel TAT variant ("operant motive test") that asks for brief statements about the content of pictures rather than complete stories. This procedure is more economical and thus allows for the application of more pictures, which may contribute to the reliability of the test. Operant motive tests of N = 870 participants are coded with respect to the motives for achievement, affiliation, and power. The multi-categorical Rasch scaling suggests adequate reliabilities for the motive dimensions.

**B140****IMPLICIT MOTIVATION AND FLEXIBILITY VERSUS RIGIDITY IN GOAL PURSUIT: WHEN POSITIVE AFFECT CO-ACTIVATES WITH DIFFERENT LEVELS OF BEHAVIOR REPRESENTATIONS** Hans Marien<sup>1</sup>, Henk Aarts<sup>1</sup>, Ruud Custers<sup>1</sup>; <sup>1</sup>Utrecht University

– Recent research showed that positive affect operates as an implicit motivator in goal pursuit when it is linked to the mental representation of behaviors (Custers & Aarts, 2005). Building on this notion, the present research examined the balance between flexibility and rigidity in goal pursuit by co-activating positive affect with different levels of behavior representations in a set-shifting task. Participants could represent the task either on a higher level (i.e., the task goal of categorizing letters) or a lower level (i.e., the task rule of using a specific color). Flexibility was defined as the ability to abandon an old task rule and apply a new task rule instead. This was assessed by measuring the switch cost in the set-shifting task. Two experiments provide evidence for this idea: flexibility increased when positive affect was co-activated with the goal representation of the task, and rigidity was increased when positive affect was co-activated with the representation of the old task rule. These findings support the positive affect as implicit motivator model. Specifically, when the representation of a goal is co-activated with positive affect people perform better on the task reflecting a higher motivation to achieve the task goal. On the other hand, when the representation of the rule is co-activated with positive affect people are less prone to abandon it, reflecting a higher motivation to persevere with the old task rule. Implications for the role of the level of behavior representations in implicit motivational processes underlying goal pursuit are briefly discussed.

**B141****SEEING THE WORLD IN SACRED TERMS SHIELDS AGAINST EXISTENTIAL ANXIETY** Pelin Kesebir<sup>1</sup>, Chi-Yue Chiu<sup>1</sup>; <sup>1</sup>University of Illinois at Urbana-Champaign

– We hypothesized that the tendency to perceive the secular world in sacred terms functions as a buffer against death anxiety and the possibly destructive effects of death anxiety, such as materialism. The sacred is associated with the qualities of transcendence (perception of a larger and sublime reality beyond appearances) and ultimacy (perception of utmost significance and value), which can render death thoughts less accessible, and/or less threatening. We developed a measure of Sacredness Perception to capture the extent to which individuals see sacredness in the seemingly secular aspects of life. Study 1 showed that after being reminded of their mortality, individuals who score high in Sacredness Perception report lower negative affect. Study 2 revealed that after being primed with mortality thoughts, individuals high in Sacredness Perception report lower death-thought accessibility. In Study 3, participants with high Sacredness Perception levels exhibited less materialistic tendencies after being reminded of their mortality. Study 4 manipulated Sacredness Perception, and found that an experimentally heightened sense of Sacredness Perception following reminders of mortality leads to lowered materialism compared to a control condition. Overall, the research program demonstrated that perceptions of sacred-

ness, independent of a religious context, help individuals to manage their existential anxiety and deal with the potentially toxic byproducts of existential anxiety such as materialism.

#### B142

##### **MENTAL CONTRASTING EFFECTS ON BEHAVIOR MEDIATED BY REALITY-MEANS ASSOCIATIONS**

Henrik Singmann<sup>2,1</sup>, Andreas Kappes<sup>1</sup>, Gabriele Oettingen<sup>1,3</sup>, <sup>1</sup>University of Hamburg, <sup>2</sup>University of Freiburg, <sup>3</sup>New York University – The self-regulatory strategy of mentally contrasting a desired future with the impeding reality transfers expectations of success into goal commitment with subsequent goal-relevant behavior (Oettingen, Pak, & Schnetter, 2001). Looking at the underlying mechanisms, we examined whether participants after mental contrasting in light of high expectations would be inclined to spell out ways of how to overcome the impeding reality. Specifically, we hypothesized that they form an association between the impeding reality and the goal-relevant means to overcome it, thereby activating the means when the situation is encountered, which should facilitate goal-relevant behavior. In our study, we told participants that improving one's fitness is critical for students and that using the stairs instead of the elevator is an adequate means for reaching an improved fitness. Thereafter, we measured participants' expectations of successfully improving their fitness, and induced a mental contrasting condition and two different control conditions, before measuring the reality-means associations (i.e., elevator-exercise association) via a lexical decision task. Finally, we sent participants three floors down for an alleged additional part of the study and observed whether they implemented the goal-relevant means (i.e., took the stairs) or not. Results showed that only participants in the mental contrasting condition established expectancy-dependent reality-means associations and expectancy-dependent goal-relevant behavior. Furthermore, reality-means associations mediated the effects of expectations on goal-relevant behavior in the mental contrasting condition.

#### B143

##### **REACTANCE, OPPOSITIONALITY, AND ENJOYMENT OF RESISTANCE IN CREATIVE PROBLEM-SOLVING**

Carolyn Morgan<sup>1</sup>, Megan Leiviska<sup>1</sup>, <sup>1</sup>University of Wisconsin, Whitewater – Exploring reactance using the self-regulation of motivation model reveals that existing scales fail to distinguish reactance from oppositionality (i.e., rebelliousness and conflict with authority) and enjoyment of resistance (i.e., interest and pleasure in being resistant). We constructed a multidimensional scale (MDRS) to assess these factors (alphas range from .85 to .90). We hypothesized that in contrast to oppositionality, reactance motivates individuals to engage in alternative approaches to activities when their freedom is restricted, leading to greater creativity. We expected differences particularly when resistance was aroused through use of "controlling" instructions (i.e., instructions using "must" and "should"). We also hypothesized that enjoyment of resistance would be related to creativity. Participants (93 women; 40 men) completed a creativity assessment containing insight problems and divergent thinking tasks. Resistance was manipulated through written instructions. Participants then completed the MDRS. Performance on the assessment, including number correct and originality, was evaluated. Analyses were conducted using median splits for reactance, oppositionality, and enjoyment of resistance. As predicted, oppositionality had no effect on number correct; however, the 2-way interaction between reactance and instructions on number correct was significant and in the expected direction. The effect of enjoyment of resistance on number correct was complex, involving a 3-way interaction with instructions and gender. A main effect of oppositionality on originality suggested that responses of participants scoring high in oppositionality were more original than responses produced by participants low in oppositionality. Reactance, oppositionality, and enjoyment of resistance appear to be distinct constructs with different consequences for self-regulation of motivation.

#### B144

##### **THE COST OF COMMITMENT: EFFICACY, RATIONALITY, AND CHOICE**

Kristen Klein<sup>1</sup>, Keren Sharvit<sup>1</sup>, Arie Kruglanski<sup>1</sup>; <sup>1</sup>University of Maryland, College Park – Prior research has shown that people perceive costlier means as more effective at obtaining a focal goal, an attributional inference known as the augmentation effect (Kelley, 1971; Shiv, Carmon, & Ariely, 2005). The authors expanded on these findings to predict that under conditions of high (vs. low) commitment to a focal goal, people would be more likely to choose the costlier means, despite its detrimentality to alternative cost-effectiveness goals. We hypothesized that individuals would perceive costly (vs. less costly) medications as more effective options for treating an illness. In addition, participants who are highly committed to fighting an illness would perceive the costly medications as more rational, and would thus be more likely to choose them than those less committed. In the week following the H1N1 (swine) flu outbreak, we presented 262 participants with an article describing the relative monetary cost and difficulty of attainment of three medications to treat either swine flu (high commitment) or the common cold (low commitment). The findings showed that participants in both commitment conditions perceived the expensive and difficult to obtain medication as most effective. However, participants who read about swine flu (vs. common cold) medications perceived the costly medication as a more rational choice and were more likely to choose it. These findings support a goal commitment model of extremism, suggesting that individuals generally perceive costly means as most instrumental to a focal goal, but the likelihood of actually using such costly means increases only under high commitment to the focal goal.

#### B145

##### **MAKING EXCUSES FOR PERSONAL GOAL FAILURES: INTEGRATING RELATIVE AUTONOMY AND THE TRIANGLE MODEL OF RESPONSIBILITY.**

Tara M. Thacher<sup>1</sup>, Daniel S. Baillis<sup>2</sup>; <sup>1</sup>University of Manitoba – In the triangle model (Schlenker et al, 1994), responsibility is determined through relationships among prescriptions or goals, events or actions, and identity. Excuses reduce responsibility by severing these relationships: Prescription-identity excuses claim that the goal was personally unimportant, Identity-event excuses argue that external circumstances overwhelmed personal control, and Prescription-event excuses claim that unclear goals or procedures prevented behavior. Relative autonomy (RA) is a construct of self-determination theory that also embraces goals, actions, and identity. The present research tested whether RA related to the propensity to make various excuses for personal goal failures, and whether RA moderated consequences of excuse-making for subsequent goal commitment. Undergraduates with an exercise goal, who provided their RA toward exercise (N = 109), explained their most recent exercise failures, either in an open-ended manner or using rating scales of the excuse typology. All participants then completed measures of their commitment to exercise, a social desirability scale, and self-reported exercise behavior of the following week. Participants with higher vs. lower relative autonomy did not significantly differ in the number and types of excuses they offered. These effects remained significant after controlling for social desirability. Prescription-identity excuse endorsement or use resulted in uniformly negative consequences for commitment to exercise. Notably, these negative relationships were absent for the other excuse types, suggesting that not all excuses are harmful. Contrary to some previous research linking autonomy with authenticity and non-defensiveness, this research showed individuals higher (vs. lower) in RA to have equal likelihood to make excuses for exercise failure.

#### B146

##### **NONCONSCIOUS VIGILANCE: PRECONSCIOUS CONTROL OVER THE INFLUENCE OF SUBLIMINAL PRIMING**

Brandon Randolph-Seng<sup>1</sup>, Darcy Reich<sup>1</sup>; <sup>1</sup>Texas Tech University – Psychological research increasingly suggests that most of the choices we make are the result of nonconscious thinking instigated by the environment in which we live. Yet how does

one nonconsciously determine which of the potentially relevant stimuli to respond to in a complex real world environment? The current studies sought to address this question by examining whether people can pre-consciously control what impact the environment has on their responses based on the current nonconscious motivations they bring to a novel situation. In two studies, participants' approach and avoidance motivations toward subliminally presented trait words were manipulated in different ways. It was predicted that, counter to the typical assimilative priming effects found in past person perception research, participants would be more or less likely to nonconsciously use the trait primes in their judgments depending on whether approach or avoidance motivations were nonconsciously associated with the trait primes. Results of two studies generally supported the hypothesis. Further, in Study 2, evidence of postfulfillment inhibition was found, strongly suggesting that the effects can be attributed to preconscious motivational processes. Based on the results of the current studies, it seems that even when individuals are not aware of the influence of some stimulus (e.g., subliminal prime), it may be possible for them to prevent being influenced by that stimulus at a particular moment in time. In this way, one's choices may often be determined outside of conscious intent, but such determinism may usually derive from within.

#### B147

**A STRUCTURAL MODEL OF TRAITS, GOALS, MEANING IN LIFE, AND WELL-BEING** Nick Stauner<sup>1</sup>, Tierra S. Stimson<sup>1</sup>, Michael Boudreaux<sup>1</sup>; <sup>1</sup>University of California, Riverside – Meaning in life, certain personality traits, and a goal-oriented lifestyle have all been identified as contributors to subjective well-being. Meanwhile, relationships have been discovered among traits and certain types of thematic goal content. Traits have also been related to meaning in life; and the recently developed Search for Meaning subscale ties the construct of meaning to motivation. This study sought to measure the relationships among personality traits, personal goals, the presence of meaning in life, the search for meaning, and life satisfaction. Eighty-nine undergraduates at UC Riverside completed the Big Five Inventory, the Personal Goals Questionnaire, the Meaning in Life Questionnaire, and the Satisfaction With Life Scale. Multiple linear regression models were tested to predict each construct from the others, and accurate models were identified for each (adjusted  $R^2 = .41 - .62$ ). Meaning is predictable from measures of life satisfaction, traits, and the search for meaning. The search for meaning is predictable from measures of goals, traits, and absence of meaning. Life satisfaction is predictable from measures of goals, meaning, and conscientiousness. Extraversion is predictable from measures of goals and other traits. These findings lend valuable insight to the study of traits, motivation, and psychological well-being by identifying and quantifying the network of relationships among these diverse personality constructs. Such information may prove useful in directing efforts to bolster psychological well-being through purposeful living and selective goal pursuit programs tailored to suit all of society's wide variety of personalities.

#### B148

**INCREASING LEVEL OF ASPIRATION BY MATCHING CONSTRUAL LEVEL AND TEMPORAL DISTANCE: THE MOTIVATING EFFECTS OF CONTEMPLATING "HOW" NOW AND "WHY" LATER** Florian Fessel<sup>1</sup>; <sup>1</sup>Union College – The current series of studies demonstrates that temporal distance and construal level have diametrically opposing effects on level of aspiration such that a concrete goal leads to a higher level of aspiration in the proximate future, but an abstract goal leads to a higher level of aspiration in the distant future. There are two theoretical reasons why this interactive effect occurs. First, based on construal level theory (Liberman, Trope, & Stephan, 2007), these combinations of a goal's abstraction and distance afford functional advantages in goal pursuit. Second, given prior demonstrations of the relationship between concreteness and proximity on the one hand, and abstraction and distance on the other hand, these combinations provide value from fit (Higgins, 2000), in that goal pursuit seems subjectively appropriate and important. Study 1 demonstrated that temporal distance indeed moderated the

effects of construal level on the level of aspiration participants set for performance on a trivia quiz. Participants in Study 2 who were primed with a concrete versus abstract mindset for a goal in one domain set different levels of aspiration for a subsequent, unrelated goal depending on the temporal distance of that goal. Finally, consistent with a value from fit account, in Study 3 temporal distance and construal level increased perceived importance in fit conditions. Taken together, this line of research points to one reason why prior research on the motivating effects of construal level has led to equivocal results by implicating the moderating role of temporal distance.

#### B149

**EFFECTS OF EXAMPLE CHOICE ON TOPIC INTEREST AND PERCEIVED CONTROL** Rolf Reber<sup>1</sup>, Hilde Hetland<sup>1</sup>, Weiqin Chen<sup>1</sup>, Elisabeth Norman<sup>1</sup>, Therese Kobbeltved<sup>1</sup>; <sup>1</sup>University of Bergen, Norway – We present an application of social psychology in multimedia learning. Specifically, we report a study on how choice of examples in a multimedia environment affects topic interest and perceived control. The starting point was example choice as a new method for teaching formal theoretical principles, such as mathematical algorithms or scientific laws. Formal principles are presented with several examples from different topics, and students choose the one that interests them most. Example choice might be related to prior knowledge, interest, and perceived control. In an experimental study, we examined the effects of degree of example choice and degree of prior knowledge on interest and perceived control in a multimedia presentation on confirmation bias. The main finding was that participants who could choose an example showed more interest for the presentation of the formal principle than participants who either were given an example by the experimenter or only saw the presentation. Importantly, interest was not related to prior knowledge of the participants. Moreover, control was lowest for the group without example and without prior knowledge. Example choice thus offers a new approach to close the gap between formal principles as presented at school and a student's interests. We discuss how principles from the psychology of motivation can be applied to multimedia contexts in order to enhance the learning experience at school. In addition, example choice provides an opportunity to enhance (a) the teaching of formal principles in methods of social psychology, and (b) science teaching in general.

#### B150

**COLLEGE STUDENTS PERCEPTIONS OF THE IMPORTANCE OF NON-COGNITIVE CONSTRUCTS FOR COLLEGE ADMISSIONS** Samaneh Pourjalali<sup>1</sup>, James C. Kaufman<sup>2</sup>; <sup>1</sup>California State University San Bernardino, <sup>2</sup>California State University San Bernardino – We examined the predictive aptitude of cognitive constructs (e.g., SAT scores) and non-cognitive constructs (e.g., conscientiousness) on academic performance and verified the constructs students themselves believe to facilitate or hinder their academic performance. An online survey study was completed by 1,066 undergraduate students from California State University San Bernardino. Importance ratings (on a scale of 1 to 5, from "not at all important" to "extremely important") revealed time management (4.54) as the highest rated non-cognitive construct. Academic goals (4.51), emotional stability (4.49), conscientiousness (4.42), self-efficacy (4.41), independence (4.36), metacognition (4.30), and practical intelligence (4.26) followed closely after. Grade Point Average was rated at (4.23) which is in line with previous research emphasizing the importance of high school GPA in predicting GPA at the college level (Bridgeman, Pollack & Burton, 2008). Further, in accordance with past research (Kaufman, Agars & Lopez, 2008), students assigned higher ratings to intrinsic motivation (4.03) than to extrinsic motivation (3.69). This suggests that students indeed realize the importance of being intrinsically motivated in the goals they pursue, and that praises, honors, and awards will only take them so far when it comes to success. Interestingly, SAT and other standardized test scores designed to measure achievement (3.20) and community involvement (3.17) were the constructs rated lowest in predicting

college success. Therefore, SATs were, in fact, rendered meaningless, by this student sample, in predicting academic performance. Implications of these findings are later discussed.

### B151

#### OPTIMISM, CONSTRUAL LEVEL, AND THE PROCESSING ON THREATENING HEALTH INFORMATION

Stephanie L. Fowler<sup>1</sup>, Andrew L. Geers<sup>1</sup>, Amanda Johnson<sup>1</sup>, Justin A. Wellman<sup>1</sup>; <sup>1</sup>University of Toledo – Recent research indicates that dispositional optimism and unrealistic optimism interact in predicting reactions to health threats. Specifically, individuals scoring high in dispositional optimism and low in unrealistic optimism are the most responsive to health threats, whereas those scoring high in both forms of optimism are the least responsive. Currently, no study has examined the mechanisms underlying this interactive effect. In the present study (N = 64), we examined one possible mechanism: level of cognitive construal. Based on construal level theory (CLT), we predicted that when faced with a looming threat, individuals high in dispositional and low in unrealistic optimism process information at concrete levels of construal, whereas individuals high in both forms of optimism process information at an abstract level of construal. To test this hypothesis, participants completed measures of both types of optimism and read about either a near or a distant health threat. Afterward, participants completed two dependent measures that assessed level of mental abstractness. A hierarchical regression analysis, conducted on a combination of the mental abstractness measures, revealed the anticipated three-way interaction ( $p=.01$ ) between dispositional optimism, unrealistic optimism, and threat condition. Consistent with CLT, individuals high in both forms of optimism psychologically distanced themselves from the near threat by processing information more abstractly. Individuals high in dispositional but low in unrealistic optimism processed the near threat more concretely. When the health threat was distant, no differences emerged. These are the first data indicating that construal level mediates the relationship between optimism and the processing of health threats.

### B152

#### REACTIONS TO CONFLICTING FEEDBACK: IS GETTING PRAISE ALWAYS GOOD?

S. Gokce Gungor<sup>1</sup>, Monica Biernat<sup>1</sup>; <sup>1</sup>University of Kansas – Previous research suggests that conflicting feedback about one's performance has negative emotional and performance outcomes (Vescio et al., 2005). The present research investigated the effect of praise in the context of performance failure on affect, perceived competence and motivation. Hundred thirty eight participants at University of Kansas role played being a recent high school graduate who applied for colleges and received a rejection letter. In a 2 praise (given or not) x 2 school (top vs. lower tier) x 2 participant gender design, we varied the content of the letter and predicted that especially praise from a lower-tier school will be perceived insincere thus will bring more negative outcomes than No praise. We found a praise X gender interaction on measures of feeling scared  $F(1,130)= 8.33, p<.01$  and afraid  $F(1,130)= 9.91, p<.005$ . Females in the praise condition felt more scared and afraid than both males in the praise, and the females in the No praise condition. They also felt not doing well in performance compared to males in the praise and females in the No praise condition,  $F(1,130)= 7.08, p<.005$ . Lastly, there was a praise X school interaction on motivation. Participants who received a praise from lower tier school were less willing to put effort to improve their credentials than those in the Lower tier/No praise condition,  $F(1, 130)= 3.8, p=.053$ . School type didn't interact with praise on every outcomes, rather overall praise brought negative affect, and harmed perceived competence, and motivation.

### B153

#### FRIENDLY CRITICISM: FEEDBACK, INTERPERSONAL CONTEXT, AND ACHIEVEMENT

Arielle Silverman<sup>1</sup>, Geoffrey L. Cohen<sup>1</sup>; <sup>1</sup>University of Colorado, Boulder – The quality of a student's relationship with a mentor can dramatically affect his or her achievement motivation. However, little is known about the aspects of mentoring relationships that are impor-

tant to motivation. The present experiment tests the role of two variables—the communal nature of the relationship and the perceived attentiveness of the instructor. It was predicted that students would show greater motivation and heightened performance when they felt that an instructor gave them individualized attention, but primarily when they had a communal relationship with the instructor, or a relationship based on a long-term shared purpose. The mere perception of attention, along with the communal nature of the relationship between participants and an ostensible instructor, was experimentally manipulated. Students wrote a short essay, received critical feedback from an alleged writing professor, and then revised their work. The feedback was manipulated to appear to be either attentive (e.g. longer due to the use of bigger font) or inattentive (e.g. shorter due to the use of smaller font), with the amount and quality of actual corrective information held constant across conditions. Additionally, the professor either expressed an interest in building long-term working relationships with students or did not. As expected, in the former communal condition, students undertook more substantive revisions when the feedback appeared attentive rather than inattentive. By contrast in the noncommunal condition, the perceived attentiveness of the feedback had no impact. The role of relationship quality in motivation, and implications for social policy, are discussed.

### B154

#### PASSION AND EMOTIONAL EXHAUSTION IN ELITE COACHES

Eric G. Donahue<sup>1</sup>, Pierre-Nicolas Lemyre<sup>2</sup>, Marc-Andre K. Lafrenière<sup>1</sup>, Robert J. Vallerand<sup>1</sup>; <sup>1</sup>Université du Québec a Montreal, <sup>2</sup>Norwegian Scholl of Sport Sciences – Recent research investigating passion in sport participation (Vallerand et al., 2006) reveals that harmonious and obsessive passion represent a great source of motivation for involvement in the sport domain. Passion is defined as a strong inclination toward an activity that people like, that they find important, that they invest time and energy in, and that has been internalized in their identity (Vallerand et al., 2003). While harmonious passion has been associated with adaptive achievement striving, obsessive passion has been linked to maladaptive achievement outcomes, such as increased stress and negative affect, interpersonal conflicts and unhealthy sport persistence. The present study was designed to examine the contribution of the two types of passion in predicting professional exhaustion in elite team-sport coaches from two different countries (Canada and Norway). Norwegian participants (N = 117) were high-level coaches in soccer, handball, and basketball competing at the highest national level in their sports, averaging 17 years of experience, while Canadian participants (N = 93) were regional coaches in football, basketball, hockey, and baseball, averaging 6 years of experience. Using SEM analyses, results revealed that obsessive passion predicts emotional exhaustion while harmonious passion is unrelated. In turn, emotional exhaustion plays an important role in vitality, well-being, positive and negative emotions, and conflicts between their work and family life conciliation. The current study findings support the use of the Dualistic Model of Passion to study exhaustion and burnout in sport coaches.

### B155

#### INDIVIDUAL DIFFERENCES IN THE RELATIONSHIPS OF GOAL CONFLICT, EMOTIONAL DISTRESS AND PAIN

Jaime Johnson Hardy<sup>1</sup>, Leslie Crofford<sup>1</sup>, Suzanne Segerstrom<sup>1</sup>; <sup>1</sup>University of Kentucky, Lexington, KY – Goal conflict (GC) refers to the competition between two goals for time and energy. More subjective GC has been related to higher distress and poorer health, but objective GC has not, leading to questions as to whether conflict results in distress or vice versa. The relationship between GC and well-being was tested in the context of fibromyalgia, a disorder characterized by pain and distress. In this context, disease characteristics may lead to an increased perception of GC (i.e., overestimation), or GC may contribute to disease characteristics. Women (n=27) with fibromyalgia recorded their pain, emotional distress and daily goals twice daily over five days. GC was rated both by the woman and independent raters and a difference score was calculated to determine GC discrepancy. Days

with higher objective ( $\beta = 1.67$ ,  $t(67) = 2.52$ ,  $p < .05$ ) and subjective ( $\beta = 1.50$ ,  $t(67) = 2.02$ ,  $p < .05$ ) GC, resulted in higher evening pain, controlling for morning pain. Days with higher morning distress were characterized by overestimation of GC ( $\beta = 0.085$ ,  $t(50) = 3.00$ ,  $p < .05$ ), controlling for previous day's GC. On such days, the subjective experience of GC remained the same as low-distress days, but objective ratings were lower. Thus, daily levels of emotional distress affect perception of goals such that the time and energy required by goals is overestimated. In contrast, pursuit of goals requiring high time and energy may deplete psychological and physical resources in this vulnerable population and result in higher experience of pain.

**B156****THE EFFECTS OF THE RELATIONSHIP BETWEEN PERSONAL GOALS AND ROMANTIC RELATIONSHIPS ON SUBJECTIVE WELL-BEING AND RELATIONSHIP QUALITY** Judith Gere<sup>1</sup>, Ulrich Schimmack<sup>1</sup>, <sup>1</sup>University of Toronto

— Many researchers have examined the effects of goal pursuit on subjective well-being and have argued that goal progress facilitates and goal conflict decreases well-being (e.g., King, 2008). However, the effects of one's intimate relationship on goal pursuit have not been studied extensively, and it is not known how they influence subjective well-being and relationship quality. Therefore, the purpose of the present study was to investigate whether conflicts between one's important goals and intimate relationship are related to subjective well-being and relationship quality. In order to investigate this issue, fifty dating couples were recruited and filled out questionnaires assessing their life satisfaction, positive and negative emotionality, relationship satisfaction, relationship cohesion, and relationship agreement. Each participant also listed ten personal strivings, and for the five most important strivings, they rated how good and how bad their romantic relationship was for that specific goal. Participants' life satisfaction and relationship agreement were positively predicted by ratings of how good their relationship was for their goals. In contrast, negative emotionality was positively, and relationship satisfaction was negatively predicted by ratings of how bad their relationship was for their strivings. Positive emotionality and relationship cohesion was unrelated to participants' strivings ratings. These results suggest that conflict between participants' personal strivings and romantic relationships is related to lower levels of subjective well-being and relationship quality.

**B157****A LONGITUDINAL ASSESSMENT OF THE MOTIVATIONAL PROPERTIES OF SELF-CONSCIOUS EMOTIONS: INTERRELATIONS BETWEEN GUILT, SHAME, AND SELF-DETERMINED SCHOOL MOTIVATION** Isabelle Green-Demers<sup>1</sup>, Sylvain Coutu<sup>1</sup>, Andre Lauzon<sup>1</sup>; <sup>1</sup>Université du Québec en Outaouais

— The main objective of the present project was to examine the key differences in the motivational properties of guilt and shame, and to assess their impact on the evolution of self-determined school motivation. According to Tangney and Dearing (2002), guilt is proactive and motivates reparation, corrective action, and pro-social behaviors. Conversely, shame is thought to motivate disengagement, social withdrawal, and defensive attitudes and behaviors. It was thus hypothesized that guilt fosters self-determined school motivation and that shame thwarts its development. Participants ( $N=244$  high school students) completed the Academic Motivation Scale, the Test of Self-Conscious Affect for Adolescents, and the State Shame and Guilt Scale in October 2006 and in April 2007. Data analyses were performed using structural equations modeling. Results fully corroborated research hypotheses. Within each of the two testing waves, situational guilt was associated positively, and situational shame negatively, with autonomous motivation. Moreover, positive change in the propensity for guilt between time 1 and time 2 was associated with increased self-determined motivation, whereas positive change in dispositional shame was associated with diminished motivation. The present project yielded a fruitful integration of the information provided by the documentation on self-conscious emotions and

self-determined motivation. It is our hope that future projects on this topic will shed further light on the divergent impact of guilt and shame on optimal motivation, a key fundamental and applied issue.

**B158****FRUITFUL PLANS: COMBINING IMPLEMENTATION INTENTIONS WITH MENTAL IMAGERY TO INCREASE GOAL ACHIEVEMENT** Julien Lacaille<sup>1</sup>, Amanda McCollam<sup>1</sup>, Ariel Rosen-Brown<sup>1</sup>, Michelle Roseman<sup>1</sup>, Evan Kelso<sup>1</sup>, Bärbel Knäuper<sup>1</sup>; <sup>1</sup>McGill University

— Past research shows that (1) forming process-oriented contingency action plans (i.e. implementation intentions) makes behaviour automatic and thereby increases the probability of carrying out goals, and (2) forming specific mental representations (i.e. mental imagery) also facilitates goal achievement. This study tested the hypothesis that mental imagery targeting key elements of implementation intentions leads to higher goal achievement. Residents of a student dormitory were assigned the goal of consuming extra portions of fruit every day for seven days and randomly assigned to one of four conditions: (1) control (active rehearsal of the goal intention without a plan-making strategy), (2) implementation intention (forming an implementation intention), (3) conventional mental imagery (imagining the goal intention), or (4) implementation intention plus targeted mental imagery condition (forming an implementation intention followed by imagining the implementation intention). Among low fruit consumers, fruit consumption at follow-up was higher for the implementation intentions plus mental imagery condition than in the other conditions, with the lowest fruit consumption in the control condition. The findings show that the effectiveness of implementation intentions can be enhanced through targeted mental imagery.

**B159****SEPARATION OF PERFORMANCE-APPROACH AND PERFORMANCE-AVOIDANCE GOALS: STATE LEVEL, STATE CHANGE LEVEL, INTRAINDIVIDUAL LEVEL, AND GENETIC LEVEL ANALYSES** Kou Murayama<sup>1</sup>, Andrew Elliot<sup>2</sup>, Shinji Yamagata<sup>3</sup>, Juko Ando<sup>3</sup>; <sup>1</sup>University of Munich, <sup>2</sup>University of Rochester, <sup>3</sup>Keio University

— The distinction between performance-approach goals (goals to do better than others) and performance-avoidance goals (goals to avoid doing worse than others), has been criticized, especially because they are highly correlated. The purpose of the current study is to examine the separation of these goals from multiple perspectives by attending to different types of correlation – state level, state-change level, intraindividual level, and genetic level correlations. In Study 1a, we conducted a series of EFA and multigroup CFA with cross-sectional samples from different cultures (US and Japan) and different age groups. Results strongly supported the separation of the goals even though they are highly correlated. These results are augmented by a subsequent simulation (Study 1b), and an ipsative factor analysis using a paired-comparison method to eliminate response bias (Study 1c). In Study 2, we turned to state-change level, by analyzing longitudinal data from US and Japanese samples. The change score between the time-points was factor analyzed. Results favored the two-factor structure of the goals, indicating the separation of the goals at the state-change level. In Study 3, participants were asked to indicate their goals in five different situations. This design allows us to examine the intraindividual covariation of the goals. Multilevel structural equation analysis supported the two-factor model at the intraindividual level, suggesting both goals are distinguishable, even within a person. In Study 4, data from Japanese twins were analyzed by a series of multivariate genetics analyses. The results showed, though highly correlated, both goals are still separable at genetic level.

**B160****PSYCHOLOGICAL CHANGES IN DEVELOPMENT OF PROBLEMATIC GAMBLING: THE LONGITUDINAL ANALYSES OF GAMBLER'S MOTIVATION AND BEHAVIORS** Yoonyoung Kim<sup>1</sup>, Yeanhok Yoo<sup>1</sup>, Cheongyeol Park<sup>2</sup>, Taekyun Hur<sup>1</sup>; <sup>1</sup>Korea University, <sup>2</sup>Human Research Center

—Previous researches on gambling problem that mostly employed cross-sectional methods have mainly focused on the addicted state and differences between problematic and non-problematic people. Therefore, the psychological processes through which non-problem gamblers transform into problem gamblers were rather inferred than confirmed. The present research used a longitudinal method in order to identify and distinguish the precedent causes, consequences, and concurrent phenomena of gambling problems. 1146 casino visitors were randomly recruited from the site of a casino in Korea and participated in a series of three surveys with 3 & 1/2 month interval (finally 474 participants completed in all the surveys). The degree of development of gamble problems was calculated by changes in the Canadian Problem Gambling Index during the survey intervals. The results revealed that development of gambling problems was predicted by 'Conscientiousness' of the Big 5 personality traits and greater confidence in gambling as precedent causes. However, other presumed factors of gambling problems such as gambling motives, life satisfaction, interpersonal relations, and etc. did not predict the development of gamble problems. Interestingly, the results also showed that 'pursuit of money' motivation was not a precedent cause but a concurrent consequence of development of gambling problems. As gambling problems got severe, surrounding others influenced more and unreasonable belief in gambling abilities was getting decreased. The results were discussed in its implications of preventive factors in gambling problems and psychological values of gambling as leisure.

**B161**

**WHEN LOSS-AVERSION IS A MOTIVATIONAL NECESSITY** Xi Zou<sup>1</sup>, Abby Scholer<sup>2</sup>; <sup>1</sup>London Business School, <sup>2</sup>Columbia University — We propose and test a motivational model as an alternative to the "loss aversion principle" to understand people's decision making under gains. Classic decision-making theories, such as prospect theory, argue that people tend to strongly prefer avoiding losses to acquiring gains. That is, in the domain of gains, people are more likely to choose the conservative option. In two studies, we suggest that people do not necessarily risk averse under gains. Risk preference is, however, a function of people's motivational character. Focusing on the domain of gains, our studies suggest that risk-aversion becomes a motivational necessity under two conditions: 1) when the individual is in a promotion-focused regulatory state (Higgins, 1997), and 2) when the risky option is no better than the conservative option in leading to further gains. That is, we observed that promotion-focused people, not prevention-focused people, showed a default preference in choosing the conservative option under gains. However, when the risky option provides a large gain that can serve the eagerness need of promotion-focused people, promotion-focused people consistently choose the risky option instead of the conservative option. We address the implications of this finding in relating to loss aversion principle and the role of a motivational model in understanding risky decision makings.

**B162**

**WHY DOES THE DARK HORSE WIN? MOOD, MISATTRIBUTION, AND THE PERFORMANCE OF THE PESSIMIST** Justin A. Wellman<sup>1</sup>, Andrew L. Geers<sup>2</sup>, Nicole D. Fairless<sup>2</sup>, Sara R. Cicchinelli<sup>2</sup>, Heather J. Pase<sup>2</sup>, Jacob M. Horn<sup>2</sup>; <sup>1</sup>Hartwick College, <sup>2</sup>University of Toledo — Recent research has found that optimists perform better at conscious goals, whereas pessimists perform better at nonconscious goals (Wellman et al., 2009). In the present study we investigated why pessimists perform better at nonconscious goals. We propose that this difference is due to affect's role in self-regulation. Specifically, when working on a conscious goal, pessimists interpret the negative affect they experience during goal pursuit as a signal to dis-

engage. This is not true, however, for nonconscious goals. This is because the negative affect that arises when pursuing nonconscious goals is not easily attributable to task performance, thus the affective signal leading to disengage is not present. To test for the mediating role of affect, we utilized a misattribution paradigm. We predicted that pessimists would perform better on a task when they could misattribute the negative affect encountered during performance to an external source. This would only be true, however, when the task itself was difficult. Participants (N = 164) completed an easy or a difficult cross-out task (difficulty manipulation). During this task, participants listened to music they were told would put them in a positive or a negative mood (misattribution manipulation). Error rate on the task was the main dependent measure. As predicted, pessimists performed better in the negative misattribution condition than in the positive misattribution condition—but this was true only in the difficult task condition. These results are the first to demonstrate the critical role of affect in the self-regulation of pessimists and help explain their varying performance.

**B163****COMPASSIONATE GOALS PREDICT BETTER RELATIONSHIPS IN JAPAN EVEN AFTER CONTROLLING FOR INTERDEPENDENT SELF-CONSTRUAL**

Yu Niiya<sup>1</sup>, Jennifer Crocker<sup>2</sup>, Dominik Mischkowski<sup>2</sup>; <sup>1</sup>Hosei University, <sup>2</sup>University of Michigan — US data show that compassionate goals to support others enhance relationships whereas self-image goals to construct and defend desired self-images undermine relationships (Crocker & Canevello, 2008). We investigated whether this finding extends to Japan, and if so, whether compassionate goals explain variance beyond interdependent self-concepts. A random sampling survey in Japan demonstrated that interdependent self-construal does not fully account for the association between compassionate goals and how one deals with relationship problems, zero-sum thinking, feelings of closeness, mindfulness, attitudes toward dissimilar others, or growth goals. The survey sample consisted of 321 Tokyo residents (56% female) ranging from 20 to 73 years of age (mean and mode = 47). Respondents selected one person they cared for most and responded to a 12-item scale assessing compassionate and self-image goals for their relationship with this person (adapted from Crocker & Canevello, 2008). They also completed an 8-item interdependent self scale (Uchida, Park, & Kitayama, 2008) and additional scales. The factor structure of compassionate and self-image goals was comparable to that in the U.S. Compassionate goals correlated moderately with interdependent self (.32\*\*), suggesting that these are related but distinct constructs. Controlling for gender, age, interdependent self, and self-image goals, compassionate goals predicted greater engagement when dealing with relationship problems ( $\beta = .23^{**}$ ), reduced zero-sum thinking (-.35\*\*), greater mindfulness (.40\*\*), greater growth goals (.40\*\*), reduced loneliness (-.22\*\*) and greater openness to others with diverging opinions (.21\*\*). These findings suggest that compassionate goals predict better relationships in Japan above and beyond the effect of interdependent self.

**B164****LEVEL OF ACTION CONSTRUAL AND PERCEIVING CONCORDANCE AMONG GOALS: IMPLICATIONS FOR POSITIVE AFFECT**

Sheri L. Clark<sup>1</sup>, Antonio L. Freitas<sup>1</sup>, June Y. Kim<sup>1</sup>, Sheri R. Levy<sup>1</sup>; <sup>1</sup>State University of New York, Stony Brook — Experiencing conflicts among one's goal pursuits can impact subjective and objective indicators of well-being (e.g., Emmons & King, 1988). Accordingly, it is important to understand how individuals come to perceive their goals as discordant or concordant with one another. Drawing on evidence that construing action in terms of its abstract purposes increases the breadth of categories applied to objects, persons, and groups (Levy, Freitas, & Salovey, 2002; Liberman, Sagristano, & Trope, 2002; Trope & Liberman, 2003), the present work tested whether construing action abstractly would be associated with perceiving high concordance among one's ongoing goals. Consider, for example, different goals one might have of "excelling at work" and of "avoiding unhealthy foods." While quite distinct in their specifics, both goals could be related to broader aims of exercising self-discipline,

achieving competence, or being generally successful in one's endeavors. Construing action abstractly, then, may promote perceiving one's different life endeavors as related coherently to one another, such that one's efforts towards those endeavors sustain rather than conflict with one another, which should promote positive affect. Data from two studies supported this reasoning. In Study 1, individual differences in level of action construal (assessed via Vallacher & Wegner's, 1989, measure) and in positive affect (assessed via Watson et al.'s, 1988, measure) correlated significantly with one another, independent of several covariates. In Study 2, perceived goal concordance (assessed via Emmons & King's, 1988, measure) helped explain the relationship between action construal and positive affect. Implications for achievement, affect, and social judgment are considered.

### B165

#### THE ACTIVATION OF GOAL STRIVER ROLES IN SOCIAL NETWORKS: TESTING COMPONENTS OF DYNAMIC NETWORK THEORY James

Westaby<sup>1</sup>, <sup>1</sup>Columbia University, Teachers College – The goal of this study was to test the antecedents of goal striver role activation in social networks. According to dynamic network theory, the activation of goal striver roles results primarily from the activation of system supporter roles in dynamic network systems. However, interactants and observers in peripheral roles are also theorized to impact goal striver activation in some settings, such as through implicit processes or social facilitation, although weaker effects are anticipated. Methodologically, hypotheses were tested using hierarchical linear modeling (HLM) in the case of 45 social networks associated with participants' major goals over a two week period. A mixed idiographic-nomothetic methodology was used. A total of 337 entities were involved across the networks. The Level-1 HLM model contained the activation of system supporters, interactants, observers, and two theoretically relevant covariates: system negator role activation (i.e., entities that have negative attitudes toward other entities engaged in goal pursuit) and the system competency of entities. The Level-2 HLM model included social network size. As predicted, findings indicated that the activation of system supporter roles was significantly associated with the activation of goal striver roles in social networks (.39), while interactant (.04) and observer (.22) roles had significantly weaker effects. Level-2 HLM findings indicated that social network size was not significantly associated with goal striver activation, suggesting that theoretical propositions may be applicable across both small and large social networks involved in human goal pursuit. In conclusion, system supporters and interactants played critical roles in motivating goal strivers in social networks.

### B166

#### INCREASING GOAL COMMITMENT: DECOUPLING REGULATORY MODE FROM REGULATORY PHASE Abigail Scholer<sup>1</sup>, E. Tory Higgins<sup>2</sup>,

<sup>1</sup>Gettysburg College, <sup>2</sup>Columbia University – As most of us can attest, change is hard. While some people start to change but fail to stick with it (failures of goal pursuit), there are also the quieter failures of those who desire change but never muster the courage to commit (failures of deliberation). Traditional self-regulatory phase models identify the primary concern of the deliberation phase as comparing and evaluating options (i.e., assessment) and the primary concern of the goal pursuit phase as action (i.e., locomotion). Building on the insights of regulatory mode theory (Higgins, Kruglanski, & Pierro, 2003), however, we propose that regulatory mode is independent of regulatory phase, such that locomotion motivation may play an important role in deliberation. Two studies provide evidence that increased locomotion motivation in deliberation is associated with increased goal commitment. Study 1 provides evidence that the locomotion effect on commitment is not mediated by the subjective value of the new state of by self-efficacy beliefs. Instead, Study 1 provides evidence that locomotion motivation leads to increased commitment to a goal to change because predominant locomotors value change as an end in itself. Study 2 uses the logic of self-regulatory hierarchies to test this mechanism within the assessment system, creating a deliberation intervention that increases the value of change for both

chronic locomotors and assessors. By demonstrating the role of locomotion motivation in deliberation, the current work highlights the value of decoupling regulatory mode from regulatory phase.

### B167

#### THE ROLE OF INDIVIDUAL REGULATORY FOCUS IN MOTIVATIONALLY MIXED GROUPS Abigail Hazlett<sup>1</sup>, Daniel C. Molden<sup>1</sup>; <sup>1</sup>Northwestern

University – Regulatory focus theory (Higgins, 1997) proposes two distinct motivational orientations; one is a focus on growth (promotion) in which goal pursuit is characterized by eager strategies. The other is a focus on security (prevention) in which goal pursuit is characterized by vigilant strategies. Much of the existing research on regulatory focus examines the impact of individual motivational orientation on individual outcomes (Molden, Lee & Higgins, 2008). Because many of our goals are formed and pursued as part of groups (e.g., project teams at work) it is also important to study how regulatory focus operates at the group level (Sassenberg & Woltin, 2009). In the present research, participants were randomly assigned to motivationally mixed groups (both promotion and prevention members) and asked to complete a group decision-making task in which choices could be more risky or conservative. The results show that individual regulatory focus interacted with how conservative or risky the group decision was to predict individual strategic inclination after the group interaction. When the group made a relatively conservative decision, prevention-focused participants shifted (relative to a pre-interaction measure) in a more conservative direction than promotion-focused participants. In contrast, when the group made a relatively risky decision, prevention-focused participants shifted in a more risky direction than promotion-focused participants. Thus prevention participants responded to the group strategy by shifting their own motivational orientation, while promotion participants did not. These results are consistent with previous findings that prevention-oriented individuals tend to be more interdependent than promotion-oriented individuals (Lee, Aaker & Gardner, 2000).

### B168

#### REGULATORY FOCUS AND AFFECTIVE FORECASTS FOR THE 2008 PRESIDENTIAL ELECTION Amber Emanuel<sup>1</sup>, John Updegraff<sup>1</sup>, David

Kalmbach<sup>1</sup>, Jeffrey Ciesla<sup>1</sup>; <sup>1</sup>Kent State University – Regulatory focus theory makes a distinction between two types of chronic goal pursuits: promotion and prevention. Promotion-focused individuals are motivated by desires and possible gains, and prevention-focused individuals are motivated by monitoring for potential losses. Given the importance of these orientations in how people pursue and react to successes and failures, we expected them to be related to the accuracy of their affective forecasts as well. We predicted that promotion-focused individuals would be more accurate in predicting affect for a positive event since these individuals are used to orienting towards gains; likewise, prevention-focused individuals would be more accurate in predicting affect for a negative event given their orientation towards losses. We tested these predictions in a study of 187 young adults' reactions to the 2008 Presidential election and measured regulatory focus with the General Regulatory Focus Measure (Lockwood, Jordan, & Kunda, 2002). Promotion-focused individuals were more accurate when predicting their happiness for a positive event (a win for one's candidate,  $p = .041$ ) and less accurate when predicting affect for a negative event (a loss for one's candidate), ( $p = .015$ ). Prevention-focused individuals were marginally accurate when predicting their happiness for a negative event, ( $p = .08$ ). Being prevention-focused was not related to accurately predicting happiness for a positive event ( $p > .10$ ). Individuals' orientation of promotion or prevention may allow individuals to be more accurate affective forecasters when predicting affect for events that match their goal orientation.

**B169**

**FACILITATION OF ACTION VS. INACTION DURING SIMULTANEOUS PURSUIT OF MULTIPLE ACTION VS. INACTION GOALS IN A COMPLEX GO/NO-GO TASK** Wei Wang<sup>1</sup>, Ibrahim Senay<sup>1</sup>, Dolores Albarracin<sup>1</sup>, C. Kathleen McCulloch<sup>2</sup>; <sup>1</sup>University of Illinois at Urbana-Champaign, <sup>2</sup>Idaho State University – Pursuing multiple goals has been traditionally addressed with respect to specific goal-directed behaviors. Our recent research has shown that people can be motivated to pursue a general action goal to achieve an active (or inactive) state regardless of the type of specific activity (or inactivity) (Albarracin et al., 2008; Albarracin, Wang, & Leeper, 2009). The present research aims to investigate how different general action states located in the general activity continuum affect the pursuit of multiple goals. Four experiments using a complex Go/No-go paradigm were conducted. In each experiment, general action states were manipulated by varying the response-cue mappings. For example, going to three out of four cues (i.e., 75%) was defined as a high action state, whereas going to one out of four cues (i.e., 25%) was defined as a low action state. The four experiments consistently demonstrated that a high general action state led to a great degree of readiness to engage in action, facilitating the execution of an action response. These results suggest that the action state in the multiple goal pursuit contexts can impact the action responses in a top-down fashion. In addition, Experiment 4 also examined the effect of the number of response trials while controlling for mapping rules. It was revealed that, under the same mapping rule, responses per se can influence action responses in a bottom-up fashion. These results have significant implications for the future research of multiple goal pursuit with respect to various objects, including responses in social interactions.

**B170**

**DIFFERENCES IN TASK ENGAGEMENT AS A FUNCTION OF SELF-CONTROL: WHY THOSE HIGHER IN SELF CONTROL MIGHT BE BETTER AT REGULATING POTENTIAL TRADE-OFFS BETWEEN INTEREST AND PERFORMANCE** Tamra Fraughton<sup>1</sup>, Carol Sansone<sup>1</sup>, Dustin Thoman<sup>2</sup>, Jonathan Butner<sup>1</sup>, Joseph Zachary<sup>1</sup>, William Thompson<sup>1</sup>; <sup>1</sup>University of Utah, <sup>2</sup>California State University, Long Beach – Sansone, Fraughton, Thoman, Zachary & Thompson (2009) suggested that students higher in self control (SCS; Tangney, Baumeister & Boone, 2004) may regulate both goals-defined and experience-defined (interest-based) motivation, without creating interest/performance tradeoffs. Students higher and lower in SCS reported similar frequency of exploring non-required web links to make studying more enjoyable. For higher SCS students, higher GPAs were predicted by greater strategy use and perceiving positive strategy effects on interest. For lower SCS students, in contrast, higher GPAs were predicted by lower strategy use and were unrelated to perceived interest effects. However, these results were self-reports only. In present study, students (n=42, 73% female) worked on an online, HTML programming lesson. We unobtrusively recorded the number of times participants published results after modifying codes in sample exercises (activities available but not required). Upon lesson conclusion, we measured recognition of words appearing in the exercises/examples, along with interest and learning (quiz). Similar to self-reports, there was no difference between higher and lower SCS groups in the frequency of (non-required) publishing during the lesson. However, more frequent publishing was associated with greater recognition of exercises/examples content (controlling for false alarms) primarily for the higher SCS group. In turn, greater recognition predicted higher quiz scores for all students, but greater interest only for those higher in SCS. This pattern suggests that although students high and low in SCS appeared to engage in the same behaviors, individuals higher in SCS were more cognitively engaged, and this engagement lead to greater learning and greater interest.

**B171**

**PROVING THEM WRONG: USING OTHERS' DOUBTS ABOUT ONESELF AS A SOURCE OF MOTIVATION** Kent C. H. Lam<sup>1</sup>, Johanna Peetz<sup>1</sup>, Roger Buehler<sup>1</sup>; <sup>1</sup>Wilfrid Laurier University – The current research presents evidence that people become especially motivated to excel when they feel that others have unjustly underestimated their abilities. Three studies tested the primary hypothesis that individuals use others' doubts about them as a source of motivation to achieve performance goals. In Study 1, participants were asked to recall a previous occasion when someone had doubted their ability to achieve a goal and to indicate how this doubt had affected them. A large majority of participants (70%) reported that the other person's doubt had increased rather than decreased their motivation to succeed. In Study 2, participants who were instructed to recall a past instance in which someone had doubted their intellectual abilities subsequently performed better on an "intellectually challenging" puzzle task than did participants in the control condition. In Study 3, participants who were explicitly doubted by an experimenter in the lab reported feeling angrier and more motivated, and consequently performed better on the same puzzle task, than did control participants who were not explicitly doubted. Taken together the results of these studies support the hypothesis that people are able to use others' doubts as a source of motivation and thereby enhance their task performance. Theoretical and applied implications of the findings are discussed.

**B172**

**WHEN "IF ONLY" PREDICTS "WHAT WILL I DO?": THE ROLE OF SPECIFICITY IN FUNCTIONAL COUNTERFACTUAL THINKING** Rachel Smallman<sup>1</sup>, Neal Roese<sup>2</sup>; <sup>1</sup>University of Illinois, Urbana-Champaign, <sup>2</sup>Northwestern University – Imagining how the past might have been different is a common feature of the mental landscape. Although there are numerous reasons why counterfactual thoughts occur, one is that they serve a behavior regulating function, involving behavior change and performance improvement. According to this perspective, counterfactuals may enhance performance by either a content-neutral pathway (via mindsets or motivation) and/or a content-specific pathway (via shift in behavioral intentions). Recent research provided evidence for one aspect of the content-specific pathway: the facilitating effect of counterfactuals on behavioral intentions. The current research further explores this relationship by examining the extent to which it depends on the specificity of both the counterfactual and the intention. For example, will the facilitation effect occur when the counterfactual is specific (with regard to an action) versus broader or more global? Further, will the facilitation effect occur when the intention is specific versus broader or more general? Using a within-subject sequential priming paradigm, individuals read a negative event description, followed by an action statement (judged in either a counterfactual or non-counterfactual manner), with reaction time to a subsequent intention statement serving as the dependent variable. Specificity was manipulated by varying the action and intentions statements so that they focused on either a specific action or a general class of behaviors. Results indicated that counterfactuals facilitate intentions, but only when both statements focused on specific actions. When counterfactual and intention statements were worded more generally, the facilitation effect disappeared. These findings clarify the content-specific pathway by which counterfactuals influence behavior.

**B173**

**"GOING FAST" VS. "GOING FAR": WHEN CONSUMERS' PREFER VELOCITY VS. DISTANCE REPRESENTATIONS.** Derek D. Rucker<sup>1</sup>, David Dubois<sup>1</sup>, Miguel Brendl<sup>1</sup>; <sup>1</sup>Northwestern University – We propose that consumers predominantly use two distinct progress markers in goal pursuit: velocity (i.e., the rate of progress) and distance (i.e., the amount of progress). We theorize that each progress marker echoes a different representation of one's progress: velocity emphasizes here-and-now, ongoing effort serving goal pursuit and is thus an indicator of rate of progress; in contrast, distance indicates the overall effort invested or needed and thus is an indicator of amount of progress. While past

research has independently studied each of the constructs in isolation, we theorize for the first time that because progressing on a goal often presupposes that one has thought about this goal prior to completing it, consumers' use and response to velocity and distance markers will depend on how consumers think about their goals. As a first step, given that velocity (distance) gives an online and concrete (projective and abstract) representation of one's progress, we test the hypothesis that consumers' response to velocity or distance systematically differs based on whether consumers think about their goals at an abstract or concrete level. Consistent with our theory, three experiments provide evidence for a matching mechanism between velocity (distance) and low (high) level of goal abstraction. Participants who experienced a match reported greater motivation and worked longer on their goals than those who experienced a mismatch, and these effects were mediated by how right consumers felt about the progress representation encountered. Both theoretical and practical relevance of the documented phenomenon are discussed.

## Prosocial Behavior

### B174

**SUBJECTIVE EASE OF RETRIEVAL AND THE CIRCLE OF MORAL REGARD** Simon Laham<sup>1</sup>; <sup>1</sup>University of Melbourne, Australia – People feel morally obligated to show concern for a variety of things in the world. These may include their children, other adults and perhaps even some non-human animals. These entities are said to reside within the moral circle. Although it may seem that the scope of the moral circle should be set in stone, recent research shows that moral circle judgments, much like other moral judgments, are malleable. Although much work has demonstrated a range of cognitive and emotional influences in the moral domain, little work to date has considered the impact of metacognition on moral judgment. This poster addresses this lack by exploring the role of subjective ease of retrieval in judgments and behaviors directed at the moral circle. Three experimental studies demonstrate that the ease with which moral circle exemplars come to mind influences the size of the moral circle. Participants asked to generate three exemplars had significantly larger moral circles than those asked to generate fifteen. Further, participants' subsequent behavior on behalf of circle members was influenced by the subjective ease with which circle exemplars were generated. Participants asked to generate three exemplars were more likely to take action on behalf of circle members and this behavioral effect was mediated by moral circle size. These studies provide one of the first demonstrations of the impact of metacognitive experiences on moral judgment and behavior and, more generally, extend the scope of subjective ease of retrieval effects to behavior.

### B175

**MORAL AND RELIGIOUS CONVICTIONS HAD DISSIMILAR EFFECTS OF PEOPLE'S INTENTIONS TO VOTE IN THE 2008 PRESIDENTIAL ELECTION** G. Scott Morgan<sup>1</sup>, Linda Skitka<sup>1</sup>, Dan Wisneski<sup>1</sup>; <sup>1</sup>University of Illinois at Chicago – The current research investigated whether people's moral and religious convictions had distinct or redundant effects on their intentions to vote in the 2008 presidential election. Four hundred and thirty six participants (208 Democrats, 67 Moderates/other, and 161 Republicans) completed online surveys shortly before the 2008 Presidential election. Participants were given a list of thirteen issues-of-the-day, and were asked to select the two issues that were most important to their thinking about the 2008 Presidential election. Participants then reported demographic information, their party identification, their levels of moral and religious conviction about their most important issues, and their intentions to vote. We entered control variables, party identification, issue-related moral conviction, issue-related religious convictions, and all interactions into a regression equation to predict intentions to vote. Results indicated that stronger moral convictions and weaker religious convictions were associated with increased intentions to vote—a finding

that did not differ for Democrats and Republicans. In short, people's moral and religious convictions had distinct and dissimilar effects on their intentions to vote in the 2008 presidential election.

### B176

**THOU SHALT NOT KILL: RELIGION AND UTILITARIAN MORAL JUDGMENTS** Olga Antonenko<sup>1</sup>, Paul Piff<sup>1</sup>, Dacher Keltner<sup>1</sup>; <sup>1</sup>University of California, Berkeley – Religion and morality are woven together into our collective human history and into the daily experiences of many people today. Political strategies, domestic policies, scientific inquiries, and medical practices are often shaped on individual and national levels by religiously guided moral beliefs. However, the exact relationship of these intimate, yet sometime contentious, bedfellows is only beginning to be examined (Cohen et al., 2006; Morewedge & Clear, 2008; Shariff, 2006). The present research aims to elaborate the relationship between religion and morality by focusing specifically on the influence of religious orientation on utilitarian moral judgments. One hundred and thirteen participants provided data on the nature and extent of their religious beliefs by completing the Religious Identity Questionnaire as well as self-report ratings of the strength of their religious orientation. Participants read and responded to four difficult moral dilemmas (Greene et al., 2004), gauging whether they approved of actions aimed to kill or harm one person in order to save several others. Affirmative responses to moral dilemmas were coded as indicative of utilitarian moral judgments. All self-report measures showed a negative association with utilitarian responses indicating that highly religious individuals are less likely to use utilitarian thinking to approach moral dilemmas. Furthermore, while individuals scoring high on the "Belief in a Greater Power" factor of the RIQ were less likely to approve of utilitarian actions, "Belief in Interconnectedness" showed no relationship with utilitarian responses. Studies are proposed to explore the relationship between belief in a greater power and moral processing.

### B177

**BEYOND THE BANALITY OF HEROISM: VARIETIES OF MORAL PERSONALITY** Lawrence J. Walker<sup>1</sup>, Jeremy A. Frimer<sup>1</sup>, William L. Dunlop<sup>1</sup>; <sup>1</sup>University of British Columbia – Four perspectives dominate thinking about moral heroism: One contends that moral action is primarily instigated by situational pressures, another holds that moral excellence entails the full complement of virtues, the third asserts a single superintending principle, and the fourth posits different varieties of moral personality. This research addresses these competing perspectives by examining the personalities of moral heroes. Participants were 50 national awardees for moral action and 50 comparison individuals. They responded to personality inventories and a life-review interview which provided a broadband assessment of personality. Cluster analysis of the moral exemplars yielded three types: a "communal" cluster was strongly relational and generative; a "deliberative" cluster had sophisticated epistemic and moral reasoning, as well as heightened self-development motivation; and an "ordinary" cluster had a more commonplace personality. These contrasting profiles imply that exemplary moral functioning can take multifarious forms and arises from different sources, reflecting divergent person by situation interactions.

### B178

**CONSEQUENCES OF CARING: EXPLICATING ANTECEDENTS OF SOCIAL POLICY SUPPORT** Liana Epstein<sup>1</sup>, Yuen Huo<sup>1</sup>; <sup>1</sup>University of California -- Los Angeles – Why do people feel like helping? Our paper explores this question, where the endpoint is prosocial, helping-focused policy directives (rather than punitive ones) intended to ameliorate social problems. To this end, we will supplement a model that differentially predicts helping-focused policy support with moral emotions developed by Pagano & Huo (2007) in order to detail the role of antecedent variables in predicting these moral emotions. We argue that a sense of connectedness to the problem is at the root of these moral emotions, with helplessness and a sense of connectedness to the victim of the problem (empathy) differentiating what ensuing moral emotion is expressed. Essentially, we

argue that in order to have an emotional reaction to the problem, one must feel linked to or touched by the scenario. If helplessness is felt, collective guilt will likely result, along with reparative policy support, whereas if a connection to the victim is felt, moral outrage will likely result, along with preventative policy support. Implications of these findings are discussed.

**B179****"AND WHO IS MY NEIGHBOR?" REVISITED: DIVERGENT EFFECTS OF GOD AND RELIGION PRIMES ON COOPERATION WITH IN-GROUP AND OUT-GROUP MEMBERS IN THE PRISONER'S DILEMMA**

Ryan S. Ritter<sup>1</sup>, Jesse Lee Preston<sup>1</sup>, <sup>1</sup>University of Illinois at Urbana-Champaign – Theory has suggested that the evolution of morality allowed our ancestors to cross the "cooperation divide" and thrive in large communities of genetically unrelated individuals. Religion as one type of culturally constructed moral system has been proposed to serve an adaptive role in this sense – supernatural beliefs and behaviors, while strange from an outsider's perspective, may be highly adaptive proximate mechanisms for establishing in-group cohesion and solidarity that can then translate into secular utility. Previous research has shown that regardless of self-reported religiosity, religious primes do in fact increase honesty and pro-social behavior toward anonymous strangers. However, little distinction has been made between religious cognitions and more universal/spiritual cognitions such as God. Additionally, no research has investigated the effects of religious primes on pro-social behaviors when the recipient is not anonymous. The current study extends past research by investigating the effects of subliminal religion, God, and control primes on pro-social behavior directed toward in-group and out-group members during a one-shot prisoner's dilemma game. Results indicate that religion primes increase cooperation rates only toward in-group members, whereas God primes increase cooperation rates only toward out-group members. These findings lend support to the religion-as-adaptation hypothesis: religion primes only increased in-group cooperation and failed to facilitate the ideal of a universal pro-social motive. This study highlights an important psychological distinction between the concepts of God and religion, and offers evidence that spiritual rather than religious concepts may prove more effective at motivating pro-social behavior directed toward out-groups.

**B180****EFFECTS OF PROSOCIAL VIDEO GAMES ON PROSOCIAL BEHAVIOR**

Tobias Greitemeyer<sup>1</sup>, Silvia Osswald<sup>2</sup>, <sup>1</sup>University of Sussex, <sup>2</sup>Ludwig-Maximilians-University – Most past research into the effects of video games has illuminated the negative effects of violent video games. In fact, playing violent games has been shown to lead to an increase in aggressive thoughts, feelings, and behavior. These effects have been mainly explained by the General Aggression Model (GAM). Recently, Buckley and Anderson (2006) expanded the GAM into a General Learning Model (GLM) to explain how video games affect behavior. However, whereas the predictive validity of the GAM for the effects of playing violent video games on aggressive tendencies is well-documented, as yet, the predictive validity of the GLM for the effects of playing prosocial games on prosocial tendencies has not been tested. This was done in the present research. Experiment 1 examined the influence of a prosocial vs. a neutral video game on spontaneous, unrequested assistance. The experimenter accidentally spilled some pencils on the floor and the participants could help him/her to pick them up. As expected, participants who had played a prosocial video game were more likely to help. This finding was replicated in Experiment 2: participants in the prosocial game condition were more willing to take part in further experiments than participants in the neutral game condition. Experiment 3 showed that playing a prosocial video game primed prosocial knowledge structures, which in turn increased prosocial behavior. Thus, it appears that the effect of playing prosocial video games on prosocial behavior works primarily through the cognitive route of the GLM.

**B181****ESCAPING AFFECT: HOW MOTIVATED EMOTION REGULATION DRIVES THE COLLAPSE OF COMPASSION**

C. Daryl Cameron<sup>1</sup>, B. Keith Payne<sup>1</sup>, <sup>1</sup>University of North Carolina at Chapel Hill – In crisis situations, people tend to feel more compassion toward one victim than toward multiple victims. Many have suggested that this collapse of compassion is an invariant feature of our affective systems, that emotions are not triggered as strongly by aggregates. The current pair of studies provide initial evidence for a different account: that the collapse of compassion is driven by motivated emotion regulation. People might view their emotion toward mass suffering as overwhelming or costly, and take steps to eliminate it. In Study 1, subjects read about one or eight children in need of aid, and half of these subjects also expected to help. When subjects did not expect to help, they displayed more compassion toward eight children than toward one child. But when people did expect to help, the collapse of compassion emerged. This reversal was driven by the reduction of compassion toward eight children when help was expected. Similarly, subjects reported the most regulatory effort when they expected to have to help eight children. Study 2 examined two moderators of emotion regulation: time course and regulation skill. All subjects expected to have to help one, four, or eight children, and rated their emotion toward these children over the course of one minute. Results showed that the collapse of compassion only emerged over time, and only for skilled emotion regulators. Additionally, self-reported interpersonal sensitivity decreased as the number of children increased. Together, these findings provide initial evidence that the collapse of compassion is driven by motivated emotion regulation.

**B182****WHY DO SOME ADOLESCENTS NEVER VOLUNTEER?**

Zeynep Cemalcilar<sup>1</sup>, <sup>1</sup>Koç University, Istanbul, Turkey – Volunteering has positive effects on adolescents' psychological and social development. However, few studies have marked a self-selection bias, suggesting that the significance of these positive consequences may decrease when volunteers' pre-participation characteristics are controlled for (e.g. Johnson, Beebe, Mortimer, and Snyder, 1998). The present short-term longitudinal study investigates the underlying dynamics of adolescents' volunteerism. First time volunteering adolescents are assessed at the time of their initial decision to volunteer on a social responsibility project and their self-perceptions (self-concept, self-esteem) and civic attitudes (social responsibility, community belonging) are compared to their peers' with similar backgrounds but did not volunteer to participate in the project. MANOVA results yielded that volunteers were more likely to be females, younger and scored higher on all measured individual characteristics compared to the non-volunteers. No significant effects of this participation were observed when pre-existing individual characteristics were controlled for. Findings are discussed in relation to developing appropriate recruitment strategies that would encourage more adolescents to be actively involved in social responsibility projects.

**B183****DOES SIMILARITY MATTER?: AN INVESTIGATION INTO THE LINK BETWEEN DEHUMANIZATION AND EMPATHY**

Jeffrey Wong<sup>1</sup>, Alexa Tullett<sup>1</sup>, Michael Inzlicht<sup>1</sup>, <sup>1</sup>University of Toronto – There are times when we read an article in the newspaper and are overwhelmed with empathy for the people involved, but there are also times when we feel virtually nothing. Why is it that some people seem to pull at our heartstrings so much more strongly than others? Looking to events that are historically devoid of empathy, perceived humanness emerges as a potentially poignant dimension affecting empathic responses and prosocial (or anti-social) behaviour. In three studies we investigated the possibility that people empathize more with those they see as more human. In the first study, humanized sponsorship profiles elicited more emotional empathy and were rated as more likely to be sponsored by participants. Consistent with these findings, our second study revealed that empathic attitudes towards animals are correlated with the tendency to

anthropomorphize (ascribe human characteristics to) certain animals. Finally, in the third study we focused on physical suffering which has been said to evoke thoughts of our animal nature and thus to prompt us to feel disgust. We measured facial disgust reactions using electromyography (EMG), along with self-reported empathy and monetary donations to fabricated charities. This time we found that the dehumanized individuals – those that were physically suffering – elicited stronger facial disgust reactions, but also more emotional empathy and greater donations. It appears, then, that perceived humanness influences our empathic responses, but that this relationship becomes more complex when other factors (such as vulnerability) are involved.

**B184**

**PROMOTING INTEREST IN ENVIRONMENTAL VOLUNTEERISM: THE UTILITY OF MESSAGE FRAMING** Patrick C. Dwyer<sup>1</sup>, Beth Nygard<sup>1</sup>, Emily Alter<sup>1</sup>, Alexander J. Rothman<sup>1</sup>; <sup>1</sup>University of Minnesota – Research on how message framing can be used to promote prosocial behavior has struggled to find a fitting theoretical framework and has yielded inconsistent results. The present study seeks to understand prosocial message framing effects through the lens of regulatory focus theory, which has guided message framing research in the health behavior domain. Rothman and colleagues (2008) have argued that when a person adopts a promotion-focused mindset, they are more responsive to a gain-framed message. Alternatively, when a person adopts a prevention-focused mindset, they are more responsive to a loss-framed message. To the extent that volunteerism is construed as something a person wants to do, thinking about volunteering should elicit more of a promotion-focused mindset, whereas to the extent that volunteerism is construed as something a person ought to do, thinking about volunteering should elicit more of a prevention-focused mindset. Therefore, we hypothesized that when volunteerism is construed as a choice, gain-framed messages will elicit greater interest in volunteering, but when volunteerism is construed as a duty, loss-framed messages will elicit greater interest in volunteering. Participants (N = 134) were randomly assigned to read one of four volunteer recruitment advertisements that reflected a 2 (construal: choice, duty) X 2 (frame: gain, loss) between-participants design. Analyses revealed the predicted interaction between frame and construal on evaluations of the ad, attitudes toward volunteering, and intentions to volunteer. Theoretical and practical implications are discussed.

**B185**

**HOW SOCIAL NETWORKS PROMOTE POLITICAL PARTICIPATION? : AN EXPLANATION FROM ALTRUISM** Kazunori Inamasu<sup>1</sup>, Makoto Shimura<sup>1</sup>, Kenichi Ikeda<sup>1</sup>; <sup>1</sup>The University of Tokyo – Since the probability that participation of single individuals will affect political outputs is very small in large populations, rational people avoid the costs of participation and become free riders. Political psychologists have struggled with this paradox of political participation. One of the major approaches to solve the paradox is study of social networks. Research to date showed that social networks created in citizen's daily life keep a lid on costs of political participation and make people get involved in politics (Huckfeldt & Sprague, 1995; Ikeda & Richey, 2005). Yet the psychological process of increasing political participation via social networks has been still unclear. In this study, we examine how social networks promote political participation based on the research of altruism in the field of political psychology (Monroe, 1996; Fowler & Kam, 2007). Our prediction is that contacts with diverse people broaden citizen's perspective that mainly focus on self or particular in-group to share a view of the world in which all people are one. In addition, acquiring the broader perspective promote political involvement, because as people become more concerned for the welfare of large number of others, they feel greater benefits of total political outcome and the benefits likely to exceed the costs of individual act of political participation. We conducted internet survey for 7662 people who lived in metropolitan areas in Japan. Results of regression analyses suggest (1) diversity in social network broaden perspective and (2) the broader perspective promote political participation.

**B186****EXAMINING THE ROLE OF IMPLICIT COGNITIONS ON VOLUNTEERISM**

Patrick L. Hill<sup>1</sup>, Daniel K. Lapsley<sup>2</sup>, Andrew J. Cavanagh<sup>2</sup>, Meghan A. Thornton<sup>2</sup>; <sup>1</sup>University of Illinois at Urbana-Champaign, <sup>2</sup>University of Notre Dame – The possibility that presumptive moral behavior can be motivated by implicit cognitions has been understudied in moral psychology. To that end three studies are reported that examine the role of implicit moral motivation on volunteer behavior. Studies 1 and 2 (total n = 174) asked participants to list and rate the attributes and traits that typically described a volunteer. Study 3 then examined whether priming volunteer traits would motivate participants to voluntarily take part in an additional study. Participants (n = 86) completed a scrambled sentence task in one of two groups; the primed group was given words rated as highly typical of volunteers, while the unprimed group was given words that were not listed as volunteer attributes. Participants then were asked whether they would take part in an additional study for another lab, without further compensation. Overall, primed (71%) and unprimed (62%) participants did not differ in their volunteer rates. However, this largely reflects participants' preference to help a female (78%) rather than a male experimenter (47%), which was true both for male and female participants. Looking only at participants' willingness to help males, primed participants (67%) did volunteer more than unprimed participants (29%). These results suggest that moral actions are influenced by implicit moral cognitions, but such effects may be less influential than situational cues to help (i.e., a female experimenter).

**B187****COMPELLED TO GIVE: MORALITY, SELF-CONSTRUAL, AND CHARITABLE INTENTIONS**

Eric M. VanEpps<sup>1</sup>, Jeni L. Burnette<sup>1</sup>; <sup>1</sup>University of Richmond – Drawing from moral foundation theory (Graham, Haidt, & Nosek, 2009) and self-construal perspectives (Lalwani & Shavitt, 2009; Markus & Kitayama, 1991), this study focused on how personal factors such as morality and one's view of the self affected attitudes and charitable intentions. Specifically, we focused on attitudes toward the homeless and donation and volunteer intentions. We recruited participants (N = 234) to complete an online survey assessing morality foundations, self-construals, and attitudes toward a charity of their choice that works with the homeless. In addition, participants indicated their levels of education, income, religious attendance, personality, and other demographic features relevant for use as control variables in analyses. Results suggest that even after controlling for impression management, demographics and relevant Big Five personality traits, individuals with higher ratings of the moral foundations fairness/reciprocity and harm/care reported more positive attitudes and more generous intentions. Additionally, higher morality-oriented self-construals and an interdependent self-construal predicted both donation and volunteering intentions. Results suggest that the desire to maintain healthy relationships with others and to publicly uphold social standards predict charitable giving. Results are discussed in terms of implications for charitable donation behavior.

**B188****THE DARK SIDE OF MORAL PRINCIPALISM II: COGNITIVE, EMOTIONAL, AND SOCIAL DIMENSIONS**

Dupont Serge<sup>1</sup>, Van Pachterbeke Matthieu<sup>1</sup>, Saroglou Vassilis<sup>1</sup>, De Wilde Corine<sup>1</sup>; <sup>1</sup>Université Catholique de Louvain. – How people can act "badly" (i.e. acting in a non-prosocial and even anti-social way) with regard to close others by following what they believe to be right (i.e. moral principles)? What are the cognitive, emotional, and social determinants of such rigid, harmful principlism? Can we prove experimentally low prosociality as a function of rigid moral principlism? In Study 1, 206 participants were administered measures of (a) rigid, non-caring moral principlism (nine hypothetical dilemmas; see the poster submitted "The dark side of moral principlism I"), (b) right-wing authoritarianism (Altemeyer, 1996), (c) need for closure (Webster & Kruglanski, 1994), (d) existential quest (Van Pachterbeke et al., 2009), (e) religiosity, (f) empathy (Davis, 1983), and (g) positive and negative affects (PANAS). Results confirmed that excessive moral principlism

reflects high authoritarianism (in general and among religious participants), high need for closure, and low existential quest. Moral principlists also reported low negative emotions, in particular the ones that indicate disturbance. However, empathy was unrelated and not negatively related - as hypothesized - to empathy. In Study 2, we thus investigated a more specific hypothesis that moral principlism does not imply low prosociality in general but does so when principles-related concerns are implied. Participants (60 students) were provided the opportunity to express willingness to help a peer who was in need (control condition) or was in need but was somehow responsible for it (was a disorganized person; target's responsibility condition). Indeed, moral principlists turned out to be less willing to help only in the target's responsibility condition.

### B189

#### INVESTING IN KARMA: WHEN WANTING INCREASES HELPING

**Benjamin A. Converse<sup>1</sup>, Jane L. Risen<sup>1</sup>, <sup>1</sup>University of Chicago** – People constantly confront doubts about outcomes of important life events that are at least partly beyond personal control. "Will that job offer come through?" "Will I get a good grade?" "Will the blood test be negative?" The salience of unknown outcomes like these induces a state of wanting. We suggest that when people want something beyond their control, they will be especially likely to proactively "invest in their own karma" by doing good deeds. Alternatively, wanting might lead people to feel deprived, which could justify not helping. We test these competing hypotheses in two studies and find that wanting increases donations of time and money. In Experiment 1, participants wrote essays about unknown outcomes they were currently awaiting (e.g., results of a job interview) or about daily routines. After the ostensible conclusion of the study, they were solicited to volunteer extra time to raise money for charity. Helping rates were higher in the wanting than the control condition. Experiment 2 tested whether the effect was specifically associated with wanting, or with more general feelings of uncertainty. Participants wrote essays about unknown outcomes, personal dilemmas (designed to arouse uncertainty), or personal preferences, and then had an opportunity to donate money to charity. Wanting increased donations relative to the other two conditions, ruling out explanations relying on uncertainty. These results extend justice research by demonstrating that, beyond changing memories or judgments to maintain just world beliefs, people may alter their behavior to proactively influence future outcomes in ways consistent with these beliefs.

### B190

#### TOO MUCH OF A GOOD THING CAN BE BAD: THE IRONY OF BEING ETHICAL

**Jeroen Stouten<sup>1</sup>, <sup>1</sup>University of Leuven** – Ethical and moral behavior is thriving these days. One example of such ethical behavior in society is the behavior of its leaders. However, research on how people are affected by ethical leadership is still in its early stages. To date, research convincingly showed that leaders being a role model for ethical behavior positively influence followers' satisfaction, commitment, organizational citizenship behavior and personal ethical behavior. Ethical leaders actively engage in fair, honest and rule-following behavior. In addition, they expect followers to share their concern for ethical behavior. In the present research it is argued that leaders also can be too concerned with ethics by excessive rule following and rigidity instead of flexibility. Hence, instead of having a positive influence on followers, these leaders exceed followers' capabilities as they may ask too much of followers turning the positive effects of leader's ethical behavior into negative ones. In three studies (using cross-sectional, longitudinal, and multisource data), results show that ethical behavior has a curvilinear relationship with followers cognition and behavior. More specifically, corroborating the hypotheses ethical leadership negatively influenced followers' cognitive load, and positively affected followers extra-role helping, and performance. Yet, at increasing levels of ethical leadership these relationships reversed and showed that cognitive load increased and extra-role helping and performance decreased. These studies dem-

onstrate the dynamic relation of ethical leadership and followers' cognitions and behavior and provide a more detailed analysis of the effects of ethical leadership and how too much of a good thing can be bad.

### B191

#### PERSONALITY PREDICTS FORGIVENESS BETTER WHEN OFFENSES ARE SEVERE

**Belinda Vicuna<sup>1</sup>, Harold Delaney<sup>1</sup>, <sup>1</sup>University of New Mexico** – With every offense comes an opportunity to forgive, however forgiveness is more challenging in some circumstances than in others. Previous research using the Big Five personality model has revealed that, across situations, Neuroticism can be a barrier to forgiveness and Agreeableness a promoter of forgiveness. Severe offenses naturally make forgiveness more difficult, but it is the interaction of personality and severity that notably impacts forgiveness. The premise of this study was that personality and the severity should interact, such that personality should play an especially important role in forgiveness for more severe offenses. To evaluate this premise, the current study used a scenario-based approach to manipulate three dimensions of the severity of an offense (intentionality, magnitude, and relationship). The factors manipulated in the scenarios all produced large and highly significant effects on forgiveness: intentional offenses were harder to forgive than accidental offenses ( $d = 1.74$ ); major offenses were harder to forgive than minor ( $d = 1.18$ ), and those in distant relationships were harder to forgive than in close relationships ( $d = 1.63$ ). Confirming the hypothesis of an interaction, Agreeableness interacted significantly with relationship between the offended and offender ( $F(1, 98) = 4.93, p = 0.029$ ), influencing forgiveness more when it was harder to forgive. Personality effects also replicated prior findings, such that Agreeableness, positively ( $r = 0.363, p < 0.001$ ) and Neuroticism negatively ( $r = -0.208, p = 0.038$ ) predicted forgiveness. Considering how personality may interact with severity to predict forgiveness suggests new directions for predicting and promoting forgiveness.

### B192

#### PERSONALITY PREDICTORS OF INTERPERSONAL FORGIVENESS AND BEHAVIORAL REVENGE

**Ruchi Sinha<sup>1</sup>, Richard DeShon<sup>1</sup>, <sup>1</sup>Michigan State University** – Interpersonal conflicts at work can result in negative emotions, cognitions and behaviors. This can lead to damaged relationships. Forgiveness as a response to conflict is an adaptive coping method (Rasmussen et al, 2000) and essential for relationship repair. The goal of this study is to examine the dispositional predictors of forgiveness and behavioral revenge post a conflict situation. A growing number of studies examining forgiveness (Maltby et al, 2001, McCullough, 2001, Tangney, 1999) have provided us with important insights. However there is a gap in the literature as majority of these studies have measured forgiveness in the context of hypothetical scenarios or have examined the relationship between personality and dispositional forgiveness (Brose et al, 2005). The present study fills this methodological gap by utilizing a creative research design that examines forgiveness in the context of a real-time actual offense. We quickly established an expectation of cooperation and created a real offense in the context of a social dilemma task. We also measured behavioral revenge as opposed to previous studies that have measured revenge in terms of self reported cognitions. In a sample of 120 adults, we examined how the following personality traits differentially relate to forgiveness and revenge: agreeableness, neuroticism, conscientiousness, rumination, negative affectivity, and personal distress. Results indicate that conscientiousness and agreeableness predict interpersonal forgiveness. Also those high on agreeableness, trait personal distress and forgiveness were less likely to take revenge. In this study we discuss both the strengths and limitations of predicting forgiveness and revenge using personality traits.

### B193

**TURNING THE KNOTS IN YOUR STOMACH INTO BOWS: REAPPRAISING AROUSAL IMPROVES PERFORMANCE ON THE GRE** Jeremy Jamieson<sup>1</sup>, Wendy Berry Mendes<sup>1</sup>, Toni Schmader<sup>2</sup>, Erin Blackstock<sup>1</sup>; <sup>1</sup>Harvard University, <sup>2</sup>University of British Columbia – This research examined the effect of reappraising arousal on physiology and GRE performance. First, participants preparing to take the GRE reported to a laboratory session where they were assigned to a reappraisal or no appraisal condition and then completed a practice GRE test. Participants in the reappraisal condition were told that arousal could help improve their performance, whereas controls were not provided with this information. We collected saliva samples at baseline and after the reappraisal manipulation that were assayed for salivary alpha amylase (sAA) to index sympathetic nervous system activation. Reappraisal participants exhibited a significant increase in sAA and outperformed controls on the GRE math section. Between one and three months later, participants took the actual GRE test and then returned to the lab where they provided their ETS GRE score reports and completed a test experience questionnaire. Reappraisal participants outperformed controls on the actual GRE math section and reported that arousal harmed performance less than controls. These findings indicate that the reappraisal may exert powerful influences on performance in and out of the laboratory.

### B194

**AN UNINTENDED WAY IN WHICH THE "FAT GENE" MIGHT MAKE YOU FAT** Ian Dar-Nimrod<sup>1</sup>, Steven Heine<sup>1</sup>; <sup>1</sup>University of British Columbia – People are routinely exposed to media coverage of genetics research: for example, many headlines have described research on "obesity genes." An important question arises: how does exposure to such arguments affect people's own efforts to control their weight? In this study we evaluated the behavioral outcomes of exposure to scientific claims regarding the existence of genes that relate to obesity. Participants read one of three different articles: an article describing evidence for an "obesity gene," an article describing evidence for how social experiences (specifically social networks) relate to obesity, or a neutral article. Following exposure to the manipulation, participants took part in an experiment that purported to investigate their food preferences; they were provided with some cookies to sample as they evaluated them. The results indicated that those participants who learned of the existence of "obesity genes" subsequently consumed significantly more cookies than participants in either of the two other conditions (which did not differ from each other). This suggests that people do not typically conceive of their weight as being due to genetic factors, but when they do, they are likely to act as though their weight is beyond their control. Implications for media coverage of genetics research will be discussed.

### B195

**AFFECTIVE AND CARDIOVASCULAR HABITUATION TO STRESS IN GIRLS AT RISK FOR DEPRESSION** Christian Waugh<sup>1</sup>, Luma Muhtadie<sup>2</sup>, Wendy Berry Mendes<sup>3</sup>, Ian Gotlib<sup>1</sup>; <sup>1</sup>Stanford University, <sup>2</sup>University of California - Berkeley, <sup>3</sup>Harvard University – Affective responses to stress are capable of potentiating physiological stress responses. Failure to habituate to repeated stress exposure can cause allostatic load to accumulate, contributing to physical and mental illness. The present study was designed to examine whether adolescent girls at high familial risk for depression exhibit impaired habituation to a repeated laboratory stressor. Eighteen high-risk (RSK) girls and 34 low-risk (CTL) girls performed a repeated mental arithmetic task while their heart rate (HR) and affective responses were measured. On average, RSK and CTL girls showed comparable habituation of HR and affective responses to the repeated stressor; only RSK girls, however, showed a significant association between affective and HR habituation. Specifically, whereas RSK girls whose negative affect decreased during the experiment showed complete HR habituation to the task, RSK girls whose negative affect increased during

the experiment failed to habituate to the stressors. These findings suggest that there is a tighter coupling between physiological and affective habituation to repeated stress among girls at risk for depression. For these high-risk girls, failure to habituate to stressors that induce negative affect may confer greater vulnerability to allostatic load and, ultimately, to physical and mental illness.

Poster withdrawn.

### B197

**PHYSIOLOGICAL RESPONSES TO ENGAGING IN SIMULATED HARMFUL BEHAVIORS** Allison Gaffey<sup>1</sup>, Fiery Cushman<sup>1</sup>, Wendy Mendes<sup>1</sup>; <sup>1</sup>Harvard University – Past psychology research has investigated the situations in which people will engage in behavior that harms others (Milgram, 1963; Darley, 1969), but the psychological mechanisms that prevent people from engaging in harmful behavior are relatively less studied. Observational data from military conflicts (Grossman, 1995) and recent research regarding moral judgment (Greene, 2001; Blair, 1995) suggest that humans may have a basic emotional aversion to performing harmful actions. Our goal is to examine whether we can use simulated harmful actions to study the emotional and visceral resistance to performing harm to other humans. We randomly assigned 88 participants to either perform or observe a series of simulated harmful actions towards an experimenter. For example, participants were asked to discharge a fake handgun directly in the face of an experimenter. Subjects assigned to the control condition performed benign actions to match the pretend harmful ones such as squirting a spray bottle instead of shooting a gun. We measured physiological responses and self-reported emotional states during these simulated actions. Our results reveal a physiological profile consistent with threat reactivity while performing harmful behaviors. Specifically participants showed a significant decrease in cardiac output and an increase in vascular resistance, whereas control participants showed no changes in sympathetic activation. These findings indicate a method to explore the emotional aversion to harm in a laboratory context.

### B198

**UPWARD SPIRALS OF THE HEART? BASELINE VAGAL TONE PREDICTS INCREASES IN SOCIAL CONNECTEDNESS, POSITIVE EMOTION, WHICH IN TURN PREDICT FUTURE BASELINE VAGAL TONE.** Bethany Kok<sup>1</sup>, Barbara Fredrickson<sup>1</sup>; <sup>1</sup>University of North Carolina at Chapel Hill – A body-mind model of affiliation and health is proposed which predicts that activity of the vagus nerve will be related to markers of other-focused positive attention and positive emotions. In a study of 73 community-dwelling adults, half of whom were trained in lovingkindness meditation, baseline vagal tone positively predicted all participants' daily reported social connectedness and positive emotions over a period of nine weeks. Individuals high in baseline vagal tone experienced their days and interactions as more positive and socially connected than individuals low in baseline vagal tone. The effects of vagal tone on social connectedness were not mediated by positive emotions or vice versa, suggesting that the vagus acts on emotions and social attention in distinct ways. Participants' rate of increase in social connectedness over time positively predicted end-of-study baseline vagal tone, even after controlling for initial baseline vagal tone. A similar relationship was seen for positive emotions, but it was only marginally significant. Individuals who experienced greater increases in social connectedness (and potentially positive emotions as well) over time ended the study with higher baseline vagal tone. This evidence suggests that vagal tone may play a significant role in the well-being process. High vagal tone may lead to greater increases in positive emotions and social connectedness, while increases in these traits may in turn heighten baseline vagal tone, leading to a potential upward spiral of increased well-being.

**B199****ASSOCIATION OF BDNF VAL66MET, 5-HTTLPR, AND THE NEUROTICISM AND INTROVERSION PERSONALITY TRAITS**

Paul Costa<sup>1</sup>, Antonio Terracciano<sup>1</sup>, Angelina Sutin<sup>1</sup>, Toshiko Tanaka<sup>1</sup>, Luigi Ferrucci<sup>1</sup>, David Schlessinger<sup>1</sup>, Barbara Deiana<sup>2</sup>, Manuela Uda<sup>2</sup>; <sup>1</sup>National Institute on Aging, NIH, DHHS, <sup>2</sup>Neurogenetica e Neurofarmacologia, Consiglio Nazionale delle Ricerche – Brain-derived neurotrophic factor (BDNF) regulates synaptic plasticity and neurotransmission, and has been linked to Neuroticism, a major risk factor for psychiatric disorders. A recent genome wide association (GWA) scan, however, found no association with Neuroticism, but identified an association between the BDNF Val66Met polymorphism (rs6265) and lower Extraversion. In this study, we replicate and extend the links between BDNF and personality traits, assessed with the Revised NEO Personality Inventory (NEO-PI-R), in independent samples from SardiNIA (n = 1560) and the Baltimore Longitudinal Study of Aging (BLSA; n = 1118). Consistent with the GWA results, we found that BDNF Met carriers were more introverted. In both samples, and in a meta-analysis inclusive of published data, we found no evidence for a main effect of the BDNF Val66Met on Neuroticism. Finally, based on recent reports of an epistatic effect between BDNF and the serotonin transporter, we explored a Val66Met x 5-HTTLPR interaction. In the larger SardiNIA sample (n = 2333), we found that subjects with the BDNF Met variant and the 5-HTTLPR LL genotype scored higher on Neuroticism. Our findings support the association between the BDNF Met variant and introversion and suggest that this variant interacts with the serotonin transporter to influence Neuroticism.

**B200****HORMONE X GENE INTERACTION PREDICTS STRESS REACTIVITY**

Robert Josephs<sup>1</sup>, Jacqueline Rivers<sup>1</sup>, Christopher Beevers<sup>1</sup>, John McGeary<sup>2</sup>; <sup>1</sup>The University of Texas at Austin, <sup>2</sup>Providence Veterans Affairs Medical Center and Brown University – Here we show that the allelic variation in the promoter region of the serotonin transporter (5-HTT) gene interacts with baseline testosterone (T) to predict vulnerability to acute stress. The 5-HTT gene has been shown to predict stress reactivity. High levels of T act, predisposing high T individuals to be biologically more reactive to certain stressors. We know of no study testing the interrelation of the reproductive axis and serotonergic system on stress reactivity. The purpose of the current study was to test for such an interrelation. Stress was induced in 53 men and women using the computerized version of the Mirror Tracing Persistence Task (Strong et al., 2003). Saliva was collected before and after the task to assess baseline T, T change, and cortisol levels, and buccal cells were collected from inside the cheek before the task for 5-HTT genotyping. We found a significant 5-HTT x baseline T interaction, but no gene main effect. Men and women with at least one s-allele showed a strong positive relationship between T and area under the curve cortisol. In contrast, men and women homozygous for the l-allele showed a no relationship between baseline T and area under the curve cortisol. We found no effects for change in T nor did we find any sex differences. Dominance, including its biological proxy T, has proven to be a powerful predictor of both acute and long-term stress. However, as Sapolsky (2005) points out, measures of dominance rarely enjoy a direct relationship to stress.

**B201****DO POLITICS GET YOUR HORMONES GOING? VOTERS' TESTOSTERONE AND CORTISOL RESPONSES TO THE OUTCOME OF THE 2008 UNITED STATES PRESIDENTIAL ELECTION**

Steven Stanton<sup>1</sup>, Jacinta Beehner<sup>2</sup>, Ekjyot Saini<sup>2</sup>, Cynthia Kuhn<sup>1</sup>, Kevin LaBar<sup>1</sup>; <sup>1</sup>Duke University, <sup>2</sup>University of Michigan at Ann Arbor – Dominance contests are a critical component of determining the leadership of social hierarchies across a wide range of species. In modern human societies, this dominance contest often takes the form of a democratic election. Across mammalian species, specific testosterone and cortisol responses are uniquely linked to winning and losing dominance competitions. However, it is unknown whether these patterns of hormone response to winning and losing extend beyond

interpersonal competitions to the societal context of political elections. The present study investigated voters' testosterone and cortisol responses to the outcome of the 2008 United States Presidential election. 183 participants at two research sites (Michigan and North Carolina) provided saliva samples at several time points before and after the announcement of the winner on Election Night. Radioimmunoassay was used to measure cortisol and testosterone levels in participants' saliva. Relative to earlier in the evening, male Barack Obama voters had stable post-outcome testosterone levels, whereas testosterone dropped in male John McCain and Robert Barr voters. There was no effect of candidate choice on testosterone change in female voters. For voters of both sexes in North Carolina, McCain and Barr voters had post-outcome cortisol increases while Obama voters had stable post-election cortisol levels. Cortisol levels after the outcome of the election were positively correlated with a measure of political conservatism in North Carolina voters. Our data suggest that voters physiologically respond to the outcome of political elections depending on if their candidate wins or loses as if they had participated in an interpersonal dominance contest.

**B202****RECEPTOR GENES FOR OXYTOCIN (OXTR) AND VASOPRESSIN (AVPR1A) PREDICT INTERPERSONAL TRUST AND BELIEF IN A JUST WORLD**

Michael Poulin<sup>1</sup>, E. Alison Holman<sup>2</sup>; <sup>1</sup>University at Buffalo, <sup>2</sup>University of California, Irvine – Two individual differences that shape social cognition and behavior are belief in a just world (BJW) and interpersonal trust. Research on the origins of these individual differences has focused on environmental influences, however, it is possible that individual differences in BJW and trust are also genetically influenced. The present study examined whether two sets of genes influence BJW and interpersonal trust: the receptor genes for the hormones/neuropeptides oxytocin and vasopressin, respectively. Research on humans and non-human animals has found that oxytocin and vasopressin are linked to a variety of social phenomena, with oxytocin specifically promoting bonding and prosocial behaviors and vasopressin tied to prosocial behaviors as well as aggression and dominance. To test whether receptor genes for oxytocin and vasopressin would predict BJW and trust, we examined data from a nationally-representative sample in the U.S. Individuals completed surveys online, including Janoff-Bulman's (1989) World Assumptions Scale, which assesses BJW and trust. Then saliva samples from a subset of these participants (N = 386) were collected by mail and DNA was extracted and analyzed. Analyses indicated that one single nucleotide polymorphism (snp 2254298) of the oxytocin receptor (OXTR) gene predicted levels of both BJW (z = 2.71, p < .01) and trust (z = 2.62, p < .01). By contrast, the length of one restriction segment (rs1) of the vasopressin receptor gene (AVPR1a) only predicted levels of BJW (z = 2.00, p < .05). Individual differences in the oxytocin and vasopressin systems may shape basic beliefs about the social world.

## Social Development

**B203****NO FAIR COPYCAT: CHILDREN'S UNDERSTANDING OF IDEAS**

Alex Shaw<sup>1</sup>, Kristina Olson<sup>1</sup>; <sup>1</sup>Yale University – Psychologists have long believed that the objects we own are part of who we are. If this is true, one might expect that our ideas would make up an even stronger part of who we are. Yet surprisingly little research has been done investigating how intuitions about ownership of ideas develop. To investigate the developmental emergence of ownership for ideas, our first two studies investigated children's responses to idea theft – plagiarism. If children respond negatively to plagiarism, this would provide evidence that they apply ownership to ideas. In Study 1 we found that 6-11 year olds and adults liked plagiarizers less than unique drawers, indicating an intolerance of idea theft by middle childhood. Study 2 investigated this question with 3-6 year olds using video stimuli. Five and six year olds evaluated plagiarizers more negatively than unique drawers, but 3-4 years olds did not differentially evaluate the drawers. These results provide prelimi-

nary evidence that by age 5 children assign ownership to ideas. In a second set of studies we investigated whether or not children's intuitions about ownership are similar for objects and ideas. Adults and children endorse the first possession heuristic for objects (Friedman, 2008), inferring that the person who first touches an object owns it. In Study 3 we investigated whether 6-9 year olds apply the same first-possession heuristic to ideas, finding evidence that they do. These experiments provide the first evidence that children apply ownership to ideas and may use similar heuristics to determine ownership for objects and ideas.

#### B204

**TRANSITIONS WITHIN FACES PREDICTS INFANTS' ABILITY TO DISTINGUISH OTHER-RACE FACES** Sarah Gaither<sup>1</sup>, Scott P. Johnson<sup>2</sup>; <sup>1</sup>Tufts University, <sup>2</sup>University of California, Los Angeles – The other-race effect is the well-documented difficulty distinguishing faces not from one's own race, but the age at which this tendency first develops is still in question. It is common knowledge that early experiences through everyday interactions and events play a crucial role in the development of face processing, but little is known about how we learn to distinguish faces from races different than our own, especially for people from multiracial backgrounds. In this study, multiracial stimuli adds to the understanding of why infants exhibit this effect which in turn helps shed light on the nature and underlying mechanism of this social perceptual phenomenon. We investigated three-month-old Caucasian, Asian, and Biracial (half Caucasian, half Asian) infants' ability to distinguish Caucasian and Asian faces, comparing the scanning techniques used while viewing these faces through an infant-controlled habituation paradigm displayed on a Tobii 1750 eye tracker. All racial groups exhibited an other-race effect, such that infants were able to distinguish faces better within their own race than outside of their race. Infants did not seem to employ a special scanning strategy when scanning faces from their own race, but with other-race faces, only infants who scanned more overall were able to distinguish them. These findings illustrate that the other-race effect is "real" within infancy and that "overcoming" this effect can be accomplished by focusing extra attention to faces as opposed to the rest of the area of a stimulus.

#### B205

**RAISING DIFFICULT CHILDREN: PARENTS' PERSONALITY AND CHILDREN'S TEMPERAMENT AS PREDICTORS OF FUTURE PARENTING AND DEVELOPMENTAL OUTCOMES** Jamie Koenig<sup>1</sup>, Robin Barry<sup>1</sup>; <sup>1</sup>University of Iowa – This multi-method, multi-trait study of 102 mothers, fathers, and children examined children's difficult temperament as a moderator of longitudinal links between parental personality traits and future parenting and child outcomes. When children were infants, their parents described themselves on the Big Five traits and three Socialization sub-traits: memories of stable and happy home, optimism, and conventionality. Children's difficult versus easy temperament was observed at 25 and 38 months in standardized laboratory paradigms that assessed anger proneness and capacity for self-regulation. The outcomes -- parents' responsive, affectively positive parenting observed in naturalistic interactions and children's conduct problems rated by parents -- were both assessed at 67 months. Regardless of child temperament, for mothers, low Neuroticism and high optimism, and for fathers, high Extraversion, optimism, and memories of stable home predicted adaptive outcomes. When raising difficult children, mothers who scored high on Openness, optimism, and memories of stable, happy homes had better outcomes than those who scored low on those traits, and fathers who scored high on Openness and low on Neuroticism had better outcomes than those who scored low on Openness and high on Neuroticism. There were no relations between parents' traits and outcomes unique to easy children. Challenges due to children's difficult temperaments can amplify links between some parental traits and outcomes.

#### B206

**WHITE AND BLACK CHILDREN'S REASONING ABOUT THE STABILITY OF LANGUAGE** Jocelyn Dautel<sup>1</sup>, Katherine Kinzler<sup>1</sup>; <sup>1</sup>University of Chicago – Past research suggests that young children view both race and language as traits that remain stable across the lifespan, and are endowed via biological inheritance (Hirshfeld, 1995; 1996; Hirshfeld & Gelman, 1997). Here we aim to directly compare children's reasoning about the stability of race and language across the lifespan in order to identify potential priorities in children's reasoning about social categories. Four populations of children viewed a series of trials in which they first saw an image of a child who was either White or Black, and spoke in either English or French. Child participants were then asked which of two adults the target child would grow up to be – one adult was a "match" to the target child in race but not in language, and the other a "match" in language but not race. Consistent with adult intuitions, 9-10-year-old White children chose the race-match. In contrast, White 5-6-year-old children in both diverse and homogeneous environments chose the language-match. Yet, Black 5-6-year-old children, like the older White children, chose the race-match. We conclude that children view language as an important marker of identity early in development, and that membership in a racial minority group may highlight children's reasoning about race as a stable marker of identity.

#### B207

**DEVELOPMENTAL UNDERSTANDING OF INTELLECTUAL PROPERTY** Jennifer Barnes<sup>1</sup>, Kristina Olson<sup>1</sup>; <sup>1</sup>Yale University – As human adults, we readily assign ownership not only to physical objects, but also to creative endeavors and ideas. While some research has investigated children's developing understanding of physical property (e.g. Friedman and Neary, 2008), very little is known about young children's understanding of intellectual property. In this study, we explored developmental trends in children's reactions when their intellectual property is violated. Four, five, and six year olds were asked to make up an imaginative story and tell it to an adult experimenter. Their stories were then retold to a third party without their permission and their reactions were videotaped. In a control condition, children were explicitly credited with making up the story, while in experimental conditions they were not given credit, either because the experimenter simply neglected to discuss the story's origin, or because the experimenter pretended to make it up herself in order to receive a prize. Five and six year old children objected significantly more often when the experimenter explicitly stole their story than when they were given credit, while four year old children behaved similarly across conditions.

#### B208

**PARENTAL DEPRESSION AND CHILDREN'S CAUSAL UNCERTAINTY** Kevin Rounding<sup>1</sup>, Jill A. Jacobson<sup>1</sup>, Eliane Boucher<sup>1</sup>; <sup>1</sup>Queen's University – Little, if any, research has examined the developmental roots of chronic causal uncertainty, that is, uncertainty about one's ability to understand the causal nature of social interactions (Weary & Edwards, 1994). High levels of parental depression are associated with increased parental rejection and less parental engagement, consistency, and synchrony with their children's behavior and emotions (Elgar et al., 2007; Lovejoy et al., 2000). We hypothesized that the noncontingent behavior of depressed parents could contribute to their children's lack of confidence in understanding social causation. We also examined if offspring's causal uncertainty played a mediational role in the relationship between parental depression and offspring's depressive symptoms. To this end, 128 college students reported their perceptions of parental levels of depression using a 34-item measure tapping symptoms for both parents (Rounding & Hart, 2008). Participants also completed the Beck Depression Inventory-II (Beck, 1996) and the Causal Uncertainty Scale (Weary & Edwards, 1994). After controlling for the effects of gender, age, and offspring's depression, parental depression was a significant predictor of offspring's causal uncertainty scores. Additionally, parental depression and causal uncertainty together accounted for 25.4% of variability in offspring depressive symptomatology. Furthermore, the relationship between

parental depression and offspring depression was partially mediated by causal uncertainty. In sum, one developmental precursor to chronic causal uncertainty appears to be exposure to high levels of parental depression, and the causal uncertainty that results from such an experience contributes to one's own depressive symptomatology. Future research should attempt to replicate these findings using a prospective design.

### B209

#### **EGO DEVELOPMENT AND SELF-ESTEEM AS PREDICTORS OF SEXUAL BEHAVIOR AMONG FEMALE ADOLESCENTS** Kara Phaedra Massie<sup>1</sup>, Krisanne Bursik<sup>1</sup>, <sup>1</sup>Suffolk University

The majority of older adolescents are sexually active. Although many adolescents are capable of making healthy choices regarding sex, there continue to be high rates of pregnancy and sexually transmitted infections among the youth demographic. In order to design interventions that better target sexual risk-taking, it is first necessary to identify factors that predict such behavior. Loevinger's model of ego development provides a lens for examining sexual risk-taking (i.e., unprotected sex, multiple sexual partners, and/or heightened substance use during sexual activity). We examined the theory-driven hypothesis that adolescents at higher developmental stages would engage in healthier sexual practices than those lower in ego development. Self-esteem has also been hypothesized to influence sexual behavior, although empirical results have been mixed. This study evaluated the relative importance of ego development and self-esteem in predicting the sexual attitudes and behaviors of female adolescents. A total of 118 women (M age = 18.12) in their first semester of college completed self-report measures of perceived sexual rights, social pressure, sexual risk-taking, and self-esteem, as well as a projective measure of ego development. Regression analyses indicated ego development was a significant predictor of perceived social pressure; self-esteem significantly predicted the endorsement of sexual rights, reduced perception of social pressure, and diminished sexual risk-taking. Although self-esteem was the better predictor of sexual attitudes and behaviors for this sample, the findings suggest a need for additional research with a broader range of developmental levels.

### B210

#### **THE ROLE OF NEED FULFILLMENT IN PREDICTING DEVELOPMENTAL EXPERIENCES IN ADOLESCENTS PARTICIPATING IN STRUCTURED EXTRACURRICULAR ACTIVITIES AND UNSTRUCTURED HOBBIES** Andrew B. Lumb<sup>1</sup>, Celine M. Blanchard<sup>1</sup>, <sup>1</sup>School of Psychology, University of Ottawa

**OBJECTIVES:** To determine how different youth activities and psychological variables from Self-Determination Theory contribute to the prediction of personal and interpersonal developmental experiences in adolescents participating in structured extracurricular activities supervised by an adult mentor, and those who participate in unstructured hobbies that are not supervised by an adult mentor. **METHODS:** Adolescents (N = 147) completed questionnaires in a classroom setting. Participants reported the number of hours spent per week participating in different types of sedentary and exercise activities, answered questions related to psychological need satisfaction as provided by adult mentors, parents, and life in general, and completed the Youth Experience Survey 2.0 to assess personal and interpersonal developmental experiences pertaining to their structured extracurricular activities or hobbies. For analyses, participants were grouped based on their involvement in structured extracurricular activities or in unstructured hobbies. **RESULTS:** For participants in structured extracurricular activities, hierarchical regression analyses revealed that higher levels of sedentary activity were associated with decreases in personal and interpersonal developmental experiences and psychological need satisfaction provided by an adult mentor significantly increased the proportion of variance accounted for in personal and interpersonal developmental experiences. Regression analyses for participants in unstructured hobbies were not significant. **CONCLUSIONS:** For adolescents in structured extracurricular activities, the fulfillment of three fundamental needs of autonomy, competence, and relatedness by an adult mentor appears to

contribute significantly to personal and interpersonal developmental experiences, above and beyond different types of youth activities experienced. Implications for these findings and future directions will be discussed.

### B211

#### **EATING AS AN ESCAPE: THE ASSOCIATION BETWEEN PEER VICTIMIZATION, IMPULSIVITY, INTERNALIZING EMOTIONS, AND DISORDERED EATING** Elizabeth Ewing Lee<sup>1</sup>, Amber Koblitz<sup>1</sup>, Katie Gordon<sup>1</sup>, Wendy Troop-Gordon<sup>1</sup>, <sup>1</sup>North Dakota State University

It has been shown that children who are victimized by their peers (e.g., bullied, teased) are more likely than other children to engage in dysregulated eating (Aime, Craig, et al., 2008; Striegel-Moore, et al., 2002). Little is known, however, as to what factors may contribute to overeating among victimized youth. For example, highly impulsive children may be the most likely to engage in out-of-control behaviors, such as overeating, as a way to cope with the negative emotions caused by peer harassment. Alternatively, victimized children who have lower levels of impulsivity may be more prone to dysregulated eating precisely because they do not engage in other, more impulsive coping strategies (e.g., fighting back). Data from 422 4th- and 5th-grade children (223 girls) were collected to test these competing theories. Regression analyses revealed that peer victimization was predictive of greater eating dysregulation only among girls who were low in impulsivity and low in internalizing distress. This finding held for both self-reported and peer-reported victimization. The results are consistent with past findings that disordered eating is correlated with difficulty identifying emotions (which may explain low self-reported internalizing symptoms despite peer victimization). Moreover, girls who are victimized, but low in impulsivity, may be more likely to overeat as a way to escape from painful emotions (Heatherington & Baumeister, 1991). These findings emphasize the importance of identifying those children who, though seemingly healthy (i.e., not impulsive or internalizing), overeat in response to victimization from peers.

## **Social Judgment/Decision-Making**

### B212

#### **PREVIOUS MERE EXPOSURE GUIDES BEHAVIORAL APPROACH CHOICES** Isaiah F. Jones<sup>1</sup>, Heather M. Claypool<sup>1</sup>, <sup>1</sup>Miami University

Previous unreinforced presentations of stimuli result in increased liking of those stimuli, a phenomenon known as the mere exposure effect (e.g., Zajonc, 1968). Though the vast majority of examinations of the mere exposure effect have focused on Likert-type judgments, in our lab, we have shown that previous mere exposure to a stimulus can facilitate the speed with which it is approached. This previous work showed that if directed to approach an object, those that are familiar will be approached faster than their novel counterparts. The current investigation, however, examined whether previous mere exposure to stimuli could direct actual behavioral choices. It was hypothesized that participants would be more likely to choose to approach previously exposed, versus novel, stimuli. Participants were randomly presented 30 Chinese ideographs, each for one second. Subsequently, participants were shown 60 ideographs, 30 of which they had previously seen and 30 of which were novel, and were asked to make either an approach or an avoidance motion toward each. As predicted, approach motions were more frequently chosen for the familiar (M=15.41) than the novel (M=14.15) stimuli,  $t(58)=2.46, p=.02$ . Thus, these findings indicate that participants are more likely to choose to approach a familiar stimulus and that the mere exposure effect is robust enough to direct overt behavior.

### B213

#### **NEGATIVE REACTIONS TOWARD INNOCENT VICTIMS OF RAPE: STRONGER EFFECTS WHEN PERPETRATORS ARE SIMILAR TO YOU** Michéle Bal<sup>1</sup>, Kees Van den Bos<sup>1</sup>, <sup>1</sup>Utrecht University

Building and extending on just world theory, we studied people's negative reactions to innocent victims of rape or sexual assault. Specifically, we focus on an

as yet unexplored variable that may help to explain these reactions, namely whether the perpetrator of the crime was similar or dissimilar to people who were confronted with what happened to the victim. Perpetrator similarity refers to whether the perpetrator belongs to the personal world of the observer or not. Following just world theory we expected that people would react more negatively toward victims of a similar perpetrator as opposed to a different perpetrator. In one behavioral study and two questionnaire-studies we found that especially men take more physical distance from an innocent victim (Study 1) and blame (Study 2) and derogate (Study 3) an innocent victim more when the perpetrator is similar to them as opposed to when the perpetrator is different from them.

**B214**

**SELF-AWARENESS AND TIME PERCEPTION** Wade Goldstein<sup>1</sup>, Sean Stevens<sup>1</sup>, David Wilder<sup>1</sup>; <sup>1</sup>Rutgers University – The present experiment examined the relationship between focus of attention and subjective perception of time. Persons immersed in a task often report that "time flies" whereas those bored find their minds wandering from the task and report that "time drags." Subjective perception of time appears to be related to focus of attention such that disruption of attention is associated with greater perceived task duration. Therefore, encouraging a person to withdraw from a task by focusing attention on oneself should result in increased estimation of time spent working on the task. To examine this hypothesis, participants performed two activities (a reading comprehension task and a mechanical task) of equal duration and were then asked to estimate the time they spent working on each. Half of the participants completed the tasks in front of a mirror, a prop used to induce self-awareness. Participants in the mirror condition made significantly longer estimates of time spent on both tasks than did subjects in the no mirror condition. Moreover, participants who were made self-aware rated one of the tasks as more boring and less interesting than those not made self-aware. Overall, results demonstrated that self-awareness triggered judgments of longer task duration than when attention was focused solely on the task. The perception of time was positively related to conscious self-awareness regardless of whether the task was "intrinsically" interesting or boring. Thus, judgments of duration may be lengthened by directing attention to the self and shortened by focusing attention externally on the task itself.

**B215**

**EFFECTS OF VERTICAL POSITION ON JUDGMENTS OF REASON AND INTUITION** Christina Carino<sup>1</sup>, Thomas Gilovich<sup>2</sup>; <sup>1</sup>University of Michigan, <sup>2</sup>Cornell University – While embodied cognition research has begun to examine the role aphors in concept representation and processing, there is a great room for expansion. Building on previous research in embodied cognition (Barsalou, 1999) and metaphor-representation (Lakoff & Johnson, 1999), we were interested in the implications of linking the abstract concepts of reason and intuition to vertical metaphors (e.g., "think with your head", "higher order cognition"). The current work provides evidence that there does exist an automatic association between reason-up and intuition-down and that this automatic association has implications for social judgments. Participants completed a judgment task in which they were asked to rate the extent to which strangers rely on their reason or intuition in everyday decision making. While the rating scale was always presented in the vertical middle of the computer screen, half of the faces were presented above the rating scale and the other half below the rating scale. Participants judged individuals whose picture was presented at a high (vs. low) vertical location as more reliant on their reason (vs. intuition) in everyday decision making. Additional studies ruled out the possibility that this biased judgment was due to biased judgments of power or niceness. The current findings suggest that even abstract embodied metaphors have the ability to bias our social judgments of those around us.

**B216****THE REPUGNANCE EFFECT: MONEY AND MORAL TRANSGRESSIONS**

Eranda Jayawickreme<sup>1</sup>, Pavel Atanasov<sup>1</sup>; <sup>1</sup>University of Pennsylvania – We present evidence for a "repugnance effect" for transgressions committed in the presence of monetary incentives. This effect follows an inverted V pattern. We hypothesized that when transgressions are committed in the presence of monetary incentives, the implicit trade-offs that the actors make may increase the actions' offensiveness, as people are uncomfortable with trading off certain values. Study 1 found that transgressions committed in the presence of a small monetary incentive (\$100) were seen as significantly more offensive than transgressions committed for no incentive or a large incentive (\$100,000). This counters the argument that extrinsic motivation (i.e. money) should discount the significance of transgressions. The repugnance effect was strongest for fairness-based violations, and for violations of moral foundations that participants listed as most important. The effect was independent of political affiliation or dispositional forgiveness ratings. Both perceived offensiveness and the repugnance effect were positively associated with subjective well-being. Study 2 found a similar inverted V pattern in a multinational sample. Unlike Study 1, transgressions committed for a large incentive were seen as significantly less offensive than compared to the other two conditions, a difference explainable by the lower average income in the international sample. Study 3 suggested a role for moral emotions, (e.g. disgust) in explaining the phenomenon. Namely, disgust ratings in the evaluation of fairness-based transgressions were significantly higher in the low incentive condition, compared to the other two conditions.

**B217****MAKING SENSE OF THE PAST: NARRATIVE AND OUTCOME ORDER AFFECTS HINDSIGHT JUDGMENTS**

Paul M. Miceli<sup>1</sup>, Lindsay A. Kennedy<sup>1</sup>, Lawrence J. Sanna<sup>1</sup>; <sup>1</sup>University of North Carolina at Chapel Hill – Hindsight bias (Fischhoff, 1975) influences how people make sense of the past. We tested the novel hypothesis that receiving information leading up to events in coherent or random order, along with receiving outcome knowledge before or afterwards, influences the sense-making process. This question is of theoretical and practical significance. For example, the CIA received information leading up to the 9/11 terrorist attacks in a random, fragmented manner before the event, making sense only retrospectively; the American public learned of the attacks first and then learned of possible reasons for them afterwards. We used a 2 (Narrative Order: Logical vs. Random) x 2 (Outcome Order: Before vs. After) between-subjects design with a fictional narrative that attempted to model the main qualities of the 9/11 attacks. Participants read the narrative in either a logical, coherent order (maintaining a time-line sequence of events) or a random order (a random shuffling of the events). Additionally, participants received information about the event outcome either before or after reading the narrative. Results provided strong support for the hypothesized interaction between narrative order and outcome order. Notably, participants rated the outcome as most inevitable in the random order narrative when the outcome was known afterwards, but most inevitable in the logical order narrative when the outcome was known beforehand. The former models the CIA's perspective on the 9/11 attacks, and the latter models the American public's possible perspective, implicating different levels of blame and perceptions that the attacks should have been foreseen and prevented.

**B218****THE ROLE OF DISGUST SENSITIVITIES IN MORAL HYPOCRISY**

Jessica A. Stansbury<sup>1</sup>, Geoffrey D. Munro<sup>1</sup>; <sup>1</sup>Towson University – The role of disgust as a contributing factor in moral hypocrisy and immoral actions was examined. Moral hypocrisy is presenting one's self as moral, while not actually acting morally (i.e., serving one's own self interest). Research shows that disgust can cause a change in a person's moral action, with an increase toward moral hypocrisy. A disgust manipulation was used to test several hypotheses that disgust influences immoral behavior. Participants completed the Disgust Scale-Revised weeks prior to the experiment. Then, 125 participants were randomly assigned to either the high

or low disgust conditions (i.e., wearing sweaters from a homeless man or a used clothing store). Using the moral hypocrisy paradigm (Batson et al., 1997), participants were presented with two different tasks, one neutral task and one task designed to elicit either high or low disgust. They were asked to assign the two tasks to themselves and another participant via selecting the task assignment or assigning the tasks using a randomized process, flipping a coin. As hypothesized, a logistic regression revealed that those experiencing high disgust were more likely to display immoral, selfish task assignment than those experiencing low disgust. Demonstrating moral hypocrisy, of those experiencing high disgust that flipped the coin, 82.1%, rather than the 50% expected by a fair coin flip, assigned themselves the easy task. As predicted, the three subscales of disgust were significant predictors of immoral actions. This suggests that disgust sensitivities can affect individuals by leading them to ignore their moral values and commit less moral actions.

**B219**

**NUDGING YOU BEHIND YOUR BACK: THE INFLUENCE OF FRIENDSHIP MENTAL REPRESENTATIONS ON RISK TAKING PROPENSITY** Kai Qin Chan<sup>1</sup>, Eddie Mun Wai Tong<sup>1</sup>, Teresa Ai Ling Moh<sup>1</sup>; <sup>1</sup>National University of Singapore – Past research has indicated that people take greater risks when their friends are around in both real life situations (e.g. driving) and in laboratory settings. In our research, we propose that risk taking scripts are a component of people's relational schema with their friends because of the frequent association between the presence of friends and risk taking instances. Across 2 experiments, the authors investigated whether the subliminal activation of cognitive representations of people's friendship would lead to greater risk taking propensity. In Study 1, participants subliminally primed with their friend's name (vs. those primed with neutral valence words) showed higher risk taking tendencies in a behavioral measurement of risk taking, the Balloon Analogue Risk Task (BART; Lejuez et al., 2002). In Study 2, we replicated Study 1's findings using yoked control name primes for comparison and also included an additional manipulation of threat and found that when threatened, those who were primed with nonfriends show a decrease in risk taking. The notion of risk taking as an interpersonal script and the independent influence of intrinsic social influences (e.g., sense of security) versus extrinsic social influences (e.g. persuasion) on risk taking are discussed.

**B220**

**WILL I DIVORCE OR HAVE A HAPPY MARRIAGE?: GENDER DIFFERENCES IN COMPARATIVE OPTIMISM AMONG U.S. COLLEGE STUDENTS** Marie Helweg-Larsen<sup>1</sup>, Hilary Harding<sup>2</sup>, Bill Klein<sup>3</sup>; <sup>1</sup>Dickinson College, <sup>2</sup>University of Georgia, <sup>3</sup>University of Pittsburgh – Previous research shows inconsistent evidence in regard to gender differences in comparative risk estimates for experiencing a happy marriage or avoiding divorce. Results from four samples of unmarried college students (N = 814) indicated that men exhibited greater comparative optimism than women for having a happy marriage/avoiding divorce. The effect was due to differences in personal risk estimation as opposed to differences in other risk estimation. For women (but not men), having divorced parents was associated with more pessimistic personal estimates. For men (but not women), greater perception of control over relationship outcomes was related to more optimistic personal estimates. Results are discussed as they relate to the existing literatures on risk perception and gender differences in romantic relationships.

**B221**

**AVOIDING RISK BY SEEKING UNCERTAINTY** James Leonhardt<sup>1</sup>; <sup>1</sup>University of California, Irvine – Expected utility theory predicts that when faced with a certain and an uncertain gamble, with equal expected utilities, decision makers will prefer certainty over uncertainty. However, the present study demonstrates that preference for certainty is mediated by responsibility; so that, all else being equal, as perceived responsibility increases preference for certainty decreases. To test this claim participants chose between two certain options and an uncertain

option. Unlike the Asian Disease Problem (Tversky and Kahneman, 1981) the uncertain option did not offer the possibility of avoiding a loss altogether and the outcome of each option was known by participants to be of equal value. Perceived responsibility was manipulated by asking participants to choose for themselves, an unidentified person, an unidentified baby, and an identified person. Uncertainty was preferred by 37% of participants when choosing for themselves, by 46% of participants when choosing for an unidentified person, by 63% of participants when choosing for an unidentified baby, and by 67% when choosing for an identifiable person. In addition, there was no gain/loss framing effect and women preferred uncertainty more than men. These results support the idea that uncertainty seeking is not always synonymous with risk seeking. When confronted with choices bearing responsibility, liability is limited by seeking options requiring the least action from the chooser. In this way, uncertainty seeking can be the result of responsibility aversion—a product of risk aversion.

**B222**

**PREDICTING STOCK SUCCESS: COMPANY NAME COMPLEXITY, PROCESSING FLUENCY, AND CONSUMER CONFIDENCE** Carly S. Hennessy<sup>1</sup>, David A. Armor<sup>1</sup>; <sup>1</sup>San Diego State University – In an influential paper, Alter and Oppenheimer (2006) report that investors are biased by the complexity of company names, expecting that simply-named companies will outperform companies with more complex names, at least over the short term. Alter and Oppenheimer interpret this finding in terms of processing fluency, arguing that (a) simple names are easier to process psychologically than complex names, and that (b) inferences based on fluency (such as of a company's familiarity or likeability) influence predictions about company performance. In three studies, we show that the name complexity effect is reliable, but reject the processing fluency interpretation. Study 1 replicated the effect of name complexity under conditions that closely resembled Alter and Oppenheimer's (2006) experiment. However, results from three additional conditions did not support fluency-based predictions: (1) drawing attention to the source of disfluency (i.e., pronounceability) did not eliminate the name complexity effect, (2) inducing participants to attribute disfluency to a lack of familiarity (a hypothesized mediator) did not yield evidence of mediation, and (3) altering the implications of disfluency (i.e., that complexly-named companies may be more creative) did not reverse the name complexity effect. Studies 2 and 3 suggest a more parsimonious explanation. In Study 2, the magnitude of the name complexity effect was found to vary in proportion to participants' prior belief in the relevance of company name pronounceability to stock performance. Study 3 established the causal effect of these beliefs experimentally. Name complexity thus influences stock valuation, but this effect is not explained by processing fluency.

**B223**

**DOES CONSIDERING DETAILS OF FUTURE SPENDING IMPROVE SPENDING PREDICTIONS?** Johanna Peetz<sup>1</sup>, Roger Buehler<sup>1</sup>; <sup>1</sup>Wilfrid Laurier University – People base important decisions on predictions concerning their future expenditures. However, recent research indicates that personal spending predictions tend to be inaccurate: People predict to spend less during a future week than they actually spend (Peetz & Buehler, 2009). We propose that one reason people underestimate their spending is that they do not consider all the subcomponents of a future expense. According to this account, spending predictions would increase if people were to unpack (list spending components before making an overall prediction) or decompose (predict spending for each component separately and sum the predictions) their future expenses. Three studies tested this hypothesis. In Study 1 students were randomly assigned to unpack, decompose, or simply predict (control condition) their spending for the next week. Actual spending was tracked with daily diaries. Whereas participants in the control condition again underestimated their spending, participants in the unpacking and decomposition conditions made unbiased predictions. The next two studies extended this paradigm to spending predictions for discrete events. Students predicted their expenses for a self-nominated future event (Study 2) and shoppers

entering a mall predicted their shopping trip expenses (Study 3). Unlike spending predictions for a future week, spending predictions for future events were unbiased in the control condition. Nevertheless, unpacking and decomposition procedures again increased spending predictions - which in this case led to the overestimation of actual spending. It appears that breaking a future expense into its subcomponents results in spending predictions that are higher, but not necessarily more accurate.

#### B224

**SPREAD OF ALTERNATIVES AS A FUNCTION OF SELF-CONSTRUAL SALIENCE AND SUBTLETY OF PRIME** Bernice L. Z. Khoo<sup>1</sup>, Ya Hui Michelle See<sup>1</sup>, Teck Hyen Ray Chee<sup>1</sup>; <sup>1</sup>National University of Singapore – Research on cross-cultural differences in cognitive dissonance has largely examined the influence of self-construal by using culture as a proxy (Heine & Lehman, 1997; Kitayama et al., 2004). In such research, participants from collectivistic cultures exhibited lower spread of alternatives than participants from individualistic cultures after making a personally relevant decision. The current research directly tests the causal role of self-construal in the spread of alternatives by manipulating self-construal. In Experiment 1, participants were primed with both a newly-developed linguistic device and pictorial primes. Contrary to past studies, collectivistic self-construal participants tended to exhibit higher spread of alternatives than individualistic self-construal participants,  $F(1, 58) = 3.51$ ,  $p = .07$ . Experiment 2 added a linguistic device only (subtle-cue) condition in order to explore two plausible explanations - Standards Model and the Set/Reset Model, for the contrast effects obtained in Experiment 1. As expected, collectivistic self-construal participants in the subtle-cue condition exhibited lower spread of alternatives than individualistic self-construal participants,  $F(1, 30) = 6.07$ ,  $p = .02$ , thus replicating past cross-cultural studies. Furthermore, the results of Experiment 1 were replicated in the blatant-cue condition,  $F(1, 31) = 3.15$ ,  $p = .09$ . This occurred even though collectivistic self-construal participants wrote a greater proportion of collectivistic self-descriptions than individualistic self-construal participants, thus suggesting that the contrast effects could be explained by correction processes described in the Set/Reset Model. Most importantly, the current research provides direct evidence for the causal relationship between self-construal and spread of alternatives that has been suggested by previous cross-cultural research.

#### B225

**BIDIRECTIONAL LINKS BETWEEN COUNTERFACTUAL THOUGHTS AND INFORMATION PROCESSING STYLES** Kai Epstude<sup>1</sup>, Jens Förster<sup>2</sup>, Neal J. Roese<sup>3</sup>; <sup>1</sup>University of Groningen, <sup>2</sup>University of Amsterdam, <sup>3</sup>Northwestern University – Thoughts about alternatives to past events have been shown to influence individuals' performance on a variety of tasks. A very consistent finding is that thoughts about what one should have done (additive counterfactuals) enhance creativity, while thoughts about what one shouldn't have done (subtractive counterfactuals) lead to an increased performance on analytic tasks. Two studies examining the underlying process of such effects are presented. In Study 1 individuals were asked to generate additive vs. subtractive counterfactual thoughts. As predicted, we found that this manipulation led to differences in global vs. local perception as measured by the Navon (1977) task. Individuals who generated additive thoughts processed information more globally. Conversely, individuals who generated subtractive counterfactual thoughts processed information more locally. In Study 2 this logic was reversed. In particular, we primed participants with a global vs. local perception style, and then asked them to generate counterfactual thoughts. As predicted, the activation of a global perception style led participants to report mainly additive counterfactual thoughts whereas the activation of a local perception style enhanced the occurrence of subtractive counterfactual thoughts. The connection to previous findings on links between counterfactual thoughts, perception styles and motivational variables (i.e. regulatory focus) will be discussed.

#### B227

**TRUST DEVELOPMENT: TESTING A NEW MODEL IN RANDOMLY ASSIGNED UNDERGRADUATE ROOMMATE PAIRS** Corrie Whitmore<sup>1</sup>, Julie Dunsmore<sup>2</sup>; <sup>1</sup>University of Alaska Anchorage, <sup>2</sup>Virginia Tech – Interpersonal trust reflects a vital component of all social relationships. Trust has been linked to a wide variety of individual and group outcomes in the literature, including personal satisfaction and motivation, willingness to take risks, and organizational success (Dirks & Ferrin, 2001, Pratt & Dirks, 2007, Simpson, 2007). This project tested a new conceptual model evaluating the roles of attachment, propensity to trust, perceived similarity of trustee to self, and social exchange processes in trust development with randomly assigned, same-sex undergraduate roommates. Two hundred and fourteen first-year students (60% female, 85% Caucasian, mean age = 18) at a large south-eastern university completed self-report measures once per week during the first five weeks of the fall semester. Perceived similarity measured the second week of classes and social exchange measured three weeks later combined to provide the best prediction of participants final trust scores. Attachment and propensity to trust, more distal predictors, did not have a significant relationship with trust. This study demonstrated that trust is strongly related to perceived similarity, as well as social exchange. A prime contribution of this study is the longitudinal, empirical test of a model of trust development in a new and meaningful relationship. Future work may build on this research design and these findings by focusing on early measurement of constructs, measuring dyads rather than individuals, and incorporating behavioral measures of trust.

#### B228

**COUNTERFACTUAL INFLATION HYPOTHESIS: COUNTERFACTUAL THINKING AND CONFIDENCE IN BLACKJACK** John Petrocelli<sup>1</sup>, Laura Crysel<sup>2</sup>; <sup>1</sup>Wake Forest University, <sup>2</sup>University of Florida – This research tests the idea that repeatedly generating counterfactual thoughts in response to recurring events can lead to impairments in memory for actual outcomes (i.e., counterfactual inflation hypothesis). Participants ( $N = 56$ ) played 40 games of blackjack and listed their thoughts after each win. They were instructed to list evaluative counterfactuals, reflective counterfactuals, or any thoughts that came to mind following each loss. Because reflective counterfactuals focus only on the alternatives to reality, and not in addition to reality (like evaluative counterfactuals), they were expected to lead to the greatest degree of overestimations of performance and confidence for future blackjack playing. The results confirmed this hypothesis, and also demonstrated that the relationship between thought-listing instructions and confidence for the future was mediated by overestimations of performance. Thus, repeatedly generating reflective counterfactual thoughts appears to lead to a special case of imagination inflation with dysfunctional implications for future confidence and risk-taking.

#### B229

**CREATIVITY AND THE UNCONSCIOUS: HOW UNCONSCIOUS THOUGHT HELPS TO CHOOSE YOUR MOST CREATIVE IDEA** Simone M. Ritter<sup>1</sup>, Ap Dijksterhuis<sup>1</sup>, Rick B. van Baaren<sup>1</sup>; <sup>1</sup>Radboud University Nijmegen, Behavioural Science Institute – When asked to introspect on the process leading to their creations or discoveries, creative people often emphasize the crucial role of the unconscious. The question we address is during which stage in the process the unconscious is important. In order to be creative, it is not only crucial to generate ideas, but also to choose the most creative one among various ideas (Simonton, 1999). Although it has long been assumed that the unconscious helps to generate ideas, empirical support is less consistent (Sio & Ormerod, 2009). Is it possible that unconscious thought is not that helpful for idea generation, but instead for selecting the most creative idea? To test this hypothesis, participants were asked to write down as many ideas as possible to solve a problem. They either did so after conscious thought, or after a few minutes of distraction during which 'unconscious thought' took place. Afterwards, participants had to choose their most creative (Study 1 & 2) and least cre-

ative idea (Study 2). Participants did not differ in the number of ideas listed, nor in the average originality of their ideas. Unconscious thinkers, however, had an important advantage: they strongly outperformed conscious thinkers in choosing the most creative idea and the least creative idea among all their ideas. These findings suggest that, when you simply want to generate ideas, it does not matter whether you think consciously or unconsciously. However, when you also want to select the most creative idea, make sure you let your unconscious do the work.

### B230

#### APPLYING PAIRED DISTINCTIVENESS TO EXPERIENCE-BASED DECISIONS

Susanne Haberstroh<sup>1</sup>, Aileen Oeberst<sup>1</sup>; <sup>1</sup>University of Osnabrück, Germany – From research on stereotyping (Hamilton & Gifford, 1976) we know that the joint occurrence of two rare events ("paired distinctiveness") can have a strong influence on judgments and decisions. In this study, we applied this approach to a new field of research in decision making - the difference between decisions from experience and decisions from description. In studies on experience-based decision making, participants usually are either presented with a fixed sample (e.g. 50 pieces of information per lottery) or participants sample the information themselves. The influence of diverging sample sizes within a pair of lotteries has not been systematically addressed so far. We combined these two research approaches by studying the impact of events with a low probability in a big or a small sample. Participants were presented with drawings of pairs of lotteries that differed in sample size (within participants: lottery 1= 20 drawings, lottery 2= 100 drawings). One of the lotteries only had one possible outcome, the second lottery was risky: Participants could win a large amount with a low probability or else nothing. Thus, the two rare events (small sample, low probability event) were either paired or not. The decision between the two lotteries was the main dependent variable. The results show that the paired distinctiveness account can be applied to experience-based decisions: Participants are more likely to give more weight to the rare event in the small sample than in the large sample, leading to more risky decisions when the two rare events are paired.

### B231

#### CRITICAL THINKING FALLACIES

Adam Schuman<sup>1</sup>, Geoffrey D. Munro<sup>1</sup>; <sup>1</sup>Towson University – Jury members are instructed to make well-reasoned judgments, but they may use less rational forms of decision-making. Previous research demonstrates that jurors may use heuristics when determining guilt and may render a verdict of guilt without being fully convinced. The current study focused on the logic and logical fallacies used by jury members when rendering a verdict. Thirty-eight participants read a criminal assault case consisting of a brief description of a police report, testimonies, and background information on the plaintiff and defendant. Participants then rendered a verdict on a 9 pt. scale and wrote open-ended responses explaining their verdicts. Following this, the responses were coded for length, forms of arguments, and logical fallacies. Correlational analyses showed that as participants' guilt verdicts increased, they were significantly more likely to use reasoned judgments as their form of argument,  $r(38) = .42$ . Reasoned judgments were defined as assertions of preferences that are supported by reason. A second correlation stated that as words increased, use of reasoned judgment increased,  $r(38) = .40$ . Finally, a correlation yielded that the more words were in a statement, the more logical fallacies were present,  $r(38) = .34$ . These findings suggest that while guilt verdicts used a form of reason, this reason may have involved logical fallacies. This may be the case because delivering a verdict of guilt produces anxiety. Therefore, participants scabbled to find justification for these verdicts by writing longer explanations, and using any reason they could think of.

### B232

#### AFFECTIVE FORECASTING FOR SELF AND OTHERS IN JAPAN: NEGATIVE AFFECT WILL BE MORE DURABLE FOR ME

Yumi Endo<sup>1</sup>; <sup>1</sup>Kansai University, Japan – Affective forecasts depend on the information used by forecasters. A recent study (Igou, 2008) on the self-other effect reported that individuals predicted that their own negative affective reactions would be shorter than would those of others because thoughts about coping strategies were more likely to arise while making predictions about themselves than while making predictions about others. Many researchers have suggested psychological differences between Western and Eastern concepts of the self. The self has been associated with "control" and "agency" in the West, but with "passivity" and "going along with the environment" in the East. This study examined whether the self-other effect in affective forecasting was generalizable to a more interdependent culture. Fifty-three university students focused on themselves or on an acquaintance to answer several questions in writing. Participants predicted that they would experience negative affective reactions for a longer period than would an acquaintance. Furthermore, we found no evidence that respondents accessed knowledge about coping strategies when they made predictions about themselves, even though they had more knowledge about their own coping strategies. Indeed, when respondents predicted the duration of the negative affect experienced by others after they described the coping strategies used by others under a knowledge-activation condition, they predicted shorter durations than they did under the prediction-first condition. However, the order of tasks did not have any effect on the predicted duration of their own reactions. These results were discussed from the perspective of cultural views on the self.

### B233

#### STATUS AS A STRATEGIC GUIDE IN COORDINATION: THE MINIMAL STATUS EFFECT

Poonam Arora<sup>1</sup>, David H. Krantz<sup>1</sup>, E. Tory Higgins<sup>1</sup>;

<sup>1</sup>Columbia University – We examine the influence of status decoupled from power in strategic coordination where power is the ability to control another's outcomes while status is the relative ranking of the individuals involved. Although status and power are distinct psychological concepts, previous research has typically coupled them. We hypothesize that status changes expectations of what the other is likely to do and thus what one should do to coordinate. Participants were randomly assigned to dyads that were assigned to one of two roles (Teammates or Competitors) prior to a status manipulation task that resulted in one becoming a Winner and the other a Loser. Thus participants began the coordination task after winning or losing and as Competitors or Teammates. In Study 1, competitors coordinated based on status, while status was immaterial to Teammates. Additionally, Competitor Losers reported being lower status. Introduction of a dominant strategy in Study 2 increased coordination rates to 100% for Teammates, while Competitors continued to use status as a focal point and only 60% coordinated. Half the Competitor dyads obtained sub-optimal outcomes because coordinating on the winner resulted in the dominant strategy only half the time. In Study 3, allowing dyadic partners to communicate raised coordination rates to 100% for both roles. Teammates were more likely to split earnings equally while Competitors continued to use status as a focal point with the Winner making more substantially more money. Full coordination allowed us to test for mediation and manipulated status mediated choice in the coordination task.

### B234

#### PERSONAL OR PROFESSIONAL: COGNITIVE INFERENCES FROM PROCESSING DISFLUENCY

Hae Joo Kim<sup>1</sup>, Melanie Dempsey<sup>2</sup>; <sup>1</sup>University of Toronto, <sup>2</sup>Ryerson University – Past research suggests that subjective experiences of ease in processing information can affect evaluative judgments (e.g., Zajonc, 1968). In contrast to the extant research showing that fluent stimuli are judged more positively across a range of evaluative judgments (Schwarz, 2004), our research demonstrates that processing disfluency can lead to favorable evaluations of positive attributes, char-

acterized by psychologically distant objects. Sixty-six participants were given a list of 5-letter acronyms as names of various organizations. Inter-mixed with filler acronyms were four easy-to-pronounce names (e.g., TEMBO) and four difficult-to-pronounce names (e.g., CCDPC), all pre-tested with respect to pronunciation difficulty. Participants rated their impressions of each organization on 7-point scales, measuring “personal” attributes ([un]warm, [un]friendly, [un]approachable) and “professional” attributes ([in]competent, [un]professional, [un]competitive). All six attributes were pretested as being equally attractive organizational traits. We find that organizations with disfluent names are rated higher on professional attributes than those with fluent names ( $M_{\text{disfluent}} = 4.77$ ,  $SD = .87$  vs.  $M_{\text{fluent}} = 4.53$ ,  $SD = .73$ ;  $p < .04$ ), whereas the opposite pattern is observed for personal attributes ( $M_{\text{disfluent}} = 3.40$ ,  $SD = .66$  vs.  $M_{\text{fluent}} = 4.39$ ,  $SD = .65$ ;  $p < .01$ ). In line with recent evidence indicating processing disfluency influences construal level (Förster, 2009; Alter & Oppenheimer, 2008), difficult-to-pronounce organizations are construed as distant; hence, individuals evaluate professional traits more positively than personal traits. These findings support the notion that these perceptions are based on a cognitive inference process that differs from the affect-as-information mechanism with which individuals use to evaluate easy-to-pronounce names.

### B235

**BRIDGING THE GAP BETWEEN HYPOTHETICAL MORAL DECISIONS AND REAL WORLD MORAL ACTION** Melissa McDonald<sup>1</sup>, C. David Navarrete<sup>1</sup>, Marc Hauser<sup>2</sup>; <sup>1</sup>Michigan State University, <sup>2</sup>Harvard University – In an investigation of the moral psychology of harm, we explore the relationship between moral judgment and action using a novel methodological approach that taps into a well-studied philosophical dilemma: a simulation of the classic trolley problem using immersive, 3-D virtual reality technology. Participants were placed in front of an operable track switch that controlled the direction of a runaway trolley car that was about to crash into either one or five travelers walking on the tracks. We found that a large majority (89%) of participants acted in a utilitarian manner, that is, they pulled the switch to cause the death of one artificial human avatar in order to save the lives of five and abstained from pulling the switch when doing so would cause five deaths compared to one. Participants showed greater autonomic arousal, as measured by skin conductance response, when the utilitarian outcome required action (pulling the switch) than when it did not. We found no effect of explicit moral beliefs or cultural/demographic factors (including race, gender, education, or conservatism) on moral action. These results highlight the importance of immersive, virtual environments as a research tool for psychological research, and attempt to bridge the gap between judgment and behavior for research questions of extreme moral gravity.

### B236

**REGULATORY FIT ENHANCES HIGH-LEVEL, INCLUSIVE PROCESSING** Leigh Ann Vaughn<sup>1</sup>; <sup>1</sup>Ithaca College – Generally speaking, people experience regulatory fit when their way of engaging with a task sustains their self-regulatory orientation or interests in the task (e.g., Higgins, 2000, 2005). Regulatory fit can add value to what people are doing or thinking, in ways independent of the value that can come from the pleasure or pain of imagined positive or negative outcomes (e.g., Higgins, 2000). The current research integrates regulatory fit theory (e.g., Higgins, 2000, 2005) and research on how mood can affect processing (e.g., Clore et al., 2001; Schwarz & Clore, 2007) to suggest that regulatory fit can strengthen usual styles of thinking in high-level, inclusive ways (cf., Schwarz & Bless, 1992; Vallacher & Wegner, 1989) - but independently of mood. Participants completed an initial, prevention-promotion regulatory-fit manipulation (e.g., Vaughn, Malik et al., 2006) then a measure of action identification (Vallacher & Wegner, 1989) or of categorization (e.g., Isen & Daubman, 1984). Those who experienced regulatory fit (vs. nonfit) in an initial task subsequently engaged in higher-level, more abstract action identification (Experiment 1) and assimilated exemplars more strongly to a superordinate category (Experiment 2). There were no significant main effects for the regulatory focus of imagined goals, con-

sistent with other research that has used this task-incident regulatory-fit manipulation. Also consistent with prior research on regulatory fit, mood did not account for these effects. Rather, it appears that regulatory fit, through enhancing engagement strength (e.g., Higgins, 2006), can enhance usual or accessible styles of task engagement independently of considering pleasurable or painful outcomes.

### B237

**THE FIRST INSTINCT FALLACY: ITS LIMITS AND ITS IMPLICATIONS FOR PERSON PERCEPTION** Samuel Karpen<sup>1</sup>, Edward Hirt<sup>1</sup>, Mersine Bryan<sup>2</sup>; <sup>1</sup>Indiana University Bloomington, <sup>2</sup>Baltimore, Maryland – The false belief that sticking with one's initial response is more profitable than switching to a probable alternative response is called the First Instinct Fallacy (Kruger, Miller, & Wirtz, 2005). This is best illustrated in the classroom where 75% of students and 20% of faculty falsely believe that switching lowers overall exam scores. Even SAT prep manuals periodically advocate sticking. Kruger et al. argue that the FIF originates from counterfactual thought. Since switching is an action, disadvantageous switching causes more counterfactual thoughts than disadvantageous sticking; hence, disadvantageous switching is more memorable than disadvantageous sticking and therefore perceived as more likely than disadvantageous sticking. The present study addressed the FIF's resistance to information that a switching or sticking strategy was failing and its implications for person perception. Participants watched a video of a game show contestant who consistently switched from or stuck to her initial answer and performed poorly (missing 6 out of 8 questions). In experiment one, we found that participants committed the FIF after watching the contestant repeatedly switch and fail, but were reluctant to adopt a switching strategy after watching the contestant repeatedly stick and fail. Furthermore, we found that observers believed that sticking contestants were more intelligent than switching contestants, despite the contestants' identical outcomes. In experiment two, we found that observers attributed a switching contestant's failure to her faulty strategy while they attributed a sticking contestant's failure to her laziness. These results demonstrate both the FIF's resistance and its effects on person perception.

### B238

**SPONTANEOUS ACTION AS A DOUBLE EDGED SWORD** Jayanth Narayanan<sup>1</sup>, Zheng Xue<sup>1</sup>, Madan Pillutla<sup>2</sup>; <sup>1</sup>National University of Singapore, <sup>2</sup>London Business School – People often make spontaneous decisions - unplanned actions without premeditation in interpersonal relationships. They trust people without deliberate forethought or planning and also retaliate emotionally to unfair treatment. The same behaviors may also result from a deliberative process. Not much is known, however, about how the spontaneity of actions affects interpersonal relationships. Using two standard economic games we attempt to answer the following questions - Would people view spontaneous acts of trust more favorably than deliberate and planned acts? (Study 1) Would they react to unfairness that is deliberate rather than spontaneous? (Study 2). In study 1, responses to positive actions are examined using the trust game (Berg, Dickhaut, & McCabe, 1995), where we examine participant's reactions to spontaneous (i.e. manipulated as quick trusting offers) and deliberate (i.e. manipulated as delayed trusting offers) trusting actions. In study 2, responses to spontaneous and deliberate negative actions (i.e. manipulated as quick or delayed unfair offers) are examined using the ultimatum game (Guth, Schmittberger, & Schwarze, 1982). Results revealed the asymmetric role of spontaneity in positive actions and negative actions: recipients returned considerably more money when positive amounts were sent quickly in the trust game compared to when there was a delay. Whereas they rejected spontaneous unfair offers more than delayed ones in the ultimatum game. These results add to the growing evidence for a model of trust development that is swift rather than incremental while also challenging common notions of punishment, which suggest that people punish deliberate acts more than spontaneous ones.

**B239****ANALYTICAL MINDSETS UNDERMINE IMPLICIT LEARNING** Shannon

**Pinegar<sup>1</sup>, Keith Markman<sup>1</sup>, Dan Lassiter<sup>1</sup>, <sup>1</sup>Ohio University** – Two studies examined the effects of instantiating analytical mindsets on implicit learning. Markman, Lindberg, Kray, and Galinsky (2007) recently demonstrated how reading about a concert attendee (Jane) who switched her seat and lost out on winning a free vacation (i.e., a counterfactual) elicits analytical processing. In Study 1, participants engaged in an implicit learning task that typically elicits better-than-chance performance – the Markovian grammar task (Reber, 1977) – and then during the learning phase of the task read versions of the Jane scenario that either did or did not elicit counterfactuals. Results indicated that participants who considered non-counterfactual scenarios performed significantly better than chance on the test of implicit learning, whereas those who considered counterfactual-inducing scenarios failed to perform better than chance. Study 2 examined performance on the test of implicit learning following the instantiation of either an additive counterfactual mind-set (e.g., "If only I HAD...") that has been shown to enhance performance on creative tasks, or a subtractive counterfactual mindset (e.g., "If only I had NOT...") that has been shown to enhance performance on analytical tasks (Markman et al., 2007). Results indicated that participants who generated additive counterfactuals performed significantly better than chance on the test of implicit learning, whereas participants who generated subtractive counterfactuals failed to perform better than chance. Overall, the results suggest that the cognitive operations that are involved when performing an analytical task may carry over to an unrelated second task and, in the case of intuition-based tasks, undermine performance.

**B240****ACTIONS SPEAK LOUDER THAN WORDS: EXPLORING THE DISSOCIATION BETWEEN MORAL ACTION AND MORAL JUDGMENT** Rimma Teper<sup>1</sup>,

**Michael Inzlicht<sup>1</sup>, <sup>1</sup>University of Toronto** – Do moral action and moral judgment go hand in hand? Recently, psychologists have directed their energy to the domain of moral judgment, assuming that when extended to moral behavior, their results will prove consistent. However, research has shown that there is often a discrepancy between individuals' actions and attitudes (Icek & Fishbein, 1977). The aim of this research was to explore the dissociation between moral judgment and moral behavior. Pilot research suggests that people expect others to act less morally than they say they would. The results of our two experiments, however, suggest the opposite. In both studies, participants were assigned to either a moral action condition, where they were placed in an actual moral dilemma, or a moral judgment condition, in which they had to predict their behavior in that moral dilemma. In Study 1, the moral dilemma was how much money participants would give to a second participant in an economic game, whereas in Study 2, we measured whether or not participants cheated on a math task. Results revealed that people acted more morally than they predicted they would: In Study 1, subjects in the action condition gave significantly more money to their partner than their counterparts in the judgment condition predicted giving. In Study 2, participants in the action condition cheated less than participants in the judgment condition predicted cheating. These studies offer a new perspective on moral psychology, suggesting that the vast amount of research conducted on moral decision-making may not be applicable to real-life situations.

**B241****THE ROLE OF PERCEIVED SIMILARITY IN INTERGROUP PERCEPTION**

**Chanmo Park<sup>1</sup>, <sup>1</sup>Brown University** – The hypotheses of social projection and self-stereotyping offer two different answers to the question of how people infer the unknown attributes of others in social life. Scholars of social projection believe that the self is a primitive and reasonable basis for judging others while scholars of self-stereotyping believe that individuals' beliefs about prevalent group attributes provide the inferential grounds for judging the self. Although a positive correlation between self and group judgments is a necessary condition for both hypotheses, the two hypotheses presume opposite causal paths. The present study

aimed to shed light on the causal role of perceived similarity in the two different inferential processes. Using a procedural priming task, the study manipulated the level of perceived similarity. Using the minimal group paradigm, the order of judgments of self, ingroup, and outgroup was systematically manipulated. Results supported the hypothesis of social projection over self-stereotyping. The similarity manipulation increased the correlations between self- and ingroup judgments, but only when self-judgments were provided first. The response latency results also favored the social projection hypothesis over its alternative. Participants made self-judgments faster than group judgments, and group judgments that matched self-judgments were faster than self-judgments that matched group judgments while matching responses were faster than mismatching responses. Although these findings are seen in the minimal laboratory situation, they likely reveal fundamental processes for understanding social judgment of real social groups.

**B242****WHAT AM I WILLING TO PAY? METHODS OF EVALUATION: A SEPARATE/ COMBINED EVALUATION EFFECT** Ashleigh Gallagher<sup>1</sup>, John Seta<sup>2</sup>,

**Catherine Seta<sup>3</sup>, Michael McCormick<sup>2</sup>, Samuel Turner<sup>2</sup>; <sup>1</sup>N.C. Sentencing & Policy Advisory Commission, <sup>2</sup>University of North Carolina at Greensboro, <sup>3</sup>Wake Forest University** – The ways in which people integrate information influence such outcomes as performance anxiety, positive and negative affect, and choice (see Seta, Crisnon, Seta & Wang, 1989; Seta, Haire & Seta, 2008). The purpose of the current studies was to examine whether method of information integration would also affect spending behavior. Participants read vignettes and were asked to allocate funds (i.e., any amount between \$0 and \$300) to purchase two items bundled together, or, in another condition, the same two items separately. In two studies, we found that people who thought about two items separately were willing to spend more money to purchase the items than were people who thought about the same two items as a unit. We obtained this result when people were asked an affective evaluation before the monetary allocation,  $F(1,47)=8.9, p<.01$ , and when no affective evaluation occurred before the monetary allocation,  $F(1,84)=15.0, p<.01$ . In a third study, we assessed willingness to protect assets through the purchase of insurance. We found that people who thought about the two items separately were willing to spend more money to insure the items against loss than were people who thought about the same two items as a unit,  $F(1, 102)=20.01, p<.01$ . These results are important theoretically because they implicate averaging/summation processes at work in fiscal decisions; and practically because they suggest that consumers may spend more money in contexts where products are presented separately rather than bundled together.

**B243****INFORMATION DISTORTION IN SELF-OTHER DECISION MAKING** Evan

**Polman<sup>1</sup>, <sup>1</sup>Cornell University** – In both organizational and social arenas, individuals make decisions for themselves and on behalf of other individuals. But research in decision making has provided little input into whether or how these decisions are psychologically different. In this paper, I propose that decisions—depending on whom they are for—vary according to the extent of information distortion, such that, individuals who choose for themselves demonstrate more postdecisional distortion (i.e., cognitive dissonance), yet less predecisional distortion than individuals who choose on behalf of others. To test this hypothesis, participants in an experiment made a decision between two restaurants. Attributes about each restaurant were presented sequentially, and preferences were measured following each attribute. As expected, participants who chose for themselves experienced more cognitive dissonance, however, among participants who chose on behalf of others, greater distortion of attribute information was observed. These findings suggest a trade-off between pre- and postdecisional distortion that manifests in self-other decision making: On one hand, making decisions for others is adaptive because the aversive state of cognitive dissonance is lessened, but it is at the expense of distorting decision-relevant information that one feels less dissonance. On the other hand, making one's own decisions is adaptive

insofar as less distortion of attribute information takes place—preventing a foundation for selecting inferior alternatives—yet more dissonance is experienced. Implications and suggestions for other differences in self-other decision making are discussed.

#### B244

**THE DARK SIDE OF MORAL PRINCIPLISM I: WHEN PRINCIPLES CONFLICT WITH CARE** Vassilis Saroglou<sup>1</sup>, Matthieu Van Pachterbeke<sup>1</sup>, Aurélie Moulaert<sup>1</sup>; <sup>1</sup>Université catholique de Louvain – Is it possible to act in a harmful for close others way by being attached to moral principles? What are the moral foundations underlying rigid moral principlists' anti-social tendencies? In Study 1, we created nine hypothetical moral dilemmas putting into conflict (a) abstract principles (honesty, integrity, social responsibility, strict equity, civil and professional loyalty), whose violation would not hurt any concrete person, and (b) readiness to help a close person in need even this meant to violate the previously mentioned principles. Participants (64 students) made their choice (principlistic or prosocial) and afterwards they provided information on (a) the importance they attributed to each of the five moral foundations (Haidt & Graham, 2007) when making their choice on each of the nine dilemmas; (b) their behavioral integrity (frequency of behaviors transgressing social rules implying honesty, not cheating, not stealing); and (c) their willingness to share with others hypothetical gains. Results confirmed the hypotheses that rigid, harmful of others, moral principlism relates negatively to "care" and prosocial behavioral tendencies, and positively to the principles of "authority" and "fairness" and to behavioral integrity. In Study 2, participants (160 adults) provided again their choices to the hypothetical dilemmas measuring moral principlism and completed afterwards the Schwartz's Portrait Values Questionnaire. Rigid moral principlism reflected high importance attributed to conservation values (tradition and conformity) and low importance attributed to hedonistic values (hedonism and stimulation). Further questions and additional evidence are provided in a second submitted poster entitled "The dark side of moral principlism II".

#### B245

**HINDSIGHT BIAS CHANGES OVER TIME IN THE 2008 U.S. PRESIDENTIAL ELECTION: DISSIPATING AND REINSTATING FEELINGS OF SUBJECTIVE EASE** Lindsay A. Kennedy<sup>1</sup>, Paul M. Miceli<sup>1</sup>, Lawrence J. Sanna<sup>1</sup>, Edward C. Chang<sup>2</sup>; <sup>1</sup>University of North Carolina at Chapel Hill, <sup>2</sup>University of Michigan – Hindsight bias, people's claim to "knowing it all along" (Fischhoff, 1975), is influenced by subjective experiences of ease or difficulty when generating reasons about known and alternative outcomes (Sanna & Schwarz, 2007; Schwarz, Sanna, Skurnik & Yoon, 2007). We found not only that the influence of subjective experiences on hindsight bias can dissipate over time, but also that these feelings can be reinstated by prompting people to reflect on the feelings they had when originally generating reasons. Participants predicted the outcome of the 2008 U.S. Presidential election 1-day prior, and recalled predictions 1-day and 3-days after the election. Before recalling predictions 1-day after, participants generated 3 or 12 reasons in favor of a McCain-Palin win instead while indicating the ease or difficulty of reason generation. Before recalling predictions 3-days after the election, participants read over their previously generated reasons. In addition, half of participants received their previous ratings of ease and difficulty. Control participants did not generate or read reasons. Results provided strong support for hypotheses: Recalled predictions were influenced by subjective experiences when generating reasons, but not when participants simply read these reasons 3-days after, suggesting that subjective experiences dissipated over time. In fact, participants were influenced by numbers of reasons here. However, recalled predictions were in line with subjective experiences for participants who also received prior ease or difficulty ratings when reading reasons, suggesting that this subtle manipulation was enough to lead them to reinstate their earlier subjective experiences.

#### B246

**MEANING AND MORAL DILEMMAS: THREATS TO MEANING ELICIT HARSHER MORAL JUDGMENTS** Daryl R. Van Tongeren<sup>1</sup>, Jeffrey D. Green<sup>1</sup>, Timothy L. Hulsey<sup>1</sup>; <sup>1</sup>Virginia Commonwealth University – The human proclivity toward maintaining a meaningful conceptualization of oneself is a growing area of theoretical interest (Heine, Proulx, & Vohs, 2006). Previous research has demonstrated that threats to meaning evoke stronger affirmation of moral schemas (Proulx & Heine, 2008), suggesting that morality might be an important component of one's meaning system. The current research examined how contemplating life's lack of meaning would affect moral judgments. Specifically, we predicted that individuals primed with meaninglessness would be morally hypersensitive (i.e., demonstrate harsher moral judgments) as a defensive maneuver aimed at regaining meaning. Participants were randomly assigned to contemplate their life's lack of meaning (i.e., meaninglessness), their own death (i.e., mortality salience), or intense physical pain. They then completed two commonly used moral judgment tasks: the trolley dilemma and the footbridge dilemma (Greene et al., 2001). These dilemmas depict a runaway trolley that will kill 5 workers on a track unless a switch is flipped to reroute the train to kill only one worker (trolley dilemma) or unless a large man is pushed from an overhead footbridge to stop the train (footbridge dilemma). Participants indicated whether each action was moral or not moral. Results indicated that participants whose meaning was threatened were significantly more likely than participants in the other conditions to judge flipping the switch or pushing the man as not moral. These results suggest that threats to meaning elicit harsher moral judgments for both utilitarian and deontological moral dilemmas and underscore the importance of morality in one's sense of meaning.

#### B247

**ON THE APPEAL OF GOD VS. GOVERNMENT IN TIMES OF UNCERTAINTY:** John Paul Schott<sup>1</sup>, Alan Lambert<sup>1</sup>; <sup>1</sup>Washington University in St. Louis – Research on the "functional" value of emotion suggests that anxiety is likely to have consequences distinct from that of other negative emotions (e.g. sadness, anger). In particular, anxiety can temporarily increase the positive appeal of attitude objects offering stability and security (cf. Kay et al. 2008). For example, anxiety could increase the appeal of a strong centralized government (authoritarianism) but it could also increase the appeal of a "supreme higher being" (religiosity). However, the conditions under which any given attitude actually plays a role in this process remains somewhat unclear. The present research sought to gain insight into these matters. In our first study (N = 158), participants were randomly assigned to an anxiety induction condition (vs. control), followed by assessment of current mood. Participants then expressed attitudes towards religiosity as well as authoritarianism as part of a larger, randomized set of attitude items. Path analyses revealed (a) a significant effect of the manipulation on anxiety but, of greater interest, (b) the effect of anxiety on authoritarianism was moderated by religiosity. In particular, anxiety fostered greater positivity towards authoritarianism, but this was only true among participants who indicated lack of belief in a supreme being. Among highly religious participants, anxiety had no effect at all. These effects were replicated in a second study (N = 51) using a different anxiety induction task. We discuss the implications of these results for conceptualizations of religion as a type of psychological buffer, and their relevance to psychological models of values and political ideology.

#### B248

**CHOICE PROCESSES AND THEIR CONSEQUENCES IN MORALLY CONFLICTING MILITARY DECISIONS** Amy R. Krosch<sup>1,2</sup>, Bernd Figner<sup>2</sup>, Elke U. Weber<sup>2</sup>; <sup>1</sup>New York University, <sup>2</sup>Columbia University – When people face morally challenging decisions, competing values often suggest contradictory courses of action. Peacekeepers have reported such situations, when strict military orders conflict with their moral intuitions and beliefs. Such conflict during decision making can have negative psychological consequences, and is hypothesized as a potential cause of Post-

traumatic Stress Disorder (PTSD). We investigated situational characteristics and individual differences that might make people more or less prone to experience the negative consequences of decision conflict. Participants ( $N = 63$ ) read and evaluated two realistic, morally challenging military scenarios developed from peacekeepers' accounts, each involving a choice between a military ethic of adhering to rules and a humanitarian ethic of helping people. Participants' skin conductance was continuously recorded, as an indicator of emotional arousal. We examined participants' ratings of choice option characteristics, decision mode-use, and emotional arousal on choice, decision difficulty, and post-decision worry. Individual differences in perceived option characteristics predicted choice. Participants generally chose the option they rated higher on positive characteristics. Decision mode-use also predicted choice. Participants' use of analytic decision modes predicted following the military ethic, affect-based decision modes predicted following the humanitarian ethic, while rule-based decision modes varied by scenario. More importantly, participants who simultaneously engaged in modes that predict opposite choices reported significantly more decision difficulty and post-decision worry than those who used only choice-congruous modes. Projections of post-decision worry were related to emotional arousal. These observed relationships in morally conflicting choices may have implications for both the treatment and prevention of posttraumatic stress in peacekeepers.

### B249

#### DIFFERENTIAL EMPATHIC NEURAL RESPONSES TO PAINFUL EXPRESSION AND PAINFUL STIMULATION APPLIED TO BODY PARTS

Wei Li<sup>1</sup>, Shihui Han<sup>1</sup>; <sup>1</sup>Peking University – Previous functional magnetic imaging studies have shown that a similar neural circuit is involved in empathy for faces with painful expressions and body parts in painful situations. The current work examined the differences in temporal neural dynamics of empathy for painful faces and body parts in painful situations. We recorded event related potentials (ERPs) from subjects who performed pain judgment tasks on perceived pictures of faces with painful or neutral expressions and pictures of hands in painful or non-painful situations. We found that subjects responded more quickly to painful than non-painful stimuli and more quickly to painful faces than hands in painful situations. The ERP results showed that empathic neural responses to faces occurred as early as 160 ms after stimulus onset at electrodes over the frontal-central areas and lasted until 480 ms. The long-latency empathic responses was more salient over the left than right hemispheres. However, empathic neural response to hands in painful situations began at 200 ms after sensory stimulation. The long-latency empathic response lasted until 680 ms and was more salient over the left than right hemispheres. Moreover, the empathic neural response induced by facial painful stimuli at 80-100ms and 500-580ms over the left central region was greater in female than male subjects. Our findings provide neuroscience evidence for differences in empathy for perceived painful expressions and painful stimulation applied to body parts.

### B250

#### AFFECT RECOGNITION ACROSS VISUAL SOCIAL VERSUS NON-SOCIAL STIMULI: EVIDENCE FOR A SOCIAL BIAS

Rowena Ng<sup>1</sup>, Kiley Hill<sup>2</sup>, Anna Järvinen-Pasley<sup>2</sup>, Anna Yam<sup>2</sup>, Mark Grichani<sup>2</sup>, Ursula Bellugi<sup>2</sup>; <sup>1</sup>University of California, San Diego, <sup>2</sup>The Salk Institute for Biological Studies – Individuals with Williams syndrome (WS) are well known for their hypersocial nature, including an increased attraction to faces. Interestingly, despite severe deficits in visual spatial processing, these individuals demonstrate strong facial recognition skills. Although many studies have highlighted an impaired ability for judging facial expressions, little is known about emotion processing across social and non-social domains in this population. This question is of interest, as individuals with WS demonstrate the opposing pattern of attention to/interest in social versus non-social stimuli to those with autism, which has important implications for

neurodevelopment. The current study examined affective visual recognition ability across the social and non-social domains by utilizing standardized facial expressions as social stimuli, and standardized images of landscapes, animals, and objects, as non-social stimuli, which were matched for emotional content. The participants included individuals with WS, cognitive-matched controls, and typically developing controls. Consistent with previous findings, both individuals with WS and cognitive-matched controls showed significantly lower levels of performance as compared to the typically developing controls. However, individuals with WS exhibited a unique pattern of performance by showing greater affect identification performance with the social compared to the non-social stimuli. The results of this study provide further support to the idea of a bias toward social information in WS. This is likely to be linked to the unique phenotype characterizing Williams syndrome, including a strong attentional preference and attraction to faces.

### B251

#### THE ROLE OF RACE AND EXPRESSION IN WEAPON IDENTIFICATION

Jennifer Kubota<sup>1</sup>, Tiffany Ito<sup>1</sup>; <sup>1</sup>University of Colorado Boulder – The purpose of this research was to examine how multiple social cues combine to affect racial bias. We specifically focused on a cue that is integral to the individual and varies naturalistically, that of emotional expression, and its impact on implicit racial stereotyping. Using a sequential priming task, participants viewed pictures of Black and White faces posing angry, happy, and neutral expressions that primed guns or tools. Happy expressions attenuated implicit stereotyping, with race bias observed following angry primes but not happy ones. This effect did not depend on the context in which the expressions were presented. Moreover, early variation in attention to race at the N200 predicted implicit bias only for angry primes. These results show that the same individual can activate different semantic associations at different points in time based on relatively subtle changes in appearance, and that a feature present in many everyday encounters (a smile) can succeed in reducing racial bias.

### B252

#### VICTIMIZATION AND THE NEED TO BELONG: AN EEG STUDY OF REACTIONS TO OSTRACISM

Haylie L. Gomez<sup>1</sup>, Linda L. Batto<sup>1</sup>, Katie L. Goodell<sup>2</sup>, Lauri A. Jensen-Campbell<sup>1</sup>; <sup>1</sup>The University of Texas at Arlington,

<sup>2</sup>The University of Texas Southwestern Medical Center – Many individual differences exist in the experience of both physical and social pain. Two factors are of key interest in this study: chronic victimization and nBelong. This research extends previous work on nBelong by adding a psychophysiological component, EEG. We expected that in a neutral condition, chronic victims would exhibit a rejection attribution bias (RAB), modeled after Dodge's (1980) hostile attribution bias. The RAB posits that when individuals are in ambiguous situations, those who are chronically victimized will attribute neutral behavior to motives of intentional exclusion, especially in the presence of high nBelong. Given existing literature on social pain, we expected that victims with high nBelong, would exhibit distress and greater activity in the right prefrontal cortex in response to ostracism. Participants were 60 undergraduates from the University of Texas at Arlington. During Phase I, they answered questions online about victimization (DIAS, CSEQ) and personality factors including nBelong. During Phase II, EEG measures were collected during a baseline stage and while playing Cyberball, a simulated ball-tossing game. Participants were assigned to one of 3 Cyberball conditions, Inclusion, Nonexclusion/Ambiguous, or Exclusion, extending previous literature focused solely on overt Inclusion and Exclusion. Participants then answered questions assessing threatened belongingness, self-esteem, control, and meaningful existence. Results indicate that nBelong moderates the relationship between victimization and right prefrontal cortex activity. The same moderating effect of nBelong was found for the relationship between victimization and threatened needs. Implications for social pain research and personality characteristics increasing vulnerability to the negative effects of ostracism are discussed.

**B253**

**AN FMRI STUDY OF THE BREAKDOWN OF AVOIDANT DEFENSES UNDER A COGNITIVE LOAD** Omri Gillath<sup>1</sup>, David Chun<sup>2</sup>, Phillip Shaver<sup>2</sup>; <sup>1</sup>University of Kansas, <sup>2</sup>University of California, Davis – Behavioral studies indicate that attachment insecurities (measured on two dimensions: attachment anxiety and avoidance) are related to regulation of attention and emotion (e.g., Gillath, Giesbrecht, & Shaver, 2009). More avoidant individuals tend to inhibit or suppress attachment-related thoughts and emotions (e.g., Fraley & Shaver, 1997), but when a cognitive load is imposed, their ability to inhibit such thoughts and emotions is disrupted (e.g., Mikulincer, Dolev, & Shaver, 2004). Neuroimaging studies have identified some of the brain regions involved in attachment-related differences in attentional control (Gillath et al., 2005). The present study was designed to broaden this line of research by examining the failure of suppression among avoidant people when under a cognitive load. Sixteen women, selected based on their anxiety and avoidance scores, performed a modified version of the emotional Stroop task under low and high loads while in an MRI scanner. Results support previous findings showing that avoidant individuals can suppress attachment-related information when under a low cognitive load (rehearsing a single-digit number) but not under a high load (rehearsing a 7-digit number). A high load was associated (as in previous studies) with suppression failure in avoidant participants and was also associated with activation in emotion-related brain regions (e.g., superior temporal gyrus) and regions related to working memory (e.g., dorsolateral prefrontal cortex, Brodmann area 9). The findings suggest that avoidant individuals' failure to suppress emotional material under a high cognitive load stems from inability to carry out two control-related tasks simultaneously (rehearsing and suppressing), resulting in increased emotionality.

**B254**

**STRUCTURAL BRAIN CORRELATES OF ACTION VERSUS STATE ORIENTATION** Hester A. H. Ruigendijk<sup>1</sup>, Sander L. Koole<sup>1</sup>, H. Steven Scholte<sup>2</sup>; <sup>1</sup>VU University Amsterdam, <sup>2</sup>University of Amsterdam – Action versus state orientation refers to opposing self-regulatory modes (Kuhl, 1994). Action orientation is characterized by flexible self-regulation of own cognitive, affective, and motivational states. State orientation is characterized by rigid and often involuntary persistence of own cognitive, affective, and motivational states. Individual differences in action versus state orientation uniquely predict a wide variety of behaviors in laboratory and field settings (Kuhl & Beckmann, 1994). Nevertheless, little is known about the brain systems that underlie action versus state orientation. To fill this gap, the present study investigated structural brain correlates of action versus state orientation. Ninety-six participants rated themselves on two facets of action versus state orientation: a) disengagement versus preoccupation, and b) initiative versus indecision. Gray matter concentrations (GMC) were determined using magnetic resonance imaging; white matter densities were determined using diffusion tensor imaging. Disengagement was associated with enhanced GMC in the left cerebellum, bilateral fusiform gyrus and in the superior frontal gyrus; and with reduced GMC in areas in the left occipital cortex. Initiative was associated with enhanced GMC in the precuneus and the middle frontal gyrus; reduced GMC in the inferior temporal gyrus, the caudate, the temporal parietal junction and in the post-central gyrus; and with higher white matter density in the corpus callosum. These results indicate that different facets of action versus state orientation relate to distinct neuro-anatomical structures. In addition, the present findings help to connect the construct of action versus state orientation to general cognitive processes involving attention, memory, and control.

**B255**

**NOT SO FAST: SOCIAL ACCOUNTABILITY REDUCES EVALUATIVE BIAS BY INCREASING RATHER THAN DECREASING COGNITIVE CONTROL** Brent L. Hughes<sup>1</sup>, Jennifer S. Beer<sup>1</sup>; <sup>1</sup>Imaging Research Center, University of Texas at Austin – The motivation to view one's self positively (i.e., self-enhance) has a powerful impact on behavior. For example, people often try to bolster their self-views by over-claiming scholarly knowledge. Over-claiming is the tendency to claim familiarity with fake knowledge items and inflate familiarity with real knowledge items (Paulhus et al., 2003). Increasing social accountability curtails over-claiming. Currently it is unclear whether social accountability reduces over-claiming because it destroys cognitive control efforts to substantiate over-claiming or whether impression management concerns engender more careful processing for familiarity claims. These two perspectives suggest that social accountability should either reduce or increase the engagement of neural regions associated with cognitive control, respectively. In an fMRI study, participants evaluated their familiarity with real and fake knowledge items. Social accountability was manipulated by the presence or absence of cues that warned participants that lists might include fake items. This study found evidence that social accountability reduces over-claiming by increasing neural activation associated with cognitive control. When participants were warned that some items might be fake, they reduced their familiarity ratings and engaged neural regions associated with cognitive control (i.e., ACC, OFC, MPFC). These findings are consistent with the engagement of self-control regions in response to concerns about social acceptance (Amodio et al., 2008; Eisenberger et al., 2003; Klucharev et al., 2009). Furthermore, findings are discussed in relation to individual differences in concerns about social acceptance (i.e., narcissism).

**B256**

**NEURAL MECHANISMS UNDERLYING DECISIONS TO HELP THE FAMILY: A SOCIAL IDENTITY PERSPECTIVE** Eva Telzer<sup>1</sup>, Carrie Masten<sup>1</sup>, Elliot Berkman<sup>1</sup>, Matthew Lieberman<sup>1</sup>, Andrew Fuligni<sup>1</sup>; <sup>1</sup>University of California, Los Angeles – Decisions to help family members may be driven by social and cultural factors. For example, youth from Latin American backgrounds both value and spend more time assisting their family than do youth from European backgrounds. In order to better understand the experiences supporting these cultural differences, we used fMRI to examine the neural mechanisms underlying decisions to help the family. During an fMRI scan, 25 adolescents (14 Latino, 11 White) completed a family assistance task, in which they allocated money to themselves and their family. According to Social Identity Theory, group identification leads individuals to try to figure out the key goals and values of group members. Therefore, we examined whether areas of the brain implicated in theory of mind and social cognition (temporal-parietal junction (TPJ), posterior superior temporal sulcus (pSTS), DMPFC dorsomedial prefrontal cortex, temporal poles) were activated during decisions to help the family. Given the cultural emphasis placed on family assistance among youth from Latin American cultures, we examined whether Latino youth would show more activation in these regions than White youth. As expected, Latino participants showed greater activation in the TPJ, pSTS, DMPFC, and temporal poles during decisions to contribute to their family compared to decisions to accept a reward. These findings suggest that Latinos may think more about their family's values and goals when making decisions to help their family, which may be one reason why Latinos often put the needs of their family before their own.

**B257**

**THE CONTRIBUTION OF COLOR AND STRUCTURE TO THE OWN-RACE EFFECT: AN EVENT-RELATED POTENTIAL STUDY** Joanne L. Brebner<sup>1</sup>, Olav Krügelson<sup>2</sup>, Todd C. Handy<sup>2</sup>, Susanne Quadflieg<sup>1</sup>, David J. Turk<sup>1</sup>; <sup>1</sup>University of Aberdeen, <sup>2</sup>University of British Columbia – It has been long established that Caucasian participants remember unfamiliar Caucasian faces more accurately than those of other racial groups, a phenomenon known as the Own-Race Bias (ORB). Two accounts have been proposed for the ORB. The perceptual-expertise account argues that the ORB results from

a reduced ability to process cross-race (CR) faces holistically due to negligible exposure to CR relative to same-race (SR) faces (possibly due to differences in their structural properties). Social-cognitive theories claim that the ORB is a consequence of categorizing (e.g. detecting skin color) rather than individuating CR faces. Using morphing software we manufactured faces with either SR skin color and facial configuration, SR color but CR configuration, CR color with SR configuration, or both CR color and configuration. During encoding, participants judged these faces on their relative age. Their recognition accuracy was then measured in a surprise memory test. ERP results indicated that perceivers were sensitive to both color and configural information in the faces, with reliable N170 and N250 differences to color cues, and P300 and LPP differences to facial configuration. However, these rapidly detected color cues dominated the recognition memory advantage, with faces with SR-consistent skin color being better remembered than faces with CR-consistent skin color, regardless of their underlying facial configuration. These findings indicate that when motivated to do so, perceivers can holistically encode faces with CR featural configurations, a finding that strongly contests perceptual-expertise accounts of the ORB, and provides support for the social-cognitive theories of racial face processing.

### B258

**WHATEVER DUDE, I'M WASTED!: THE EFFECT OF ALCOHOL ON AFFECT AND THE ERROR RELATED NEGATIVITY (ERN)** Sarah Lust<sup>1</sup>, Erika Henry<sup>1</sup>, J. Scott Sauls<sup>1</sup>, Bruce Bartholow<sup>1</sup>; <sup>1</sup>University of Missouri – Research has shown that a moderate dose of alcohol reduces the amplitude of the ERN, a component of the event-related brain potential (ERP) associated with error processing, and interferes with post-error performance adjustments (Ridderinkhof et al., 2002). However, it has been unclear whether this effect is due to impaired error detection or to reduced emotional distress associated with error commission. In the present study, 96 healthy adults (age 21-35) were randomly assigned to consume alcohol (M BAC = .09%), a placebo (M BAC = .00%), or a control beverage prior to completing an arrow flanker task. After each trial, participants judged the perceived accuracy of their response by pressing 1 of 3 keys (sure incorrect, unsure, and sure correct). Participants were faster and more accurate ( $ps < .01$ ) on compatible than incompatible trials. But, as predicted, there were no significant differences between beverage groups for either behavioral measure. Moreover, response accuracy judgments did not differ across beverage groups ( $ps > .50$ ), indicating that alcohol did not impair error detection. Consistent with previous work (Bartholow et al., 2009), alcohol participants reported less negative affect (NA) and similar levels of positive affect (PA) post-drinking compared to baseline, whereas control and placebo participants' post-drinking PA decreased while their NA did not change. These post-drinking decreases in NA and increases in PA were correlated with smaller ERNs on error trials. Together, these findings suggest that alcohol's effect on the ERN is likely mediated by its effect on reducing NA, not impaired error detection.

### B259

**OXYTOCIN INCREASES EMPATHIC ACCURACY IN ADULTS ENDORSING TRAITS OF AUTISM** Jennifer Bartz<sup>1</sup>, Jamil Zaki<sup>2</sup>, Natasha Ludwig<sup>1</sup>, Niall Bolger<sup>2</sup>, Alexander Kolevzon<sup>1</sup>, Eric Hollander<sup>1</sup>, Kevin Ochsner<sup>2</sup>; <sup>1</sup>Mount Sinai School of Medicine, <sup>2</sup>Columbia University – Oxytocin—a neuropeptide long implicated in pro-social behavior in animals—was recently found to facilitate the ability to decipher the mental states of others depicted in photographs in healthy men. These findings suggest that oxytocin may help individuals with autism spectrum disorders (ASD), who have deficits in social cognition. However, it is unclear whether oxytocin would facilitate the complex, dynamic social cues that people encounter in everyday life. We investigated whether oxytocin facilitates naturalistic social cognition, and whether individual differences in ASD traits predict response to oxytocin. Twenty-seven healthy men participated in this double-blind, within-subject design study. Participants received intranasal oxytocin (Syntocinon) or placebo, and performed the Empathic Accuracy (EA) task in which they watched targets discussing autobiographical events, and provided continuous ratings of how each

target was feeling. Importantly, the targets themselves made similar ratings of how they felt. EA was assessed by calculating the timecourse correlation between dynamic ratings made by targets and perceivers. ASD traits were measured with the Autism Spectrum Quotient (AQ). As predicted, individual differences in AQ was associated with EA change (EA-oxytocin minus EA-placebo),  $B = .33$ ,  $sr = .33$ ,  $p < .05$  (one-tailed). Additional analyses revealed that those who endorsed more autistic traits performed more poorly on placebo than those who endorsed fewer traits,  $t(23) = 2.29$ , and, critically, showed the greatest improvement from oxytocin,  $t(23) = -1.77$ ,  $p < .05$  (one-tailed). These data suggest that oxytocin facilitates more complex, dynamic social cognition, especially for those who have difficulties in this regard.

### B260

**SELF-OTHER OVERLAP PREDICTS NEURAL RESPONSE TO OBSERVED ERRORS** Jacob Hirsh<sup>1</sup>, Sonia Kang<sup>1</sup>, Alison Chasteen<sup>1</sup>; <sup>1</sup>University of Toronto – The Anterior Cingulate Cortex (ACC) has been implicated in conflict detection, anxiety, and performance monitoring processes. An electrophysiological signal associated with these processes is the Feedback-Related Negativity (FRN), which peaks between 200 ms and 350 ms after the receipt of negative feedback. Researchers have recently demonstrated that the FRN also occurs when observing another person receive negative feedback. The current study examined whether the neural activity in response to another person's errors is moderated by the nature of the relationship between the two individuals. Specifically, we measured the magnitude of participants' FRN responses using electroencephalography while they watched strangers or friends complete a Stroop task with performance feedback. Results showed stronger feedback-related activation of the ACC, as indexed by the FRN, for those who observed friends compared to those who observed strangers. This effect was mediated by the degree to which participants included the other in their conception of the self. This study contributes to a growing body of research showing that social factors can greatly impact neural processing, demonstrating that vicarious responses to negative feedback are moderated by self-other closeness.

### B261

**PERCEIVED FAMILIAL SOCIAL STATUS MODULATES THE NEURAL RESPONSE TO VIEWING EMOTIONAL FACIAL EXPRESSIONS IN ADOLESCENTS** Keely Muscatell<sup>1</sup>, Baldwin Way<sup>1</sup>, Jennifer Pfeifer<sup>2</sup>, Naomi Eisenberger<sup>1</sup>, Mirella Dapretto<sup>1</sup>; <sup>1</sup>University of California, Los Angeles, <sup>2</sup>University of Oregon – Research has demonstrated that subjective perceptions of low social status are related to a number of negative outcomes, including increased risk of mortality, and greater physiological stress reactivity following a socially threatening event. Recently, the potential neural mechanisms of these effects have been explored. In particular, it was demonstrated that young adults' perceptions of their parents' social status were associated with amygdala activity when viewing threatening facial expressions, such that individuals whose parents were lower status showed greater amygdala activity. In the present study, we sought to determine if a similar effect occurred in adolescents. Specifically, we predicted that adolescents' perceptions of their family's social status would modulate the neural response to viewing threatening facial expressions. To test this prediction, 27 adolescents (age 13 years) completed a revised version of the MacArthur Subjective Social Status Scale, in which they were asked to indicate where their family stood on a ladder intended to represent the hierarchy in American society. Participants also underwent an fMRI scan while they observed faces that displayed emotional expressions. Results revealed that, while viewing angry faces, adolescents who rated their families as lower in social status exhibited greater neural activity in the dorsal anterior cingulate cortex and anterior insula, regions involved in processing the distress of physical and social pain. Thus, as has been found with adult samples, low familial social status is associated with increased neural sensitivity to social threat in adolescents.

**B262****CHANGING PERSPECTIVE TO INDUCE THE ACTOR-OBSERVER EFFECT FROM IDENTICAL VISUAL CONTENT: DOES ACTION REPRESENTATION FACILITATE MENTAL SIMULATION?** Laura Case<sup>1</sup>, Vilayanur Ramachandran<sup>1</sup>; <sup>1</sup>UCSD Center for Brain and Cognition – Studies of the actor-observer effect have shown that taking another person's perspective changes judgments about the person and his actions, inducing a first-person attribution style such as situational attribution. However, these studies are limited in that they often vary both visual content as well as perspective. The current study investigates whether similar shifts in judgment can be induced by changing only visual perspective, via differential engagement of the mirror neuron system (MNS) known to occur when actions are viewed from an egocentric viewpoint, as opposed to an allocentric viewpoint (Jackson et al., 2006). There is much evidence for the role of the MNS in the neural representation of observed actions, however it is unknown whether the system can also drive cognitive judgments. In the current experiment, all participants watched the same video clip: hands trying to build a card tower, viewed from above. Half of the subjects watched the clip from the egocentric visual viewpoint (arms extend from bottom of screen), while half watched the clip rotated 180 degrees to create an allocentric visual viewpoint (arms extend from top). Participants then reported their perceived identification with, control of, and frustration with the hands, as well as ratings of task difficulty, actor's effort and ability, and endorsement of naïve ability theories. We found more situational attribution in ratings of the egocentric video. Our study demonstrates that visual viewpoint alone can create actor-observer effects in judgment, which suggests that action representation facilitates first person cognitive processing, a key feature of mental simulation.

of mental simulation.

**B263****DISTINGUISHING GENERIC SOCIAL THEORIES FROM PERSON-SPECIFIC THEORIES IN MEDIAL PREFRONTAL CORTEX** B. Locke Welborn<sup>1</sup>, Joshua C. Poore<sup>1</sup>, Elliot T. Berkman<sup>1</sup>, Emily Falk<sup>1</sup>, Matthew D. Lieberman<sup>1</sup>; <sup>1</sup>UCLA – The medial prefrontal cortex (MPFC) has frequently been implicated in tasks that require inferring an individual's mental state or making dispositional attributions. However, it remains unclear precisely which social dimensions influence the activity of the MPFC in representing and reasoning about the static and dynamic elements of others' mental lives. Perceived similarity to the self has recently been advanced as a plausible variable that may affect our social judgments, or even alter our strategies in making mental-state and trait attributions to others. The specificity, richness, and depth with which we represent others has received less attention as a variable that may influence MPFC in mentalizing and trait-attribution. In the present study, we investigate the effects of perceived similarity to oneself and perceived dissimilarity from the generic unknown person. We report on differential MPFC activations associated with whether the participant is applying a generic or person-specific theory of the target individual, regardless of whether the individual is similar to the participant. The results suggest that qualitatively different processes may be involved in thinking about others in terms of generic social norms versus an idiosyncratic theory of that individual.

of that individual.

**B264****UNDERSTANDING YOUR ENEMIES: THE ROLE OF MEDIAL PREFRONTAL CORTEX IN DECIDING WHO AND WHAT TO TRUST** Catherine Mulvenna<sup>1</sup>, Emily Falk<sup>1</sup>, Elliot Berkman<sup>1</sup>, Matthew Lieberman<sup>1</sup>; <sup>1</sup>UCLA – Social decision-making involves specific social cognitive processes, such as self-reflective thought and mentalizing about others, which can be used to try to understand adaptive and non-adaptive patterns of behavior. Recently, social cognitive neuroscience research has highlighted the role of cortical areas linked to mentalizing during decision-making tasks involving trust and persuasion. Mentalizing is the process in which one thinks of, or reads, the mental states of others, and has been most associated with the medial prefrontal cortex. Here we used functional magnetic resonance imaging in conjunction with a novel decision-making paradigm that

involved a high-risk intelligence-information sharing scenario. Participants (n=18) made consecutive forced-choice decisions to trust or not trust pieces of information that could prevent or allow an adversary attack on their own group/team. Results showed a significant main effect relative to the source of information participants were processing in medial prefrontal cortex (MPFC). Region of Interest analysis revealed significant deactivation in the MPFC when participants were making a trust decision on behalf of their own team on information from an enemy source (relative to an ally, neutral or own-team source). This suggested a reduction in mentalizing during decision making solely when processing information from an enemy source. A top down bias against thinking of the mental states of enemies when processing critical information could have negative consequences on decision-making accuracy in applied settings.

involved a high-risk intelligence-information sharing scenario. Participants (n=18) made consecutive forced-choice decisions to trust or not trust pieces of information that could prevent or allow an adversary attack on their own group/team. Results showed a significant main effect relative to the source of information participants were processing in medial prefrontal cortex (MPFC). Region of Interest analysis revealed significant deactivation in the MPFC when participants were making a trust decision on behalf of their own team on information from an enemy source (relative to an ally, neutral or own-team source). This suggested a reduction in mentalizing during decision making solely when processing information from an enemy source. A top down bias against thinking of the mental states of enemies when processing critical information could have negative consequences on decision-making accuracy in applied settings.

**B265****COMPARING THE NEURAL CORRELATES OF SELF AND OTHER-REFERENTIAL JUDGMENTS: A META-ANALYSIS OF FUNCTIONAL NEUROIMAGING STUDIES** Bryan T. Denny<sup>1</sup>, Hedy Kober<sup>1</sup>, Tor D. Wager<sup>1</sup>, Kevin N. Ochsner<sup>1</sup>; <sup>1</sup>Columbia University – The uniqueness of the self relative to others has long been of great interest to psychologists. In particular, judgments made about the self or about others have been shown to have divergent consequences for memory, affect, and behavior. The advent of functional neuroimaging has allowed for the investigation of the functional neural architecture underlying such judgments, but different studies using a range of methodologies have shown some variability in the specificity and localization of self and other-related neural activations. We performed a comprehensive meta-analysis of 108 functional neuroimaging studies involving self and other judgments using a novel multi-level kernel-based approach in order to determine whether the neural correlates of task judgments made with respect to the self or others are reliably different. We were particularly interested in differentiable activation patterns in the medial prefrontal cortex (mPFC), a key component in several theories of how the brain supports self-relevant cognition. We found that dorsomedial PFC (dmPFC) activation was reliably associated with making judgments when the target of the judgment was another person relative to the self, whereas judgments made with reference to the self relative to others were associated with more ventral mPFC and ventrolateral PFC (vlPFC) activation. Additional non-parametric chi-square analyses showed consistent findings. These results lend support to current theories of the neural instantiation of self and other-referential judgments that highlight a role for mPFC in making self-relevant judgments and provide support for a ventral-dorsal distinction between the neural mechanisms supporting self and other-relevant cognition.

of other-relevant cognition.

**B266****NEURAL EVIDENCE FOR PALLIATIVE APPROACH MOTIVATION AFTER THREAT** Kyle Nash<sup>1</sup>, Ian McGregor<sup>1</sup>, Michael Inzlicht<sup>2</sup>, Jacob Hirsch<sup>2</sup>; <sup>1</sup>York University, <sup>2</sup>University of Toronto – Various self-threats have been found to cause individuals with high self-esteem (HSE) to become defensively arrogant, self-enhancing, and jingoistic. Two studies assess the palliative hypothesis that such responses mute distress by activating neural processes related to approach motivation, namely, relative left-frontal EEG activity. In Study 1 we measured EEG activity after a threat manipulation that has caused HSEs to respond with arrogant defenses in past research. Among HSEs, results revealed relative left frontal EEG activation after threat. Study 2 then assessed whether approach-oriented neural activity functions to decrease reactivity to psychological conflict. We measured EEG activity and error related negativity (ERN) after commission of errors on a Stroop task. The same pattern of relative left-frontal EEG activity that had been heightened by threat in Study 1 was associated with muted ERN amplitude localized to the Anterior Cingulate Cortex in Study 2. Given that ERN amplitude has been implicated as a "cortical alarm bell" sensitive to the experience of anxiety, these results support the palliative hypothesis that arrogant defenses by threatened HSEs represent reactive approach motivation efforts to relieve distress.

of distressed HSEs represent reactive approach motivation efforts to relieve distress.

**B267****A NEURAL PREDICTOR OF PERSUASION-INDUCED BEHAVIOR CHANGE**

Emily B. Falk<sup>1</sup>, Elliot T. Berkman<sup>1</sup>, Traci Mann<sup>2</sup>, Matthew D. Lieberman; <sup>1</sup>University of California, Los Angeles, <sup>2</sup>University of Minnesota – Although persuasive messages often alter people's self-reported attitudes and intentions, these self-reports do not necessarily predict behavior change. Social cognitive neuroscience represents a new methodological approach to social psychological inquiry relying on techniques such as functional magnetic resonance imaging (fMRI). In the present study, we demonstrate that fMRI can predict behavior change in the week following exposure to persuasive messages about sunscreen use, above and beyond individuals' self-reported attitudes and intentions to use sunscreen. Additionally, an iterative cross-validation approach predicted an average 23% of the variance in behavior change, beyond self-reported attitudes and intentions. Thus, neural signals can predict behavioral changes that are not predicted from self-reported measures alone, and may provide an important complimentary tool to current focus-grouping and other social psychological methods.

**B268****REGULATORY FOCUS MODULATES REWARD-RELATED NEURAL ACTIVITY**

Samantha Mowrer<sup>1</sup>, Andrew Jahn<sup>1</sup>, William Cunningham<sup>1</sup>; <sup>1</sup>The Ohio State University – Motivation is an organizing force that can shape the perception and experience of rewards. It can exert influence throughout the reward processing stream, from attention to emotions to behavior. The current research used fMRI to examine how regulatory focus, a motivational principle coupled with reward and distinct affective experiences, would impact neural reward processing. Participants were randomly assigned to promotion or prevention focus and then completed a task in which they could experience successful and unsuccessful outcomes of stimuli representing potential gains and losses. Results showed regulatory focus modulated activation in a region of anterior but not posterior orbitofrontal cortex (OFC). Posterior OFC responded to potentially rewarding stimuli, while anterior OFC was responsive to rewarding outcomes and regulatory focus. Specifically, promotion focus enhanced sensitivity to successful outcomes in this anterior region, which may be a function of promotion focus itself or due to regulatory fit. OFC is a major confluence of sensory and affective information, and these findings provide further evidence for functional distinctions within this region, tying motivation to specific affective processes. Further results revealed that areas of dorsolateral prefrontal cortex (dlPFC) were influenced by regulatory focus in a manner consistent with laterality of representations of approach and avoidance motivation in the cortex. Thus, it is possible that dlPFC differentially maintained approach and avoidance-related information consistent with the strategic inclinations of one's currently active regulatory focus.

**B269****RELIGION AND THE ANTERIOR CINGULATE CORTEX: RELIGIOUS BELIEF QUIETS THE CORTICAL ALARM BELL**

Alexa Tullett<sup>1</sup>, Michael Inzlicht<sup>1</sup>, Ian McGregor<sup>2</sup>; <sup>1</sup>University of Toronto, <sup>2</sup>York University – Atheists and theists alike have claimed that religion might serve to shelter its followers from the staggering complexity and uncertainty in the world around us. If this is true, religion might insulate its adherents from anxiety in the face of stress. Consistent with this possibility, the error-related negativity (ERN) – a neural signal associated with anxious response to conflict, error, and uncertainty – is smaller for people who believe in God. This signal arises from the anterior cingulate cortex (ACC), a brain area termed the "cortical alarm bell" because of its role in alerting us to significant events and stimulating behavioural change. Still unclear, however, is the order of causation; does religiousness cause the ERN to be smaller, or does having a lower ERN predispose people to believe in religion? To test the first alternative we manipulated the salience of religion by priming it both overtly (study 1) and implicitly (study 2). In the first study, participants who wrote about what religion meant to them had lower ERNs than controls during the Stroop task and made fewer errors, suggesting that the

anxiety-reducing effects of the prime had positive consequences for performance. In the second study, religion was primed implicitly using a scrambled sentence task that included religiously themed words. This time, the prime caused the ERN to decrease for religious people, but to increase for non-religious people relative to controls. It seems, then, that thinking about religion can quell anxiety in believers, while provoking anxiety in non-believers.

## Social Support

**B270****THE PURSUIT OF COMMUNICATION GOALS IN TRANSGRESSION DISCOURSES AND THEIR CONSEQUENCES FOR FORGIVENESS**

Collin Barnes<sup>1</sup>; <sup>1</sup>The University of Oklahoma – The purpose of this study was to single out one aspect of transgression discourses – namely, the presentation of offense stories by victims to third-parties – and determine how the pursuit of different communication goals shapes victims' descriptions of offenses and forgiveness of wrongdoers. Participants described a recent offense from their lives with the goal of soliciting either a sympathetic or objective response from a third-party. In another condition, participants wrote about an offense as they would in a personal journal. One week later, participants wrote about the offense again, but under no communication goal restrictions. Forgiveness was assessed at each time point. At time one, offense stories written with the goal of soliciting an objective response from a third-party were significantly less negative in tone and included significantly fewer negative consequences and statements of perpetrator-directed blame than those written in the other conditions. Also, forgiveness was significantly higher in the objectivity condition than in the sympathy condition. No condition difference in forgiveness emerged at time two, but participants who initially pursued the goal of soliciting objectivity included significantly fewer perpetrator-directed blame statements in their time two offense stories than participants in the journal condition and somewhat fewer than participants in the sympathy condition, though this latter difference only approached significance. Together, these results highlight some of the ways that victims tailor offense stories to solicit specific responses from third-parties and suggests that doing so has consequences for forgiveness.

**B271****THE RELATION OF SOCIAL SUPPORT TO DEPRESSION IN MASSIVE ONLINE ROLE PLAYING GAMES**

Erin Dupuis<sup>1</sup>, Matthew Ramsey<sup>2</sup>; <sup>1</sup>Loyola University New Orleans, <sup>2</sup>University of New Hampshire – MMORPGs are a unique form of videogame in which users enter a graphically lush environment where they take on the role of an adventurer, go on quests, and form extensive social ties with other players. It has been claimed that involvement in massively multiplayer online roleplaying games (MMORPGs) provides users with a sense of support and community. In the present study, we examined the possible buffering effects of MMORPGs on depression. First, we examined whether higher involvement in MMORPGs was associated with higher levels of perceived social support. Second, we examined whether, consistent with past research, higher levels of perceived social support was associated with lower levels of non-clinical depression. Of an original 321 participants, 88 indicated that they currently played MMORPGs; we ran our analyses on this select sample. Using Structural Equation Modeling, we found that the aforementioned claim was not supported; involvement in MMORPGs was not associated with perceived social support. However, we further confirmed that a lack of perceived social support is associated with higher levels of depression. Past research has shown that involvement with MMORPGs is associated with several negative outcomes (e.g., social isolation and depression). If individuals do not at least gain a sense of social support and community from their time spent playing online (and, more importantly, the psychological benefits that go along with this sense) it is difficult to imagine that the leisure benefits of these games outweigh their sometimes negative consequences.

**B272**

**DOES RELIGION MATTER? THE ROLES OF ETHNIC AND RELIGIOUS IDENTITY, SUPPORT, AND UNSUPPORT** Miki Talebi<sup>1</sup>, Renate Ysseldyk<sup>1</sup>, Kimberly Matheson<sup>1</sup>, Hymie Anisman<sup>1</sup>; <sup>1</sup>Carleton University – Of late, Canada has seen a shift in the ethnic and religious minority groups that constitute its immigrant population. There is reason to believe that with the influx of immigrants, Canadians are becoming increasingly resentful of the resources and space that immigrants are occupying. As a result, immigrants might perceive Canadians as being unsupportive. However, the social support that immigrants receive from one another can play a particularly significant role in limiting the distress experienced by immigration. Working within a social identity framework, the present on-line investigation examined the role that ethnic and religious identity, perceived ingroup support, and unsupport played in relation to resilience to general life challenges among Canadian immigrants (N=132). It was of particular interest to determine whether religion or ethnicity, as aspects of social identity and as a source of social support, would be differentially related to resilience. Hierarchical regression analyses revealed that religious ingroup support buffered against the negative impacts of outgroup unsupport on resilience, whereas no such relationship was apparent with respect to ethnic identity. Specifically, as ingroup religious support decreased, encountering unsupport from the outgroup was more strongly associated with lower resilience. In contrast, when perceived availability of religious support was high, encountering unsupport from the outgroup was unrelated to resilience. It seems that the buffering effects of social support may be attributed to the unique aspect of religious identity and the social support emanating from the religious group.

**B273**

**WHEN YOUR FAILURE BECOMES MY FAILURE: THE CHALLENGE OF PROVIDING SUPPORT TO LOW SELF-ESTEEM INDIVIDUALS** Denise C. Marigold<sup>1</sup>, Justin V. Cavallo<sup>2</sup>, John G. Holmes<sup>2</sup>; <sup>1</sup>Renison University College at University of Waterloo, <sup>2</sup>University of Waterloo – Social support research has focused largely on the outcomes of support interactions for support recipients. The present study examined outcomes for support providers. We investigated the potential costs of providing support to low self-esteem individuals (LSEs), who tend to over-react to negative events (Brown & Dutton, 1995; Murray et al., 2002) but have little motivation to repair their moods (compared to high self-esteem individuals (HSEs); Heimpele et al., 2002). One member of each of 52 friendship dyads was assigned the role of support recipient and asked to share either a success or failure experience. Their partner was asked to provide support. Responses to post-interaction questionnaires revealed that when LSEs shared a failure, their partners reported more negative outcomes – more negative ratings of the interaction, and lower perceived regard and relationship quality – than did partners of HSEs. Coding of the interaction behaviours showed that in the failure condition, partners were less likely to validate LSEs' thoughts and feelings relative to HSEs', and that LSEs were more likely than HSEs to reject the support offered by their partners. The SE of the recipient had no effect in the success condition. The results suggest that when discussing failure experiences, support providers may attempt to cheer up LSEs by refuting overly negative statements, but LSEs prefer to stay focused on the negative aspects of the event. This tug-of-war leads support providers to feel as if they failed in the task of support provision, which invokes a cascade of dependence regulation behaviours.

**B274**

**DOES PARENTAL OPINION MATTER: HOW SELF-CONSTRUAL AND SOCIAL NETWORK OPINIONS CAN INFLUENCE ROMANTIC RELATIONSHIP DYNAMICS** Lauren Colvin<sup>1</sup>, H. Colleen Sinclair<sup>1</sup>; <sup>1</sup>Mississippi State University – Several studies have examined the correlation between social network opinion and romantic relationship dynamics. However, there are inconsistent findings with regard to the impact of parent opinion. The present studies will contribute to examining the possible rea-

sons for disparities by not only operationalizing type of opinion and source of opinion experimentally and non-experimentally, but also by examining whether strength of parental influence varies for those high in interdependence. For Study 1 (n=249) participants completed an online survey which assessed their perceived degree of social network approval of their current romantic relationship. In addition, measures were included to assess relationship quality outcomes (e.g., love, satisfaction) and self-construal (Singelis, 1994). It was anticipated that reported approval from ones parents would be more strongly associated with the romantic relationship outcomes for individuals high in interdependence than for individuals low in interdependence, which was confirmed. Friend opinion was equally important for both groups. Study 2 (n=202) manipulated hypothetical scenarios by varying Type of Opinion (approval, disapproval) and Source of Opinion (parents, friends). It was hypothesized that approval from ones social network would be associated with greater love for one's partner and higher commitment than if ones social network disapproved, which was confirmed. We also confirmed that both high and low interdependents value the opinions of friends. In contrast, parental opinion was more important for people higher on interdependence than those lower on interdependence. Implications for social network and self-construal research will be addressed.

**B275**

**SOCIAL RELATIONS AND PHYSICAL ACTIVITY: A NEW MEASURE OF SOCIAL STRAIN** Kelly Cotter<sup>1</sup>, Samia Javaid<sup>1</sup>, André Coté<sup>1</sup>, Gabriel Winn<sup>1</sup>; <sup>1</sup>Sacramento State University – Social relationships influence health directly as well as indirectly via health behaviors including physical activity. Higher social support typically predicts more physical activity, but the relationship of social strain to physical activity remains controversial. To determine the influence of social strain on physical activity we created a measure of social strain for exercise (SE) and examined cross-sectional data from 204 undergraduates (71% women). As expected, SE from family members was significantly related to perceived family strain ( $r = .31, p < .001$ ) and received family strain ( $r = .32, p < .001$ ), and SE from friends was significantly related to perceived friend strain ( $r = .27, p < .001$ ) and received friend strain ( $r = .22, p < .001$ ). SE was also positively correlated with social support for exercise from friends ( $r = .25, p = .002$ ) and from family ( $r = .16, p = .04$ ). A multiple regression analysis controlling for perceived support and strain from friends and family, received support and strain from friends and family, and exercise support from friends and family ( $R^2 = .17, F(12, 127) = 2.20, p = .02$ ) revealed that higher family SE was associated with less physical activity ( $\beta = -.19, p = .06$ ), while friend SE had an opposite, though not significant, relationship to physical activity ( $\beta = .15, p = .15$ ). Results suggest that SE may relate differently to physical activity depending on the source.

**B276**

**MECHANISMS INFLUENCING REACTIONS TO BEREAVED INDIVIDUALS: THE RELATIONS AMONG SOCIAL ATTRACTION, PERSEVERATION, MOOD AND EXPECTED GRIEF DURATION.** Alyssa Boasso<sup>1</sup>, Janet B. Ruscher<sup>1</sup>; <sup>1</sup>Tulane University – People generally overestimate the amount of time that others will take to recover after a negative life event. These inaccurate and varied estimations of grief duration likely result from the negative affect that grieving individuals induce in their social supporters (e.g., sadness and agitation) and the ensuing type of information processing (e.g., systematic versus heuristic) associated with the aroused affective state. The present study investigated how perseveration about a negative life event in conjunction with social attractiveness differentially impacted social supporters' moods as well as their expectations regarding grief duration. To investigate the mechanisms that directly and indirectly impact expectations about grief duration, female participants read a blog written by a female peer who was either socially attractive or socially unattractive and who was either perseverating or not perseverating about the unexpected passing of her mother. Participants reported their present mood and predicted the length of time they expected it to take for the blogger to recover. Analyses revealed that agitated mood

mediated the relation between the attractiveness-by-perseveration interaction and expected grief duration such that unattractive perseverators elicited greater frustration and were expected to take more time to move forward (i.e., they ineffectively cope with loss) compared to their attractive perseverating counterparts. Results suggest that perseverating individuals influence social supporters' moods which subsequently impact inferences about grief duration. These findings have implications for understanding how social supporters perceive and interact with people who are actively coping with negative life events, thereby informing potential strategies for effective social interaction.

**B277****META-ANALYSIS OF THE RELATIONSHIPS BETWEEN SOCIAL SUPPORT AND PSYCHOLOGICAL AND BEHAVIORAL WELL-BEING IN CHILDREN AND ADOLESCENTS** Po Sen Chu<sup>1</sup>, Donald Saucier<sup>2</sup>, Eric Hafner<sup>3</sup>, Sara Smith<sup>4</sup>;

<sup>1</sup>Kansas State University – Research has explored the associations between social support and well-being among children and adolescents, but the overall relationship is still unclear in terms of its magnitude. This meta-analysis intended to explore: 1) the overall association between social support and psychological well-being (e.g., the alleviation of depression, anxiety, or suicide ideation) and behavioral well-being (e.g., GPA, social skills, fewer conduct problems) in children and adolescents, 2) whether the strength of the association changed over time, and 3) whether the strength of the association was significant among participants with significant life stressors (e.g., teenage pregnancy, abuse victims). Studies between 1988 and 2007 measuring the relationships between social support and psychological and behavioral well-being were aggregated and analyzed using meta-analysis. The results indicated significantly positive but moderately sized associations between social support and psychological and behavioral well-being. Furthermore, the moderator analyses indicated: 1) the relationship was stronger among outcomes related to psychological well-being than among outcomes related to behavioral well-being; and 2) the relationships between social support and well-being have increased over the years. Finally, the relationships were significant and positive for both participants with or without significant life stressors, consistent with the buffering and main effect social support models offered by Cohen and Wills (1985). The implications and possible applications of the relationship between social support and well-being among children and adolescents are discussed.

**B278****REGULATORY FOCUS AND SUPPORT FOR ASPIRATIONS AND OBLIGATIONS IN ROMANTIC RELATIONSHIPS: A DYADIC PERSPECTIVE** Heike A. Winterheld<sup>1</sup>, Jeffrey A. Simpson<sup>2</sup>;

<sup>1</sup>California State University, East Bay, <sup>2</sup>University of Minnesota, Twin Cities Campus – Informed by regulatory focus theory, we investigated social support exchanges between romantic partners in ongoing relationships. The theory proposes two fundamental motivational orientations: a prevention focus (concerned with safety and security), and a promotion focus (concerned with hopes and aspirations). The theory lends itself to understanding how different motivations of support providers and recipients might shape the quality of support transactions in different support-relevant domains (i.e., support in response to aspirations/goals versus obligations/stressors). We tested a series of theoretically-derived predictions regarding regulatory focus, support provision, and perceptions of support from romantic partners. 101 couples completed a regulatory focus measure. One week later, they engaged in 4 separate discussions, taking turns to discuss a personal aspiration or obligation. Participants completed measures of their motivation to support their partner, and measures regarding their individual and relational well-being. Although the results revealed that certain situational factors appear to elicit the expression of people's chronic regulatory orientations during support transactions, these chronic regulatory tendencies typically transcended the situational context. Importantly, chronic regulatory focus had both actor and partner effects when predicting support provision and support perceptions. Thus, this work highlights (1) that

regulatory focus not only affects the quality of individuals' own experiences, but the experiences of their partners as well, and (2) that social support is an intrinsically interpersonal, dyadic process, necessitating the study of both recipients' and providers' perceptions and behaviors. The implications for furthering our understanding of the social support and the regulatory focus literatures will be discussed.

**B279****INVISIBLE INSTRUMENTAL SUPPORT: AN EXPERIMENTAL MANIPULATION** Katie D. Garner<sup>1</sup>, Linda K. Acitelli<sup>1</sup>;

<sup>1</sup>University of Houston, Houston, TX – There are known benefits of receiving social support; however, support has also been shown to produce negative effects. Invisible support has been introduced (e.g., Bolger & Amarel, 2007) to resolve these conflicting findings. Invisible support is argued to be a buffer against negative effects of visible social support as it avoids suggesting that the recipient is inefficacious. Earlier manipulations involved receiving invisible emotional support or advice with the support provider visible to the participant. The current study is an extension of past research on the benefits of invisible support and provides a unique attempt to manipulate the visibility of instrumental support. All 78 undergraduate students attempted to complete a jigsaw puzzle alone in a room. Some participants' puzzles were partially complete or not even started (no support condition). Participants who received the partially completed puzzle were either told that their friend started the puzzle for them (visible support condition) or were not given any explanation (invisible support condition). As expected, manipulation checks showed that participants in the visible condition were more likely to report receiving support than those in the invisible and no support conditions. Further, results suggested that those in the visible support condition felt their own abilities played less of a role in completing the task than those in the other conditions. Unexpected results revealed a relationship approaching significance between invisible support receipt and negative affect. Reasons for this trend are discussed with a focus on the manipulation, power, and the nature of different types of support.

**B280****"I'M NOT SATISFIED WITH YOUR SUPPORT, BUT IT DOESN'T HURT ME:" SOCIAL SUPPORT AND FRIENDSHIP-CONTINGENT SELF-ESTEEM** Tara N. Brown<sup>1</sup>, Amber L. Bush<sup>1</sup>, Rachel E. Levine<sup>1</sup>, Kathrin Milbury<sup>2</sup>;

<sup>1</sup>University of Houston, <sup>2</sup>The University of Texas M. D. Anderson Cancer Center – Receiving social support may not always benefit the recipient. Satisfaction with the received support may be relatively more important. For instance, dissatisfaction with received support from a close other has been linked to lower self-esteem and more suicidal ideation (Mireault & de Man, 1996). Yet, there is reason to believe that satisfaction with received support may be more crucial for some individuals, particularly for those with who are high in friendship-contingent self-esteem (FCSE; Cambron, Acitelli, & Steinberg, 2009). FCSE is self-worth that is dependent on the quality of one's friendships and is associated with daily fluctuations in self-esteem. Thus, we hypothesized that individuals higher in FCSE would report lower self-esteem on days in which they were less satisfied with the received support from a close friend, relative to those with lower FCSE. Individuals (N = 52) completed baseline measures of FCSE, and event-contingent diary records across 14 days. Specifically, participants completed one record each time they felt they received support from a specific close same-sex friend they had identified at the onset of the study. On each record, participants provided details about the support interaction including measures of support satisfaction and state self-esteem. Multilevel modeling supported the hypothesis revealing that greater dissatisfaction with received support was associated with lower state self-esteem, especially for those who were higher in FCSE. Thus, having self-esteem that is less tied to one's friendships appears to buffer the negative implications that dissatisfaction with social support would otherwise have on one's self-worth.

**B281**

**A LONGITUDINAL STUDY OF SUPERVISORS, PEERS, AND TEAMS AS SOURCES OF SOCIAL SUPPORT, STRESS AND SATISFACTION AT WORK: THE CASE OF PUBLIC SERVICE EMPLOYEES** Daniel Pelletier<sup>1</sup>, Charlene Sullivan<sup>1</sup>; <sup>1</sup>University of Quebec in Outaouais – Public service employees have been subjected to increasing demands at work due to downsizing, accountability, and results based management. These top-bottom pressures directly affect supervisors, teams, peers and individuals who react to them in different ways. The aim of this research was to study the individual and combined effects of high and low levels of appreciation for supervisors, teams and peers on perceived social support, stress and overall job satisfaction through time. The sample included 105 023 public service employees from various canadian government agencies representing approximately 60% of the entire canadian federal work force. Data was collected using the PSES (Public Service Employee Survey), a multi-instrument questionnaire measuring a variety of constructs such as job satisfaction, social support, stress, harassment, fairness, social climate, demands, control and so forth. The sample took part in the study in 1999, 2002, 2005, and 2008. Participants were included in a repeated measures factorial design (3 sources X 2 levels of appreciation) with various indicators of social support, stress and job satisfaction as independent variables. MANOVAs and ANOVAs were computed and significant effects were decomposed using Scheffé post hoc tests. A significant multivariate effect of the factors was found [ $F(\text{multi}) = 7,023$ ;  $p < .01$ ]. Subsequent univariate and post hoc tests indicated that non homogeneous levels of appreciation for supervisor, team, and peers are the norm in the public service, with the perception of social support decreasing steadily from T1. Implications of these results for the well-being of public service employees are discussed.

**B282**

**GIVING CREDIT WHEN CREDIT IS DUE: THE ROLE OF SELF-ESTEEM IN SOCIAL SUPPORT ATTRIBUTIONS AND FRIEND EVALUATION** Kathrin Milbury<sup>1</sup>, Linda Acitelli<sup>2</sup>; <sup>1</sup>The University of Texas M. D. Anderson Cancer Center, <sup>2</sup>University of Houston – Interestingly, social support has been linked not only to beneficial but also harmful outcomes. Extending the threat to self-esteem model, the current study examines the effectiveness of received support from a friend as a function of self-esteem (SE) and contingent self-worth (CSW) in a performance context. We predicted that, after experiencing performance failure, individuals with high SE and low CSW (academic) are less likely to evaluate the support provider positively and attribute subsequent success to received support than individuals with low SE and high CSW. After completing baseline measures, 36 undergraduates and their close friends (totaling 72 participants) believed they were in an experiment examining electronic communication. Participants were asked to exchange a supportive email with their friend after receiving either negative (ego threat condition) or neutral feedback (control condition) on a performance task. All participants received a standardized supportive message. Inconsistent with the hypotheses, participants high SE and low CSW rated the support provider more positively compared to participants with low SE with high CSW in the ego threat condition. These effects were reversed in the control condition. Further, in the ego-threat condition, participants with high SE and low CSW gave more credit to received support on a subsequent performance success compared to participants with low SE and high CSW. Although the results of this study do not seem to support the threat to self-esteem model, they are consistent with findings in the relationship literature, highlighting the importance of the relationship between the support provider and recipient.

**B283**

**SOCIAL TIES AND CARDIOVASCULAR FUNCTION: AN EXAMINATION OF RELATIONSHIP POSITIVITY AND NEGATIVITY DURING A LABORATORY STRESSOR** Wendy Birmingham<sup>1</sup>, Bert Uchino<sup>1</sup>, Timothy W. Smith<sup>1</sup>, Kathy C. Light<sup>1</sup>, David M. Sonbonmatsu<sup>1</sup>; <sup>1</sup>University of Utah – The quality and quantity of one's relationships have been reliably linked to morbidity and mortality. Prior work has focused on these relationships as they naturally occur in friendships. Such work has documented relationships that differ in their underlying positive and negative substrates (see Uchino et al., 2007). For instance, we have found that some close relationships are characterized by high levels of both positivity and negativity (ambivalence) which may be a significant source of stress (Holt-Lunstad et al., 2003). Thus, one aim of this study is to examine if a more controlled experimental manipulation of relationship positivity and negativity resulted in similar influences on cardiovascular reactivity during stress. In this study, we manipulated relationship positivity and negativity with an experimenter and examined its influence on cardiovascular reactivity. Results revealed that high levels of experimenter positivity was associated with lower systolic blood pressure (SBP) reactivity [ $F(2,326)=4.09$ ,  $p < .03$ ]. Relationships negativity, on the other hand, was related to lower diastolic blood pressure (DBP) reactivity in men only [ $F(1,163)=4.30$ ,  $p < .05$ ] which could be indicative of effort withdrawal in response to an aversive situation. Importantly, internal analysis found a ratings-based positivity X negativity interaction on SBP reactivity ( $b=1.71$ ,  $p=.01$ ) such that participants who tended to view the experimenter with relatively high levels of both positivity and negativity (ambivalence) had the highest levels of SBP reactivity.

**B284**

**SOCIAL SUPPORT AVAILABILITY AND STRESS APPRAISAL** Britta Larsen<sup>1</sup>, Nicholas J. S. Christenfeld<sup>1</sup>, Jason Jones<sup>1</sup>, Ryan S. Darby<sup>1</sup>; <sup>1</sup>University of California, San Diego – According to the buffering hypothesis, social support can enhance health by making stressful experiences less stressful. While this theory has received empirical support, it remains unclear what psychological mechanisms mediate this effect. Specifically, it is unclear whether social support affects perceptions of the demands of the situation (primary appraisal) and/or of the resources available to meet them (secondary appraisal). Also unknown is whether support affects appraisal differently for men and women. In the current study, participants ( $N = 504$ ) were given 12 hypothetical stressful situations and were assigned to imagine facing each alone, with a male friend, or with a female friend. Participants then rated the stressfulness of each situation, and what resources (e.g. the participant's sense of humor, a friend's money) they would use to address it. Results showed no difference in ratings of stressfulness between the conditions. Those facing stressors with friends, however, utilized significantly more resources. Females and males relied on their own resources equally, but females used others' resources more than men. Overall, participants requested help from female friends more than from male friends. Divided by gender, however, this trend held only for males, while females requested help equally from men and women. The results suggest that social support does not affect primary appraisal, but can significantly affect secondary appraisal of stressors and increase the number of resources used to address stressful situations. For males, however, the degree to which they use help from others depends on the gender of the support provider.

**B285**

**SOCIAL RELATIONSHIPS AND HEALTH: SUBLIMINAL ACTIVATION OF RELATIONAL SCHEMAS AND CONCURRENT CARDIOVASCULAR RESPONSE** McKenzie Carlisle<sup>1</sup>, Bert N. Uchino<sup>1</sup>, Wendy Birmingham<sup>1</sup>, Matthew Cribbet<sup>1</sup>, Timothy W. Smith<sup>1</sup>, David Sanbonmatsu<sup>1</sup>; <sup>1</sup>University of Utah – The links between relationships and cardiovascular functioning have shown that support from our social ties may protect, or "buffer" a person from possible pathogenic cardiovascular reactions associated with stressful events (Cohen & Wills, 1985). However, not all social ties

are sources of positivity during support, and negative relationships may contribute to the development of cardiovascular disorders through excessive physiological reactivity. In addition, most work has focused on the actual presence of relationships on reactivity (cf. Thorensstein & James, 1999). Alternatively, recent work has emphasized the importance of relationship schemas that can be activated in the absence of any direct social presence (Smith, Ruiz, & Uchino, 2004). The current study examined if non-conscious activation of relationship schemas influence cardiovascular reactivity during stressful tasks. Specifically, we subliminally primed (cf. Baldwin, 1994; Levy, 2000) participants ( $N=63$ ) with names of people in their social network who were rated as either negative or positive sources of support. Immediately following the primes, participants performed a series of stressor tasks while we took concurrent measurements of cardiovascular reactivity. Results of the analyses revealed that participants who were primed with negative network ties had the highest heart rate reactions to the subsequent stressor [ $F(1,59)=4.65, p=.03$ ]. These data suggest that subliminal priming of relationship constructs influence cardiovascular function and may explain links between social conflict and negative health outcomes.

### B286

**SOCIAL SUPPORT AND STUDENTS' ADJUSTMENT TO COLLEGE: THE ROLE OF IMPLICIT AND EXPLICIT SELF-ESTEEM** Marlee Kind Berman<sup>1</sup>, Nicole E. Noll<sup>2</sup>, Andrew Karpinski<sup>2</sup>; <sup>1</sup>John Jay College of Criminal Justice, City University of New York, <sup>2</sup>Temple University – Previous research suggests social support is related to students' successful adjustment to college (Moore, 2003). In the current study, we investigated whether self-esteem, as assessed by indirect and direct measures, moderated the relationship between social support and adjustment to college. We hypothesized that the relationship between social support and adjustment to college would be stronger for those students with lower levels of self-esteem than for those students with higher levels of self-esteem. Two hundred fifty-four Temple University undergraduates (ages 17-26) completed a questionnaire packet containing demographic questions and measures of social support, adjustment to college, implicit self-esteem (the Name-letter task), and explicit self-esteem (the Rosenberg self-esteem scale). Consistent with previous research, results indicated a strong positive correlation between social support and adjustment to college ( $\beta = .51$ ). This relationship was moderated by explicit self-esteem ( $\beta = .11$ ), but this relationship was in the opposite direction of the hypothesized relationship. Follow-up tests revealed a stronger relationship between social support and adjustment to college for those with higher explicit self-esteem than for those with lower explicit self-esteem. Implicit self-esteem did not moderate the relationship between social support and college adjustment ( $\beta = -.07$ ), but we did observe an independent, direct positive relationship between implicit self-esteem and adjustment to college ( $\beta = .11$ ). Because these results do not address the causal relationships between these variables, additional research is needed to investigate effective strategies for meeting the needs of socially isolated students.

### B287

**SOCIAL SUPPORT DEFICITS MODERATED BY EMOTIONAL INSTABILITY AND INTRUSIVE THOUGHTS** Roger G. Tweed<sup>1</sup>, Niloufar Saffari<sup>1</sup>, Nicole Pernet<sup>1</sup>; <sup>1</sup>Kwantlen Polytechnic University – Some evidence suggests that the relation between social support and depression is bidirectional. In other words, social support may reduce the depth of depression, and also depression may drive away social support. We hypothesized that the relation is even more complicated because other variables will moderate the extent to which depression drives away social support. In particular, intrusive thoughts and emotional instability may make the depression more obvious to potential support providers. Thus, these features may moderate the extent to which depression is associated with deficits in social support. All 226 participants had recently experienced spousal bereavement. The depression and social support data were collected 6, 18, and 48 months after the loss. As expected, both intrusive thoughts and emotional instability moderated the relation between

social support and depression. Depression was especially associated with social support deficits 6-months post-loss if the participant also scored high on the measure of emotional instability. Depression was also especially associated with social support deficits if intrusive thinking was still elevated 48 months post-loss.

### B288

**A LONGITUDINAL INVESTIGATION OF THE CONSEQUENCES OF SECURE BASE SUPPORT IN CLOSE RELATIONSHIPS** Meredith Van Vleet<sup>1</sup>, Brooke C. Feeney<sup>1</sup>; <sup>1</sup>Carnegie Mellon University – The provision of a secure base is theorized to be an important function that relationships serve across the lifespan. However, little research has been conducted regarding this type of support, and no research has tested the long-term implications of the presence or absence of secure base support in adult relationships. This project is a longitudinal investigation in which a sample of newlywed couples was followed over their first year of marriage to identify important outcomes of secure base support using questionnaire methods. Changes in exploration behavior, self perceptions and growth, relationship quality, attachment, and health were examined at Year 2 as a function of secure base support provision at Year 1. Results indicated that secure base support predicted benefits in all of these areas. Spouse's secure base support was predictive of increases in general pursuit of exploration, progress towards a specific goal, increases in self efficacy, personal growth, relationship satisfaction, and felt positive emotions towards one's spouse. Also, receipt of secure base support predicted decreases in felt negative emotions towards one's spouse and attachment avoidance. Moreover, wives' secure base support predicted increases in husbands' self esteem, feelings of closeness towards one's spouse, and decreases in relationship conflict, attachment anxiety, symptoms of depression, anger, anxiety, as well as physical symptoms of illness. Implications of the results and directions for future research will be discussed.

### B289

**RELATIVELY GREATER LEFT PREFRONTAL ACTIVITY ATTENUATES STRESS IN OLDER ADULTS WITH LOW SOCIAL SUPPORT** Amanda Steiner<sup>1</sup>, James Coan<sup>1</sup>; <sup>1</sup>University of Virginia – Perceived social support minimizes stress during major life transitions. Additional research suggests a pattern of relatively greater left prefrontal activity indexes approach-related emotion-regulation strategies that buffer against withdrawal-related negative affect. In our previous work (Steiner, Coan, & Damiano, 2008) we observed that students with low levels of social support were protected against difficulties adjusting to college when they utilized an approach-related emotion regulation style as indexed by relatively greater left prefrontal activity. In the present study, we used perceived social support and prefrontal asymmetry (pFA) to predict self-reported stress in older adults, hypothesizing that pFA would similarly moderate the relationship between perceived social support and stress in aging populations. Results indicated that pFA did indeed interact with perceived social support to predict level of stress among older adults. Specifically, relatively greater left prefrontal activity was associated with lower levels of reported stress in individuals who perceived themselves as having low social support. By contrast, individuals reporting high social support showed no relationship between pFA and reported stress. These findings suggest that an approach-related emotion regulation style indexed by relatively greater left pFA buffers individuals from stressors associated with low perceived social support across the lifespan.

### B290

**WHEN NOT TO BE A CHAMELEON: SIMILAR LANGUAGE USE IS ASSOCIATED WITH UNSKILLED SOCIAL SUPPORT** Alexandra Suppes<sup>1</sup>, Niall Bolger<sup>1</sup>, Jamil Zaki<sup>1</sup>, Gertraud Stadler<sup>1</sup>, Christine Paprocki<sup>2</sup>, Sean Lane<sup>3</sup>; <sup>1</sup>Columbia University, <sup>2</sup>University of North Carolina, Chapel Hill, <sup>3</sup>New York University – Support that is "invisible" (reported as having been provided by the support provider but not by the support recipient), is often associated with better outcomes than "visible" support, which has been associ-

ated with elevated anxiety and depression (Bolger & Amarel, 2007). This raises the question, what makes some support visible and other support not? Similarity in word usage may indicate that providers and recipients are echoing back a need for support and lack of efficacy, features that are associated with visible support (e.g., Shrout, Herman & Bolger, 2006). To examine this we looked at language similarity in 40 heterosexual couples engaged in two 7-minute support discussions. Afterwards, participants watched video recordings of their discussions during which providers continuously rated support provision and recipients continuously rated support receipt. This allowed us to calculate the total length of time visible or invisible support was provided. Next, correlations between partners word usage in each discussion were calculated. Increased similarity was related to more visible support, but it was unrelated to invisible support. Although communicative alignment is known to have social benefits, including increased dyadic rapport and social affiliation, these data suggest one context where similarity may not be optimal.

### B291

#### **CONTACT WITH INGROUP MEMBERS AS A MEDIATOR OF THE RELATIONSHIP BETWEEN RACIAL IDENTITY AND SOCIAL SUPPORT**

Jennifer S. Pratt-Hyatt<sup>1</sup>, Isis H. Settles<sup>2</sup>, Stevie C.Y. Yap<sup>2</sup>; <sup>1</sup>Northwest Missouri State University, <sup>2</sup>Michigan State University – Previous research has shown that, for members of racial minorities, identification with one's racial group is associated with positive well-being outcomes (Rowley et al., 1998), and that social support is one mediator of this relationship (Yap et al., 2009). It has been suggested that racial minority members who are highly identified with their race may have more positive contact with other ingroup members and that this increased contact may be associated with feelings of social support. With this study, we tested this hypothesis using a community sample of 155 African American adults. Ingroup contact was assessed using three measures: number of same-race friends, participation in race-based organizations, and religious participation. Religious participation was included because statistics show that a majority of religious congregations are comprised of same-race individuals (DeYoung, 2004), which suggests that African Americans are likely to encounter many same-race individuals through religious participation. A simultaneous multiple mediation analysis was used to test the hypothesis that these three contact variables would mediate the relationship between racial centrality and social support. Same-race friendships and religious participation were found to mediate the relationship, but participation in race-based organizations was not. Implications for the role of identity in the promotion of well-being among racial minorities are discussed.

### B292

#### **STRESS AND COPING AMONG ASIAN-AMERICANS AND EUROPEAN-AMERICANS: A PSYCHOLOGICAL ENTERPRISE OR AN INSTRUMENTAL WORLD?**

Chiung-Yi Tseng<sup>1</sup>, Joan G. Miller<sup>1</sup>; <sup>1</sup>The New School for Social Research – The claim has been made that Asian cultural groups tend to emphasize forms of implicit social support that do not involve disclosing one's problems to others and that rely less on the exchange of informational, emotional, or tangible resources than do the forms of explicit social support emphasized among European-Americans. Calling into question aspects of this claim, the present two-study investigation compared everyday social support provision among samples of 60 European-American and 90 Asian and Asian-American college students. Findings from both the Brief COPE as well as open-ended interviews revealed that Asian-Americans turned to others for tangible support more frequently than did European-Americans, while not differing from European-Americans in their reliance on others for informational and emotional support. Results also indicated that conceptions of the nature of the stressor mediated the types of coping strategies adopted. European-Americans tended to conceptualize stressors in predominately psychological terms, which was linked to inward problem-focused coping; whereas Asian-Americans tended to conceptualize stressors predominately in terms of situational demands, which was linked to modes of coping that emphasized instrumental problem solving. Implications are

drawn regarding the nature of the direct provision of support that occurs in the types of close social networks found in many collectivist cultures. Limitations are also noted in the cultural sensitivity of certain existing scale measures of social support.

### B293

#### **THE IMPACT OF RESPONSIVE SOCIAL SUPPORT FROM A ROMANTIC PARTNER OR A STRANGER IN AN IMMERSIVE VIRTUAL ENVIRONMENT ON PSYCHOSOCIAL AND BEHAVIORAL INTERPERSONAL OUTCOMES**

Heidi Kane<sup>1</sup>, Cade McCall<sup>2</sup>, Nancy Collins<sup>2</sup>, Jim Blasovich<sup>2</sup>; <sup>1</sup>University of California Los Angeles, <sup>2</sup>University of California Santa Barbara – Social support interactions provide individuals with diagnostic information about others' concern for their well-being and investment in their relationships. We argue that in these interactions responsiveness plays a key role in the development and maintenance (or deterioration) of close relationships. However, few studies have experimentally examined the impact of responsive social support on these important interpersonal outcomes. Furthermore, even less is known about the impact of responsive social support from a stranger. Therefore, the primary goal of this study was to examine the impact of responsive social support from either a romantic partner or stranger on psychosocial and interpersonal outcomes within the context of an anxiety-provoking situation. We created an anxiety-provoking cliff-walking task for participants using immersive virtual reality technology (virtual reality). We then manipulated the presence or absence of their romantic partner or a stranger during this task. In addition, in the presence conditions, we manipulated the support-provider's behavior to be either neglectful or responsive. Results revealed that the presence of a responsive support-provider during the task made participants feel more secure, comforted, understood, and valued than the presence of a neglectful support-provider. These effects were most pronounced when the support-provider was a romantic partner. In addition, participants in the neglectful conditions physically distanced themselves from support-providers during a subsequent unrelated task. These results provide evidence for the importance of responsiveness in both ongoing and new relationships; even at a low level of acquaintance people attended to information about responsiveness and adjusted their thoughts, feelings, and behavior accordingly.

### B294

#### **AFFILIATION WITH NEW PEER ACQUAINTANCES: INTERPERSONAL DYNAMICS DURING TWO INITIAL SOCIAL SUPPORT INTERACTIONS**

Brooke Feeney<sup>1</sup>, Jude Cassidy<sup>2</sup>, Edward Lemay<sup>3</sup>, Fatima Ramos-Marcuse<sup>4</sup>; <sup>1</sup>Carnegie Mellon University, <sup>2</sup>University of Maryland, College Park, <sup>3</sup>University of New Hampshire, <sup>4</sup>University of Maryland School of Nursing – Despite the massive literatures on social support and affiliation, research examining the influence of a prior social support interaction on a subsequent interaction as new relationships are forming has been lacking. Thus, the goal of this investigation was to provide insight into social support dynamics that occur when pairs of adolescent peers meet for the first time and discuss current life concerns with one another in two separate interactions. Each adolescent was placed into the role of a "support-seeker" for one discussion and a "support-provider" for the other. Results indicated that (a) the behaviors of new interaction partners are coordinated during an interaction and become even more coordinated within a subsequent interaction, (b) behaviors exhibited during an initial interaction influence behaviors exhibited during a subsequent interaction, (c) seeking and provision of support increase across interactions, (d) individuals affiliate in similar ways across interactions, and (e) gender moderates some effects. Implications of results and their contributions to existing literatures are discussed.

**BILINGUAL JEWISH-ARABIC SCHOOLS IN ISRAEL: PERCEIVED STEREOTYPES, IMPLICIT SOCIAL IDENTITY AND IMPLICIT SELF-ESTEEM** Jenny Kurman<sup>1</sup>, Mouna Karkabi<sup>1</sup>, Faisal Azaiza<sup>1</sup>; <sup>1</sup>University of Haifa, Israel

— This study compares Arab and Jewish students attending bilingual schools in Israel with their peers in segregated schools, in terms of implicit social identity, implicit self-esteem and perceptions of out-group attitudes toward ingroup members. Bilingual education creates an alternative reality within the schools, enabling long-term acquaintance and in-depth exposure to the perspective, narrative and life style of the other group within a context of equality. Bilingual education may reduce the conflictual atmosphere between the Jewish and the Arabic populations on the micro-level. Exposure to a positive atmosphere may be related to more positive characteristics of minority members. The main hypothesis was that Arab children in bilingual schools will report more positive perceptions of self-esteem and social identity than their peers in segregated schools, due to the more egalitarian atmosphere and less negative stereotype against them. 255 5th and 6th grade students from 6 primary schools in Israel participated in the study. 76 of them were attending bilingual schools and 188 were attending segregated Jewish and Arabic schools. The IAT was used to examine implicit social identity and implicit self-esteem. Contrary to expectations, Arab children in segregated schools had a more positive implicit social identity than those attending bilingual schools. Meanwhile, Jewish children in bilingual schools had higher implicit self-esteem than those attending segregated schools. Bilingual schools do not seem to improve stereotypical perceptions of members from the out-group. Possible causes for these unexpected findings and implications are discussed.

Friday, January 29, 12:30 – 2:00 pm, Grande Ballroom

## Aggression/Anti-Social

### C1

#### **DON'T DWELL ON IT: THE IMPACT OF RUMINATION ON EGO DEPLETION AND AGGRESSION**

A. Hahm<sup>1</sup>, W. C. Pedersen<sup>1</sup>, K. Crowe<sup>1</sup>, K. Fong<sup>1</sup>, Y. Renteria<sup>1</sup>, R. Sorau<sup>1</sup>, T. F. Denson<sup>2</sup>; <sup>1</sup>California State University, Long Beach, <sup>2</sup>University of New South Wales – Previous studies have found a link between rumination and increased aggression (e.g., Bushman, 2002; Bushman, Bonacci, Pedersen, Vasquez, & Miller, 2005). The current study was the first to assess the impact of rumination on ego depletion. It also was the first to investigate ego depletion as an underlying mechanism in the link between rumination and subsequent aggressive behavior. Ego depletion refers to a state where self-control capacities are diminished, which subsequently affects one's ability to override or restrain behavioral impulses (Baumeister, Muraven, & Tice, 2000). Aggressive behavior may be viewed as a failure of self-control because it represents an inability to restrain aggressive impulses (Gailliot & Baumeister, 2007). Participants were either provoked or not and then were induced to ruminate or were distracted for 20 minutes. Self-control resources and aggressive behavior were then assessed. Consistent with expectations, provocation and rumination significantly interacted such that provoked participants who ruminated exhibited significantly (1) less self-control resources and (2) more aggression relative to the combination of the other experimental conditions. Furthermore, self-control partially mediated the effect of provocation and rumination on aggressive behavior. These findings enhance our understanding of the role that ego depletion plays in the impact of provocation and rumination on the intensification of aggression. Implications of this work for reducing instances of aggression are also discussed.

### C2

#### **BELIEF IN THE "MYTH OF PURE EVIL" AND SENTENCING RECOMMENDATIONS FOR CHILD SEX OFFENDERS**

John K. Rempel<sup>1</sup>, Christopher T. Burris<sup>1</sup>; <sup>1</sup>St. Jerome's University – Suggested strategies for dealing with child sex offenders range from treatment and rehabilitation to calls for banishment, isolation, and suffering. We hypothesized that more extreme forms of punishment would be associated with construing offenders as incarnations of "the myth of pure evil" (Baumeister, 1997) – i.e., joyfully, arrogantly, and irrevocably committed to inflicting unjustifiable suffering and chaos in pursuit of their selfish ends. Fifty-six participants completed a 9-item Myth of Pure Evil scale (alpha = .81) and read one of two accounts of a convicted repeat offender who manipulated young teenage boys into a sexual relationship. In one version the offender's "evil" nature was inferred by his interest in books on the occult, whereas in the other his reading preferences were "inspirational." Participants subsequently rated the applicability of ten increasingly punitive sentencing recommendations for him: Four – a life sentence, life plus solitary confinement, long-term imprisonment with chemical "castration," and long-term imprisonment with surgical castration – formed an extreme punishment scale (Cronbach's alpha = .87). Extreme punishment was advocated when the offender was seen as exemplifying the myth of pure evil,  $r = .34$ ,  $p < .02$ , and this link tended to be stronger when the "evil" cue was present ( $r_s = .52$ ,  $p < .01$ , and  $.21$ , ns, in the occult and inspirational conditions, respectively). Thus, perceiving child sex offenders as irrecoverably evil, especially when cued with myth-congruent "evil" symbols, predicts advocacy of extreme – and arguably inhumane – forms of punishment.

### C3

#### **SELF-MONITORING AS A MODERATING FACTOR OF AGGRESSIVE RESPONSES TO OSTRACISM**

Dorothee Dietrich<sup>1</sup>, Kaitlyn Hawkinson<sup>1</sup>, April Palo<sup>1</sup>; <sup>1</sup>Hamline University – Twenge, Baumeister, Tice and Stucke (2001) showed that social rejection leads to aggression. Furthermore, Twenge and Campbell (2003) demonstrated that the individual difference of narcissism moderates this effect with highly narcissistic individuals acting more aggressively after experiencing rejection than individuals low in narcissism. The purpose of this study was to determine if the individual difference of self-monitoring also moderates the social rejection-aggression effect. Snyder and Gangestad (2000) describe high self-monitors as "highly responsive to social and interpersonal cues of situationally appropriate performance." Therefore, we examined the effects of ostracism/acceptance on aggressive responses with self-monitoring as a covariate, hypothesizing that high self-monitors react more strongly to ostracism than low self-monitors due to their heightened sensitivity. Seventy-five participants completed the self-monitoring scale and were randomly assigned to ostracism or social acceptance conditions. Participants played Cyberball (Williams, Cheung & Choi, 2000), a virtual ball toss game in which the ostracized participants don't receive the ball by their co-players after the first few ball tosses. Participants then completed a questionnaire including eight items evaluating their team members, providing an opportunity for aggressive responses. As hypothesized, ANCOVA of the aggression index (composite of eight items alpha = .93) showed that self-monitoring was a significant covariate [ $F(1, 75) = 7.33$ ,  $p = .008$ ]. In addition, the main effect for ostracism/acceptance was significant [ $F(1, 75) = 38.67$ ,  $p = .001$ ] after controlling for self-monitoring. Further analysis showed that self-monitoring was positively correlated with aggression in the ostracism condition [ $r(38) = .38$ ,  $p = .02$ ] but not in the acceptance condition [ $r(37) = .18$ ,  $p = .27$ ].

### C4

#### **SEEING IS BELIEVING: EFFECTS OF ALCOHOL CUES ON AGGRESSIVE BEHAVIORS**

Baptiste Subra<sup>1</sup>, Dominique Muller<sup>1</sup>, Laurent Begue<sup>1</sup>, Brad J. Bushman<sup>2</sup>, Florian Delmas<sup>1</sup>; <sup>1</sup>University of Grenoble, <sup>2</sup>University of Michigan – Research to date has shown a strong link between alcohol and aggression. Evidence from experimental studies indicates that the mere belief that one has consumed alcohol increases aggression (e.g., Begue et al., 2009). A compelling explanation is that the mere exposure to alcohol-related cues automatically activates aggressive thoughts and behaviors (Bartholow & Heinz, 2006). Based on this assumption, two experiments tested whether alcohol-related cues automatically activate aggressive thoughts and increase aggressive behaviors. In Study 1, accessibility of aggressive thoughts was assessed on 502 participants using a lexical decision task, where target words were preceded by a prime (Photographs of weapons, alcoholics, or nonalcoholics beverages) exposed supraliminally (300 ms). Our results revealed that participants made faster lexical decisions concerning aggression related words following alcohol-related primes or weapon-related primes compared with neutral primes. In Study 2, 80 participants were given the chance to harm another person after being exposed to alcohol-related cues, aggressive cues, or neutral cues. In order to test our hypothesis in the most stringent manner possible, cues were presented outside of consciousness (17 ms). Our results revealed that participants exposed either to alcohol or aggressive subliminal primes were more aggressive toward the experimenter than participants exposed to neutral subliminal primes, and the effect even lasted a few days in participants exposed to alcohol subliminal primes. These two experiments demonstrate that mere exposure to alcohol-related cues increase aggressive thoughts and behaviors. We don't need to drink alcohol to become aggressive: just seeing bottles of alcohol increases aggressive thoughts and actions.

**C5****THE MODERATING EFFECT OF AGE ON THE RELATION BETWEEN VIOLENT VIDEO GAMES, AGGRESSIVE PERSONALITY, AND AGGRESSIVE BEHAVIOR OVER TIME**

Rick Trinkner<sup>1</sup>, Donald O. Bucolo<sup>1</sup>, Ellen S. Cohn<sup>1</sup>, Cesar J. Rebellon<sup>1</sup>, Karen Van Gundy<sup>1</sup>; <sup>1</sup>University of New Hampshire – Researchers debate whether violent video games lead to aggression with some arguing that exposure to such games increases aggression (Anderson, 2004), while other researchers suggest that such a relation does not exist (Ferguson et al., 2008). Critics of the violent video game-aggression link argue that when other predictors of aggression (e.g., aggressive personality) are included in models, violent video game exposure no longer predicts aggression (Ferguson et al., 2008). However, researchers have only investigated this association utilizing cross-sectional research designs. In the current study, we tested whether violent video game exposure and aggressive personality would predict future aggressive behavior among adolescents aged 13 and 16. Participants completed scales assessing aggressive personality variables (i.e., trait aggression, impulsivity, risk-seeking, temper), violent video game exposure, and aggressive behavior in the Fall of 2007 and a year later in the Fall of 2008. Lagged models assessing change in aggressive behavior revealed that, while controlling for aggressive personality, exposure to violent video games led to increased aggressive behavior only among the cohort of 16 year olds; violent video game exposure had no relation to future aggressive behavior among 13 year olds. These results suggest that development has a moderating effect on the relation between violent video games and aggressive behavior (c.f. Kirsch, 1993). Future researchers should include other predictors of aggressive behavior in their models to determine the robustness of the association among violent video games and aggression.

**C6****EVALUATION OF THE INTERPERSONAL CONFLICT CONSTRUCT: IMPLICATIONS FOR MEASUREMENT**

Robert Wright<sup>1</sup>, Cynthia Mohr<sup>1</sup>, Robert Sinclair<sup>2</sup>; <sup>1</sup>Portland State University, <sup>2</sup>Clemson University – Interpersonal conflicts are a significant source of stress, leading to a variety of negative outcomes. The literature, however, contains varying definitions and measures of the interpersonal conflict construct (e.g., Barki & Hartwick, 2004; Jensen-Campbell & Graziano, 2000). As such, the current study sought to uncover consistent themes among interpersonal conflicts and then explore cognitive appraisals of these particular aspects of interpersonal conflict. Specifically, a checklist of interpersonal conflict was developed from themes identified in written descriptions of interpersonal conflict based on methods by Hsieh and Shannon, 2005 and then examined for differences of cognitive appraisal (e.g., how meaningful, how undesirable). Data were gathered from a sample of nurses (n = 144) reporting on interpersonal conflicts with nurse peers in a mixed-method weekly design over a 12-week period. Results provide preliminary support for the checklist as a reliable and valid tool in examining interpersonal conflict, particularly applicable to group performance contexts. Furthermore, results indicate that appraisals of conflicts vary according to different aspects of conflict, supporting examination of interpersonal conflict according to the identified themes. For example, conflicts regarding others' irresponsibility (i.e., failure to perform task) were rated as significantly more meaningful than all other conflicts ( $p < .05$ ) and conflicts characterized by feelings of dislike or animosity were significantly more undesirable than conflicts without ( $p < .05$ ). Implications for future research on interpersonal conflict are discussed in light of the checklist findings.

**C7****WORSE THAN STICKS AND STONES? BULLYING IS LINKED WITH ALTERED HPA AXIS FUNCTIONING AND POORER HEALTH**

Jennifer M. Knack<sup>1</sup>, Aubrey Thompson<sup>2</sup>, Lauri A. Jensen-Campbell<sup>2</sup>; <sup>1</sup>University of Ottawa, <sup>2</sup>University of Texas at Arlington – We examined whether HPA axis activation (as measured through salivary cortisol levels) may be an underlying mechanism in the link between peer victimization and physical health

problems. Adolescents (N = 107) and their parent participated in a two-part study examining peer victimization, neuroendocrine functioning, and physical health. In phase 1, adolescents completed questionnaires assessing their social experiences (e.g., peer victimization) and health. They later returned for phase 2 which consisted of 2 sessions. In session 1, adolescents learned to collect salivary cortisol samples. They collected 4 samples over each of 2 non-sports school days. In session 2, adolescents completed the Trier Social Stress Test (TSST) in which they prepared and delivered a speech while salivary cortisol was collected. Peer victimization predicted more frequent and severe health problems and more visits to health professionals ( $t(105) = 7.31, 6.76, 4.98, ps < 0.01$ ). Moreover, we found a victimization X slope interaction for cortisol awakening response (CAR),  $t(375) = 2.91, b = 0.10, p < 0.01$ , such that being bullied was linked with a flatter CAR. We found that this CAR partially mediated the link between victimization and health problems. During the TSST, victims reported more stress ( $r = 0.28, p < 0.01$ ) and exhibited altered cortisol levels. Higher cortisol immediately after the stressor and lower cortisol 30 minutes after the stressor were associated with more health problems. This study was an important first step in understanding how peer victimization alters biological functioning and health.

**C8****TRAITS ARE MORE THAN JUST SITUATIONAL SENSITIVITIES**

Edward Witt<sup>1</sup>, M. Brent Donnellan<sup>1</sup>; <sup>1</sup>Michigan State University – The Traits as Situational Sensitivities Model (TASS model; Marshall & Brown, 2006) posits that personality attributes (e.g., trait aggression) operate in a threshold-like manner such that individuals with higher levels of a given trait require less situational press to evoke trait-relevant behaviors. The TASS model also predicts that personality attributes are the most powerful predictors of behavior in situations of medium strength (i.e., the model predicts a specific statistical interaction). We evaluated these propositions using a hot sauce study (Liebermann et al., 1999) to serve as a conceptual replication of Study 1 in Marshall and Brown (2006). Participants (N = 273) randomly received one of three levels of provocation (none, medium, strong) in the form of written feedback to a personally-relevant essay. Participants were then given the opportunity to retaliate against the person who ostensibly gave them feedback. Analyses revealed main effects for personality measures and for level of provocation for predicting hot sauce allocation; however, we found no evidence that personality effects were more pronounced at medium levels of provocation. Moreover, we found few differences between our objectively moderate and strong provocations on any outcome measure designed to assess psychological features of the situation. Results suggest that both personality attributes and situational attributes are linked to expressions of retaliatory aggression in the laboratory; whereas statistical interactions are much more elusive. Implications of these findings as well as potential methodological and conceptual concerns with the TASS model are discussed.

**C9****ATTENUATING THE EFFECT OF NARCISSISM ON AGGRESSION: POWER RESTORATION AND ITS LIMITATIONS**

Alison Sheldon<sup>1</sup>, William C. Pedersen<sup>1</sup>, Archie Arena<sup>1</sup>, Kimhoan Chu<sup>1</sup>, Katie Crowe<sup>1</sup>, Melissa Drysdale<sup>1</sup>, Keshia Fields<sup>1</sup>, Elizabeth Machado<sup>1</sup>, Jon Nieva<sup>1</sup>, Monica Romero<sup>1</sup>, Reyna Sorauf<sup>1</sup>, Ana Truong<sup>1</sup>; <sup>1</sup>California State University, Long Beach – Previous studies indicate that narcissism increases aggressive responding (e.g., Bushman & Baumeister, 1998). Social Interactionist theorists maintain that one motive for aggression is the restoration of power (e.g., Tedeschi & Felson, 1994). The current study is the first to investigate the interactive effect of provocation, narcissism and power restoration on subsequent aggression. Furthermore, it is the first experiment to directly compare two types of power restoration – random allocation versus “earned” power. Participants were either provoked or not and then informed they would (a) manage another subject as a result of random assignment, (b) manage another subject based on their answers to a previous leadership questionnaire, or (c) simply work with another participant (control condition). Participants then had an opportunity to

aggress. Several findings emerged. First, there was a 3-way interaction between power restoration, provocation, and narcissism. Replicating previous findings, higher levels of narcissism predicted increased aggression for provoked participants in the control condition ( $b=1.33$ ,  $p<.01$ ). However, power restoration served to attenuate the impact of narcissism on aggression,  $b=-0.17$ ,  $p>.10$ . Conversely, in the absence of an initial provocation narcissism was a marginal positive predictor of aggression ( $b=0.82$ ,  $p=.07$ ) in the control condition but following power allocation narcissism became a significant positive predictor of aggressive behavior,  $b=1.03$ ,  $p<.01$ . Second, the specific type of power restoration (i.e., random vs. earned) did not differentially impact aggression. Results suggest that increasing an individual's power is not a panacea against aggression. Implications of this work for reducing instances of aggression are also discussed.

### C10

**THE IMPACT OF ALCOHOL PRIMING AND PROVOCATION AMBIGUITY ON AGGRESSIVE BEHAVIOR** Marianne Grosvenor<sup>1</sup>, William Pedersen<sup>1</sup>, Aryun Hahm<sup>1</sup>, Stephanie Kirby<sup>1</sup>, Laura Matthews<sup>1</sup>, Sandra Mendoza<sup>1</sup>, Krysteena Stephens<sup>1</sup>, Eddie Vasquez<sup>2</sup>, Bruce Bartholow<sup>3</sup>; <sup>1</sup>California State University, Long Beach, <sup>2</sup>University of Kent, <sup>3</sup>University of Missouri, Columbia – Previous research has shown that priming with alcohol cues (e.g. alcohol-related words, pictures) impacts perceptions of hostility (Bartholow & Heinz, 2006). The ability of alcohol priming to increase actual aggressive behavior, however, may be more likely to occur in the context of ambiguous rather than unambiguous provocations because the former incidents are more susceptible to attributional distortion (Pedersen, Gonzales, & Miller, 2000). The current study is the first to assess the moderating effect of provocation ambiguity on alcohol-primed aggression. In addition, it is the first to employ a physical measure of aggressive behavior in investigating the impact of priming alcohol cues on aggression. Participants were primed with either alcohol or neutral cues followed by a high ambiguity provocation, low ambiguity provocation, or a no provocation control. Prime content and prime ambiguity interacted to impact subsequent aggressive behavior. As expected, alcohol priming significantly augmented aggression only when paired with a highly ambiguous provocation. Implications for the reduction of aggression and directions for future research are also discussed.

### C11

**THE IMPORTANCE OF FRAMING: PAIRING PRESCRIPTIVE MESSAGES WITH DESCRIPTIVE NORMS TO REDUCE AGGRESSION** Vanessa E. Hettinger<sup>1</sup>, Joseph A. Vandello<sup>1</sup>; <sup>1</sup>University of South Florida – Aggressive behavior in males may be partially driven by a mistaken belief that aggression is common and socially expected. This research examines whether manipulation of descriptive norms for aggression (depicting aggression as rare or common) influences likelihood of aggressing in conflict situations. We predicted that participants in the 'high norm' (common) condition would report being more likely to aggress in response to conflict than participants in the 'low norm' (rare) condition. Additionally, this research probed the effect of message framing in shaping the interaction between descriptive and injunctive norms. Guided by deviance regulation theory, we predicted that when the implanted descriptive norm for aggression was high, a positively framed message (about the benefits of non-aggression) would be more effective in reducing participants' reported likelihood to aggress than a negatively framed message (about the negative consequences of aggression). In this questionnaire study, participants [ $N = 60$ ] read a fake newspaper article which reported statistics on frequency of aggression in college males, and statistics about the traits and life outcomes of aggressive or non-aggressive people, and then were asked to indicate their likely response to hypothetical conflict scenarios. Overall, participants in the high norm condition reported being significantly more likely to aggress than participants in the low norm condition. However, high norm participants who also received the positively framed message were much less likely to

aggress (equivalent to the low norm condition) than those who received the negatively framed message or no message. Thus, proper message framing was important for reducing aggression.

### C12

**PREDICTING CONFLICT ACTS: AN ALTERNATIVE TO THE FIVE CONFLICT "STYLES"** Mark Davis<sup>1</sup>, Michael Schoenfeld<sup>1</sup>, Elizabeth Flores<sup>1</sup>; <sup>1</sup>Eckerd College – For decades, interpersonal conflict research has been almost entirely based on the "conflict styles" approach, which identifies five broad ways of approaching conflict: collaborative, competitive, obliging, avoidant, and compromising. Instruments based on this approach have had success at predicting conflict-related outcomes. However, we believe this predictive power could be improved by using instruments that assess concrete, specific behavioral tendencies instead of broad styles. We believe that this will occur for the same reason that more specific, less global, attitude measures are often better predictors of behavior. To test this notion, 160 undergraduates completed a widely-used measure of conflict styles (Rahim Organizational Conflict Inventory) and a behavior-based measure that assesses the tendency to engage in 15 specific responses to conflict (Conflict Dynamics Profile). Participants also indicated whether or not they had engaged in each of 37 conflict-related actions over the past 60 days. Factor analyses of these 37 items revealed six interpretable "conflict acts": manipulateness, anger, demeaning behavior, maliciousness, making amends, and compliance. Two series of hierarchical regressions were conducted to predict these six conflict acts; in one series the style measure was entered first and in the other the behavioral measure was entered first. As expected, the behavioral measure was a superior predictor. It accounted for more variance than the styles measure whether entered on the first step or the second step of the equation. Thus, these results support the view that conflict acts are significantly better predicted by using specific behavioral predictors rather than the familiar five styles.

### C13

**HIGHLY ABUSIVE, HIGH SELF-ESTEEM WOMEN FIND ABUSIVE MEN MORE ACCEPTABLE: IMPLICATIONS FOR DOMESTIC VIOLENCE TREATMENT PROGRAMS** Christine Chang-Schneider<sup>1</sup>, William B. Swann, Jr.<sup>1</sup>; <sup>1</sup>University of Texas at Austin – We proposed that women who are in psychologically abusive relationships find psychologically abusive behavior more acceptable than those in healthy relationships. 80 women who self-identified as being in either highly abusive or low-abusive relationships (Conflict Tactics Scale-2 [CTS-2], Straus et al. 1996) watched a 5-minute video depicting a psychologically abusive interaction between a male and a female. They were then asked 1) how likely would you be to remain in this relationship? and 2) how acceptable was the behavior in this video? Women receiving high levels of abuse in their current relationship were more likely to endorse that they would stay in the depicted abusive relationship than those receiving little abuse. This effect, however, was fully mediated by how psychologically abusive the woman, herself, was in her current relationship. Specifically, the more psychologically abusive the woman was, the more she endorsed that she would likely remain in the abusive relationship depicted in the video. Similarly, the tendency for women receiving high as compared to low levels of psychological abuse to regard yelling behavior as acceptable was moderated by both how psychologically abusive the woman was in her current relationship and her self-esteem. That is, women who were the highest in psychological abusiveness toward their partner and the highest in self-esteem found the yelling more acceptable than their counter parts. Implications for increased focus on women's roles in domestic violence intervention are discussed.

**C14****SHORT-TERM CONSEQUENCES AND LONG-TERM FORMATIONS OF CYBERBULLYING BEHAVIOR: TESTING PROXIMATE AND DISTAL MODELS** Christopher Barlett<sup>1</sup>, Douglas Gentile<sup>1</sup>, <sup>1</sup>Iowa State University –

Cyberbullying, defined as the use of technology to support deliberative, repeated, and hostile behavior towards others, is a very serious societal problem. To date, the research on cyberbullying has been descriptive and atheoretical. The purpose of the current study was to test a theoretical model describing the short-term process of cyberbullying and the long-term development of cyberbullying attitudes. All participants (N = 394) completed several questionnaires measuring cyberbehavior, victimization, vengeance, stress, positive attitudes towards cyberbullying, and guilt. Results from the best fitting proximate model (GFI = .92, AGFI = .84, CFI = .92, RMSEA = .12 (90% CI: .10 to .142)) showed two routes predicting cyberbullying frequency. The first route begins with cyberbullying predicting relational aggression ( $\beta = .26, p < .01$ ) and stress ( $\beta = .19, p < .01$ ). The stress is related to vengeance ( $\beta = .13, p < .05$ ), which predicts positive attitudes towards cyberbullying ( $\beta = .34, p < .01$ ) that feeds back into aggression ( $\beta = .40, p < .01$ ) and using cyberbullying tactics ( $\beta = .09, p < .05$ ). The second route predicts that cybervictimization is related to vengeance, which predicts positive attitudes towards cyberbullying. Results from the distal model showed that the power differential in cyber compared to traditional bullying ( $\beta = .22, p < .01$ ) and anonymity in cyberbullying ( $\beta = .32, p < .01$ ) both predicted the formation of positive attitudes towards cyberbullying (GFI = .98, AGFI = .94, CFI = .97, RMSEA = .08 (90% CI: .05 to .11)).

**C15****WHY SOME PEOPLE KICK THE BARKING DOG HARDER THAN OTHERS: THE IMPACT OF TRAIT DISPLACED AGGRESSION, PROVOCATION INTENSITY, AND RUMINATION ON TRIGGERED DISPLACED AGGRESSION** Nicholas Kelley<sup>1</sup>, William Pedersen<sup>1</sup>, Daniel Simons<sup>2</sup>, Jenn Eifler<sup>1</sup>, Kasey Fong<sup>1</sup>, Naoko Kitabayashi<sup>1</sup>, Celina Garcia<sup>1</sup>, John Dosta<sup>1</sup>, Marianne Grosvenor<sup>1</sup>, Neil Young<sup>3</sup>, Laura Mathews<sup>1</sup>, Christina Pedram<sup>4</sup>;

<sup>1</sup>California State University, Long Beach, <sup>2</sup>University of North Carolina, Chapel Hill, <sup>3</sup>Queen's University Belfast, Northern Ireland, <sup>4</sup>University of California, Irvine – Recently we developed the first measure of trait displaced aggression -- the Displaced Aggression Questionnaire (DAQ; Denson, Pedersen, & Miller 2006). The current study looks at the moderating effect of trait displaced aggression on the ability of provocation intensity, rumination, and a triggering event to augment aggressive behavior. Participants first completed the DAQ. Then following a provocation of either high or moderate intensity, participants were induced to ruminate or were distracted for 15 minutes. They then had the opportunity to aggress against another person who either acted in a neutral or mildly annoying fashion (viz. triggering event). Several findings emerged. First, those induced to ruminate before the triggering event displayed more aggression than did distracted participants. Second, the magnitude of this difference was greater for participants who received a high intensity compared to moderate intensity provocation. Third, there was a three-way interaction between trait displaced aggression, rumination, and a triggering event. Specifically, rumination increased aggressive behavior in the context of a triggering event but not in its absence. This impact of rumination, however, only held for participants with medium or high levels of trait displaced aggression. In contrast, the aggressive behavior of individuals with low levels of trait displaced aggression was unaffected by either rumination or a trigger. Implications for the reduction of violent behavior are also discussed.

**C16****COMPARING INDIRECT AGGRESSION AND INDIRECT VICTIMIZATION IN ADULTS: THE ROLE OF SOCIAL DESIRABILITY, TRAIT AGGRESSION, AND SEX** Natalie Barlett<sup>1</sup>, Christopher Barlett<sup>2</sup>; <sup>1</sup>Kansas State University, <sup>2</sup>Iowa State University –

While there has been a long history of research on physical aggression, much less has been conducted on indirect aggression and even less examining indirect aggression in adulthood. The few

studies that have focused on adults have found that adults are capable of using high levels of indirect aggression and suffer from being the victims of this covert form of aggression. The current study sought to understand indirect aggression and victimization with an adult sample using a relatively new measure of indirect aggression and victimization. Adult participants (N = 506) completed measures of trait aggression, social desirability, indirect aggression, and indirect victimization. Two linear regression analyses were conducted with sex, trait aggression, and social desirability as the independent variables and indirect aggression and indirect victimization as dependent variables. Results showed differences in the relationships for the independent variables between indirect aggression and indirect victimization. Specifically, sex differences emerged for indirect aggression ( $\beta = .12, p < .05$ ), but not indirect victimization ( $\beta = -.05, p > .05$ ). Social desirability was significantly related to indirect victimization ( $\beta = -.10, p < .05$ ), but not indirect aggression ( $\beta = -.01, p > .05$ ). Finally, trait aggression was related to both indirect aggression and indirect victimization ( $\beta s > .42, ps < .05$ ). These results suggest that males and those high on trait aggression reported using more indirect aggression, and those high on trait aggression and low on social desirability reported experiencing more indirect victimization. Additional analyses and implications will be discussed.

**C17****CHARACTERISTICS OF SEXUAL ASSAULTS AND WORST DATES THAT DO OR DO NOT INVOLVE ALCOHOL CONSUMPTION** Angela J. Jacques-Tiura<sup>1</sup>, Antonia Abbey<sup>1</sup>, Rhiana Wegner<sup>1</sup>; <sup>1</sup>Wayne State University –

Theories of the etiology of sexual aggression typically focus on perpetrators' attitudes and personality characteristics. Although these theories are useful, they typically ignore situational factors that encourage sexual aggression. Most sexual assaults (SA) occur in the context of a date and approximately 50% include alcohol use by the victim, perpetrator, or both. This study examined differences in heterosexual interactions related to alcohol consumption and sexual aggression. Participants were 470 single men aged 18-35 who had dated a woman within the past 2 years from the Detroit metropolitan area. Participants completed an audio computer-assisted self-interview. SA perpetration since age 14 was assessed with a 16-item behaviorally-specific measure. They were then asked to describe one SA experience in detail or to describe their worst date if they had not perpetrated an SA. Forty-three percent of participants acknowledged SA; 39% of incidents involved him drinking and 40% involved her drinking. SA perpetrators had a more established relationship with the woman, spent time at his house, used more isolating tactics, misperceived her intentions longer, and had more consensual sex during the incident than nonperpetrators. When both the man and woman drank, they were more likely to spend time at a party, bar, or social setting, were less likely to have planned to spend time together that day, and engaged in more consensual sexual activity than when neither person drank. This study demonstrates that the synergy of attitudes and situational factors should be considered for the advancement of SA theory.

**C18****RESPONSES TO SEXUAL ASSAULT: DO SOME PERPETRATORS REGRET WHAT THEY DID AND LEARN FROM THE EXPERIENCE?** Rhiana Wegner<sup>1</sup>, Antonia Abbey<sup>1</sup>, Angela J. Jacques-Tiura<sup>1</sup>; <sup>1</sup>Wayne State University –

Many researchers have examined the causes of sexual assault in an attempt to explain the alarmingly high rates of self-reported perpetration in college and community samples of men. In contrast, few researchers have examined factors related to likelihood of re-perpetration and the role of post-assault appraisals. Abbey and McAuslan (2004) found that perpetrators who did not perpetrate again over a one year interval reported feeling greater remorse, having learned more, and blaming the victim less. The current study examines cross-sectional predictors of recognizing that one made a mistake and learning from it in a community sample of 204 sexual assault perpetrators. Participants completed audio computer-assisted self-interviews that assessed perpetration since age 14 with behaviorally-specific items that asked about having sex with a woman

when they knew she didn't want to have sex or when she was unable to consent. Although 75% of perpetrators felt at least somewhat responsible for the incident, only 8% strongly agreed that they had made a mistake and learned how to treat women better. In multiple regression analyses, predictors of remorse included greater use of isolating and controlling behaviors, fewer prior consensual sexual activities with the woman, greater belief that she was just playing hard to get, and committing a more severe assault. Additionally, greater embarrassment at the end of the interview was positively associated with greater remorse and learning. The implications of remorse as a form of emotion- and problem-focused coping are discussed.

### C19

**VIOLENT VIDEO GAME PLAY REDUCES MEMORY FOR BRANDS APPEARING IN GAME** Bryan Gibson<sup>1</sup>, Brad J. Bushman<sup>2</sup>, Andre Meizer<sup>3</sup>, Katherine Zielaskowski<sup>1</sup>; <sup>1</sup>Central Michigan University, <sup>2</sup>University of Michigan & VU University Amsterdam, <sup>3</sup>University of Luxembourg – Product placement is a marketing strategy in which branded products appear within movies, television, and video games (Balasubramanian et al., 2006). The goal is to increase memory and liking of the placed brand. Research on traditional television commercials found that brand memory declines when the television show is violent (Bushman, 1998; 2005). We explored whether this effect extends to brands placed within video games. Participants (N = 155) played a video game for 30 minutes, under instructions to play either violently (i.e., try to run over pedestrians) or non-violently (i.e., try to go as fast as possible). Participants then received a surprising free recall test for brands appearing in the game. They next completed a recognition task with 32 brands, 16 of which appeared in game, and 16 which did not. Measures of game enjoyment and attitude toward 2 brands appearing in the game and 2 matching brands not appearing in the game were also collected. Violent play participants recalled fewer brands, and were less accurate in identifying brands appearing in the game than those in the nonviolent condition. Controlling for enjoyment did not alter these effects. Further, for one brand appearing in game there was a significant brand recognition by game instruction interaction such that in the violent condition participants recognizing the brand had lower brand attitudes than participants not recognizing the brand. Results suggest that, memory for placed brands is impaired during violent play, and that recognizing a brand appearing during violent play actually harms brand attitude.

### C20

**INSIDE THE MIND OF SEX OFFENDERS: ILLUMINATING THE ROLE OF IMPLICIT RAPE ATTITUDES IN SEXUAL OFFENDING** Laura Widman<sup>1</sup>, Michael Olson<sup>1</sup>; <sup>1</sup>University of Tennessee – Rape supportive attitudes may be important predictors of sexual assault perpetration; yet, past research has assessed rape supportive attitudes almost exclusively through self-report measures with methodological and theoretical limitations. To address these limitations, the purpose of the current project was to extend a novel implicit rape attitude evaluative priming procedure (Widman & Olson, 2009) by examining the implicit attitudes of convicted sex offenders and demographically-matched community men, and situating implicit attitudes within a broader theoretical framework of sexual assault. Participants were 36 convicted sex offenders and 48 demographically-matched community men (29 with a self-reported history of sexual assault, 19 without a history of sexual assault). Between group comparisons revealed sex offenders convicted of an offense against an adult woman held more pro-rape implicit attitudes than non-offending community men; yet these same convicted offenders reported less positive rape attitudes when assessed via self-report (arguably attributable to socially desirable responding). Additionally, within the community sample, implicit attitudes predicted the frequency of sexual assault perpetration and accounted for significant variance in sexual offending beyond self-reported rape attitudes (i.e., rape myth acceptance, hostility toward women, sexual dominance). Further, implicit attitudes accounted for sexual assault perpetration when situated within the most comprehensive theoretical model of sexual assault, the Confluence

Model (Malamuth, 2003). Finally, results revealed extremely high rates of sexual assault in the community sample and provide unique descriptive data on the self-reported sexual assaults of convicted sex offenders. Findings suggest implicit rape attitudes must be considered in future research on sexual offending.

### C21

**ANTECEDENTS AND OUTCOMES OF WORKPLACE BULLYING: A PERSPECTIVE ON RACE/ETHNICITY** Brent Lyons<sup>1</sup>, Frederick T.L. Leong<sup>1</sup>; <sup>1</sup>Michigan State University – Aggression directed at race/ethnic minorities is a growing concern in contemporary organizations and despite the known severity in outcomes of workplace bullying, racial bullying is under explored in current literature. In this study, we model antecedents and outcomes of workplace bullying through a racial lens. Two hundred and forty nine White and non-White undergraduate students with at least two years of work experience completed an online survey with measures pertaining to antecedents and outcomes of workplace bullying: general bullying, social dominance orientation, self-esteem, interpersonal trust, and satisfaction with life. Additionally, only non-White participants completed surveys related to racial bullying, sensitivity to racial discrimination, and race-related stress. To ensure consistency in survey length, White participants completed a measure of interpersonal sensitivity. A gender by race interaction predicted experiences of general workplace bullying: White males reported highest levels of victimization and non-White males reported lowest levels. Social dominance orientation significantly predicted experiences of general bullying, but an interaction with gender or race did not explain additional variance. Overall, general bullying predicted lower life satisfaction but only for females. General bullying did not predict levels of interpersonal trust. Antecedents and outcomes of racial bullying were buffered by self-esteem. Experiences of race-related stress only predicted racial bullying for individuals with low self-esteem, not for individuals with high self-esteem. Though racial bullying did predict lower levels of life satisfaction and interpersonal trust, the effect on trust was not apparent when racial bullying is low and self-esteem is high. The implications for these findings are discussed.

### C22

**NARCISSISM AND AGGRESSION: THE MEDIATING EFFECT OF NEGATIVE AFFECT UNDER CONDITIONS OF IMPLICIT AND EXPLICIT EGO-THREAT** Jennifer Boutwell<sup>1</sup>, Erin Gollivan<sup>1</sup>, Joshua Foster<sup>1</sup>, Dennis Reidy<sup>1</sup>; <sup>1</sup>University of South Alabama – Provocation is a powerful catalyst of aggression, especially for those high in narcissism. Moreover, this may be most apparent under conditions of social comparison to peers. In the present study, a sample of collegiate men and women completed the NPI and participated in a sham aggression paradigm. In this paradigm, participants were told that the purpose of the study was to assess the effects of age and attentional capacity on creativity, under conditions of distraction. Participants were first instructed to write a creative essay about a common social interaction. They were further informed that their essays would be evaluated by a computerized measure of creativity and would be compared to an ostensible peer's essay. After reading their peer's superior essay, participants were informed they had been randomly assigned to the control condition, while their peer was assigned to a distraction condition, which involved holding their nondominant hand in ice water while completing additional creativity assessments. Finally, participants were required to determine the level of distraction for their peer by choosing the temperature at which their hand must be submerged. It was expected that individuals with higher NPI scores would be more aggressive as demonstrated by setting a lower (i.e., more painful; more intense) temperature for their peers. Hierarchical regression analyses support our hypotheses, indicating that those high in narcissism use aggression (i.e., indirect physical aggression, displaced aggression, reactive aggression, etc) in response to possible criticism.

**C23****DOES BEING BULLIED INFLUENCE COGNITIVE PERFORMANCE?**

Madeline Rex-Lear<sup>1</sup>, Jennifer Knack<sup>2</sup>, Priya Iyer<sup>3</sup>, Lauri Jensen-Campbell<sup>4</sup>; <sup>1</sup>University of Texas at Arlington, <sup>2</sup>University of Ottawa, <sup>3</sup>University of Texas at Arlington, <sup>4</sup>University of Texas at Arlington – Victimization has been repeatedly linked with poorer academic performance. Despite these statistics, comprehensive examinations that focus on the mechanisms for these associations have been slow to develop. To the extent that being bullied can be viewed as a social stressor, it should influence outcomes much the same way other stressors do. Indeed, high cortisol levels have been associated with poorer memory and cognitive functioning (Lupien et al., 1998; Newcomer et al., 1999). In addition, stress has also been implicated in the dysfunction of the anterior cingulate and medial prefrontal cortex (Bremner et al., 2003). As such, two studies examined whether (1) victimization was correlated with poorer performance on the Stroop, WCST, and Go-NoGo tasks, which assess cognitive functioning; (2) victimization predicted actual academic performance and standardized test scores; and (3) cortisol mediated the link between victimization and scholastic competence. In study 1 (N= 103), being bullied in early adolescence was associated with greater variability in responding in the Go/No-Go task, more noncongruent errors and greater RTs on the Stroop, and more perseverative responses on the WCST. Victimization was also associated with poorer grades and lower standardized test scores. In Study 2 (N = 107), victimization was associated with poorer scholastic competence. More interesting perhaps, victimization was positively associated with a flattened cortisol awakening response, which in turn predicted poorer scholastic performance. These preliminary findings suggest that being bullied may impair biological and cognitive functioning.

**C24****BRING IT ON: ANGRY FACIAL EXPRESSIONS POTENTIATE APPROACH-MOTIVATED MOTOR BEHAVIOR**

Benjamin Wilkowski<sup>1</sup>, Brian Meier<sup>2</sup>; <sup>1</sup>University of Wyoming, <sup>2</sup>Gettysburg College – While many psychological models suggest that human beings are invariably motivated to avoid negative stimuli, more recent theories suggest that people are frequently motivated to approach angering social challenges in order to confront and overcome them. To examine these competing models, three studies were conducted to determine whether angry facial expressions potentiate motor movements serving the goal of physical approach. Participants were asked to categorize the emotional expression of presented faces by executing approach movements toward faces or avoidance movements away from them. Across all studies, participants were faster to initiate approach movements toward angry facial expressions than to initiate avoidance movements away from such expressions. Moreover, this approach advantage for angry facial expressions was significantly greater than participants' responses to both emotionally-neutral (Studies 1 and 3) and fearful (Study 2) expressions. Further data indicated that this pattern was due to the activation of a flexible goal to approach angry facial expressions, rather than a hard interface between angry facial expressions and specific arm movements. The approach advantage for angry facial expressions was apparent regardless of whether arm flexions or arm extensions were involved (Studies 1-3), and it was most apparent when physical approach appeared to be effective in overcoming the social challenge posed by angry facial expressions (Study 3). In sum, the results support models contending that people are motivated to approach and overcome the social challenge posed by angry facial expressions.

**C25****DOES A MASSACRE MATTER? EFFECTS OF TRAIT AGGRESSION AND INDIVIDUAL DIFFERENCES IN PLAY ON SUBSEQUENT AGGRESSIVE BEHAVIOR**

Amanda Bolton<sup>1</sup>, John Ellard<sup>1</sup>; <sup>1</sup>University of Calgary – Studies have found that violence in video games increases aggressive behavior (Anderson et al., 2004); however, they have largely ignored that video games are interactive. Since players decide what actions to take, some

players are being exposed to more violence than others, which is partly accounted for by trait aggression (Bolton & Fouts, 2005). This experiment examined whether differences in post-play aggression are the result of individual differences in game play violence and/or trait aggression. University students' trait aggression was assessed in a first session. In a second session, participants were randomly assigned to play a high violence (HV) or low violence (LV) game for 20 minutes. Afterwards, participants were asked to participate in a surprise optional study on "food preferences" where they poured hot sauce into a cup for the "next participant" to drink entirely; greater hot sauce indicated greater aggressive behavior. Replicating previous research (e.g., Bushman, 1995), participants gave more hot sauce after playing the HV versus the LV game, and trait aggression moderated the amount of hot sauce in only the HV game condition. In terms of play, more violent play in the LV game was related to giving more hot sauce. Violent play in the HV game interacted with difficulty and motivation, but also showed greater hot sauce amounts. Lastly, trait aggression was related to participants' play in the HV game, but not the LV game. In conclusion, trait aggression and differences in play individually account for some post-play aggressive behavior.

**C26****CATHARSIS BELIEF AS A MOTIVATOR TO PLAY VIOLENT VIDEO GAMES**

Jodi Whitaker<sup>1</sup>, Brad Bushman<sup>1</sup>; <sup>1</sup>University of Michigan – Two studies examined the link between belief in catharsis, anger, and the type of video game a person chooses to play. Belief in catharsis coupled with later being angered was hypothesized to increase the desire to play a violent video game as opposed to a non-violent one. In the first experiment, participants were induced to either believe that venting one's anger was a healthy and good practice or that such venting was an unhealthy and poor option. Half of the participants were later angered by receiving a poor grade on an essay, while the other half received a high grade. Afterwards, all participants chose which video games they would most like to play from a list describing eight fictional video games. ANOVA on the results showed that participants who believed catharsis was beneficial and were later angered were more likely to choose to play violent video games ( $F(1,108)=5.09, p<.03$ ). In the second experiment, the same methods were employed with one important difference. Instead of manipulating belief in catharsis, pre-existing belief in catharsis was measured using the Angry Mood Improvement Inventory. Again, multiple regression on the results showed that as the tendency to vent one's anger increased, so did the desire to play a violent video game ( $F(1,147)=6.13, p<.01$ ). These results of these two experiments indicate that belief in catharsis is a motivating factor in the decision of what kind of video game to play, especially when one is angered.

**Attitudes/Persuasion****C27****EFFECTS OF CONFEDERATE FLAG EXPOSURE ON ERROR THROUGHPUT IN AN IMPLICIT ASSOCIATION TASK**

Richard Anderson<sup>1</sup>, Jennifer DiVeto<sup>1</sup>, Anne Gordon<sup>1</sup>, Leisha Colyn<sup>1</sup>; <sup>1</sup>Bowling Green State University – An implicit association test (IAT) was used to assess participants' implicit racial attitudes after viewing a Confederate or control (Netherlands) flag. The sample (N = 77) consisted predominantly of White, female, non-Southerners (78%). After viewing one of the two flags, the participant saw a sequence of randomly ordered words, each of which was a person's first name or an evaluative descriptor. The task was to press either of two keys to classify names as typically Black (African American) or White (European American), or to classify descriptors as positive or negative. In some blocks, one key was for Black names or positive words and the other was for White names or negative words. In other blocks one key was for Black names or negative words and the other was for White names or positive words. Results indicated anti-Black/pro-White bias regardless of whether performance was measured in terms of response time, errors, or errors per second (the number of errors divided by the sum of response times). However, we found that only the errors-per-second

ond measure was uncorrelated with explicit bias (as measured by the Modern Racism Scale). And it was for that measure—errors per second—that IAT bias was greater after viewing the Confederate flag than after viewing the control flag. It was concluded that the Confederate flag can evoke implicit bias, and that this bias is likely not related to explicit attitudes about the flag.

### C28

**CHANGING BEHAVIOUR THROUGH AFFECTIVE-BASED VERSUS COGNITIVE-BASED ATTITUDINAL MESSAGES** Mark Conner<sup>1</sup>, Ryan Rhodes<sup>2</sup>; <sup>1</sup>University of Leeds, <sup>2</sup>University of Victoria – Recent research has distinguished between outcome expectancies based on whether the outcomes are positive or negative, occur in the immediate or distant future, and are instrumental or affective in nature. Although most persuasive messages about health behaviors (e.g., physical activity) tend to focus on negative, distal, instrumental outcomes recent research has indicated the power of proximal affective outcomes (both positive and negative) to predict these behaviors. However, comparatively little research has examined whether persuasive messages focusing on affective outcomes can impact on engagement with such behaviors. The present research reports two studies investigating the impact of an affective-based or an instrumental-based message compared to a control on self-reported physical activity levels. 383 (Study 1) and 197 (Study 2) students were randomly allocated to one of three conditions (control – no message, affective-outcome based message, instrumental-outcome based message) and completed questionnaire measures tapping components of the Theory of Planned Behavior in relation to exercise and reported their level of exercise (3 weeks later). In Study 2 measures of need for affect (NFA) and need for cognition (NFC) were also completed. Results showed that the affective-based message consistently produced greater increases in self-reported level of exercise over baseline compared to the other conditions and that this effect was partly mediated by affective attitude change. Study 2 indicated these effects to be significantly stronger among those high in NFA or low in NFC. These findings indicate the value of messages that target affective outcomes in changing health behaviors such as physical activity.

### C29

**EXPLORING THE INFORMATION ORDER MATCHING EFFECT IN PERSUASION** J. Shelly Paik<sup>1</sup>, Leandre R. Fabrigar<sup>1</sup>, Richard E. Petty<sup>2</sup>, Charlene E. Turner<sup>1</sup>; <sup>1</sup>Queen's University, <sup>2</sup>Ohio State University – Previous research has demonstrated greater attitude change when information is presented in the same order at persuasion as encountered when the attitude was originally formed (e.g., Edwards, 1990). Although traditionally interpreted as evidence for affective/cognitive matching effects in persuasion there is no clear evidence that these differences in the basis of attitudes and persuasion were responsible for these matching effects (Fabrigar & Petty, 1999). This research program examined whether the affect/cognition distinction is indeed responsible for the information order matching effect. Experiment 1 was a conceptual replication of Edwards (1990) but included scales of attitude-relevant affect and cognition to directly examine the role of these constructs. The persuasion matching effect was replicated. However, the affect and cognition scales suggested no evidence that this effect was due to differences in affect/cognition across orders. In experiment 2, the affective/cognitive bases of attitudes were held constant by presenting participants with only cognitive information of varying order. We replicated the persuasion matching effect but in a context with no affect/cognition distinction suggesting this distinction is not required to produce the effect. Although information in Edwards' studies differed in affect/cognition, they were confounded with complexity. Therefore, experiment 3 was conducted to examine the viability of complexity as the driving force behind the order matching effect. Some participants received passages that varied in complexity whereas others received passages that did not differ in complexity and these passages were presented in varying sequence. Again, we found the persuasion matching effect and it emerged regardless of complexity.

### C30

**SWAYING THE MASSES: THE EFFECT OF ARGUMENT STRENGTH AND LINGUISTIC ABSTRACTNESS ON ATTITUDES** Jessica M. Barber<sup>1</sup>, Natalie J. Shook<sup>1</sup>; <sup>1</sup>Virginia Commonwealth University – Two studies were conducted to investigate how the use of different types of language affects persuasion. Participants read arguments supporting a hypothetical toothpaste that differed in terms of argument strength (strong versus weak) and linguistic abstractness (abstract versus concrete). Subsequently, they evaluated the toothpaste and indicated their intentions to purchase or try the toothpaste. In addition, half of the participants in the second study were subjected to a cognitive load manipulation (i.e., rehearsing a ten-digit number) in order to limit their level of cognitive elaboration. Results indicated that strong arguments and those containing concrete descriptions led to more positive attitudes and behavioral intentions toward the toothpaste, whereas weak messages comprised of abstract terms gave rise to the least favorable evaluations and intentions. These findings represent the first demonstration of the effect of language type on attitude change and suggest that future research into the functions of differential linguistic abstractness in a persuasive context will broaden our understanding of attitude change.

### C31

**TIME CRAWLS WHEN YOU'RE NOT HAVING FUN: PRIMING PSYCHOLOGICAL ENTITLEMENT CHANGES TIME PERCEPTION** Edward Hughes O'Brien<sup>1</sup>, Brad J. Bushman<sup>1</sup>, Phyllis A. Anastasio<sup>2</sup>; <sup>1</sup>University of Michigan (Ann Arbor, MI), <sup>2</sup>Saint Joseph's University (Philadelphia, PA) – The present experiment tested whether psychological entitlement can be temporarily primed, and whether psychological entitlement can change time perception. Entitlement was subliminally primed with word lists that contained 0%, 20%, or 80% entitlement words, while subjects participated in what they thought were vigilance tasks. Subjects then estimated how long the tasks took to complete, how quickly the time went by, and how interesting the tasks were. We also timed how quickly they walked away upon leaving the experiment. Subjects primed with entitlement words viewed their time as especially valuable: they rated the ostensibly boring tasks as significantly slower and less interesting, and walked significantly faster following the experiment. Firstly, these findings demonstrate that entitlement can be manipulated as a temporary state (even when done so at a subliminal level). Secondly, those primed with entitlement perceive the passage of time in a much more egotistic, self-important way; feeling entitled may prompt the desire to end dull tasks (e.g. completion of the study), quickly receive rewards (e.g. research credit), or get to a more desirable destination. The current study corroborates a major theme in entitlement and narcissism literature: like most resources in life, the resource of time seems more precious to those who feel entitled.

### C32

**WHEN DO ATTITUDES GUIDE INTENTIONS? A COGNITIVE CONSISTENCY PERSPECTIVE ON ATTITUDE-INTENTION RELATIONS** Laura Creighton<sup>1</sup>, Bertram Gawronski<sup>1</sup>; <sup>1</sup>University of Western Ontario – Major theories of attitude-behavior relations (e.g., theory of planned behavior) propose that attitudes, subjective norms, and perceived behavioral control independently influence behavioral intentions. Even though previous findings are consistent with this claim, the assumption of independent main effects seems questionable on theoretical grounds. For instance, one might wonder how high perceived behavioral control can by itself produce a corresponding intention if the attitude toward the behavior is negative. Drawing on Festinger's (1957) dissonance theory, we argue that the relation between attitudes and intentions depends on the consistency of the attitude with subjective norms and perceived behavioral control. According to this conceptualization, subjective norms and perceived behavioral control do not have independent impacts on behavioral intentions. Instead, subjective norms and perceived behavioral control function as gatekeepers that moderate the translation of the attitude into a corresponding intention. Results from a study on the use of

bicycles as transportation mode provides preliminary support for this claim. Even though analyses in terms of traditional models replicated the previously obtained main effects of attitudes, subjective norms, and perceived behavioral control on intentions, further analyses revealed that these main effects were driven by a higher-order interaction in which subjective norms and perceived behavioral control moderated the relation between attitudes and intentions. Specifically, attitudes were significantly related to intentions only when both subjective norms and perceived behavioral control were high; however, there was no relation between attitudes and intentions when either subjective norms or perceived behavioral control were low. Implications for research on attitudes are discussed.

### C33

**THE IMPACT OF REPLICATION RATE ON ATTITUDE REVISION IN RELATION TO SCIENCE CLAIMS** Ralph Barnes<sup>1</sup>, Stephanie Tobin<sup>2</sup>, Heather Moynihan<sup>3</sup>, <sup>1</sup>Salem State College, <sup>2</sup>University of Houston, <sup>3</sup>Columbus State Community College – One way to cast doubt on a scientific finding is to inform the public that other studies have failed to replicate the result. The goal of the current study was to determine the degree to which individuals revise their attitude about a science claim based on a particular study after learning about the percentage of successful replications of the that study. Ninety-seven undergraduate participants at three institutions were presented with a number of fictional science claims and asked to indicate their attitudes towards these claims. Participants also indicated their attitudes towards these claims after being informed that only a certain percentage of studies had succeeded in replicating the initial results. Differences between initial attitudes and those formed after participants were informed of the percentage of successful replications revealed the impact of replication rate on subjects' attitudes. Unsurprisingly, higher rates of successful replication were associated with increased faith in the original claim. Surprisingly, however, only when reported replication rates dropped below 30% did they lead to a decrease in favorable attitudes about the original claim. Clearly information regarding the rate of successful replication impacts nonscientists differently than scientists. This finding may shed light on how the public views science claims and counter claims presented in mass media.

### C34

**THE SHARED REALITY OF SEXISM** Robert Tillery<sup>1</sup>, Tom Pyszczynski<sup>1</sup>, <sup>1</sup>University of Colorado at Colorado Springs – Culture places specific expectations on individuals. Living up to these social expectations creates a situation in which we verify for others what is expected of them. The products of social expectation become a shared reality. A shared reality establishes the groundwork for shared social existence. At the core of this hypothesis, is the concept that individuals take on the perspective of others they are communicating with. A shared reality is transmitted and obtained through communication. This study examines the role of shared reality and the expectation of communication on sexism. The participants (N=178) were recruited from the potential juror pool at a municipal complex. Participants completed measures of feminism and authoritarianism. An expectation of communication was created by statements that they would discuss concepts of gender relations with the female or male research assistants collecting the surveys. Sexism was measured using the Ambivalent Sexism Inventory, containing items related to hostile and benevolent sexism. In confirmation of our hypotheses; it was found that traditional females, who expected to communicate with other women, significantly endorsed benevolently sexist statements, greater than those females who did not expect to communicate with anyone. In addition, males who expected to communicate other males showed a significant increase in hostile sexism from males expecting to talk to women, in other words, a locker room effect. These results demonstrate a change in sexist attitude, and the reality of the sexist behavior that will be expected and acceptable, while interacting with others of differing genders and sexist beliefs.

### C35

**ATTITUDES INFLUENCE AUTOMATIC RACIAL FACE CATEGORIZATION** Yina Ma<sup>1</sup>, Shengmin Yang<sup>2</sup>, Shihui Han<sup>1</sup>; <sup>1</sup>Peking University, China, <sup>2</sup>School of Ethnology and Sociology, Central University of Nationalities, China – Previous studies suggest that distinct encoding mechanisms are involved in the processing of same-race (SR) and cross-race (CR) faces in human adults and result in differential recognition of SR and CR faces. The present study investigated whether and how attitudes toward target faces influence racial face processing. Experiment 1 showed that, in a task of judging orientations of Caucasian and Asian faces, Chinese responded faster to racial CR than SR faces whereas European Americans' performances showed a reverse pattern. Experiment 2 found that, when judging orientations of Han Chinese and Uigur Chinese faces, Han Chinese responded faster to racial SR than CR faces. More importantly, both CR and SR advantages observed in Experiments 1 and 2 were eliminated by inducing negative attitudes toward the faces with response advantage using a negative association priming procedure. Our findings provide evidence for automatic categorization of racial faces in a perceptual, race irrelevant task, which, however, is strongly modulated by attitudes toward target faces.

### C36

**THE STRUCTURE AND ORIGINS OF ATTITUDE-STRENGTH RELATED BELIEFS** Jay K. Wood<sup>1</sup>, Steven M. Smith<sup>2</sup>, Leandre R. Fabrigar<sup>1</sup>, Michelle G. Fitzsimmons<sup>2</sup>; <sup>1</sup>Queen's University, <sup>2</sup>Saint Mary's University – Researchers have long recognized that various subjective beliefs that people hold regarding their attitudes can be useful in distinguishing strong from weak attitudes. However, there is little understanding regarding the underlying structure of these beliefs (i.e., the precise manner in which different strength-related beliefs are associated with one another). In the present research, we sought to confirm the existence of 12 distinct strength related beliefs, and more importantly, to test a theory positing that the relationships among those beliefs could be explained by 4 higher-order factors. In Study 1, participants were asked to complete multiple items measuring each of 12 beliefs that have been commonly explored in the attitudes literature. A confirmatory factor analysis supported the existence of 12 distinct belief constructs. Additionally, confirmatory factor analyses indicated that a 4-factor superordinate structure provided a good representation of the pattern of relationships among these beliefs. The 4 factors correspond to the perceived validity of the knowledge on which the attitude is based, the evaluative consistency of the knowledge base, the functional relevance of the attitude, and the intensity of the attitude. Some beliefs were influenced by only one of these 4 factors whereas other beliefs reflected the combined influence of more than one higher-order factor. Study 2 explored potential antecedents to each factor in an effort to gain further insight into the higher-order structure. Aspects of the attitude formation process were manipulated to examine if they influenced different beliefs in a manner consistent with the proposed 4-factor framework.

### C37

**OPTIMIZING INTERACTIVE PERSUASIVE COMMUNICATIONS: HOW PERCEPTIONS OF THE MESSAGE SOURCE RELATE TO HIV RISK-REDUCTION** John L. Christensen<sup>1</sup>, Adam S. Wiswell<sup>2</sup>, Paul Robert Appleby<sup>1</sup>, Lynn Carol Miller<sup>1</sup>, Stephen J. Read<sup>1</sup>; <sup>1</sup>University of Southern California, <sup>2</sup>Pepperdine University – Dual process models of persuasion (e.g., ELM, HSM) suggest message effectiveness depends upon often one-sided judgments of the communicator (e.g., "I believe you're humorous"). Mass media, however, limits meta-judgments of the communicator's evaluation of us (e.g., "I believe you accept me"). These meta-judgments may involve more processing and may more deeply enhance long-term persuasiveness. Interactive media, with characters responsive to user decisions, can overcome this restriction. To assess the link between both one-sided and meta-judgments on immediate and long-term persuasion, 140 at-risk men who have sex with men interacted with a video-based, HIV-prevention training simulation in a longitudinal trial. Indi-

viduals assumed the role of the main character and made virtual sexual decisions in contexts similar to those encountered in real-life. Two persuasive guide characters delivered relevant appeals following risky choices. Immediately after the intervention at time 1 (T1), subjects indicated their intentions to avoid unprotected anal intercourse. They were then instructed to think about the guides and provide ratings of attractiveness, humor, and believability as well as perceived identification with and acceptance by the guides. Subjects reported follow-up risk-taking 3 months later at time 2 (T2). A linear regression analyzing T1 data indicated that none of the attributes predicted immediate intention to avoid real-life risk-taking. However, a negative binomial regression revealed that perceived T1 humor was positively associated with T2 risk-taking while perceptions of T1 believability and acceptance were negatively associated with T2 risk-taking; these findings were statistically significant. Implications for theories of persuasion and HIV risk-reduction are discussed.

### C38

**THE EFFECT OF ATTITUDE CERTAINTY ON WILLINGNESS TO PAY** Brittany Shoots-Reinhard<sup>1</sup>, Richard Petty<sup>1</sup>, Pablo Briñol<sup>2</sup>; <sup>1</sup>The Ohio State University, <sup>2</sup>Universidad Autónoma de Madrid – Recent research shows that when people have a "feeling of rightness" (due to regulatory fit) when they are evaluating a product, they are willing to pay more for that product. This feeling of rightness could be similar to attitude certainty, which is also defined as a feeling of validity about an evaluation. When people are certain of their attitudes, those attitudes are more predictive of behavior (e.g., willingness to buy or try a product; purchasing behavior) than when people are less certain. We propose that not only should people be more willing to buy a product to the extent that they are certain of their positive attitudes towards it, but they also should be willing to pay more for it as certainty increases. In order to test this hypothesis, participants viewed an OSU mug, reported their attitudes towards it, their certainty in those attitudes, and their willingness to pay for the product. There were no main effects of either attitudes or attitude certainty on willingness to pay. However, the interaction of attitudes and certainty was significant. As expected, attitudes were more predictive of willingness to pay when people were certain of their attitudes than when they were uncertain. These results suggest that attitude certainty impacts willingness to pay for a product, and that certainty may be as important in affecting people's willingness to pay for products as attitudes are.

### C39

**TO HELP OR NOT TO HELP: HOW RACISM AND TARGET RACE AFFECT THE DECISION TO HELP** Jessica L. McManus<sup>1</sup>, Megan M. Dwyer<sup>1</sup>, Donald A. Saucier<sup>1</sup>; <sup>1</sup>Kansas State University – Researchers have examined differential amounts of help provided to Black and White individuals to study contemporary forms of prejudice (e.g., Crosby, Bromley, & Saxe, 1980). Various situational factors have been identified that might explain the differences in the amount of help provided to Blacks and Whites (Saucier, Miller, & Doucet, 2005). However, what is less clear is why individuals decide to provide more help to ingroup, rather than outgroup, targets. We used Latane and Darley's (1970) five-step helping model to examine how racism may affect the decision to help individuals of different races. White participants (N = 96) read vignettes in which individuals needed help. Target individuals were either identified as Black or their race was not specified. Participants responded to items corresponding to each of the steps of helping (1. noticing the event; 2. interpreting the event as an emergency; 3. taking responsibility to help; 4. deciding how to help; and 5. deciding to provide help) and completed racism and empathy measures. After controlling for sex and empathy, difference regressions revealed that racism scores differentially predicted Steps 3 and 5 of the helping model. Participants with higher racism scores were less likely to take responsibility for helping Black targets than targets of a non-specified race. Participants with higher racism scores were also less likely to report that they would decide to provide help for Black targets

than targets of a non-specified race. These findings contribute to our understanding of the relationship between contemporary forms of prejudice and prosocial behavior.

### C40

**IMAGE OF DEATH INHIBITS THE EARTHQUAKE PREPAREDNESS ACTIONS** Junko Toyosawa<sup>1</sup>; <sup>1</sup>Osaka Kyoiku University – Meta analysis of fear appeal studies showed that efficacy, as well as fear and risk perception were important in promoting risk preventive actions (Witte & Allen, 2000). As for earthquake, people took many preparedness actions when efficacy was higher than fear and risk perception (Mulilis & Duval, 1995). But in Japan, many people lost their lives in earthquake, and people who have the image of death may be difficult to have higher efficacy. In addition, earthquake causes many types of damage (e.g., fire, tsunami, house collapse), and the way of coping are also various. So, it is important to clarify the image of earthquake, and to examine the relations between images, fear, risk perception, efficacy, and earthquake preparedness actions. One hundred and ninety-nine undergraduate students answered the questions concerning image of earthquake and their preparedness actions. They also answered the questions about fear, risk perception (probability of the occurrence of big earthquake, severity of the consequence of big earthquake), and efficacy (self-efficacy toward preparedness actions, effectiveness of preparedness actions). The results showed that image of earthquake were classified into 21 categories. Multi regression analysis showed that image of fear, confusion, lifeline stop, refuse, and rescue facilitated preparedness actions, while image of death inhibited them. Furthermore, path analysis showed that image of death heightened fear and risk perception, while it lowered efficacy. Fear, risk perception, and efficacy facilitated preparedness actions. These results suggest that paying attention to the side that we can control is important in facilitating people's earthquake preparedness actions.

### C41

**THE AGONY OF AMBIVALENCE AND WAYS TO RESOLVE IT: INTRODUCING THE MAID MODEL** Frenk van Harreveld<sup>1</sup>, Joop van der Pligt<sup>1</sup>, Yael De Liver<sup>2</sup>, Bastiaan Rutjens<sup>1</sup>, Mark Rotteveel<sup>1</sup>; <sup>1</sup>University of Amsterdam, The Netherlands, <sup>2</sup>Utrecht University, The Netherlands – While it has been assumed that people are averse towards attitudinal ambivalence, empirical evidence is mixed. Our research integrates literature on ambivalence with theories on decision-making to gain more understanding of when ambivalence is indeed associated with psychological discomfort and how ambivalent attitude holders cope with their discomfort. In a first study we manipulated ambivalence and found ambivalence only to be related to physiological arousal when a choice had to be made. Feeling ambivalent about an issue without having to choose did not result in more arousal. A second study showed the same pattern and indicates that the relation between ambivalence and arousal is mediated by uncertainty about outcomes. In the third study these findings are corroborated using self-report measures indicating that ambivalence-induced discomfort is related to specific (negative) emotions. We conclude with a discussion of the MAID (model of ambivalence-induced discomfort), which describes the behavioral and psychological consequences of ambivalence. More specifically, the model describes when ambivalence is unpleasant and the coping strategies that can be employed. The latter depends on the availability of the required cognitive resources and on the negative emotions that are anticipated in relation to decisional outcomes. With our research and our model, we aim to show that research on attitudes can benefit more from research on affect and decision-making and vice versa. A focus on the psychological and behavioral consequences of ambivalence can enhance insight into an attitude that is related to many daily behaviors and one that is increasingly prevalent in modern society.

**C42****INFLUENCING THE EVALUATION OF MULTIPLY CATEGORIZABLE OBJECTS**

Alison Young<sup>1</sup>, Russell H. Fazio<sup>1</sup>, <sup>1</sup>The Ohio State University – Depending on the category to which we assign a given object, our evaluation of that object may change. For instance, if we categorize a flu shot as an immunization, we may see it more positively than if we categorize it as an injection. One method for promoting the use of one category over another and potentially influencing participants' attitudes toward an object is rehearsal of the attitude toward the category. Previous research has found that enhancing attitude accessibility this way increases the likelihood that an object will be categorized in terms of this more attitude-evoking category (Smith, Fazio, & Cejka, 1996). The stimulus materials for this experiment involved 22 triads consisting of a target (e.g., flu shot) and two relevant category labels, one positive (e.g., immunization) and one negative (e.g., injection). In initial tasks, participants rehearsed their attitudes toward one of the categories and made animacy judgments about the other. Task order and the category label rehearsed were counterbalanced. The dependent measure consisted of likeability judgments of each target. We found that when the participants had rehearsed their attitudes toward the negative category, they later rated the multiply categorizable target more negatively than when they had rehearsed their attitudes toward the positive category. Attitudes toward targets, then, can be modified by making a potential categorization more hedonically impactful, i.e., more attitude-evoking. The likelihood that a given category will determine how an object is construed can be increased by making a person's attitude toward that category more accessible through attitude rehearsal.

**C43****EXPLICIT AND IMPLICIT ATTITUDES TOWARD ATHEISTS AND OTHER UNRELIGIOUS CONCEPTS**

Garrett Strosser<sup>1</sup>, Robert Lawson<sup>2</sup>, <sup>1</sup>New Mexico State University, <sup>2</sup>William Paterson University – While national polls suggest that atheists are one of the most despised social groups by Americans, little research has dealt with the issue of attitudes toward this group. This study sought to address this topic by evaluating explicit and implicit attitudes held by American atheists and theists towards both religious believers and nonbelievers and related religious/unreligious concepts. Theoretically, the study addresses the issue as to whether or not implicit and explicit measures tap into the same underlying attitudinal domain. To assess implicit attitudes, participants completed a paper-and-pencil version of the Implicit Association Test (IAT), (Lemm, Lane, Sattler, Khan, & Nosek, 2008) in which pre-tested religious and unreligious words were paired with pleasant and unpleasant words. To assess explicit attitudes, participants completed two feeling thermometers in which they rated how "warm" versus "cold" they felt toward both religious believers and nonbelievers. Findings from the paper IAT indicate that while theists showed an implicit attitudinal bias favoring religious concepts over unreligious concepts, atheists showed no implicit preference for unreligious or religious concepts. However, atheists reported less warm feelings towards religious believers than theists reported. Overall, the correlation between the explicit attitude measure and the IAT is weak and nonsignificant. This finding is interpreted as showing a partial dissociation between the two measures; while theists displayed a preference for religious concepts at both the explicit and implicit levels, atheists only favored unreligious concepts at the explicit level.

**C44****EGO-DEPLETION INCREASES THE USE OF HEURISTIC CUES WHEN ASSESSING THE REPUTATION OF POTENTIAL INTERACTION PARTNERS**

Chris Stiff<sup>1</sup>, <sup>1</sup>University of Nottingham – When faced with informational cues regarding a potential interaction partner, persuasion research suggests individuals will either process them systematically (i.e. with careful consideration of their content and rhetorical fortitude) or heuristically (i.e. with greater attention paid to characteristics surrounding an argument, such as its source) (Chaiken, 1980). Past research has

suggested that variables such as motivation or cognitive load influence which route is taken. In this work, we aimed to examine how the availability of self-control resources may impinge on information processing, and influence the assessment of a target's reputation - an aggregation of the socially shared information regarding a potential interaction partner (Stiff, 2008) Using the "muscle-model" of self-control (Baumeister, Bratslavsky, Muraven, & Tice, 1998), we hypothesized that participants whose self-control was depleted by an initial task would lack the resources to process subsequently presented information in a controlled manner and would be more influenced by heuristic cues compared to participants who undertook a filler task. An initial pilot study found support for this idea, with depleted participants giving more extreme responses to reputational information compared to those who were non-depleted. In the main experimental study, participants who were depleted found high status sources more persuasive, gave more extreme reputation ratings based on these sources' feedback comments, and altered their proposed spending behaviour based on source status. Non-depleted participants by contrast were not affected by source status, supporting the idea of resource-dependent processing styles. Implications and extensions of this research are then discussed.

**C45****SOCIAL VIGILANTISM AND ASSERTION OF RELIGIOUS BELIEFS: PREDICTING BELIEF DEFENSE AND DISSEMINATION**

Megan Strain<sup>1</sup>, Donald Saucier<sup>1</sup>, <sup>1</sup>Kansas State University – Religion has produced social conflict throughout history (e.g., the Crusades, Middle Eastern conflict, September 11th attacks), often stemming from individuals' attempted dissemination of their beliefs onto others. Social vigilantism (SV) is an individual difference in the tendency to impress one's "superior" beliefs onto others that also predicts resistance to persuasion (Saucier & Webster, 2009). Consequently, SV may provide insight, beyond measures of religiosity, about how and why individuals uphold and attempt to spread their religious beliefs. Thus, we investigated the relationship between SV and individuals' use of resistance strategies (e.g., counterarguing) when their religious beliefs were questioned. Participants completed measures of intrinsic, extrinsic, and quest religiosity, Christian orthodoxy, and religious fundamentalism, as well as the SV scale. To assess resistance to persuasion, participants were asked to imagine a situation in which their beliefs about God were challenged. They then indicated how likely they would be to respond by using various resistance strategies in the imagined situation. As expected, hierarchical regressions showed that SV was positively and uniquely associated with the use of three resistance strategies: negative affect, counterarguing, and impression of views. These results indicate that, when presented with an opposing religious viewpoint, individuals' tendencies to defend and disseminate their own views can be predicted, above and beyond their own beliefs about religion, by an individual difference in their tendency to impress their beliefs onto others.

**C46****COSTS AND BENEFITS BE DAMNED: THE IMPACT OF MORAL CONSTRUALS ON VOTING INTENTIONS**

Ingrid Johnsen<sup>1</sup>, Dominic Packer<sup>2</sup>, Jay Van Bavel<sup>1,3</sup>, William Cunningham<sup>1</sup>, <sup>1</sup>Ohio State University, <sup>2</sup>Lehigh University, <sup>3</sup>New York University – Rational choice models suggest that people make decisions based on cost-benefit analyses. Applied to voting, these models predict that people will generally not vote because the costs typically outweigh any direct benefits, and therefore have trouble accounting for the number of people who do vote. Additional research has shown that morality may affect voting, such that people who believe that voting is a duty or select candidates based on moral issues are more likely to vote. We reconcile these perspectives by showing that voting can be construed in multiple ways, and that different construals have important implications for voting intentions. This study is among the first to experimentally manipulate construals of the same action to investigate how moral versus pragmatic considerations affect judgments and behavioral intentions. Immediately prior to the 2008 U.S. Presidential Election, participants wrote about pragmatic or moral concerns associ-

ated with voting, and rated their intentions to vote. Results showed that when participants thought about voting from a pragmatic perspective, intentions to vote were predicted by traditional cost-benefit variables. When participants thought about voting from a moral perspective, intentions to vote were predicted by the extent to which they valued voting. In direct contrast to rational models, participants in the moral condition who valued voting heightened their intentions to vote in the presence of obstacles (e.g., long lines, inclement weather). In conclusion, voting behavior is influenced by multiple considerations, which exert differential effects on decision-making depending on current construals (pragmatic vs. moral) of the act.

#### **C47 BONDING OF ATTITUDES ABOUT ATHEISTS TO RELIGIOUS AND SECULAR IDEOLOGIES**

**John Edwards<sup>1</sup>, Nayantara Abraham<sup>1</sup>; <sup>1</sup>Loyola University Chicago** – Among the people most despised in the United States yet least studied as targets of prejudice and discrimination are atheists. Because atheism involves rejection of religion, it may be that different attitudes toward atheists are bonded differently to religious versus secular ideologies. This study explored the relationships between specific aspects of religiosity and secularism to specific components of attitudes about atheists. Participants (152 students at a culturally diverse Jesuit university) completed a 34-item multi-factor attitude measure of beliefs, feelings, and behavior dispositions regarding atheists, a 36-item multi-factor measure of religiosity, and a 39-item multi-factor measure of secular humanist principles. Attitudes were negatively related to religiosity ( $r = -.72$ ) and positively related to secular humanism ( $r = +.76$ ). Combinations of correlation, regression, and factor analysis tests revealed that attitudes were negatively related to five traditional aspects of religiosity, e.g., religious practices, fundamentalism, and, especially, using religion as the guide to morality. Attitudes were positively related to a non-traditional aspect of religiosity as an ongoing quest marked by uncertainty, and to six aspects of secular humanism such as separation of church and state, maintaining an open-minded search for verifiable truth, and, especially, using objective evidence and rationality, not religious doctrine, as the basis for morality. These relationships were strongest with components of attitudes involving aversive feelings (disgust, anger), stereotyped beliefs (immoral, arrogant), and perceived negative impact of atheists on American society. These findings suggest reasons or justifications for tolerant versus intolerant attitudes toward atheists among different people, and ambivalent attitudes within individuals.

#### **C48 THE INFLUENCE OF FREQUENCY ON JUDGMENTAL EXTREMITY**

**Meghan Norris<sup>1</sup>, Leandro R. Fabrigar<sup>1</sup>, Duane T. Wegener<sup>2</sup>, Richard E. Petty<sup>3</sup>; <sup>1</sup>Queen's University, <sup>2</sup>Purdue University, <sup>3</sup>The Ohio State University** – Researchers have long noted that repeated expression of a judgment can cause that judgment to become more extreme. Two potential explanations are explored. The first is that repeatedly making a judgment alters the representation of that stimulus in memory so that it becomes more extreme. The second explanation, response mapping ambiguity, suggests that stimuli representations do not become more extreme, but rather people become more confident in their judgments and misinterpret the meaning of extreme responses on rating scales to imply confidence in the judgment rather than extremity per se. To test these ideas, a 3 (level of frequency: 3 vs. 5 vs. 8) X 2 (type of scale: ambiguous numerical rating scale vs. unambiguous colour shade scale) X 2 (ideograph set size: 15 ideographs versus 27 ideographs) mixed-design experiment was conducted in which respondents judged the color of novel ideographs. Results showed a significant two way interaction between the frequency of judgment and scale type. With the numeric rating scale, colour judgments became more extreme as frequency of rating increased. However, when using the less ambiguous colour shade scale, ratings did not become more extreme. This suggests a response mapping ambiguity explanation for judgmental extremity. Interestingly, frequency did influence confidence ratings of these color judgments such that the more often a judgment was made,

the more confident participants became in their judgments. Further analyses tested whether confidence mediates the relationship between frequency and extremity within each scale. Implications are discussed.

#### **C49 IS IT FAIR TO BE GREEN? HOW PERCEPTIONS OF THE ENVIRONMENT AND PAST BEHAVIOUR INFLUENCE JUSTICE PRINCIPLES AND WILLINGNESS TO SUPPORT ECOLOGICAL INITIATIVES**

**Paul Conway<sup>1</sup>, Matthew Maxwell-Smith<sup>1</sup>, James Olson<sup>1</sup>; <sup>1</sup>The University of Western Ontario** – The way that people conceptualize the environment and their past behaviour may influence their willingness to engage in future environmental action. Participants ( $N = 105$ ) read a textbook passage that described the environment as either a living thing with inherent value or a repository of resources to be extracted for human benefit. We also manipulated participants' perceptions of their own prior environmental behavior. Following a procedure designed by Chaiken and Baldwin (1981), some participants were led to believe they frequently act in 'green' ways (by checking off many actions they "occasionally" perform), whereas others were led to believe they rarely act in green ways (by checking off few actions they "always" perform). Participants who read that the environment was a resource for human consumption were more likely to endorse "microjustice" principles, such as individual rights and allocation systems based on merit, but no more likely to endorse "macrojustice" principles such as responsibility to other species and future generations (see also Clayton, 1998). Participants who perceived themselves as engaging in many 'green' behaviours were more willing to pay extra taxes for ecological initiatives. These findings imply that exposure to media emphasizing the natural world as a resource available for human consumption (such as the business section of a newspaper) may enhance a concern with microjustice principles and individual gain at the expense of motivation for environmental action. They also imply that environmentally friendly behaviour can be enhanced by fostering self-perceptions consistent with ecological responsibility.

#### **C50 PERCEPTIONS OF SEXUAL HARASSMENT AS A FUNCTION OF HETEROSEXIST ATTITUDES AND VICTIM/PERPETRATOR SEXUAL ORIENTATION**

**Dawn M. Howerton<sup>1</sup>, Lisa A. Harrison<sup>2</sup>; <sup>1</sup>University of Tennessee, Knoxville, <sup>2</sup>California State University, Sacramento** – Until recently, sexual harassment research has focused on man-to-woman harassment, but this is not the only type of harassment with which society should be concerned. In sexual harassment cases, men are creating unfriendly work environments for women, women are doing the same for men, and same-sex sexual harassment (SSSH) creates hostile work environments for both genders. Where SSSH is concerned, one might wonder if heterosexist attitudes influence perceptions of the event. The present research examines whether heterosexist attitudes, victim/perpetrator gender and victim/perpetrator sexual orientation interact to influence perceptions of SSSH. Three hundred and eighty-two participants read one of eight SSSH scenarios in which the victim's and perpetrator's gender and sexual orientation were manipulated, completed the ATLGM (Herek, 1988) and PSHQ (Katz, Hannon, & Whitten, 1996); measuring heterosexist attitudes and SSSH perceptions, respectively. Analysis yielded no significant results of woman-to-woman sexual harassment; however, where man-to-man sexual harassment was concerned, participants were more likely to perceive SSSH when they held strong heterosexist attitudes, and also when the perpetrator was gay. Those with weak heterosexist attitudes were more likely to take the victim's and perpetrator's sexual orientation into account when perceiving SSSH, while those with strong heterosexist attitudes were more likely to perceive SSSH when the perpetrator was gay, regardless of victim sexual orientation. The present research adds to our understanding of heterosexism by demonstrating that individuals utilize heterosexist attitudes

when perceiving man-to-man sexual harassment, and supports the notion that heterosexism has a greater impact on perceptions of gay men than lesbians.

### C51

**SORE LOSERS. WHEN COMPETITIONS PRODUCE SORE OR GRACIOUS LOSERS** Margaret Gerbasi<sup>1</sup>, John Darley<sup>1</sup>; <sup>1</sup>Princeton University – Three studies examine the attributional factors leading to soreness or graciousness in response to a competitive event as well as the behavioral consequences of adopting a sore or gracious orientation. Study 1 uses a longitudinal field study of the 2008 United States Presidential Primaries and General Election to assess the influence of soreness on attitudes and voting behavior, finding that soreness resulting from the favored candidate losing in the Primaries results in perceptions of unfairness and less actual voting behavior in the General Election. Study 2 uses a field study to assess the relationship between internal and external attributional patterns and soreness as a result of the 2008 Superbowl outcome, finding that attributional patterns, rather than the supported team winning or losing the game predicts soreness. Finally, Study 3 demonstrates that when internal versus external explanations for why both the winner and loser received the outcomes they did are systematically varied, feelings of fairness and liking towards people associated with rivals ensue when the loci of causality match for both teams, but feelings of unfairness and relative disliking ensue when the loci of causality mismatch. This research suggests that that attributions made for the outcomes of competitive events influence attitudes and behavior. As such, managing the locus of attributions, as in Study 3, can result in relatively gracious attitudes and potentially more positive intergroup outcomes.

### C52

**I AGREE WITH WHAT MY NEIGHBOR SAID: CLUSTERING OF ATTITUDES IN RETIREMENT COMMUNITIES** Zebbedia Gibb<sup>1</sup>, Helen C. Harton<sup>1</sup>; <sup>1</sup>University of Northern Iowa – Dynamic social impact theory (Latané, 1996) suggests that culture can emerge or self-organize from the bottom-up through everyday local social influence. This cultural emergence is in part defined by regional differences in attitudes and behaviors. Several studies have shown that markers of subcultures of belief emerge quickly in experimental (e.g., Latané & L'Herrou, 1996) and classroom (e.g., Harton et al., 2002) groups. Field studies have mirrored these results, with distinct cultures developing in housing units of college residence halls across a semester (e.g., Cullum & Harton, 2007). College students, however, may be particularly susceptible to social influence (Sears, 1986). In this study, we examined spatial clustering by residence location in two large retirement communities and expanded the topics to be investigated to mood and life satisfaction as well as attitudes. About half of the residents of the communities completed questionnaires assessing their mental health, mood, attitudes, and interactions. They also indicated where they lived within the complex. Attitudes about issues that were in the news at the time of the administration, such as gay marriage and universal health care, showed stronger geographic clustering than did attitudes about issues that were not as topical, providing further evidence that relevance may be important in determining which factors are more likely to define cultures. Negative affect clustered by apartment location as well. Implications of the results for retirees' quality of life and how better to serve them are also discussed.

### C53

**EVALUATING THE ERROR CHOICE ATTITUDE MEASURE'S RESISTANCE TO SOCIALLY DESIRABLE RESPONDING AND THE IMPACT OF TWO OF ITS PROCEDURAL FEATURES ON ITS PERFORMANCE.** Ronald D. Porter<sup>1</sup>, Leandre R. Fabrigar<sup>1</sup>, Nicole A. Vigneault<sup>1</sup>, Natalie O. Rosen<sup>1</sup>; <sup>1</sup>Queen's University, Kingston, Ontario, Canada – Hammond (1948) developed an indirect measure of attitude called the Error Choice (EC) technique. The purpose of this technique was to overcome socially desirable responding (SDR). The premise of the EC technique is that when people are faced with a knowledge question and they are uncertain of the correct answer, their guessing will be influenced by their attitudes. Following the prom-

ising results of his initial EC study, Hammond made a number of recommendations he believed would improve the efficacy of the EC technique. Unfortunately, subsequent EC research failed to test whether the EC measure was actually resistant to SDR or whether Hammond's recommendations would actually improve the performance of an EC measure. In the current study (N = 357), we experimentally manipulated the level of social desirability and two features of the EC measure hypothesized to influence its performance (inclusion of filler items and time pressure). Participant's responses on the direct measure of attitude did reveal a significant main effect of SDR thereby confirming the efficacy of our social desirability manipulation. As hypothesized the EC measure was resistant to SDR. This was true regardless of whether filler items were present in the EC measure or participants were placed under time pressure to complete the measure.

### C54

**HOW IMPORTANT ARE ATTITUDE-RELEVANT ACTIONS IN PREDICTING ATTITUDE BEHAVIOR-CONSISTENCY?** Phoebe Lin<sup>1</sup>, Rusty McIntyre<sup>1</sup>; <sup>1</sup>Wayne State University – Psychologists would argue that we infer our attitudes toward others based on self actions, behaviors that we have performed toward others. Research on attitude-behavior consistency has failed to yield consistent results, as reported attitudes were not likely to predict how individuals would behave (Ajzen & Fishbein, 1977; LaPiere, 1934; Lord & Lepper, 1999; Wicker, 1969). Previous studies, however, have focused only on self actions. For instance, if an individual donated money to the homeless, he/she would infer a positive attitude toward this group. If, however, the homeless person attacked the individual, would this change the individual's attitude toward the social group? How important are the actions that others take toward the attitude holder in measuring attitude-behavior consistency? The present research takes actions that social group members have taken toward us in addition to self actions in measuring attitude-behavior consistency. It is predicted that participants who ruminate over both sets of actions will show greater attitude-behavior consistency than those who only indicate self actions, other actions, or no actions.

### C55
